32.3.1 System Configuration Control Register (SYSCFG)

SYSCFG enables or disables high-speed operation, selects the host controller function or function controller function, controls DP_0 and DM_0 pins, and enables or disables the operation of this module.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SCKE	—	—	HSE	DCFM	DRPD	DPRPU	—	—	—	USBE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	SCKE	0	R/W	USB Module Clock Enable Enables or halts the supply of the 48-MHz clock to this module. 0: The clock supply to the USB module is halted. 1: The clock supply to the USB module is enabled. When this bit is 0, only this register and BUSWAIT are readable and writable. Other registers in the USB module are readable but not writable.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	HSE	0	R/W	High-Speed Operation Enable 0: High-speed operation is disabled. When the function controller function is selected: Full-speed operation only When host controller function is selected: Full-speed or low-speed operation 1: High-speed operation is enabled. (This module detects the transmission rate.) (1) When the host controller function is selected When HSE is 0, the USB port performs low-speed or full-speed operation. If the USB detects that a low-speed peripheral device is attached to the USB port, be sure to set the HSE bit to 0. When HSE is 1, this module executes the reset handshake protocol, and according to the result, the USB port is automatically driven to high-speed or full-speed operation mode. Change this bit after the ATTCH interrupt is detected and before resetting the USB bus (before setting USBRESET to 1). (2) When the function controller function is selected When HSE is 0, this module performs full-speed operation. When HSE is 1, this module executes the reset handshake protocol, and according to the result, this module automatically performs high-speed or full-speed operation. Change this bit while the DPRPU bit is 0.
6	DCFM	0	R/W	Controller Function Select Selects the function of this module. 0: The function controller function is selected. 1: The host controller function is selected. Change this bit while the DPRPU and DRPD bits are 0. During the HNP processing, however, this bit can be set according to the processing sequence.

Bit	Bit Name	Initial Value	R/W	Description
5	DRPD	0	R/W	D+ Line/D- Line Resistance Control Enables or disables pull-down of the D+ and D- lines when the host controller function is selected. 0: Pull-down is disabled. 1: Pull-down is enabled. Set this bit to 1 when the host controller function is selected. During the HNP processing, however, this bit can be set according to the processing sequence. Set this bit to 0 when the function controller function is selected.
4	DPRPU	0	R/W	D+ Line Resistance Control Enables or disables pull-up of the D+ line when the function controller function is selected. 0: Pull-up is disabled. 1: Pull-up is enabled. When this bit is set to 1 with the function controller function selected, this module pulls up the D+ line at 3.3V, and informs the USB host of ATTACH. Clearing this bit to 0 cancels the pull-up of the D+ line, and informs the USB host of DETACH. Set this bit to 1 when the function controller function is selected. During the HNP processing, however, this bit can be set according to the processing sequence. Set this bit to 0 when the host controller function is selected.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	USBE	0	R/W	USB Module Operation Enable Enables or disables the USB module operation. 0: The USB module operation is disabled. 1: The USB module operation is enabled. Tables 32.4 and 32.5 list the registers and bit names initialized when this bit is cleared to 0. Change this bit while the SCKE bit is 1. When the host controller function is selected, set the DPRD bit to 1, eliminate chattering with the LNST bit, confirm that the USB bus is stable, and then set this bit to 1.

Table 32.4 Registers Initialized by Writing 0 in the USBE Bit (When the function controller function is selected)

Register Name	Bit Name	Remarks
SYSSTS	LNST	The value is retained when the host controller function is selected.
DVSTCTR	RHST	
INTSTS0	DVSQ	The value is retained when the host controller function is selected.
USBADDR	USBADDR	The value is retained when the host controller function is selected.
USEREQ	BRequest, bmRequestType	The value is retained when the host controller function is selected.
USBVAL	wValue	The value is retained when the host controller function is selected.
USBINDX	wIndex	The value is retained when the host controller function is selected.
USBLENG	wLength	The value is retained when the host controller function is selected.

Table 32.5 Registers Initialized by Writing 0 in the USBE Bit (When the host controller function is selected)

Register Name	Bit Name	Remarks
DVSTCTR	RHST	
FRMNUM	FRNM	The value is retained when the function controller function is selected.
UFRMNUM	UFRNM	The value is retained when the function controller function is selected.

32.3.2 CPU Bus Wait Register (BUSWAIT)

BUSWAIT specifies the number of access waits from the CPU to this module.

This register is writable even if the SCKE bit in SYSCFG is 0.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	BWAIT[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	BWAIT[3:0]	1111	R/W	CPU Bus Wait Specify the number of access waits to this module. 0000: 0 waits (2 access cycles) 0001: 1 wait (3 access cycles) 0010 to 1110: 2 to 14 waits (4 to 16 access cycles) 1111: 15 waits (17 access cycles) initial value The following restriction is provided for access cycles to the registers of addresses beginning with H'04 of this controller. Restriction for wait: The cycle of continuous accesses to the registers of this controller must be 80 ns or more. To satisfy this restriction, control waits using the frequency of system clock HPϕ. Choose the best value within the initial value of 17 clock cycles (maximum). This setting is the same as the waits in accesses to the FIFO port register. The maximum speed of accesses to the FIFO port is as follows: MBW = 10 (32-bit width) : Max. 48 Mbytes/s MBW = 01 (16-bit width) : Max. 24 Mbytes/s MBW = 00 (8-bit width) : Max. 12 Mbytes/s

32.3.3 System Configuration Status Register (SYSSTS)

SYSSTS monitors the USB data bus line status (D+ and D- lines).

This register is initialized by a power-on reset or a USB reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVCMON[1:0]		—	—	—	—	—	—	—	HTACT	—	—	—	ID MON	LNST[1:0]	
Initial value:	—*	—*	0	0	0	1	0	0	0	0	0	0	0	—*	—*	—*
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15, 14	OVCMON [1:0]	Undefined*	R	OVCN_0/OVCN2_0 Pin Monitor Indicate the input state of the OVCN_0 and OVCN2_0 pins. 00: OVCN_0 = Low, OVCN2 = Low 01: OVCN_0 = Low, OVCN2 = High 10: OVCN_0 = High, OVCN2 = Low 11: OVCN_0 = High, OVCN2 = High Connection of an external device to the OVCN_0 and OVCN2 pins allows SRP as an OTG function.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
9 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	HTACT	0	R	Indicates that this module is processing when the host controller function is selected. 0: Idle state 1: Processing
5 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2	IDMON	Undefined*	R	Indicates the input state of the IDIN pin. 0: IDIN = Low 1: IDIN = High Connection of an external device to the IDIN pin allows a device ID as an OTG function to be reflected in this bit.
1, 0	LNST[1:0]	Undefined*	R	USB Data Line Status Monitor Indicate the USB data bus line (D+ and D- lines) status. Table 32.6 shows the USB data bus line status. Read these bits after the attach processing (DPRPU = 1) when the function controller function is selected or read them after enabling pull-down of the D+ and D- lines (DRPD = 1) when the host controller function is selected.

Note: * These bits depend on the state of the DP_0, DM_0, OVCN_0, OVCN2, and IDIN pins.

Table 32.6 USB Data Bus Line Status

LNST[1]	LNST[0]	Low-Speed Operation (only when host controller function is selected)	Full-Speed Operation	High-Speed Operation	Chirp Operation
0	0	SE0	SE0	Squelch	Squelch
0	1	K-State	J-State	UnSquelch	Chirp J
1	0	J-State	K-State	Invalid	Chirp K
1	1	SE1	SE1	Invalid	Invalid

Legend:

Chirp: The reset handshake protocol (RHSP) is being executed with high-speed operation is enabled (HSE = 1 in SYSCFG).
Squelch: SE0 or idle state
UnSquelch: High-speed J-State or high-speed K-State
Chirp J: Chirp J-State
Chirp K: Chirp K-State
Invalid: Invalid

32.3.4 Device State Control Register (DVSTCTR)

DVSTCTR controls and monitors the USB data bus state.

