A Mailserver on Ubuntu 16.04: Postfix, Dovecot, MySQL

By Reason
May 7th, 2016
[Permalink](#)

This long post contains a recipe for building a reasonably secure Ubuntu 16.04 mailserver, using Postfix, Dovecot, and MySQL, with anti-spam packages in the form of AntiVirus, SpamAssassin, and Postgrey. Local users and virtual mailboxes are managed through the Administration of users and domains is achieved through the Postfix Admin provided by Roundcube.

This is an updated version of earlier [Ubuntu 12.04](#) and [Ubuntu 14.04](#) recipes. If people graciously helped to fix bugs and make improvements in the original issue here please do let me know.

Introduction

Building a Linux mailserver from scratch to your own liking is a painful process for one of the few folk who do that day in and day out - there is no way to do it that generally consists of a range of different packages that separately handle mail, and spam-related tasks: they must all talk to one another correctly, and have good configuration documentation, and there is no one obvious best practice for how to store user data, or how to glue the various different components together. There are many different viable setups for moving mail between Postfix and Dovecot, but the process of assembly tends to be unforgiving on matters such as file ownership and permissions, and specific processes, and tiny errors in esoteric configuration files. Unless you are very careful the end result will likely be either insecure or otherwise subtly non-functional. It is the best of bad outcomes.

You must also pay attention to adding support for the dominant tools used in the spam suppression industry, such as [Sender Policy Framework \(SPF\)](#) and [DomainKeys Identified Mail \(DKIM\)](#). These also risk mail from your server being flagged for the spam folder or ignored by email providers. This is a broad subject and a changing ecosystem worthy of a long post.

There are a number of fairly up to date recipes for creating mailservers on Linux. One is [an Ubuntu recipe by Ivar Abrahamsen](#), which gives you Postfix for SMTP, MySQL for storing account information, virtual user mail directories, and an array of other tools that are effective when working in concert. It's a good set of documents, as the goal is producing a secure mailserver as the end result. In the past I have made use of it as a basis for my mail servers, and recommend it.

There are also a great many partial recipes and out of date guides that can be found on the internet - than a help - especially when it comes to Dovecot, which has changed its configuration in many versions. The configuration is completely different, and so are many of the binaries. When I chose to migrate my servers from Courier to Dovecot because of its better support for virtual mailboxes, I found a good all-in-one-place guide, and hence the existence of the first recipe. Since then I've added new versions as Ubuntu updates its long term support releases.

You should at least skim the whole of this post before setting forth to folk avoid unpleasant surprises, and there are some notes at the end on alter are worth reading before you get started.

Outlining the Goal

The end result of following this guide will be a secure mail server for following software packages:

- Postfix: sends and receives mail via the SMTP protocol. It will o mailservers if the mail is sent by an authenticated user, but anyone for local delivery.
- Dovecot: a POP and IMAP server that manages local mail directorie and download their mail. It also handles user authentication.
- Postgrey: greylists incoming mail, requiring unfamiliar deliverers to resend. This is one of the better tools for cutting down on spam.
- amavisd-new: a manager for organizing various antivirus and spam cl
- Clam AntiVirus: a virus detection suite.
- SpamAssassin: for sniffing out spam in emails.
- Postfix Admin: a web front end for administering mail users and doma
- Roundcube: a webmail interface for users.

The server will accept plain text or encrypted SMTP and POP/IMAP conne will not allow user authentication without encryption. It will pass through ; mail sent by local users, removing identifying information from the origina

Using Amazon Web Services

This post is written assuming the use of [Amazon Web Services](#) to host a any hosting service can be used. Very little of the material here is concer So if you are working with another service, just skip over the AWS-spec equivalent operations in the service that you have chosen to use. Note services are equal when it comes to how email providers view mail comin it is [pointless](#) to even try hosting any significant mail service at Digi blacklisted by many services, and you will have no leverage with any of th to trying to ensure delivery.

If not setting up in AWS, at the very least ensure that you firewall you outset. In many services a new server or virtual instance is completely ex want to lock it down immediately with something like [Uncomplicated F](#) below, replacing MY_IP_ADDRESS with your IP address:

```
1 | sudo su
2 | apt-get install ufw
3 | ufw enable
4 | ufw allow from MY_IP_ADDRESS
```

After you have completed setup then you can open up your server communicate with the rest of the world.

Use of example.com and mail.example.com

Throughout the instructions in this post `example.com` is used as the domain. The domain has the hostname `mail.example.com`. So wherever you see these with your chosen domain and mail server hostname.

Fire up an Ubuntu 16.04 AWS Instance with a Suitable

Start up a new server instance. At the time of writing, Ubuntu 16.04 is the quick start menu for launching a new instance. Mail servers don't get you aren't in the business of email: 2G of RAM is enough for the recipe only because ClamAV and Amavis are memory hogs. Thus while **micro in larger instance types** should be more than enough to support a personal server, or the throughput of a mailing list of a few thousand members.

Firewall settings in AWS are managed through assignment of Security Groups. Create one before starting the server. The Security Group should allow inbound traffic to these ports:

- 25 (SMTP)
- 80 (HTTP)
- 110 (POP3)
- 143 (IMAP)
- 443 (HTTPS)
- 465 (SMTPS)
- 993 (IMAPS)
- 995 (POP3S)

The above is in addition to whatever rules you might have for SSH access. A good idea is to leave that open to the world, so lock it down to the IP address range. Another idea is to restrict all inbound traffic to the server to your own IP addresses. You can adjust the rules to allow traffic from the rest of the world after you're certain you're shipshape.

Some Basic Configuration

The baseline Ubuntu instance is lacking in nearly every package you might want. It's fairly close to scratch. You'll log in as the "ubuntu" user and then switch to root with the "sudo su" command; most of what you need to do requires root access:

```
1 | sudo su
```

You must **set up an Elastic IP** to give your server a permanent IP address. It will have its own strange-looking hostname, so changing to the domain the server is on the list.

```
1 | hostname mail.example.com
```

Now set the contents of `/etc/hostname` to be the hostname:

```
1 | echo "mail.example.com" > /etc/hostname
```

And add your hostname to the first line of `/etc/hosts`:

```

1 | 127.0.0.1 mail.example.com localhost
2 |
3 | # There will be IPv6 configuration below the first line, but l
4 | ...

```

Now you will want to regenerate the server's default self-signed SSL certificate for your domain name. You may have purchased an SSL certificate for your mail server and completely secure to run a mail server using a self-signed certificate. Warning screens when using webmail hosted on the server and warning when connecting via POP, IMAP, or SMTP.

```

1 | apt-get install --assume-yes ssl-cert
2 | make-ssl-cert generate-default-snakeoil --force-overwrite

```

Now Build a LAMP Web Server

The list of goals here includes webmail and a web-based administrative interface. As a starting point you will need to set up a LAMP web server, which stands for Linux, Apache, MySQL, and PHP. There is a shortcut to install all of the basic LAMP packages, so start by updating and installing those packages. Notice the "^" character at the end of the command.

```

1 | apt-get update
2 | apt-get upgrade --assume-yes
3 | apt-get install --assume-yes lamp-server^

```

During this installation process you will be asked to enter and confirm a password. Choose something sensible and wait for the remaining installations to complete. You can also add an array of necessary or useful additional packages for PHP, such as the PHP parser, and GD image processing support. Note that the old standby openssl is no longer necessary, as this functionality is **a part of core PHP now**. At this point you can choose to install your own taste and to support any other applications you might want to run.

```

1 | apt-get install --assume-yes \
2 |   php7.0-mcrypt \
3 |   php7.0-curl \
4 |   php7.0-gd \
5 |   php7.0-mbstring \
6 |   php-apcu \
7 |   php-xml-parser

```

Configure PHP

The default configuration settings for PHP and the additional packages are located in `/etc/php/7.0/apache2/php.ini` and `/etc/php/7.0/mods-available` respectively. So unless you have something complicated or high-power, you can just change anything.

Use OpenSSL to Create a Unique Diffie-Helman Group

Good security is requiring ever more work on the part of system administrators. More recent attacks on SSL is known as **Logjam**, and defending against

non-standard addition to application SSL settings. Creating your own : saving it to a configuration file is the first step:

```
1 | openssl dhparam -out /etc/ssl/private/dhparams.pem 2048
2 | chmod 600 /etc/ssl/private/dhparams.pem
```

Configure Apache

The expected end result for the Apache webserver is that it will serve a site with various web applications: (a) Roundcube for webmail, and (b) Postfix Admin. All HTTP requests will be redirected to use HTTPS, as there is no good reason to run any of applications that will reside on the server.