This register is initialized by a power-on reset. The WKUP bit is initialized and the RESUME bit becomes undefined by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	HNP BTOA	EXT LP	PWEN	WKUP	RWU PE	USB RST	RES UME	UACT	—	RHST[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W*	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	HNPBTOA	0	R/W	Switches HNP (Host Negotiation Protocol) From B (Device) to A (Host). This bit is used to switch the function controller function (device B) to the host controller function (device A) when the OTG uses the HNP. 0: Normal operation 1: Switching OTG B to A is enabled. When this bit is 1, the internal function controller remains suspended until the HNP processing finishes even when DPRPU = 0 or DCFM = 1. Furthermore, even if the falling edge of the D+ signal is detected, the resume (RESM) interrupt is not generated. When the HOST ATTACH (pull-up at the other side) is detected or the HNP processing timeout occurs, write 0 in this bit. Write 1 in this bit only in the suspended state with the function controller function selected.
10	EXTLP_0	0	R/W	Controls the EXTLP_0 pin output state. 0: EXTLP0 Low output 1: EXTLP0 High output
9	PWEN_0	0	R/W	Controls the PWEN_0 pin output state. 0: PWEN_0 Low output 1: PWEN_0 High output

Bit	Bit Name	Initial Value	R/W	Description
8	WKUP	0	R/W*	Wakeup Output Enables or disables the remote wakeup (resume signal output) to the USB bus when the function controller function is selected. 0: The remote wakeup signal is not output. 1: The remote wakeup signal is output. This module controls the remote wakeup signal output time. When this bit is set to 1, this module outputs 10 ms K-State and then clears this bit. The USB Specification requires the USB bus idle state to be maintained for at least 5 ms before transmitting the remote wakeup signal. For this reason, this module outputs K-State after waiting for 2 ms even if 1 is written in this bit immediately after the suspended state is detected. Write 1 in this bit only when the device is in the suspended state (DVSQ = 1xx in INTSTS0) and remote wakeup is enabled by the USB host. When setting this bit to 1, do not stop the internal clock even in the suspended state (Write 1 in this bit with SCKE set to 1). Write 0 in this bit when the host controller function is selected.
7	RWUPE	0	R/W	Wakeup Detection Enable Enables or disables remote wakeup (resume signal output) for the peripheral device of the down port when the host controller function is selected. 0: Remote wakeup output to the down port is disabled. 1: Remote wakeup output to the down port is enabled. When the remote wakeup signal is detected while this bit is 1, this module detects the resume signal (2.5 μs K-State) for the down port and performs resume processing to drive K-State. When this bit is set to 0, the remote wakeup signal (K-State) from the peripheral device connected to the selected port is ignored even if it is detected by this module. While this bit is 1, do not halt any internal clocks even in the suspended state (keep SCKE = 1). Also do not reset the USB bus from the suspended state by writing 1 in the USBRST bit. This is prohibited by USB Specification 2.0. Set this bit to 0 when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
6	USBRST	0	R/W	Bus Reset Output Controls the USB bus reset signal output when the host controller function is selected. 0: The USB bus reset signal is not output. 1: The USB bus reset signal is output. When this bit is set to 1 with the host controller function selected, this module drives SE0 of the USB port to perform the USB bus reset processing. When the HSE bit is 1 at this time, this module executes the reset handshake protocol. While USBRST is 1 (until the software writes 0 in this bit), this module continues the SE0 output. Secure the time specified in the USB Specification 2.0 for the USB bus reset time period (USBRST = 1). If 1 is written in this bit during communication (UACT = 1) or during resume (RESUME = 1), this module does not reset the USB bus until the UACT and RESUME bits are cleared to 0. Immediately after this bit is cleared to cancel a USB bus reset, write 1 in the UACT bit. Set this bit to 0 when the function controller function is selected.
5	RESUME	0	R/W	Resume Output Controls the resume signal output when the host controller function is selected. 0: The resume signal is not output. 1: The resume signal is output. When this bit is set to 1, this module drives the port into K-State to output the resume signal. While RESUME is 1 (until the software writes 0 in this bit), this module continues the K-State output. Secure the time specified in the USB Specification 2.0 for the resume time period (RESUME = 1). Write 1 in this bit only in the suspended state. Immediately after this bit is cleared to cancel the resume, write 1 in the UACT bit. Set this bit to 0 when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
4	UACT	0	R/W	USB Bus Enable Enables or disables the USB bus operation (output control of the SOF or μSOF packet to the USB bus) when the host controller function is selected. 0: Down port operation is disabled. (SOF/μSOF packets are not sent.) 1: Down port operation is enabled. (SOF/μSOF packets are sent.) When this bit is set to 1, this module drives the USB port into the USB bus enable state, sends the SOF packet, and performs data communication. The SOF or μSOF packet is sent within one (micro) frame time period after the software writes 1 in this bit. When this bit is set to 0, this module enters the idle state after the SOF or μSOF packet is sent. This module sets this bit to 0 in the following cases: When the DTCH interrupt is detected during communication (UACT = 1) When the EOFERR interrupt is detected during communication (UACT = 1) Write 1 in this bit at the end of USB reset processing (clearing the USBRST bit) or at the end of resume processing from the suspended state (clearing the RESUME bit). Set this bit to 0 when the function controller function is selected.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	RHST[2:0]	000	R	Reset Handshake Indicate the reset handshake state. (1) When the host controller function is selected: 000: Transmission rate is undefined (when powered or not connected). 1xx: The reset handshake processing is in progress. 001: Low-speed connection 010: Full-speed connection 011: High-speed connection After the software writes 1 in USBRST, these bits become 100. When HSE is set to 1 for the port, these bits become 111 when this module detects ChirpK from the peripheral device. When the software writes 0 in USBRST of the selected port and this module finishes driving SE0, this module determines the value of the RHST bits. (2) When the function controller function is selected: 000: Transmission rate is undefined. 100: The reset handshake processing is in progress. 010: Full-speed connection 011: High-speed connection When this module detects a USB bus reset with the HSE bit set to 1 for the port, these bits become 100. After that, when this module outputs ChirpK and detects ChirpJK from the USB host three times, these bits become 011. Unless high-speed mode is fixed within 2.5 ms after the ChirpK output, these bits become 010. When this module detects a USB bus reset with the HSE bit set to 0 for the port, these bits become 010. When the RHST bits are fixed to 010 or 011 after this module detected a USB bus reset, the DVST interrupt occurs.

32.3.5 Test Mode Register (TESTMODE)

TESTMODE controls the USB test signal output in high-speed operation mode.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	UTST[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	UTST[3:0]	0000	R/W	Test Mode Table 32.7 shows the test mode operation of this module. Control the USB test signal output in high-speed operation mode. These bits are valid only in high-speed operation mode. Use this test mode when the RHST bits in DVSTCTR are 011. Since bit 3 (UTST3) of these bits depends on the DCFM bit (controller function select), set these bits according to the DCFM bit. Furthermore, after the test with these bits, cancel this test mode by a power-on reset. When the host controller function is selected: Set these bits after setting DRPD to 1. This module outputs waveforms to the USB port for which DRPD = 1 and UACT = 1 are set. This module also performs high-speed termination for the USB port. Set the UTST bits using the following steps. 1. System reset 2. Clock initiation 3. DCFM = 1, DPRD = 1 (Setting HSE to 1 is not needed.) 4. USBE = 1 5. Set the UTST bits to a value according to the test content. 6. Set the UACT bit to 1.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	UTST[3:0]	0000	R/W	Change the UTST bits using the following steps. 1. UACT = 0, USBE = 0 2. USBE = 1 3. Set the UTST bits to a value according to the test content. 4. Set the UACT bit to 1. When Test_SE0_NAK (1011) is set, this module does not output the SOF packet to the port for which UACT is set to 1. When Test_Force_Enable (1101) is set, this module outputs the SOF packet to the port for which UACT is set to 1. Furthermore in this test mode, even if this module detects a high-speed disconnection (DTCH interrupt), this module does not control the hardware related to the detection. Before setting the UTST bits, set the PID bit of all pipes to NAK. When performing normal USB communication after setting test mode, issue a system reset. When the function controller function is selected: Set these bits according to the SetFeature request from the USB host during high-speed communication. While these bits are 0001 to 0100, this module does not enter the suspended state.

Table 32.7 Test Mode Operation

	UTST Bits Setting	
Test Mode	**When function controller function is selected**	**When host controller function is selected**
Normal operation	0000	0000
Test_J	0001	1001
Test_K	0010	1010
Test_SE0_NAK	0011	1011
Test_Packet	0100	1100
Test_Force_Enable	—	1101
Reserved	0101 to 0111	1110 to 1111

32.3.6 CFIFO Port Register

CFIFO is a port register to read data from or write data to the FIFO buffer memory.

Each FIFO port consists of this register (CFIFO) for data read/write from/to the FIFO buffer memory, the select registers (CFIFOSEL, D0FIFOSEL, and D1FIFOSEL) to select pipes to be allocated to a FIFO port, and the control registers (CFIFOCTR, D0FIFOCTR, and D1FIFOCTR).

Each FIFO port provides the following features.

- Make accesses to the FIFO buffer for DCP through the CFIFO port.
- Make accesses to the FIFO buffer with DMA transfers through the DMAC module for USB high-speed only.
- When using a function specific to FIFO ports (DMA transfer function, etc.), the pipe number (selected pipe) specified by the CURPIPE bits cannot be changed.
- Register groups of a FIFO port do not affect other FIFO ports.
- Do not allocate the same pipe number to different FIFO ports.
- There are two FIFO buffer states where the access mastership is on the CPU side and on the SIE side. When the FIFO buffer access mastership is on the SIE side, the CPU cannot make an access to the FIFO buffer.

This register is initialized by a power-on reset.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FIFOPORT[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	FIFOPORT [31:0]	All 0	R/W	FIFO Port Read receive data from the FIFO buffer or write transmit data to the FIFO buffer using these bits. Access to this register is enabled only when the FRDY bit in each control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is set to 1. Valid bits in this register vary with the value of the MBW bits. Table 32.8 shows the valid bits in this register.

Table 32.8 Operation of This Register when Accessed

Access Size	Bits 31 to 24	Bits 23 to 16	Bits 15 to 8	Bits 7 to 0
32 bits	N + 3 address	N + 2 address	N + 1 address	N + 0 address
16 bits	Write: Invalid, Read: Prohibited*		N + 1 address	N + 0 address
8 bits	Write: Invalid, Read: Prohibited*			N + 0 address

Note: * Reading an invalid register with word access or byte access is prohibited.

32.3.7 FIFO Port Select Registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL)

CFIFOSEL, D0FIFOSEL, and D1FIFOSEL select pipes to be allocated to FIFO ports and control accesses to each FIFO port.

Do not specify the same pipe number for the CURPIPE bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL. When the CURPIPE bits in D0FIFOSEL and D1FIFOSEL are set to B'000, no pipe is specified.

Do not change any pipe number when DMA transfer is enabled.

This register is initialized by a power-on reset.

(1) CFIFOSEL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCNT	REW	—	—	MBW[1:0]		—	—	—	—	ISEL	—	CURPIPE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	RCNT	0	R/W	Read Count Mode Specifies read mode of the DTLN bits in CFIFOCTR. 0: Clears the DTLN bits after reading all receive data in the CFIFO (or after reading receive data of one side of the double buffer). 1: Counts down the DTLN bits at each reading of CFIFO receive data.
14	REW	0	R/W	Buffer Pointer Rewind Specifies whether to rewind the buffer pointer or not. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound. When the selected pipe is in the receive direction and this bit is set to 1 during FIFO buffer reading, the FIFO buffer can be read from the first data. (In the case of a double buffer, the first data of one side that is being read can be read again.) Do not set this bit to 1 concurrently with the CURPIPE setting change. Be sure to confirm that the FRDY bit is 1 when setting this bit to 1. To rewrite the FIFO buffer data from the first data for a pipe in the transmit direction, use the BCLR bit.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11, 10	MBW[1:0]	00	R/W	CFIFO Port Access Bit Width Specify the bit width for accesses to the CFIFO port. 00: 8 bits 01: 16 bits 10: 32 bits 11: Setting prohibited When the selected pipe is in the receive direction and data read is started after these bits are set, do not change these bits until all data is completely read. When the selected pipe is in the receive direction, set the CURPIPE and MBW bits at the same time. When the selected pipe is in the transmit direction, no bit width can be changed (from 8 bits to 16/32 bits or from 16 bits to 32 bits) during data write to the buffer memory. When 8-bit width or 16-bit width is selected, data of odd bytes can also be written by controlling the byte access.
9 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	ISEL	0	R/W	CFIFO Port Access Direction when DCP is Selected 0: Buffer memory read is selected. 1: Buffer memory write is selected. To change this bit when the selected pipe is DCP, write 1 or 0 in this bit, read the value of this bit, confirm that the write value equals the read value, and then proceed with the next processing. If this bit is changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of this bit is rewritten, and then further access is enabled. Set this bit concurrently with the CURPIPE bits.

Bit	Bit Name	Initial Value	R/W	Description
4	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
3 to 0	CURPIPE [3:0]	0000	R/W	CFIFO Port Access Pipe Select Set the number of pipe to be used for data read or write through the CFIFO port. 0000: DCP 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 Other than above: Setting prohibited To change these bits, write a value in these bits, read the value of these bits, confirm that the write value equals the read value, and then proceed with the next processing. Do not write the same pipe number in the CURPIPE bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL. If these bits are changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of these bits is rewritten, and then further access is enabled.

Note: * Only reading 0 is enabled.

(2) D0FIFOSEL, D1FIFOSEL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCNT	REW	DCLRM	DREQE	MBW[1:0]		—	—	DEZPM	—	—	—	CURPIPE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W*	R/W	R/W	R/W	R/W	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	RCNT	0	R/W	Read Count Mode Specifies read mode of the DTLN bits in DnFIFOCTR. 0: Clears the DTLN bits after reading all receive data in the DnFIFO (or after reading receive data of one side of the double buffer). 1: Counts down the DTLN bits at each reading of DnFIFO receive data. When making an access to the DnFIFO with the BFRE bit set to 1, set this bit to 0.
14	REW	0	R/W*	Buffer Pointer Rewind Specifies whether to rewind the buffer pointer or not. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound. When the selected pipe is in the receive direction and this bit is set to 1 during FIFO buffer reading, the FIFO buffer can be read from the first data. (In the case of a double buffer, the first data of one side that is being read can be read again.) Do not set this bit to 1 concurrently with the CURPIPE setting change. Be sure to confirm that the FRDY bit is 1 when setting this bit to 1. When making an access to the DnFIFO with the BFRE bit set to 1, do not set this bit to 1 when the short packet data is completely read. To rewrite the FIFO buffer data from the first data for a pipe in the transmit direction, use the BCLR bit.

Bit	Bit Name	Initial Value	R/W	Description
13	DCLRM	0	R/W	Buffer Memory Auto-Clear Mode after Reading Data of Selected Pipe Enables or disables buffer memory auto-clear mode after reading data of the selected pipe. 0: Buffer memory auto-clear mode is disabled. 1: Buffer memory auto-clear mode is enabled. When this bit is 1 and a Zero-Length packet is received while the FIFO buffer allocated to the selected pipe is empty or when a short packet is received with the BFRE bit set to 1 and the packet data is completely read, this module performs buffer clear (BCLR = 1 processing) of the FIFO buffer. When using this module with the BRDYM bit set to 1, be sure to set this bit to 0.
12	DREQE	0	R/W	DMA Transfer Request Enable Enables or disables making a DMA transfer request. 0: DMA transfer request is disabled. 1: DMA transfer request is enabled. To enable a DMA transfer request, set the CURPIPE bits and then set this bit to 1. Set this bit to 0 before changing the CURPIPE setting.
11, 10	MBW[1:0]	00	R/W	FIFO Port Access Bit Width Specify the bit width for accesses to the DnFIFO port. 00: 8 bits 01: 16 bits 10: 32 bits 11: Setting prohibited When the selected pipe is in the receive direction and data read is started after these bits are set, do not change these bits until all data is completely read. When the selected pipe is in the receive direction, set the CURPIPE and MBW bits at the same time. When the selected pipe is in the transmit direction, no bit width can be changed (from 8 bits to 16/32 bits or from 16 bits to 32 bits) during data write to the buffer memory. When 8-bit width or 16-bit width is selected, data of odd bytes can also be written by controlling the byte access.