Firstly configure the following lines in `/etc/apache2/conf-enabled/ssl.conf`. This is information that Apache gives out in its response headers:

```
1 | #
2 | # ServerTokens
3 | # This directive configures what you return as the Server HTTP
4 | # Header. The default is 'Full' which sends information about
5 | # and compiled in modules.
6 | # Set to one of: Full | OS | Minimal | Minor | Major | Prod
7 | # where Full conveys the most information, and Prod the least
8 | #
9 | ServerTokens Prod
10 |
11 | #
12 | # Optionally add a line containing the server version and virtual
13 | # host name to server-generated pages (internal error documents,
14 | # mod_status and mod_info output etc., but not CGI generated
15 | # documents or custom error documents).
16 | # Set to "EMail" to also include a mailto: link to the
17 | # Set to one of: On | Off | EMail
18 | #
19 | ServerSignature Off
```

Make sure that `mod_rewrite`, `mod_ssl`, a few other useful modules, are enabled - you'll need these line items to be able to force visitors to use HTTPS:

```
1 | a2enmod deflate expires headers rewrite ssl
2 | a2ensite default-ssl
```

Edit these lines in `/etc/apache2/mods-available/ssl.conf` to ensure that protocols are not used:

```
1 | # Aiming for perfect forward secrecy where possible, and
2 | # attacks such as Logjam. See:
3 | # https://weakdh.org/sysadmin.html
4 | # https://hynek.me/articles/hardening-your-web-servers-ssl-ciphers
5 | SSLCipherSuite ECDHE-RSA-AES128-GCM-SHA256:ECDHE-ECDSA-AES128
6 | SSLHonorCipherOrder on
7 |
8 | # The protocols to enable.
9 | # Available values: all, SSLv3, TLSv1, TLSv1.1, TLSv1.2
10 | # SSL v2 is no longer supported
11 | SSLProtocol all -SSLv2 -SSLv3
```

The default site configuration in `/etc/apache2/sites-available/000-default.conf` is something like this for the sake of simplicity:

```

1 <VirtualHost *:80>
2   ServerName mail.example.com
3   ServerAdmin webmaster@localhost
4
5   DocumentRoot /var/www/html
6   <Directory "/var/www/html">
7     Options FollowSymLinks
8     AllowOverride All
9   </Directory>
10
11  ErrorLog ${APACHE_LOG_DIR}/error.log
12
13  # Possible values include: debug, info, notice, warn, error
14  # alert, emerg.
15  LogLevel warn
16
17  CustomLog ${APACHE_LOG_DIR}/access.log combined
18 </VirtualHost>

```

But of course your taste and needs may vary. Keeping the same simple approach for an SSL configuration in `/etc/apache2/sites-available/default-ssl.conf` can be done as follows:

```

1 <IfModule mod_ssl.c>
2   <VirtualHost _default_:443>
3     ServerName mail.example.com
4     ServerAdmin webmaster@localhost
5
6     # Set the HTTP Strict Transport Security (HSTS) header to
7     # HTTPS for 1 Year, including subdomains, and allow this
8     # added to the preload list.
9     Header always set Strict-Transport-Security "max-age=31536000"
10
11    # Prevent clickjacking by controlling who can put the site in an
12    # frame. Only needed for text/html, but doesn't hurt to be set
13    # generally.
14    Header set X-Frame-Options "SAMEORIGIN"
15
16    # Prevent mime based attacks by telling browsers that you don't
17    # to use the declared mime type regardless of what the content
18    # type is.
19    Header set X-Content-Type-Options "nosniff"
20
21    DocumentRoot /var/www/html
22    <Directory "/var/www/html">
23      Options FollowSymLinks
24      AllowOverride All
25    </Directory>
26
27    ErrorLog ${APACHE_LOG_DIR}/error.log
28
29    # Possible values include: debug, info, notice, warn, error,
30    # alert, emerg.
31    LogLevel warn
32
33    CustomLog ${APACHE_LOG_DIR}/ssl_access.log combined
34
35    # SSL Engine Switch:
36    # Enable/Disable SSL for this virtual host.
37    SSLEngine on
38    #
39
40    # ... more default SSL configuration ...
41

```

```

42 |         # You will probably need to change this next Directory di
43 |         # in order to match the earlier one.
44 |         <Directory "/var/www/html">
45 |             SSLOptions +StdEnvVars
46 |         </Directory>
47 |
48 |         # ... yet more default SSL configuration ...

```

If you are using a purchased rather than self-signed SSL certificate, the certificate bundle from the issuer. If you don't want to pay for a valid SSL a look at setting up with [Let's Encrypt](#) or a similar free certificate auth wildcard certificate for *.example.com, a less costly certificate covering www.example.com and mail.example.com, or you may have separate certificates you care about. Place the relevant certificate, private key, and CA certificate locations:

- /etc/ssl/private/example.com.key
- /etc/ssl/certs/example.com.crt
- /etc/ssl/certs/ca-bundle.crt

The key must not be password protected, and it must be locked down so you can read it:

```
1 | chmod 600 /etc/ssl/private/example.com.key
```

Now change these lines in /etc/apache2/sites-enabled/default-ssl.conf:

```

1 | # A self-signed (snakeoil) certificate can be created by in
2 | # the ssl-cert package. See
3 | # /usr/share/doc/apache2/README.Debian.gz for more info.
4 | # If both key and certificate are stored in the same file,
5 | # SSLCertificateFile directive is needed.
6 | SSLCertificateFile /etc/ssl/certs/example.com.crt
7 | SSLCertificateKeyFile /etc/ssl/private/example.com.key
8 |
9 | # Server Certificate Chain:
10 | # Point SSLCertificateChainFile at a file containing the
11 | # concatenation of PEM encoded CA certificates which form the
12 | # certificate chain for the server certificate. Alternative
13 | # the referenced file can be the same as SSLCertificateFile
14 | # when the CA certificates are directly appended to the server
15 | # certificate for convenience.
16 | SSLCertificateChainFile /etc/ssl/certs/ca-bundle.crt

```

To push visitors to HTTPS, put something similar to the following snippet in

```

1 | RewriteEngine On
2 |
3 | # Redirect all HTTP traffic to HTTPS.
4 | RewriteCond %{HTTPS} !=on
5 | RewriteRule ^/?(.*) https://%{SERVER_NAME}/$1 [R,L]

```

Make Use of that Diffie-Helman Group

The configuration needed to use the Diffie-Helman group in /etc/ssl/private is [the version of Apache](#). For the version used in Ubuntu 16.04, add or edit

available/ssl.conf:

```
1 | # Protect against Logjam attacks. See: https://weakdh.org
2 | SSLOpenSSLConfCmd DHParameters "/etc/ssl/private/dhparams.pem"
```

Now restart Apache to pick up the changes, after which you should be homepage and see that you are automatically redirected to HTTPS.

```
1 | service apache2 restart
```

Install the Mailserver Packages

Now we're ready to start in on the harder stuff. As for the LAMP server, the basic packages for a mail server. Again, note the "^" at the end of the

```
1 | apt-get install --assume-yes mail-server^
```

When Postfix installs, you will be asked to choose a general type of mail (Internet site). You will be asked for the system mail name, which is the host name, e.g. mail.example.com. When Dovecot installs you will be asked whether you have a certificate. Here answer no, as you will be adjusting the Dovecot configuration to use a default snakeoil certificate or, ideally, your purchased SSL certificate.