Bit	Bit Name	Initial Value	R/W	Description
9 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	DEZPM	0	R/W	DEZPM: Zero-Length Packet Addition Mode If the DMA transfer size that is set for the the USBHS-DMAC modules is an integral multiple of the maximum packet size, a null packet is added after all of the data has been sent. 0: Disables addition of packets. 1: Enables addition of packets. This bit is applied to pipes used to write to the FIFO buffer. DEZPM must be set before starting DMA transfers. If the DEZPM bit is set after DMA transfers complete, no null packets are added. Note : This mode depends on the buffer size(PIPEBUF.BUFSIZE[4:0]). A null packet is added after transferring data up to buffer size which is defined by PIPEBUF.BUFSIZE[4:0]. When transfer data size is over 2Kbytes, this mode must not be used because max size of buffer is 2Kbytes. In that case, please add the null packet by SW with BVAL bit of FIFO Port Control Registers.
6 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CURPIPE [3:0]	0000	R/W	FIFO Port Access Pipe Select Set the number of pipe to be used for data read or write through the D0FIFO and D1FIFO ports. 0000: No pipe 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 Other than above: Setting prohibited To change these bits, write a value in these bits, read the value of these bits, confirm that the write value equals the read value, and then proceed with the next processing. Do not write the same pipe number in the CURPIPE bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL. If these bits are changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of these bits is rewritten, and then further access is enabled.

Note: * Only reading 0 is enabled.

32.3.8 FIFO Port Control Registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR)

CFIFOCTR, D0FIFOCTR, and D1FIFOCTR specify buffer memory write end and CPU buffer clear, as well as indicate whether the FIFO port is accessible or not. These registers correspond to each FIFO port.

These registers are initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BVAL	BCLR	FRDY	—	DTLN[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*1	R/W*2	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	BVAL	0	R/W*1	Buffer Memory Enable Flag This flag is set to 1 upon completion of data write in the FIFO buffer of the CPU of the pipe selected by the CURPIPE bits. 0: Invalid 1: Write end When the selected pipe is in the transmit direction, set this bit to 1 in the following cases. This module sets the FIFO buffer of the CPU to the SIE side to enable data transmission. To send a short packet, set this bit to 1 upon completion of data write. To send a Zero-Length packet, set this bit to 1 before writing data to the FIFO buffer. For pipes of continuous transfer mode, set this bit to 1 after writing data that is a positive integer multiple of MaxPacketSize and less than the BufferSize value. When data with the size specified by MaxPacketSize is written to a pipe of continuous transfer mode, this module writes 1 in this bit and sets the FIFO buffer of the CPU to the SIE side to enable data transmission. Set this bit to 1 when this module shows FRDY = 1. When the selected pipe is in the receive direction, do not set this bit to 1.

Bit	Bit Name	Initial Value	R/W	Description
14	BCLR	0	R/W*[2]	CPU buffer clear Clears the CPU side FIFO buffer of the selected pipe. 0: Invalid 1: Clears the CPU side FIFO buffer. When the FIFO buffer assigned to the selected pipe is set to a double buffer, and even when both sides of the buffer are readable, this module clears only one side of the FIFO buffer. When the selected pipe is DCP, this module clears the FIFO buffer when this bit is set to 1 irrespective of whether the FIFO buffer is on the CPU side or SIE side. When clearing the SIE side FIFO buffer, be sure to set the PID bits in DCP to NAK and then set the BCLR bit to 1. When the selected pipe is in the transmit direction, and if 1 is written in the BVAL and BCLR bits at the same time, this module clears the previously written data, and makes a Zero-Length packet transmittable. When the selected pipe is not DCP, write 1 in this bit while the FRDY flag indicates 1.
13	FRDY	0	R	FIFO Port Ready Indicates whether the CPU (DMAC) can access the FIFO port. 0: The FIFO port is not accessible. 1: The FIFO port is accessible. This module indicates FRDY = 1 in the following cases. However, since there is no data to read, no data can be read from the FIFO port. In these cases, set the BCLR bit to 1 to clear the FIFO buffer to make transmission/reception of the next data available. When a Zero-Length packet is received with the FIFO buffer assigned to the selected pipe empty When a short packet is received with BFRE set to 1 and the packet data is completely read
12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11 to 0	DTLN[11:0]	H'000	R	Receive Data Length Indicate the receive data length. The value of these bits during FIFO buffer reading varies as follows depending on the setting of the RCNT bit. When RCNT = 0: This module indicates the reecive data length with these bits until the CPU (DMAC) finishes reading one side of the FIFO buffer. When BFRE is 1, this module retains the reecive data length until the BCLR bit is set to 1 after the FIFO buffer read is completed. When RCNT = 1: This module decrements the value of the DTLN bits in each read cycle (-1 when MBW = 0, and -2 when MBW = 1) When reading out from a single FIFO buffer is complete, DTLN = 0 for this module. However, the behavior is different when double-buffering has been specified. If reading out of data from one side is not finished before the other side is full of received data, when all data have been read out from the first side, the DTLN bits reflect the amount of data received in the other side. When reading these bits during FIFO buffer reading while the RCNT bit is 1, note that this module updates the value in these bits within 150 ns after each FIFO port read cycle.

Notes: 1. Only writing 1 is enabled.
2. Only reading 0 and writing 1 are enabled.

32.3.9 Interrupt Enable Register 0 (INTENB0)

INTENB0 specifies masking of each interrupt. When this module detects an interrupt for which 1 is written in the corresponding bit in this register by the software, this module generates a USB interrupt.

When interrupt source detection conditions are satisfied irrespective of the register setting (interrupt enable/disable), this module sets the corresponding status bit in INTSTS0 to 1.

When the software changes an interrupt enable bit (0 to 1) whose interrupt source status bit in INTSTS0 is set to 1, this module generates a USB interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VBSE	RSME	SOFE	DVSE	CTRE	BEMPE	NRDYE	BRDYE	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	VBSE	0	R/W	VBUS0_0 and VBUS1_0 Interrupt Enable Enables or disables USB interrupt outputs when the VBINT interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
14	RSME	0	R/W	Resume Interrupt Enable Enables or disables USB interrupt outputs when the RESM interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
13	SOFE	0	R/W	Frame Number Update Interrupt Enable Enables or disables USB interrupt outputs when the SOFR interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
12	DVSE	0	R/W	Device State Transition Interrupt Enable* Enables or disables USB interrupt outputs when the DVST interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
11	CTRE	0	R/W	Control Transfer Stage Transition Interrupt Enable* Enables or disables USB interrupt outputs when the CTRT interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
10	BEMPE	0	R/W	Buffer Empty Interrupt Enable Enables or disables USB interrupt outputs when the BEMP interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
9	NRDYE	0	R/W	Buffer Not Ready Response Interrupt Enable Enables or disables USB interrupt outputs when the NRDY interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
8	BRDYE	0	R/W	Buffer Ready Interrupt Enable Enables or disables USB interrupt outputs when the BRDY interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: * The RSME, DVSE, and CTRE bits can be set to 1 only when the function controller function is selected. Do not enable interrupts of these bits when the host controller function is selected.

32.3.10 Interrupt Enable Register 1 (INTENB1)

INTENB1 specifies masking of each interrupt when the host controller function is selected. When this module detects an interrupt for which 1 is written in the corresponding bit in this register by the software, this module generates a USB interrupt.

When interrupt source detection conditions are satisfied irrespective of the register setting (interrupt enable/disable), this module sets the corresponding status bit in INTSTS1 to 1.

When the software changes an interrupt enable bit (0 to 1) whose interrupt source status bit in INTSTS1 is set to 1, this module outputs a USB interrupt.

When the function controller function is selected, do not allow any interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVRCRE	BCHGE	—	DTCHE	ATTCHE	—	—	—	—	EOFERRE	SIGNE	SACKE	—	—	—	—

15	OVRCRE	0	R/W	OVRCR Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
14	BCHGE	0	R/W	USB Bus Change Interrupt Enable Enables or disables USB interrupt outputs when the BCHG interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
12	DTCHE	0	R/W	Disconnection Detect Interrupt Enable Enables or disables USB interrupt outputs when the DTCH interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
11	ATTCHE	0	R/W	Connection Detect Interrupt Enable Enables or disables USB interrupt outputs when the ATTCH interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
10 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	EOFERRE	0	R/W	EOF Error Detect Interrupt Enable Enables or disables USB interrupt outputs when the EOFERR interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
5	SIGNE	0	R/W	Setup Transaction Error Interrupt Enable Enables or disables USB interrupt outputs when the SIGN interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
4	SACKE	0	R/W	Setup Transaction ACK Interrupt Enable Enables or disables USB interrupt outputs when the SACK interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

32.3.11 BRDY Interrupt Enable Register (BRDYENB)

BRDYENB enables or disables the BRDY bit to be set to 1 when the BRDY interrupt of a pipe is detected.

When this module detects the BRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBRDY bit of the pipe in BRDYSTS and also sets the BRDY bit in INTSTS0 to 1 and generates the BRDY interrupt.

When one or more PIPEBRDY bits in BRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BRDY interrupt.

This register is initialized by a power-on reset.

32.3.12 NRDY Interrupt Enable Register (NRDYENB)

NRDYENB enables or disables the NRDY bit to be set to 1 when the NRDY interrupt of a pipe is detected.

When this module detects the NRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPENRDY bit of the pipe in NRDYSTS and also sets the NRDY bit in INTSTS0 to 1 and generates an NRDY interrupt.

When one or more PIPENRDY bits in NRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates an NRDY interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0	PIPE0 NRDYE	0	R/W	Pipe 0 NRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

32.3.13 BEMP Interrupt Enable Register (BEMPENB)

BEMPENB enables or disables the BEMP bit to be set to 1 when the BEMP interrupt of a pipe is detected.

When this module detects the BEMP interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBEMP bit of the pipe in BEMPSTS and the BEMP bit in INTSTS0 to 1 and generates the BEMP interrupt.

When one or more PIPEBEMP bits in BEMPSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BEMP interrupt.

This register is initialized by a power-on reset.

32.3.14 SOF Output Configuration Register (SOFCFG)

SOFCFG specifies an effective period of transactions, the BRDY interrupt status clear timing, and others.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TRNENSEL	—	BRDYM	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R/W	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	TRNENSEL	0	R/W	Transaction Effective Period Switching Specifies a transaction effective period where this module sends a token in one frame in a port in full-speed or low-speed communication. 0: Low-speed is not supported. 1: Low-speed is supported. This bit is valid only when the host controller function is selected. This bit does not affect the high-speed transaction effective period even when the host controller function is selected. Set this bit to 0 when the function controller function is selected.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	BRDYM	0	R/W	Status Clear Timing of Each Pipe BRDY Interrupt Specifies the timing to clear the BRDY interrupt status of each pipe. 0: The software clears the status. 1: This module clears the status by reading or writing the FIFO buffer.

Bit	Bit Name	Initial Value	R/W	Description
5	—	0	R	Reserved This bit is reserved. Write the value that was read immediately before. Note: The initial value of this bit is 0 immediately after a power-on reset. Be sure to set this bit to 1 during the initialization routine of this module.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

32.3.15 Interrupt Status Register 0 (INTSTS0)

INTSTS0 indicates the status of detected interrupts.

This register is initialized by a power-on reset. The DVSQ2 to DVSQ0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Initial value:	0	0	0	*1	0	0	0	0	*3	*2	*2	*2	0	0	0	0
R/W:	R/W*7	R/W*7	R/W*7	R/W*7	R/W*7	R	R	R	R	R	R	R	R/W*7	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	VBINT	0	R/W*7	VBUS0_0 and VBUS1_0 Interrupt Status*4*5 0: No VBUS0_0 and VBUS1_0 interrupt is generated. 1: A VBUS0_0 and VBUS1_0 interrupt is generated. This bit indicates 1 when this module detects a change in the VBUS0_0 and VBUS1_0 pin input level (high to low or low to high level). This module indicates the VBUS0_0 and VBUS1_0 pin input value using the VBSTS bit. When a VBINT interrupt occurs, read the VBSTS bit several times by the software and confirm that the read value is equal each time to eliminate chattering.
14	RESM	0	R/W*7	Resume Interrupt Status*4*5*6 0: No resume interrupt is generated. 1: A resume interrupt is generated. This bit indicates 1 when this module detects a falling of the DP pin level in the suspended state (DVSQ = 1XX) with the function controller function selected. The read value is invalid when the host controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
13	SOFR	0	R/W*7	Frame Number Update Interrupt Status*4 0: No SOF interrupt is generated. 1: An SOF interrupt is generated. (1) When the host controller function is selected When the UACT bit is set to 1 by the software, this bit is set to 1 at the frame number update timing. (This interrupt is detected every millisecond.) (2) When the function controller function is selected This module indicates SOFR = 1 at the frame number update timing. (This interrupt is detected every millisecond.) Even when an SOF packet from the USB host is corrupted, this module detects an SOFR interrupt using the internal interpolation.
12	DVST	0/1*1	R/W*7	Device State Transition Interrupt Status*4*6 0: No device state transition interrupt is generated. 1: A device state transition interrupt is generated. When this module detects a change in device state with the function controller function selected, this module updates the DVSQ value and set this bit to 1. When this interrupt occurred, clear the status before this module detects the next device state transition. The read value is invalid when the host controller function is selected.
11	CTRT	0	R/W*7	Control Transfer Stage Transition Interrupt Status*4*6 0: No control transfer stage transition interrupt is generated. 1: A control transfer stage transition interrupt is generated. When this module detects a control transfer stage transition with the function controller function selected, this module updates the CTSQ value and set this bit to 1. When this interrupt occurred, clear the status before this module detects the next stage transition in control transfers. The read value is invalid when the host controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
10	BEMP	0	R	Buffer Empty Interrupt Status 0: No BEMP interrupt is generated. 1: A BEMP interrupt is generated. This module indicates BEMP = 1 when at least one of the PIPEBEMP bits in BEMPSTS corresponding to the pipes for which 1 is set in the PIPEBEMPE bits in BEMPENB is set to 1 (when this module detects a BEMP interrupt of one or more pipes for which BEMP interrupts are enabled by the software). For PIPEBEMP status assertion conditions, see section 32.4.2 (3), BEMP Interrupt. When the software writes 0 to all PIPEBEMP bits corresponding to the pipes for which interrupts are enabled by the PIPEBEMPE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.
9	NRDY	0	R	Buffer Not Ready Interrupt Status 0: No NRDY interrupt is generated. 1: An NRDY interrupt is generated. This module indicates NRDY = 1 when at least one of the PIPENRDY bits in NRDYSTS corresponding to the pipes for which 1 is set in the PIPENRDYE bits in NRDYENB is set to 1 (when this module detects an NRDY interrupt of one or more pipes for which NRDY interrupts are enabled by the software). For PIPENRDY status assertion conditions, see section 32.4.2 (2), NRDY Interrupt. When the software writes 0 to all PIPENRDY bits corresponding to the pipes for which interrupts are enabled by the PIPENRDYE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.