What this set of packages provides to you is pretty much just the bare mailserver that manages its users as straightforward Unix users and does not store data. That is not the goal here, so we need the rest of the cast, such as Dovecot, and a coterie of spam-mashing packages:

```
1 | apt-get install --assume-yes \
2 | postfix-mysql \
3 | dovecot-mysql \
4 | postgrey \
5 | amavis \
6 | clamav \
7 | clamav-daemon \
8 | spamassassin \
9 | libdbi-perl \
10 | libdbd-mysql-perl \
11 | php7.0-imap \
12 | postfix-policyd-spf-python
```

The libdbi-perl and libdbd-mysql-perl packages are required by Amavis. It provides support for POP3 as well as the IMAP protocol, and will be needed for the possible options for PHP webmail applications. The postfix-policyd-spf provides support for **Sender Policy Framework (SPF)** on incoming mail to block spam. You will want to have php7.0-imap running and ready:

```
1 | service apache2 restart
```

Next you'll want to install a few optional packages that extend the abilities of the mailserver packages by allowing greater inspection of attached files:

```
1 | apt-get install --assume-yes \
2 | pyzor \
```

```

3 | razor \
4 | arj \
5 | cabextract \
6 | lzop \
7 | nomarch \
8 | p7zip-full \
9 | ripole \
10 | rpm2cpio \
11 | tnef \
12 | unzip \
13 | unrar-free \
14 | zip \
15 | zoo

```

Configure MySQL

A few alterations to the default MySQL configuration in `/etc/mysql/my.cnf`. Add the following:

```

1 | # This removes NO_ZERO_IN_DATE and NO_ZERO_DATE, which cause p
2 | # Postfix Admin code, from strict mode.
3 | sql_mode=ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,ERROR_FOR_DIVI

```

Then restart the MySQL server:

```

1 | service mysql restart

```

Create a Mail Database and User in MySQL

Log in to MySQL as the root user, entering the password you set earlier:

```

1 | mysql -uroot -p

```

Now set up a database and user for the mail software. This database accounts and mail domains, using schema set up by the Postfix Admin. Use a better password than the example used below, but note that it will be entered in plain text in log files. If an attacker gains shell access to the server, it doesn't matter how good your password is. Unauthorized access to the database is largely provided by the fact that MySQL is listening on port 3306 by the firewall, but it never hurts to have good passwords in place regardless. Multiple layers of defense is always a good strategy.

```

1 | create database mail;
2 | grant all on mail.* to 'mail'@'localhost' identified by 'mailp

```

Install Postfix Admin 3.0.2 and the MySQL Schema

Postfix Admin is installed as follows. To start things off, download the package, move it into a subdirectory of your webroot, and change ownership to the web user:

```

1 | wget http://downloads.sourceforge.net/project/postfixadmin/postfixadmin-3.0.2.tar.gz
2 | tar -xvf postfixadmin-3.0.2.tar.gz
3 | rm -f postfixadmin-3.0.2.tar.gz
4 | mv postfixadmin-3.0.2 /var/www/html/postfixadmin
5 | chown -R www-data:www-data /var/www/html/postfixadmin

```

Next up is an interesting sort of a two-phase setup process. First, create `/var/www/html/postfixadmin/config.local.php`:

```
1 touch /var/www/html/postfixadmin/config.local.php
2 chown www-data:www-data /var/www/html/postfixadmin/config.local.php
```

Entries made in `/var/www/html/postfixadmin/config.local.php` will override those in `/var/www/html/postfixadmin/config.inc.php`. Add the following lines:

```
1 <?php
2 // Configuration options here override those in config.inc.php
3
4 // You have to set $CONF['configured'] = true; before the
5 // application will run.
6 $CONF['configured'] = true;
7
8 // Postfix Admin Path
9 // Set the location of your Postfix Admin installation here.
10 // YOU MUST ENTER THE COMPLETE URL e.g. http://domain.tld/postfixadmin
11 $CONF['postfix_admin_url'] = 'https://mail.example.com/postfixadmin';
12
13 // Database connection details.
14 $CONF['database_type'] = 'mysql';
15 $CONF['database_host'] = 'localhost';
16 $CONF['database_user'] = 'mail';
17 $CONF['database_password'] = 'mailpassword';
18 $CONF['database_name'] = 'mail';
19
20 // Site Admin
21 // Define the Site Admin's email address below.
22 // This will be used to send emails from to create mailboxes
23 // from Send Email / Broadcast message pages.
24 // Leave blank to send email from the logged-in Admin's Email
25 $CONF['admin_email'] = 'admin@example.com';
26
27 // Mail Server
28 // Hostname (FQDN) of your mail server.
29 // This is used to send email to Postfix in order to create mailboxes
30 $CONF['smtp_server'] = 'localhost';
31 $CONF['smtp_port'] = '25';
32
33 // Encrypt
34 // In what way do you want the passwords to be crypted?
35 // md5crypt = internal postfix admin md5
36 $CONF['encrypt'] = 'md5crypt';
37
38 // Default Aliases
39 // The default aliases that need to be created for all domain
40 $CONF['default_aliases'] = array (
41     'abuse' => 'admin@example.com',
42     'hostmaster' => 'admin@example.com',
43     'postmaster' => 'admin@example.com',
44     'webmaster' => 'admin@example.com'
45 );
46
47 // Footer
48 // Below information will be on all pages.
49 // If you don't want the footer information to appear set this to false
50 $CONF['show_footer_text'] = 'YES';
51 $CONF['footer_text'] = 'Return to mail.example.com';
52 $CONF['footer_link'] = 'https://mail.example.com';
53
54 // Mailboxes
55 // If you want to store the mailboxes per domain set this to true
```

```

56 // Examples:
57 //   YES: /usr/local/virtual/domain.tld/username@domain.tld
58 //   NO:  /usr/local/virtual/username@domain.tld
59 $CONF['domain_path'] = 'NO';
60 // If you don't want to have the domain in your mailbox set t
61 // Examples:
62 //   YES: /usr/local/virtual/domain.tld/username@domain.tld
63 //   NO:  /usr/local/virtual/domain.tld/username
64 // Note: If $CONF['domain_path'] is set to NO, this setting w
65 $CONF['domain_in_mailbox'] = 'YES';
66
67 // Specify '' for Dovecot and 'INBOX.' for Courier.
68 $CONF['create_mailbox_subdirs_prefix']='';

```

Note that the last items above are only for the purposes of defining how they don't set system paths for mailboxes. The actual system paths to be defined in the Dovecot configuration outlined in a later section of this configuration options relating to optional functionality that can be used by exploring the documentation and the main configuration file `/var/www/html/postfixadmin/config.local.php`

Next open up a web browser and visit your mail server at:

```
1 | https://mail.example.com/postfixadmin/setup.php
```

Postfix Admin will automatically create its database schema at this point. On the setup page to choose a setup password and generate a hash of that password. Save the configuration file `/var/www/html/postfixadmin/config.local.php` and save it.

```

1 // In order to setup Postfixadmin, you MUST specify a hashed p
2 // To create the hash, visit setup.php in a browser and type a
3 // on submission it will be echoed out to you as a hashed valu
4 $CONF['setup_password'] = '...a long hash string...';

```

Then return to the setup page. You can now use the password you selected to create an administrator account.

You should close off access to `http://mail.example.com/postfixadmin/setup.php`. Create a file `/var/www/html/postfixadmin/.htaccess` and put the following

```

1 <Files "setup.php">
2 deny from all
3 </Files>

```

Create the Domain and Accounts in Postfix Admin

Now navigate to the main Postfix Admin login page:

```
1 | https://mail.example.com/postfixadmin/
```

Log in as the newly created administrator account, and then choose the 'Add Domain' option in order to create the `example.com` domain. Make sure that you have the 'Add Domain' option selected and note that you will probably want to change the default limits to allow for more aliases. Next navigate to Domain List -> Domain List and click on the 'Add Domain' button. From that page you can then add mail users (Add mailbox) and aliases (Add alias). The database schema, but it won't do anything else at this point as none of the other configuration options are configured to use the database.

Make sure that you create a mailbox for `admin@example.com` since your that address. While the alias addresses do tend to receive spam, it is a very legitimate mail arriving at these addresses, as it can alert you to problems on your personal mail server, but very important if you are in the business of seeking good deliverability.

Postfix Admin does have another useful function during this lengthy setup: mail to local users through the web interface, which is helpful when testing and debugging down errors.

Create a User to Handle Virtual Mail Directories

Virtual mail users are those that do not exist as Unix system users. They use different methods of authentication or mail delivery and don't have home directories or mailboxes. Things here: mail users are defined in the database created by Postfix Admin. Mail will be kept in subfolders per domain and accounts. For example, `admin@example.com` will have a mail directory of `/var/vmail/example.com`. These directories will be owned by a single user called `vmail`, and Dovecot will create and update mail files.

```
1 useradd -r -u 150 -g mail -d /var/vmail -s /sbin/nologin -c "Virtual Mail User"
2 mkdir /var/vmail
3 chmod 770 /var/vmail
4 chown vmail:mail /var/vmail
```

Note that the user and virtual mail directory folder are using the "mail" group. This allows users in that group to modify the contents.

Configure Dovecot

Dovecot will manage IMAP and POP3 connections, local mail directories, and mailboxes handed off from Postfix. It will also manage authentication for SMTP connections. Having two separate authentication systems when Dovecot can handle both is not ideal. Across a number of files in `/etc/dovecot` and subfolders thereof, an intimidating task, it is all laid out fairly logically. The first thing to do is ensure Dovecot uses the data in the database created by Postfix Admin, so you will need to edit `/etc/dovecot/dovecot-sql.conf.ext` such that it uses the MySQL database configuration.

```
1 # Database driver: mysql, postgres, sqlite
2 driver = mysql
```

```
1 # Examples:
2 # connect = host=192.168.1.1 dbname=users
3 # connect = host=sql.example.com dbname=virtual user=virtual
4 # connect = /etc/dovecot/authdb.sqlite
5 #
6 connect = host=localhost dbname=mail user=mail password=mailpassword
```

```
1 # Default password scheme.
2 #
3 # List of supported schemes is in
4 # http://wiki2.dovecot.org/Authentication/PasswordSchemes
5 #
6 default_pass_scheme = MD5-CRYPT
```

```

1 | # Define the query to obtain a user password.
2 | #
3 | # Note that uid 150 is the "vmail" user and gid 8 is the "mail
4 | #
5 | password_query = \
6 |     SELECT username as user, password, '/var/vmail/%d/%n' as use
7 |     'maildir:/var/vmail/%d/%n' as userdb_mail, 150 as userdb_uid
8 |     FROM mailbox WHERE username = '%u' AND active = '1'

```

```

1 | # Define the query to obtain user information.
2 | #
3 | # Note that uid 150 is the "vmail" user and gid 8 is the "mail
4 | #
5 | user_query = \
6 |     SELECT '/var/vmail/%d/%n' as home, 'maildir:/var/vmail/%d/%n
7 |     150 AS uid, 8 AS gid, concat('dirsize:storage=', quota) AS q
8 |     FROM mailbox WHERE username = '%u' AND active = '1'

```

Then change the controlling definitions in `/etc/dovecot/conf.d/10-auth.c` the SQL configuration files. While you are there, you should also make `ssl` disabled unless the connection is encrypted or local:

```

1 | # Disable LOGIN command and all other plaintext authentication
2 | # SSL/TLS is used (LOGINDISABLED capability). Note that if the
3 | # matches the local IP (ie. you're connecting from the same co
4 | # connection is considered secure and plaintext authentication
5 | disable_plaintext_auth = yes

```

```

1 | # Space separated list of wanted authentication mechanisms:
2 | # plain login digest-md5 cram-md5 ntlm rpa apop anonymous gs
3 | # gss-spnego
4 | # NOTE: See also disable_plaintext_auth setting.
5 | auth_mechanisms = plain login

```

```

1 | ##
2 | ## Password and user databases
3 | ##
4 | #
5 | # Password database is used to verify user's password (and no
6 | # You can have multiple passdbs and userdbs. This is useful i
7 | # allow both system users (/etc/passwd) and virtual users to
8 | # duplicating the system users into virtual database.
9 | #
10 | #
11 | # <doc/wiki/PasswordDatabase.txt>
12 | #
13 | # User database specifies where mails are located and what us
14 | # own them. For single-UID configuration use "static" userdb.
15 | #
16 | # <doc/wiki/UserDatabase.txt>
17 | #
18 | #!include auth-deny.conf.ext
19 | #!include auth-master.conf.ext
20 | #
21 | #!include auth-system.conf.ext
22 | # Use the SQL database configuration for authentication rathe
23 | # any of these others.
24 | #!include auth-sql.conf.ext
25 | #!include auth-ldap.conf.ext
26 | #!include auth-passwdfile.conf.ext
27 | #!include auth-checkpassword.conf.ext

```

```
28 | #!include auth-vpopmail.conf.ext
29 | #!include auth-static.conf.ext
```

Next up, you must tell Dovecot where to put the virtual user mail directories in `/etc/dovecot/conf.d/10-mail.conf`:

```
1 | # Location for users' mailboxes. The default is empty, which
2 | # tries to find the mailboxes automatically. This won't work
3 | # doesn't yet have any mail, so you should explicitly tell Dovecot
4 | # location.
5 | #
6 | # If you're using mbox, giving a path to the INBOX file (eg.
7 | # isn't enough. You'll also need to tell Dovecot where the others
8 | # are kept. This is called the "root mail directory", and it must be
9 | # the path given in the mail_location setting.
10 | #
11 | # There are a few special variables you can use, eg.:
12 | #
13 | # %u - username
14 | # %n - user part in user@domain, same as %u if there's no domain
15 | # %d - domain part in user@domain, empty if there's no domain
16 | # %h - home directory
17 | #
18 | # See doc/wiki/Variables.txt for full list. Some examples:
19 | #
20 | # mail_location = maildir:~/Maildir
21 | # mail_location = mbox:~/mail:INBOX=/var/mail/%u
22 | # mail_location = mbox:/var/mail/%d/%1n/%n:INDEX=/var/index.html
23 | #
24 | # <doc/wiki/MailLocation.txt>
25 | #
26 | mail_location = maildir:/var/vmail/%d/%n
```

```
1 | # System user and group used to access mails. If you use multiple
2 | # users, you can override these by returning uid or gid fields. You can
3 | # also use names. <doc/wiki/UserIds.txt>
4 | mail_uid = vmail
5 | mail_gid = mail
```

```
1 | # Valid UID range for users, defaults to 500 and above. This is
2 | # to make sure that users can't log in as daemons or other system
3 | # users. Note that denying root logins is hardcoded to dovecot binary
4 | # and can't be done even if first_valid_uid is set to 0.
5 | #
6 | # Use the vmail user uid here.
7 | first_valid_uid = 150
8 | last_valid_uid = 150
```

Let Dovecot know about either your snakeoil or purchased certificate in `/etc/dovecot/conf.d/10-ssl.conf`. Remember to include your CA certificate and the certificate issuer:

```
1 | # SSL/TLS support: yes, no, required. <doc/wiki/SSL.txt>
2 | ssl = yes
3 | #
4 | # PEM encoded X.509 SSL/TLS certificate and private key. They should be
5 | # dropped on root privileges, so keep the key file unreadable by
6 | # root. Included doc/mkcert.sh can be used to easily generate a
7 | # certificate, just make sure to update the domains in dovecot.conf
8 | #
9 | # The generated snakeoil certificate:
10 | #ssl_cert = </etc/ssl/certs/ssl-cert-snakeoil.pem
```

```

11 #ssl_key = </etc/ssl/private/ssl-cert-snakeoil.key
12 # Purchased certificate:
13 ssl_cert = </etc/ssl/certs/example.com.crt
14 ssl_key = </etc/ssl/private/example.com.key
15
16 # If key file is password protected, give the password here.
17 # give it when starting dovecot with -p parameter. Since this
18 # world-readable, you may want to place this setting instead
19 # root owned 0600 file by using ssl_key_password = <path.
20 #ssl_key_password =
21
22 # PEM encoded trusted certificate authority. Set this only if
23 # ssl_verify_client_cert=yes. The file should contain the CA
24 # followed by the matching CRL(s). (e.g. ssl_ca = </etc/ssl/c
25 ssl_ca = </etc/ssl/certs/ca-bundle.crt

```

You must also update the following lines in `/etc/dovecot/conf.d/10-ssl` protocols that are no longer secure are not used:

```

1 # DH parameters length to use. In light of Logjam, has to be
2 # See: https://weakdh.org/sysadmin.html
3 ssl_dh_parameters_length = 2048
4
5 # SSL protocols to use. Don't use the no-longer secure protoc
6 ssl_protocols = !SSLv2 !SSLv3
7
8 # SSL ciphers to use. See:
9 # https://weakdh.org/sysadmin.html
10 # https://hynek.me/articles/hardening-your-web-servers-ssl-ci
11 ssl_cipher_list = ECDHE-RSA-AES128-GCM-SHA256:ECDSA-AES
12
13 # Prefer the server's order of ciphers over client's.
14 ssl_prefer_server_ciphers = yes

```

Next, edit these lines in `/etc/dovecot/conf.d/10-master.conf` to add the Po

```

1 service auth {
2     # auth_socket_path points to this userdb socket by default.
3     # used by dovecot-lda, doveadm, possibly imap process, etc.
4     # full permissions to this socket are able to get a list of
5     # get the results of everyone's userdb lookups.
6     #
7     # The default 0666 mode allows anyone to connect to the soc
8     # userdb lookups will succeed only if the userdb returns an
9     # matches the caller process's UID. Also if caller's uid or
10    # socket's uid or gid the lookup succeeds. Anything else ca
11    #
12    # To give the caller full permissions to lookup all users,
13    # something else than 0666 and Dovecot lets the kernel info
14    # permissions (e.g. 0777 allows everyone full permissions).
15    unix_listener auth-userdb {
16        mode = 0666
17        user = vmail
18        group = mail
19    }
20
21    unix_listener /var/spool/postfix/private/auth {
22        mode = 0666
23        # Assuming the default Postfix user and group
24        user = postfix
25        group = postfix
26    }

```

You may have to explicitly set a postmaster address in `/etc/dovecot` "Invalid settings: postmaster_address setting not given" showing up in the log. Make sure that a suitable alias or mailbox exists for your chosen postmaster address.

```
1 | # Address to use when sending rejection mails.
2 | # Default is postmaster@<your domain>.
3 | postmaster_address = postmaster@example.com
```

You must now ensure that the Dovecot configuration is accessible to both the `postmaster` and `mail` users.

```
1 | chown -R vmail:dovecot /etc/dovecot
2 | chmod -R o-rwx /etc/dovecot
```

A final note on Dovecot: it only creates a user's mail directory when mail is received for that user. So creating a user in Postfix Admin will not result in the immediate creation of `/var/vmail`, and that's just fine.