Bit	Bit Name	Initial Value	R/W	Description
8	BRDY	0	R	Buffer Ready Interrupt Status Indicates the BRDY interrupt status. 0: No BRDY interrupt is generated. 1: A BRDY interrupt is generated. This module indicates BRDY = 1 when at least one of the PIPEBRDY bits in BRDYSTS corresponding to the pipes for which 1 is set in the PIPEBRDYE bits in BRDYENB is set to 1 (when this module detects a BRDY interrupt of one or more pipes for which BRDY interrupts are enabled by the software). For PIPEBRDY status assertion conditions, see section 32.4.2 (1), BRDY Interrupt. When the software writes 0 to all PIPEBRDY bits corresponding to the pipes for which interrupts are enabled by the PIPEBRDYE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.
7	VBSTS	0/1*[3]	R	VBUS Input Status 0: The VBUS0_0 and VBUS1_0 pin is low level. 1: The VBUS0_0 and VBUS1_0 pin is high level.
6 to 4	DVSQ[2:0]	000/001*[2]	R	Device State 000: Powered state 001: Default state 010: Address state 011: Configuration state 1xx: Suspended state The read value is invalid when the host controller function is selected.
3	VALID	0	R/W*[7]	USB Request Receive 0: Not detected 1: A setup packet is received. The read value is invalid when the host controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	CTSQ[2:0]	000	R	Control Transfer Stage 000: Idle stage or setup stage 001: Control read data stage 010: Control read status stage 011: Control write data stage 100: Control write status stage 101: Control write (NoData) status stage 110: Control transfer sequence error 111: Setting prohibited The read value is invalid when the host controller function is selected.

Notes:
1. The initial value is B'0 after a power-on reset, and B'1 after a USB bus reset.
2. The initial value is B'000 after a power-on reset, and B'001 after a USB bus reset.
3. The initial value is 1 when the VBUS0_0 and VBUS1_0 pin is high level, and is 0 when the VBUS0_0 and VBUS1_0 pin is low level.
4. To clear the VBINT, RESM, SOFR, DVST, or CTRT bit, write 0 only to bits to be cleared and write 1 to the other bits. Do not write 0 to status bits that indicate 0.
5. When a status change shown in the VBINT or RESM bit is detected while the clock is halted (SCKE = 0) and the corresponding interrupt is enabled, the interrupt is output. Clear the interrupt status of these bits by the software after the clock is enabled.
6. A status change of the RESM, DVST, or CTRT bit occurs only when the function controller function is selected. When the function controller function is selected, disable the corresponding interrupt enable bits to 0 (disabled).
7. Only writing 0 is enabled.

32.3.16 Interrupt Status Register 1 (INTSTS1)

INTSTS1 monitors the status of each interrupt.

By using INTSTS0 when the function controller function is selected or INTSTS1 when the host controller function is selected, occurrence of interrupts can be monitored with either of these registers.

Enable interrupts generated due to a status change shown by each bit in this register only when the host controller function is selected.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVRCR	BCHG	—	DTCH	ATTCH	—	—	—	—	EOFERR	SIGN	SACK	—	—	—	—
Initial value:	—	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W*1	R	R/W*1	R/W*1	R	R	R	R	R/W*1	R/W*1	R/W*1	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	OVRCR	Undefined	R/W	OVRCR Interrupt Status This interrupt is generated when the OVCN_0 or OVCN2 pin input status changes. 0: No OVRCR interrupt is generated. 1: An OVRCR interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
14	BCHG	0	R/W*[1]	USB Bus Change Interrupt Status Indicates the USB bus change interrupt status. 0: No BCHG interrupt is generated. 1: A BCHG interrupt is generated. When a full-speed or low-speed signal level change occurs in the USB port (from J-State, K-State, or SE0 to J-State, K-State, or SE0), this module detects a BCHG interrupt and indicates BCHG = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates an interrupt. The current input state of the USB port is indicated by the LNST bits in SYSSTS. When a BCHG interrupt occurs, read the LNST bits several times by the software and confirm that the read value is equal each time to eliminate chattering. A USB bus change can also be detected while the internal clock is halted. The read value is invalid when the function controller function is selected.
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
12	DTCH	0	R/W*[1]	USB Disconnection Detect Interrupt Status Indicates the USB disconnection detect interrupt status when the host controller function is selected. 0: No DTCH interrupt is generated. 1: A DTCH interrupt is generated. When a USB bus disconnection is detected, this module detects a DTCH interrupt and indicates DTCH = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates an interrupt. This module detects a USB bus disconnection based on the USB 2.0 Specification. After detecting a DTCH interrupt, this module performs the following hardware control irrespective of the setting of the corresponding interrupt enable bit. The software must terminate communication of all pipes with the USB port and drives this module into a state of waiting for ATTACH to the USB port (an ATTCH interrupt is generated). Clears the UACT bit of the port in which a DTCH interrupt is detected to 0 and indicates the UACT bit. Drives the port in which a DTCH interrupt is detected into the idle state. The read value is invalid when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
11	ATTCH	0	R/W*[1]	ATTCH Interrupt Status Indicates the ATTCH interrupt status when the host controller function is selected. 0: No ATTCH interrupt is generated. 1: An ATTCH interrupt is generated. When this module detects J-State or K-State of full-speed or low-speed signal level for 2.5 μs in the USB port, this module detects an ATTCH interrupt and indicates ATTCH = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates an interrupt. Conditions for this module to detect an ATTCH interrupt are as follows: When K-State, SE0 or SE1 changes to J-State and then J-State continues for 2.5 μs When J-State, SE0 or SE1 changes to K-State and then K-State continues for 2.5 μs The read value is invalid when the function controller function is selected.
10 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
6	EOFERR	0	R/W*[1]	EOF Error Detect Interrupt Status Indicates the EOFERR interrupt status when the host controller function is selected. 0: No EOFERR interrupt is generated. 1: An EOFERR interrupt is generated. When this module detects that communication is not completed at the EOF2 timing specified in the USB 2.0 Specification, this module detects an EOFERR interrupt and indicates EOFERR = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates an EOFERR interrupt. After detecting an EOFERR interrupt, this module performs the following hardware control irrespective of the setting of the corresponding interrupt enable bit. The software must terminate communication of all pipes with the USB port and perform reenumeration for the USB port. Clears the UACT bit of the port in which an EOFERR interrupt is detected to 0 and indicates the UACT bit. Drives the port in which an EOFERR interrupt is detected into the idle state. The read value is invalid when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
5	SIGN	0	R/W*[1]	Setup Transaction Error Interrupt Status Indicates the setup transaction error interrupt status when the host controller function is selected. 0: No SIGN interrupt is generated. 1: A SIGN interrupt is generated. When a peripheral device does not send an ACK response three times in a row in the SETUP transaction issued by this module, this module detects a SIGN interrupt and indicates SIGN = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates a SIGN interrupt. This module detects a SIGN interrupt when any of the following response is generated to SETUP transactions (three times in a row). When the peripheral device sends no response and therefore this module detects a timeout When the ACK packet is corrupted When a handshake signal (NAK, NYET, or STALL) other than ACK is received The read value is invalid when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
4	SACK	0	R/W*[1]	Setup Transaction ACK Response Interrupt Status Indicates the setup transaction ACK response interrupt status when the host controller function is selected. 0: No SACK interrupt is generated. 1: A SACK interrupt is generated. When this module receives an ACK response from a peripheral device in the SETUP transaction issued by this module, this module detects a SACK interrupt and indicates SACK = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates a SACK interrupt.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Notes: 1. To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

2. When a status change shown in the BCHG bit is detected while the clock is halted (SCKE = 0) and the corresponding interrupt is enabled, the interrupt is output. Clear the BCHG interrupt status by the software after the clock is enabled.

   Any interrupts other than the BCHG bit are not detected while the clock is halted (SCKE = 0).

32.3.17 BRDY Interrupt Status Register (BRDYSTS)

BRDYSTS indicates the BRDY interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	PIPE9BRDY	0	R/W*1	Pipe 9 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8BRDY	0	R/W*1	Pipe 8 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7BRDY	0	R/W*1	Pipe 7 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6BRDY	0	R/W*1	Pipe 6 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5BRDY	0	R/W*1	Pipe 5 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
4	PIPE4BRDY	0	R/W*1	Pipe 4 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
3	PIPE3BRDY	0	R/W*[1]	Pipe 3 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2BRDY	0	R/W*[1]	Pipe 2 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1BRDY	0	R/W*[1]	Pipe 1 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0BRDY	0	R/W*[1]	Pipe 0 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.