Configure Amavis, ClamAV, and SpamAssassin

Before configuring Postfix, we may as well take a short detour into configuring Amavis, ClamAV, and SpamAssassin. Their default configuration is close to what most people will need, and too many of the optional additional packages you may have installed. If you have some knowledge, you can of course spend a fair amount of time here crafting in-depth configurations, but this is a **quick and straightforward process**, however. Note that here we are only dealing with integration with Postfix - e.g. additions to the `/etc/postfix/main.cf` section of this post.

First add Amavis and ClamAV users to one another's groups to enable their use of each other's services.

```
1 | adduser clamav amavis
2 | adduser amavis clamav
```

This also requires editing the following lines in `/etc/clamav/clamd.conf`:

```
1 | # Needed to allow things to work with Amavis, when both amavis
2 | # users are added to one another's groups.
3 | AllowSupplementaryGroups true
```

Then turn on Amavis by editing `/etc/amavis/conf.d/15-content_filter_checks` to be the default, so uncomment the `@bypass...` lines:

```
1 | use strict;
2 |
3 | # You can modify this file to re-enable SPAM checking through
4 | # and to re-enable antivirus checking.
5 |
6 | #
7 | # Default antivirus checking mode
8 | # Please note, that anti-virus checking is DISABLED by
9 | # default.
10 | # If You wish to enable it, please uncomment the following lines
11 |
12 | @bypass_virus_checks_maps = (
13 |     \bypass_virus_checks, \bypass_virus_checks_acl, \bypass
14 |
15 | #
16 | # Default SPAM checking mode
```

```

17 | # Please note, that anti-spam checking is DISABLED by
18 | # default.
19 | # If You wish to enable it, please uncomment the following li
20 |
21 | @bypass_spam_checks_maps = (
22 |     \%bypass_spam_checks, \@bypass_spam_checks_acl, \$bypass_s
23 |
24 | 1; # ensure a defined return

```

Now enable SpamAssassin by editing these lines in `/etc/default/spamassa`

```

1 | # Change to one to enable spamd
2 | ENABLED=1

```

```

1 | # Cronjob
2 | # Set to anything but 0 to enable the cron job to automaticall
3 | # spamassassin's rules on a nightly basis
4 | CRON=1

```

SpamAssassin under Amavis will only check mail that's determined to be are a couple of ways to tell Amavis which mails are for local delivery, but database set up by Postfix Admin. Edit `/etc/amavis/conf.d/50-user` to look

```

1 | use strict;
2 |
3 | #
4 | # Place your configuration directives here. They will overri
5 | # earlier files.
6 | #
7 | # See /usr/share/doc/amavisd-new/ for documentation and examp
8 | # the directives you can use in this file
9 | #
10 |
11 | # Three concurrent processes. This should fit into the RAM av
12 | # AWS micro instance. This has to match the number of process
13 | # for Amavis in /etc/postfix/master.cf.
14 | $max_servers = 3;
15 |
16 | # Add spam info headers if at or above that level - this ensu
17 | # are always added.
18 | $sa_tag_level_deflt = -9999;
19 |
20 | # Check the database to see if mail is for local delivery, an
21 | # should be spam checked.
22 | @lookup_sql_dsn = (
23 |     ['DBI:mysql:database=mail;host=127.0.0.1;port=3306',
24 |     'mail',
25 |     'mailpassword']);
26 | $sql_select_policy = 'SELECT domain from domain WHERE CONCAT(
27 |
28 | # Uncomment to bump up the log level when testing.
29 | # $log_level = 2;
30 |
31 | #----- Do not modify anything below this line -----
32 | 1; # ensure a defined return

```

Next make sure the ClamAV database is up to date by running `freshclam`.

```

1 | freshclam

```

You will have to restart these processes to pick up the new configuration:

```

1 | service clamav-daemon restart
2 | service amavis restart
3 | service spamassassin restart

```

Configure Postfix

Postfix handles incoming mail via the SMTP protocol, and its configuration to integrate with the various other packages we have installed so far. At hand off incoming mail to the spam and virus checkers before passing it to communicate with Dovecot in order to authenticate virtual users who are to send mail.

Firstly you must create a set of files that describe for Postfix where to domains. Note that the "hosts" directive in these files must be exactly the the MySQL server configuration. If one side says "localhost" and the other may find that Postfix cannot connect to MySQL - strange but true. Here are

/etc/postfix/mysql_virtual_alias_domainaliases_maps.cf

```

1 | user = mail
2 | password = mailpassword
3 | hosts = 127.0.0.1
4 | dbname = mail
5 | query = SELECT goto FROM alias,alias_domain
6 |     WHERE alias_domain.alias_domain = '%d'
7 |     AND alias.address=concat('%u', '@', alias_domain.target_domain)
8 |     AND alias.active = 1

```

/etc/postfix/mysql_virtual_alias_maps.cf

```

1 | user = mail
2 | password = mailpassword
3 | hosts = 127.0.0.1
4 | dbname = mail
5 | table = alias
6 | select_field = goto
7 | where_field = address
8 | additional_conditions = and active = '1'

```

/etc/postfix/mysql_virtual_domains_maps.cf

```

1 | user = mail
2 | password = mailpassword
3 | hosts = 127.0.0.1
4 | dbname = mail
5 | table = domain
6 | select_field = domain
7 | where_field = domain
8 | additional_conditions = and backupmx = '0' and active = '1'

```

/etc/postfix/mysql_virtual_mailbox_domainaliases_maps.cf

```

1 | user = mail
2 | password = mailpassword
3 | hosts = 127.0.0.1
4 | dbname = mail
5 | query = SELECT maildir FROM mailbox, alias_domain
6 |     WHERE alias_domain.alias_domain = '%d'

```

```
7 |     AND mailbox.username=concat('%u', '@', alias_domain.target_d
8 |     AND mailbox.active = 1
```

/etc/postfix/mysql_virtual_mailbox_maps.cf

```
1 | user = mail
2 | password = mailpassword
3 | hosts = 127.0.0.1
4 | dbname = mail
5 | table = mailbox
6 | select_field = CONCAT(domain, '/', local_part)
7 | where_field = username
8 | additional_conditions = and active = '1'
```

/etc/postfix/mysql_virtual_sender_login_maps.cf

```
1 | user = mail
2 | password = mailpassword
3 | hosts = 127.0.0.1
4 | dbname = mail
5 | query = SELECT goto FROM alias WHERE address='%s'
```

Now create the file `/etc/postfix/header_checks`, which will contain some headers when relaying mail. This improves privacy for the sending users original IP address and mail software identifiers, for example. This file Postfix configuration:

```
1 | /^Received:/                IGNORE
2 | /^User-Agent:/              IGNORE
3 | /^X-Mailer:/                IGNORE
4 | /^X-Originating-IP:/        IGNORE
5 | /^x-cr-[a-z]*:/             IGNORE
6 | /^Thread-Index:/            IGNORE
```

The following is the complete main Postfix configuration file at `/etc/postfix/main.cf`. It contains a number of complex choices and options on how mail is relayed and how the scope of this post to explain each and every choice of best practice detail. I strongly suggest that you spend some time reading up on Postfix as it is easy to fall down and produce a suboptimal or faulty mailserver.

```
1 | # See /usr/share/postfix/main.cf.dist for a commented, more
2 |
3 | # The first text sent to a connecting process.
4 | smtpd_banner = $myhostname ESMTMP $mail_name
5 | biff = no
6 | # appending .domain is the MUA's job.
7 | append_dot_mydomain = no
8 | readme_directory = no

```

To be clear, if you are using a purchased SSL certificate - and have a CA certificate - then you will have to alter these lines in `/etc/postfix/main.cf`:

```

1 # The default snakeoil certificate. Comment if using a purchased
2 # SSL certificate.
3 # smtpd_tls_cert_file=/etc/ssl/certs/ssl-cert-snakeoil.pem
4 # smtpd_tls_key_file=/etc/ssl/private/ssl-cert-snakeoil.key
5
6 # Uncomment if using a purchased SSL certificate.
7 smtpd_tls_cert_file=/etc/ssl/certs/example.com.crt
8 smtpd_tls_key_file=/etc/ssl/private/example.com.key
9
10 # The snakeoil self-signed certificate has no need for a CA file
11 # if you are using your own SSL certificate, then you probably
12 # a CA certificate bundle from your provider. The path to that
13 # here.
14 smtpd_tls_CAfile=/etc/ssl/certs/ca-bundle.crt

```

You must also expand `/etc/postfix/master.cf`, and here is the entire file after the default material from the package install, such as commented options:

```

1 #
2 # Postfix master process configuration file. For details on
3 # of the file, see the master(5) manual page (command: "man
4 # on-line: http://www.postfix.org/master.5.html).
5 #
6 # Do not forget to execute "postfix reload" after editing this
7 #

154 # Integration with the SPF check package.