Notes: 1. To clear the status of each bit in this register when BRDYM is 0, write 0 only to bits to be cleared and write 1 to the other bits.
2. When BRDYM is 0, be sure to clear this interrupt before making an access to the FIFO.

32.3.18 NRDY Interrupt Status Register (NRDYSTS)

NRDYSTS indicates the NRDY interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PIPE9 NRDY	PIPE8 NRDY	PIPE7 NRDY	PIPE6 NRDY	PIPE5 NRDY	PIPE4 NRDY	PIPE3 NRDY	PIPE2 NRDY	PIPE1 NRDY	PIPE0 NRDY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	PIPE9NRDY	0	R/W*	Pipe 9 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8NRDY	0	R/W*	Pipe 8 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7NRDY	0	R/W*	Pipe 7 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6NRDY	0	R/W*	Pipe 6 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5NRDY	0	R/W*	Pipe 5 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
4	PIPE4NRDY	0	R/W*	Pipe 4 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
3	PIPE3NRDY	0	R/W*	Pipe 3 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2NRDY	0	R/W*	Pipe 2 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1NRDY	0	R/W*	Pipe 1 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0NRDY	0	R/W*	Pipe 0 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: * To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

32.3.19 BEMP Interrupt Status Register (BEMPSTS)

BEMPSTS indicates the BEMP interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PIPE9 BEMP	PIPE8 BEMP	PIPE7 BEMP	PIPE6 BEMP	PIPE5 BEMP	PIPE4 BEMP	PIPE3 BEMP	PIPE2 BEMP	PIPE1 BEMP	PIPE0 BEMP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	PIPE9BEMP	0	R/W*	Pipe 9 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8BEMP	0	R/W*	Pipe 8 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7BEMP	0	R/W*	Pipe 7 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6BEMP	0	R/W*	Pipe 6 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5BEMP	0	R/W*	Pipe 5 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
4	PIPE4BEMP	0	R/W*	Pipe 4 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
3	PIPE3BEMP	0	R/W*	Pipe 3 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2BEMP	0	R/W*	Pipe 2 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1BEMP	0	R/W*	Pipe 1 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0BEMP	0	R/W*	Pipe 0 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: * To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

32.3.20 Frame Number Register (FRMNUM)

FRMNUM indicates the sources of isochronous errors and a frame number.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	OVRN	0	R/W*	Overrun/Underrun Detect Status Indicates whether an overrun or underrun error is detected or not in a pipe that is performing isochronous transfer. 0: No error is detected. 1: An error is detected. Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register. (1) When the host controller function is selected This module indicates OVRN =1 in any of the following cases. When the OUT token transmit timing comes when transmit data write to the FIFO buffer is not completed in a transmit direction pipe of isochronous transfer type When the IN token transmit timing comes with no side of the FIFO buffer empty in a receive direction pipe of isochronous transfer type (2) When the function controller function is selected This module indicates OVRN =1 in any of the following cases. When the IN token is received when transmit data write to the FIFO buffer is not completed in a transmit direction pipe of isochronous transfer type When the OUT token is received with no side of the FIFO buffer empty in a receive direction pipe of isochronous transfer type

Bit	Bit Name	Initial Value	R/W	Description
14	CRCE	0	R/W*	Receive Data Error Indicates whether a CRC error or bit stuffing error is detected or not in a pipe that is performing isochronous transfer. 0: No error is detected. 1: An error is detected. Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register. (1) When the host controller function is selected When a CRC error is detected, this module generates an internal NRDY interrupt request. (2) When the function controller function is selected When a CRC error is detected, this module does not generate an internal NRDY interrupt request.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	FRNM [10:0]	H'000	R	Frame Number This module modifies this bit at the SOF transmit timing (every 1 ms) or when an SOF is received and indicates the latest frame number. Read these bits twice and confirm that the read value is equal each time.

Note: * Only writing 0 is enabled.

32.3.21 μ Frame Number Register (UFRMNUM)

UFRMNUM indicates a μ frame number.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	UFRNM[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	UFRNM[2:0]	000	R	μ Frame Indicate a μ frame number. In high-speed operating mode, these bits indicate a μ frame number. In other operating modes, these bits indicate B'000. Read these bits twice and confirm that the read value is equal each time.

32.3.22 USB Address Register (USBADDR)

USBADDR indicates a USB address.

This register is valid only when the function controller function is selected. To set the address of a peripheral device when the host controller function is selected, use the DEVSEL bits in PIPEMAXP.

This register is initialized by a power-on reset or USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	USBADDR[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	USBADDR[6:0]	H'00	R	USB Address Indicate the USB address allocated by the host when the SET_ADRESS request is successfully processed with the function controller function selected. When this module detects a USB reset, these bits indicate H'00. When the host controller function is selected, these bits are invalid.

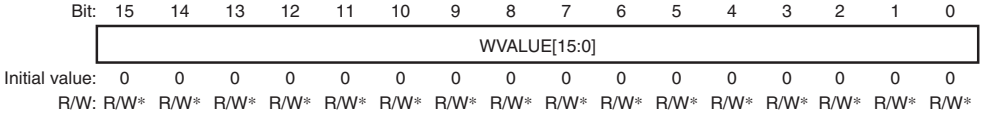
32.3.23 USB Request Type Register (USBREQ)

USBREQ stores the setup request for control transfers.

When the function controller function is selected, USBREQ stores the values of received bRequest and bmRequestType. When the host controller function is selected, USBREQ sets the values of bRequest and bmRequestType to be sent.

This register is initialized by a power-on reset or USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BREQUEST[7:0]								BMREQUESTTYPE[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*



Bit	Bit Name	Initial Value	R/W	Description
15 to 8	BREQUEST [7:0]	H'00	R/W*	Request Store the value of USB request bRequest. (1) When the host controller function is selected Set the value of USB request data of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.
7 to 0	BMREQUEST TYPE[7:0]	H'00	R/W*	Request Type Store the value of USB request bmRequestType. (1) When the host controller function is selected: Set the value of USB request data of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected: Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.

Note: * When the function controller function is selected, these are read-only bits and cannot be modified. When the host controller function is selected, these are readable/writable bits.

32.3.24 USB Request Value Register (USBVAL)

When the function controller function is selected, USBVAL stores the value of received wValue. When the host controller function is selected, USBVAL sets the value of wValue to be sent.

This register is initialized by a power-on reset or USB bus reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WVALUE [15:0]	H'0000	R/W*	Value Store the value of USB request wValue. (1) When the host controller function is selected Set the value of USB request wValue of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected Indicate the value of USB request wValue received in the SETUP transaction. These bits cannot be modified.

Note: * When the function controller function is selected, these are read-only bits and cannot be modified. When the host controller function is selected, these are readable/writable bits.

32.3.25 USB Request Index Register (USBINDX)

USBINDX stores the setup request for control transfers.

When the function controller function is selected, USBINDX stores the value of received wIndex. When the host controller function is selected, USBINDX sets the value of wIndex to be sent.

This register is initialized by a power-on reset or USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WINDEX[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WINDEX [15:0]	H'0000	R/W*	Index Store the value of USB request wIndex. (1) When the host controller function is selected Set the value of USB request wIndex of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected Indicate the value of USB request wIndex received in the SETUP transaction. These bits cannot be modified.

Note: * When the function controller function is selected, these are read-only bits and cannot be modified. When the host controller function is selected, these are readable/writable bits.

32.3.26 USB Request Length Register (USBLENG)

USBLENG stores the setup request of control transfers.

When the function controller function is selected, USBLENG stores the value of received wLength. When the host controller function is selected, USBLENG sets the value of wLength to be sent.

This register is initialized by a power-on reset or USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WLENGTH[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WLENGTH [15:0]	H'0000	R/W*	Length Store the value of USB request wLength. (1) When the host controller function is selected Set the value of USB request wLength of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected Indicate the value of USB request wLength received in the SETUP transaction. These bits cannot be modified.

Note: * When the function controller function is selected, these are read-only bits and cannot be modified. When the host controller function is selected, these are readable/writable bits.