```

```
155 | policy-spf unix - n n - - sp
156 | user=nobody argv=/usr/bin/policyd-spf
```

Note that Amavis is restricted to three processes, which should be fine for. The processes are memory-heavy, so start low and add more only if you see [the notes in this guide](#) for pointers on how to do that.

Restart Everything, and Test the Server

Restart all the necessary processes to pick up configuration changes:

```
1 | service postfix restart
2 | service spamassassin restart
3 | service clamav-daemon restart
4 | service amavis restart
5 | service dovecot restart
```

Now start testing! Keep an eye on `/var/log/mail.log` for error messages. IMAP, send mail to an account created on the server, and send mail from up the firewall to allow global access to the relevant ports before doing. Google is your friend when it comes to searching on specific error messages of any specific problem.

AWS Mail Restrictions and Reverse DNS Lookup

Once configured, with IP address set and DNS records set up, you'll need to put in place for your server and the AWS outgoing mail restrictions [standard customer service form](#). This doesn't take long, and it can actually be necessary, prior to the server completion.

Install and Set up Monit for Monitoring

Monit is a very useful monitoring tool that helps rescue your server through `apt-get`:

```
1 | apt-get install --assume-yes monit
```

The following are a set of fairly trivial instructions that set monit to watch the Amavis processes, but without issuing notifications or doing much more than restarting Amavis. Amavis configuration specifies a fairly infrequent check, as it is possible to have a large number of concurrent connections per process (which is set at a low 128) where it refuses connections because you're sending mail too rapidly. Restarting Amavis at that point just makes things worse, boosting load and queuing connections that are then queued and reattempted for any period while Amavis is truly down and waiting.

Create the following files in the Monit configuration directory.

/etc/monit/conf.d/amavis

```
1 | check process amavisd with pidfile /var/run/amavis/amavisd.pid
2 |     every 5 cycles
3 |     group mail
4 |     start program = "/usr/sbin/service amavis start"
5 |     stop program = "/usr/sbin/service amavis stop"
```

```
6 | if failed port 10024 protocol smtp then restart
7 | if 5 restarts within 25 cycles then timeout
```

/etc/monit/conf.d/apache2

```
1 | check process apache2 with pidfile /var/run/apache2/apache2.p
2 |   group www
3 |   start program = "/usr/sbin/service apache2 start"
4 |   stop program = "/usr/sbin/service apache2 stop"
5 |   if failed host localhost port 80 protocol http
6 |     with timeout 10 seconds
7 |     then restart
8 |   if failed host localhost port 443 type tcpssl protocol http
9 |     with timeout 10 seconds
10 |    then restart
11 |    if 5 restarts within 5 cycles then timeout
```

/etc/monit/conf.d/dovecot

```
1 | check process dovecot with pidfile /var/run/dovecot/master.pi
2 |   group mail
3 |   start program = "/usr/sbin/service dovecot start"
4 |   stop program = "/usr/sbin/service dovecot stop"
5 |   group mail
6 |   # We'd like to use this line, but see:
7 |   # http://serverfault.com/questions/610976/monit-failing-to-
8 |   #if failed port 993 type tcpssl sslauto protocol imap for 5
9 |   if failed port 993 for 5 cycles then restart
10 |  if 5 restarts within 25 cycles then timeout
```

/etc/monit/conf.d/mysql

```
1 | check process mysqld with pidfile /var/run/mysqld/mysqld.pid
2 |   group database
3 |   start program = "/usr/sbin/service mysql start"
4 |   stop program = "/usr/sbin/service mysql stop"
5 |   if failed host localhost port 3306 protocol mysql then resta
6 |   if 5 restarts within 5 cycles then timeout
```

/etc/monit/conf.d/postfix

```
1 | check process postfix with pidfile /var/spool/postfix/pid/mast
2 |   group mail
3 |   start program = "/usr/sbin/service postfix start"
4 |   stop program = "/usr/sbin/service postfix stop"
5 |   if failed port 25 protocol smtp then restart
6 |   if 5 restarts within 5 cycles then timeout
```

/etc/monit/conf.d/spamassassin

```
1 | check process spamassassin with pidfile /var/run/spamassassin.
2 |   group mail
3 |   start program = "/usr/sbin/service spamassassin start"
4 |   stop program = "/usr/sbin/service spamassassin stop"
5 |   if 5 restarts within 5 cycles then timeout
```

/etc/monit/conf.d/sshd

```
1 |
```

```

1 | check process sshd with pidfile /var/run/sshd.pid
2 |   start program "/usr/sbin/service ssh start"
3 |   stop program "/usr/sbin/service ssh stop"
4 |   if failed host 127.0.0.1 port 22 protocol ssh then restart
5 |     if 5 restarts within 5 cycles then timeout

```

Now enable the local Monit HTTP interface by editing `/etc/monit/monit` lines. This enables use of commands such as `monit status`. Run `monit` available options.

```

1 | ## Monit has an embedded HTTP interface which can be used to
2 | ## services monitored and manage services from a web interfac
3 | ## interface is also required if you want to issue Monit comm
4 | ## command line, such as 'monit status' or 'monit restart ser
5 | ## for this is that the Monit client uses the HTTP interface
6 | ## commands to a running Monit daemon. See the Monit Wiki if
7 | ## enable SSL for the HTTP interface.
8 | #
9 | set httpd port 2812 and
10 |   use address localhost # only accept connection from loca
11 |   allow localhost # allow localhost to connect to th
12 | #   allow admin:monit # require user 'admin' with pass

```

Then restart Monit to pick up the new orders:

```

1 | service monit restart

```

Monit offers options for notifications, a web console, restarting on high other amenities, so you may want to add more to this very basic config familiar with the application. One important item to note is that once at Monit will no longer monitor that service, even after both service and Mc Check to see which services are being monitored by running:

```

1 | monit status

```

Then monitor a service with:

```

1 | # monit monitor <name>, e.g.:
2 | monit monitor mysqld

```

Install Roundcube for Webmail

Roundcube is a straightforward PHP webmail package: if all you need is via a web interface then this is for you. There are other, more complex options out there but you pay the price for that in the time taken to install. Roundcube is a much less onerous experience, but unfortunately the instructions online on how to install Roundcube are, shall we say, somewhat confused the wrong path if working from a package install on Ubuntu. Here instead manage things.

Start by installing the necessary packages. The plugin packages aren't essential, so check them over to see what is available:

```

1 | apt-get install --assume-yes \
2 |   roundcube \

```

```

3 | roundcube-plugins \
4 | roundcube-plugins-extra \
5 | php-mail \
6 | php-mail-mimedecode \
7 | php-mime-type \
8 | php-mail-mime \
9 | php7.0-intl \
10 | php7.0-zip
11 |
12 | pear install Net_IDNA2-0.1.1

```

In the package installation process you will be asked whether the installed database type is MySQL. Answer Yes, then choose mysql as the database type. You'll be asked for a password for the database user, so enter it. Then you will be asked to enter and confirm a password for the Roundcube user that will be created for you. The same comments on passwords apply here for the root and mail user.

The php7.0-intl and php7.0-zip modules should in theory be enabled by default, but I had some problems getting PHP and Apache to realize that fact. Try enabling them manually on the web server, which is what finally worked for me:

```
1 | phpenmod intl zip
```

Either way, restart Apache to pick up changes:

```
1 | service apache2 restart
```

Edit the following lines in `/etc/roundcube/config.inc.php` to tell Roundcube that other Roundcube applications are running on the same machine as it is:

```

1 | // The mail host chosen to perform the log-in.
2 | // Leave blank to show a textbox at login, give a list of hosts
3 | // to display a pulldown menu or set one host as string.
4 | // To use SSL/TLS connection, enter hostname with prefix ssl:
5 | // Supported replacement variables:
6 | // %n - hostname ($_SERVER['SERVER_NAME'])
7 | // %t - hostname without the first part
8 | // %d - domain (http hostname $_SERVER['HTTP_HOST'] without t
9 | // %s - domain name after the '@' from e-mail address provide
10 | // For example %n = mail.domain.tld, %t = domain.tld
11 | // WARNING: After hostname change update of mail_host column
12 | //           required to match old user data records with the
13 | $config['default_host'] = 'localhost';
14 |
15 | // SMTP server host (for sending mails).
16 | // To use SSL/TLS connection, enter hostname with prefix ssl:
17 | // If left blank, the PHP mail() function is used
18 | // Supported replacement variables:
19 | // %h - user's IMAP hostname
20 | // %n - hostname ($_SERVER['SERVER_NAME'])
21 | // %t - hostname without the first part
22 | // %d - domain (http hostname $_SERVER['HTTP_HOST'] without t
23 | // %z - IMAP domain (IMAP hostname without the first part)
24 | // For example %n = mail.domain.tld, %t = domain.tld
25 | $config['smtp_server'] = 'localhost';

```

As `/etc/roundcube/config.inc.php` overrides `/etc/roundcube/defaults.inc.php`, a large number of the overall properties, you will have to add these lines to `config.inc.php` in order to tell Roundcube to (a) redirect non-secure HTTP connections to HTTPS and (b) enable caching:

```

1 // enforce connections over https
2 // with this option enabled, all non-secure connections will
3 // set the port for the ssl connection as value of this optio
4 $config['force_https'] = true;
5
6 // Type of IMAP indexes cache. Supported values: 'db', 'apc'
7 $config['imap_cache'] = 'db';
8
9 // Backend to use for session storage. Can either be 'db' (de
10 $config['session_storage'] = 'db';

```

Ensure that you update the following configuration option in `/etc/roundcube` value for this installation:

```

1 // this key is used to encrypt the users imap password which i
2 // in the session record (and the client cookie if remember pa
3 // please provide a string of exactly 24 chars.
4 // YOUR KEY MUST BE DIFFERENT THAN THE SAMPLE VALUE FOR SECURI
5 $config['des_key'] = 'enter a unique value here';

```

At this point Roundcube is now installed and minimally configured, but it's not yet accessible via the webroot. The Roundcube webroot containing PHP files and views is located at `/var/lib/roundcube`, and the next step is to make that available to visitors by creating a symlink in the webroot:

```
1 | ln -s /var/lib/roundcube /var/www/html/roundcube
```

Now redirect the default landing page for visitors to Roundcube, which is currently `/var/www/html/index.html` out of the way:

```
1 | mv /var/www/html/index.html /var/www/html/index.bak.html
```

Then expand `/var/www/html/.htaccess` to include a rule to redirect just HTTP traffic to HTTPS. Being this selective leaves the open the option of adding other rules to `/var/www/html` for whatever you might want to use them for, and preserving the original `/var/www/html/index.html`.

```

1 RewriteEngine On
2
3 # Redirect all HTTP traffic to HTTPS.
4 RewriteCond %{HTTPS} !=on
5 RewriteRule ^/?(.*) https://%{SERVER_NAME}/$1 [R,L]
6
7 # Send / to /roundcube.
8 RewriteRule ^/?$ /roundcube [L]

```

You can now test Roundcube by visiting `http://mail.example.com` and logging in.

Add Two Factor Authentication to Roundcube

Two factor authentication (2FA) is increasingly a good idea in this age of cyber threats. Adding it is entirely optional, but note that there is a decent 2FA plugin for Roundcube called [2Steps Verification](#). The documentation in that repository covers installation and configuration, which isn't hard to do at all, so it won't be repeated here.

Options to Help Ensure Deliverability

If you want a quiet life free from worries about whether your mail destination, then you should take the small amount of additional time to mail server. These modifications go a long way towards ensuring the triggering false positives from spam filters. It is becoming ever harder the reaches its recipients. Set up a mail server in the cloud that happens to some time in the past used by spammers, or engage in a serious discussion spam, and you can wave goodbye to the certainty of delivery of your mail similar email providers. These entities maintain their own arcane anti-spam and distinct from the open world of IP address blacklists. Resolving issues attention of anyone who might help is essentially impossible if you don't have

Thus everyone who builds their own mail server should set up the two providers pay attention to when it comes to the decision tree for their [Policy Framework \(SPF\)](#) and [DomainKeys Identified Mail \(DKIM\)](#).

Set Up Sender Policy Framework (SPF)

SPF requires only that you add a TXT record to your DNS zone for the domain on the tools provided by your domain registrar, or the tools you set up your own nameservers. If using a registrar's web interface to make DNS changes, the option to enter a subdomain for the record. If you do, then leave that

This generic SPF TXT record authorizes mail originating from mail servers identified by MX records and all other servers associated with your domain

```
1 | "v=spf1 a mx -all"
```

Note that the double quotes are a necessary part of the SPF TXT record. Other than this are possible, as outlined in the [SPF documentation](#). You can see examples in the wild by using the dig command. e.g.:

```
1 | dig google.com txt
```

Server Setup For DomainKeys Identified Mail (DKIM)

Setting up DKIM is a little more involved than SPF. First install the necessary

```
1 | apt-get install --assume-yes opendkim opendkim-tools
```

Add the following to `/etc/opendkim.conf`:

```
1 | Domain    example.com
2 | KeyFile   /etc/postfix/dkim.key
3 | Selector  dkim
4 | SOCKET    inet:8891@localhost
```

Add the following to `/etc/default/opendkim`:

```
1 | SOCKET="inet:8891@localhost"
```

Append a suitable DKIM configuration to `/etc/postfix/main.cf`:

```
.
```

```

1 | # -----
2 | # DKIM
3 | # -----
4 | milter_default_action = accept
5 | milter_protocol = 6
6 | smtpd_milters = inet:localhost:8891
7 | non_smtpd_milters = inet:localhost:8891

```

Now you can generate a private key for signing outgoing mail. Note that is the value given to Selector in `/etc/openssl.conf`. This can be any consistent about replacing `dkim` with your desired value everywhere in the command to generate the key and associated materials in the form `dkim.txt`. The former is the RSA private key, while the latter contains the into your DNS records.

```

1 | openssl genrsa -t -s dkim -d example.com

```

Move the key into place and grant suitable permissions, but don't forget to backed up somewhere safe:

```

1 | mv dkim.private /etc/postfix/dkim.key
2 | chmod 660 /etc/postfix/dkim.key
3 | chown root:opendkim /etc/postfix/dkim.key

```

You'll need to restart Postfix and OpenDKIM services to pick up the configuration mail is signed using DKIM:

```

1 | service opendkim start
2 | service postfix restart

```

DNS Setup For DomainKeys Identified Mail (DKIM)

Next up is the DNS record setup. How you do this is again completely dependent on how it is managed for you - everyone's tools are different. Note that create raw TXT records with specific subdomains, which will prevent you from If this is the case, then you will have to transfer your domain to a real registrar the toys.

The file `dkim.txt` contains the following content, the full TXT record for subdomain `dkim._domainkey` and a long set of encoded content as the given to Selector in `/etc/openssl.conf`.

```

1 | dkim._domainkey IN TXT ( "v=DKIM1; k=rsa; t=y; "
2 | "p=MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQC9ru1Ko58JIb5h+3MMEnY

```

When adding the DNS record you should omit the `k=rsa; t=y;` portion of to the key format and that defaults to RSA. The second denotes that the be included. Thus the value to add looks like this:

```

1 | "v=DKIM1; p=MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQC9ru1Ko58JIb

```

It is helpful to view examples in the wild for the purposes of comparison. You should enter the value into your records. You can use the **DKIM key checker**. Note that the `dkim._domainkey` is the subdomain in the following command:

```
1 | dig dkim._domainkey.twitter.com txt
```

Monitor the OpenDKIM Service

Add a configuration file `/etc/monit/conf.d/opendkim`:

```
1 | check process opendkim with pidfile /var/run/opendkim/opendkim
2 |     group mail
3 |     start program = "/etc/init.d/opendkim start"
4 |     stop program = "/etc/init.d/opendkim stop"
5 |     if 5 restarts within 5 cycles then timeout
```

Then restart Monit:

```
1 | service monit restart
```

Sharing a DKIM Key for Multiple Domains

If you are serving multiple domains from the same mail server, then the configuration should be:

```
1 | Domain      *
2 | KeyFile     /etc/postfix/dkim.key
3 | Selector    dkim
4 | SOCKET      inet:8891@localhost
```

This will work unless you are running a mailing list or similar, in which case you should be careful of addresses in domains other than the list domain. In that case, see **ServerFault question and answer** for more complex configurations that can be used.

Testing the SPF and DKIM Configuration

The only certain test is to send mail from the server and inspect it. A decision which will report on the validity of the SPF and DKIM additions to mail. DNS changes a chance to propagate before using it.

Notes on Postgrey

You'll find that Postgrey has its own idiosyncratic notion of what default configuration **should work**. There are whitelist configuration files for `/etc/postgrey/whitelist_clients` and `/etc/postgrey/whitelist_recipients` which are not actually used by default. If you want to use them, you must either copy them to the default location or edit the default configuration:

```
1 | cp /etc/postgrey/whitelist_clients /etc/postfix/postgrey_whitelist_clients
2 | cp /etc/postgrey/whitelist_recipients /etc/postfix/postgrey_whitelist_recipients
```

Or, alternatively, edit `/etc/default/postgrey`:

```
1 | # postgrey startup options, created for Debian
```

```

2
3 # you may want to set
4 # --delay=N how long to greylist, seconds (default: 300)
5 # --max-age=N delete old entries after N days (default: 35)
6 # see also the postgrey(8) manpage
7
8 POSTGREY_OPTS="--inet=10023"
9 POSTGREY_OPTS="$POSTGREY_OPTS --whitelist-clients=/etc/postgr
10 POSTGREY_OPTS="$POSTGREY_OPTS --whitelist-recipients=/etc/pos
11
12 # the --greylist-text commandline argument can not be easily
13 # POSTGREY_OPTS when it contains spaces. So, insert your tex
14 #POSTGREY_TEXT="Your customized rejection message here"

```

Notes on Serving Multiple Domains

You can create multiple domains in Postfix Admin if so desired, under Additional domains added in Postfix Admin can be aliased to existing do Alias Domain, such that address@example1.com is always forwarded to ; can stand as distinct domains with their own mailboxes, aliases, and so fo

Depending on your use case, you might also want to adjust some of the accessing the site at mail.example1.com, mail.example2.com, and so redirect to SSL to recognize all of the domains used.

Roundcube should work for multiple domains, but requires you to [cre](#) Fortunately the instructions are clear.

The tricky part of the setup for multiple domains relates to SSL certific DNS lookup for outgoing mail. Postfix [requires](#) one IP address per certifica could be provisioned with multiple IP addresses and certificates, which \ Alternatively, use a single IP address and [multi-domain UCC certificate](#) wants the reverse DNS lookup to be consistent, however, and in a addresses, the outgoing mail will all appear to be coming from the single domain it is sent from. This is a problem. The simplest solution to work ar is to assign the same mail.example.com MX record for all of the domains are some [examples that explain this setup](#) if you look around online.

Notes on Setting Up as a Backup MX

A backup mail server will receive mail when the primary is offline, and the it is available. For a personal mail server this is probably unnecessary, but want to set up the server you are building as one of the backup mail serv to this recipe are required. These are taken from [a short guide](#) that you m

1) Firstly create /etc/postfix/mysql_relay_domains_maps.cf containing th

```

1 user = mail
2 password = mailpassword
3 hosts = 127.0.0.1
4 dbname = mail
5 query = SELECT domain FROM domain WHERE domain='%s' AND backup

```

2) Then add the following to /etc/postfix/main.cf:

```

1 # This is a backup MX server, and this line tells Postfix
2 # where to send the mail.

```

```
3 | relay_domains = proxy:mysql:/etc/postfix/mysql_relay_domains_m
```

3) In the domain configuration in Postfix Admin, check the "Mail server is

4) To enable delivery to the backup, the MX DNS records must include an primary mail server. E.g.:

```
1 | name                priority ip-address
2 | mail.example.com    10      172.10.10.10
3 | mail-backup.example.com 20      172.10.10.11
```

5) Lastly, you will need to set up a script or process of change replicat entries for users and domains are the same in primary and backup mail MX flag.

Notes on Managing Quotas

If you've been following carefully, you will note that nothing has been s disk space quotas. It was not an important goal for the work that p instructions. As things stand the necessary fields for quota managment (are not used, as (a) the quota module isn't enabled by default in Dovecot, to use quotas by default.

So if you want to enable disk quotas, you should first of all alter the Post /var/www/html/postfixadmin/config.inc.php by adding /var/www/html/postfixadmin/config.local.php :

```
1 | // Quota
2 | // When you want to enforce quota for your mailbox users set t
3 | $CONF['quota'] = 'YES';
4 | // You can either use '1024000' or '1048576'
5 | $CONF['quota_multiplier'] = '1024000';
```

```
1 | // Optional:
2 | // Show used quotas from Dovecot dictionary backend in virtua
3 | // mailbox listing.
4 | // See: DOCUMENTATION/DOVECOT.txt
5 | //      http://wiki2.dovecot.org/Quota/Dict
6 | //
7 | $CONF['used_quotas'] = 'YES';
8 |
9 | // if you use dovecot >= 1.2, set this to yes.
10 | // Note about dovecot config: table "quota" is for 1.0 & 1.1,
11 | // table "quota2" is for dovecot 1.2 and newer
12 | $CONF['new_quota_table'] = 'YES';
```

Next, you will want to enable and configure the quota and imap_quota manages quotas while the latter enables reporting on quotas via IMAP. Y following documentation for instructions on how to do this:

- [Quota \(Dovecot 2.*\)](#)
- [Quota Configuration \(Dovecot 2.*\)](#)

These configuration changes will be made in 10-mail.conf and 90-quota directory.

Bypassing Spam and Virus Checks for Local Mail

If you're in the business of sending out newsletters or frequent updates, you probably don't want to completely control the content in those emails, then you probably don't want to run spam and virus checks for those items. It's a pointless use of server processing cycles, and it's a waste of space on the server if you are making it process the full range of checks on each and every message.

To have amavisd-new skip the checks for mail originating from a known source (e.g. mail coming from a web application on another server, etc), edit `/etc/amavis/conf.d/50`

```
1 | # Replace 111.111.111.111/32 with your desired list of client
2 | # ranges which will bypass checks.
3 | @mynetworks = qw( 127.0.0.0/8 [::1] 111.111.111.111/32 );
4 |
5 | # Rules for clients defined in @mynetworks
6 | $policy_bank{'MYNETS'} = {
7 |   bypass_spam_checks_maps    => [1], # don't spam-check inter
8 |   bypass_banned_checks_maps => [1], # don't banned-check int
9 |   bypass_header_checks_maps => [1], # don't header-check int
10| };
```

Replace `111.111.111.111/32` with whatever set of IP address ranges you want to bypass checks. All mail arriving from those sources will fall into MYNETS for amavisd-new checking. If bypassing by IP address doesn't fit your needs, you can find a list of users, destinations, or sources in [a helpful, if dated guide to amavisd-new](#)

Some Final Notes on Security

You'll note that there are a fair number of configuration files that contain sensitive data in this server, and that includes PHP files sitting in the webmail directory. The dominant security concern: the mail users are virtual and only the server has access to them. On AWS the default setup is for SSH login to use the ubuntu user, but only the ubuntu user has a key setup to allow login. You can also restrict access to selected IP addresses via the security group applied to the server. Furthermore, to ensure that no web visitor can directly view configuration files - a security group rule is included, which covers the rare case where some error causes PHP files to be served as text. MySQL access is from localhost only, in any case.

All in all the lowest bar from a traditional security perspective is probably what you get when you run a couple of complicated PHP web applications with database access. These applications involve a way to upload and execute an arbitrary PHP script or shell command with full permissions, or various other XSS attacks allowing for session hijacking. Just by getting into the databases, compromise of the webroot is common. Major PHP webmail applications have exhibited vulnerabilities in the past years, but at some point you have to pick your software. On the whole, the security of webmail with the output of established development communities whose members have a good record of vulnerabilities found and fixed, and where there are a large number of eyes on the codebase.

These are all good reasons for setting up your webmail on a different server and Dovecot - something to bear in mind.

Of course being on AWS - or indeed any sort of easily available hosting in the cloud - in your front room - means that the US government has free access to your data. It's particularly feel up to the task, and you may never know a copy w

forthcoming evolutions in virtual hosting services will be some form of operations such that you can have the convenience of an AWS-style service that it affords the present day panopticon-in-the-making.

Further, it is apparently the case that all email traffic between mail servers of governmental agencies. Unfortunately the present state of SMTP in the servers do not implement the ability to pass emails over an encrypted connection. To setup and enforce encryption for POP, IMAP, and webmail connections between mail servers is often plain text. Forcing your connections with other servers will mean that a large fraction of your email will be rejected. Thus the configuration provided for Postfix in this post is for one that sends and received will be encrypted if the mail server on the other end of the connection is also configured to do so.