32.3.27 DCP Configuration Register (DCPCFG)

DCPCFG specifies the data transfer direction of the default control pipe (DCP).

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	DIR	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	DIR	0	R/W	Transfer Direction Specifies the data stage and status stage transfer direction of control transfers when the host controller function is selected. 0: Data receive direction 1: Data transmit direction When the function controller function is selected, set this bit to 0.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

32.3.28 DCP Maximum Packet Size Register (DCPMAXP)

DCPMAXP specifies the maximum packet size of the DCP.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DEVSEL[3:0]				—	—	—	—	—	MXPS[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	DEVSEL [3:0]	0000	R/W	Device Select Specify the address of the peripheral device that is a remote party for control transfers when the host controller function is selected. 0000: Address 0000 0001: Address 0001 : : 1001: Address 1001 1010: Address 1010 Other than above: Setting prohibited Set DEVADDn corresponding to the value of these bits, and then set these bits. When setting DEVSEL = 0010, for example, set the address in DEVADD2. Set these bits when CSSTS = 0, PID = NAK, and the SUREQ bit is 0. To change these bits after changing the PID bits in DCP from BUF to NAK, check CSSTS = 0 and PBUSY = 0 and then change these bits. However, the software does not have to check the PBUSY bit when this module changed the PID bit to NAK. When the function controller function is selected, set these bits to B'0000.
11 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
6 to 0	MXPS [6:0]	H'40	R/W	Maximum Packet Size Set the payload of DCP data (maximum DCP packet size) in these bits. The initial value of these bits is H'40 (64 bytes). Set a value in the MXPS bits based on the USB Specification. Set the MXPS bits when CSSTS = 0, PID = NAK, and the CURPIPE bits are not set. When setting these bits to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS bits are 0 or set the PID bits to BUF.

32.3.29 DCP Control Register (DCPCTR)

DCPCTR is used to monitor the buffer memory status, change/check the data PID sequence bit, and set the response PID for a DCP.

This register is initialized by a power-on reset. The PID2 to PID0 bits in CCPL are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	SUREQ	CSCLR	CSSTS	SUREQCLR	—	—	SQCLR	SQSET	SQMON	PBUSY	PINGE	—	CCPL	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R	R/W*2	R/W*1	R	R/W*1	R	R	R/W*1	R/W*1	R	R	R/W	R	R/W*1	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	Buffer Status Indicates whether the DCP FIFO buffer is accessible or not. 0: The buffer is not accessible. 1: The buffer is accessible. This bit indicates as follows depending on the ISEL value. When ISEL = 0, this bit indicates whether the buffer is ready to read receive data. When ISEL = 1, this bit indicates whether the buffer is ready to write transmit data.

Bit	Bit Name	Initial Value	R/W	Description
14	SUREQ	0	R/W*[2]	Sending SETUP Token When the host controller function is selected, a setup packet is sent by writing 1 to this bit. 0: Invalid 1: A setup packet is sent. After processing the SETUP transaction, this module generates a SACK interrupt or SIGN interrupt and clears this bit to 0. When the SUREQCLR bit is set to 1 by the software, this module clears this bit to 0. Set this bit to 1 after setting the USB request to be sent in the SETUP transaction in the DEVSEL bits, USBREQ, USBVAL, USBINDX, and USBLENG registers. Check that PID bits in DCP are set to NAK before setting the SUREQ bit to 1. Furthermore, do not change the values of the DEVSEL bits, USBREQ, USBVAL, USBINDX, and USBLENG registers after setting this bit to 1 until the SETUP transaction is completed (while SUREQ = 1). Set this bit to 1 only when sending a SETUP token. In other cases, be sure to set this bit to 0. When the function controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
13	CSCLR	0	R/W*[1]	Split Transactions C-SPLIT Status Clear When the host controller function is selected, the CSSTS bit can be cleared to 0 by writing 1 to this bit for data transfer using split transactions. In this case, the next transfer of DCP restarts with S-SPLIT. 0: Invalid 1: Clears the CSSTS bit to 0. When this bit is set to 1 by the software, this module clears the CSSTS bit to 0. To forcibly restart the next transfer with S-SPLIT in data transfer using split transactions, set this bit to 1 by the software. Since this module automatically clears the CSSTS bit to 0 at the end of C-SPLIT in normal split transactions, the software needs not clear the CSSTS bit. Control the CSSTS bit with this bit while communication is halted by clearing the UACT bit or when it is clarified that no data transfer is performed by detection of DETACH. Even if this bit is set to 1 when CSSTS is 0, CSSTS remains 0. When the function controller function is selected, be sure to set this bit to 0.
12	CSSTS	0	R	Split Transactions COMPLETE SPLIT (C-SPLIT) Status When the host controller function is selected, the C-SPLIT status of split transactions is indicated. 0: START-SPLIT (S-SPLIT) transaction is being processed or a device that is not used in split transactions is being processed. 1: C-SPLIT transaction is being processed. This module sets this bit to 1 when starting C-SPLIT, and clears this bit to 0 when C-SPLIT end is detected. When the function controller function is selected, the read value of this bit is invalid.

Bit	Bit Name	Initial Value	R/W	Description
11	SUREQCLR	0	R/W*[1]	SUREQ Bit Clear When the host controller function is selected, the SUREQ bit can be cleared to 0 by writing 1 to this bit. 0: Invalid 1: Clears the SUREQ bit. This bit always indicates 0. When communication is halted with the SUREQ bit set to 1 in the SETUP transaction, set this bit to 1 by the software. Since this module automatically clears the SUREQ bit to 0 at the end of normal SETUP transaction, the software needs not clear the SUREQ bit. Control the SUREQ bit with this bit while communication is halted by clearing the UACT bit or when it is clarified that no data transfer is performed by detection of DETACH. When the function controller function is selected, be sure to set this bit to 0.
10, 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SQCLR	0	R/W*[1]	Toggle Bit Clear The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA0. 0: Invalid 1: The expected value is set in DATA0. This bit always indicates 0. Do not set the SQCLR and SQSET bits to 1 at the same time. Set this bit to 1 when CSCTS = 0, PID = NAK, and the CURPIPE bits are not set. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
7	SQSET	0	R/W*[1]	Toggle Bit Set The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA1. 0: Invalid 1: The expected value is set in DATA1. Do not set the SQCLR and SQSET bits to 1 at the same time. Set this bit to 1 when CSCTS = 0, PID = NAK, and the CURPIPE bits are not set. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
6	SQMON	1	R	Sequence Toggle Bit Monitor Indicates the expected value of the sequence toggle bit for the next transaction in DCP transfer. 0: DATA0 1: DATA1 When the transaction is successfully completed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled. When the function controller function is selected, this module sets this bit to 1 (sets the expected value in DATA1) when the setup packet is successfully received. When the function controller function is selected, this module does not read this bit in IN transactions or OUT transactions in the status stage.

Bit	Bit Name	Initial Value	R/W	Description
5	PBUSY	0	R	Pipe Busy Indicates whether the DCP communication state is shifted to the NAK state or not when the DCP changed the PID bits from BUF to NAK. 0: Transition to the NAC state is not completed. 1: Transition to the NAC state is completed. When this module starts the USB transaction for the corresponding pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to check whether changing the pipe setting is enabled or not.
4	PINGE	0	R/W	PING Token Output Enable When this bit is set to 1 with the host controller function selected, this module sends the PING token in the transmit direction transfer. The transmit direction transfer is started with the PING transaction. 0: Sending the PING token is disabled. 1: Normal PING operation When an ACK handshake is detected in the PING transaction, this module executes an OUT transaction for the next transaction. When a NAK handshake is detected in an OUT transaction, this module executes a PING transaction for the next transaction. When the software sets this bit to 0 with the host controller function selected, this module does not send the PING token in the transmit direction transfer. The transmit direction transfer is always performed in OUT transactions. Change this bit when CSSTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. When the function controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	CCPL	0	R/W*[1]	Control Transfer End Enable Enables the status stage end of control transfers when the function controller function is selected. 0: Invalid 1: The control transfer end is enabled. When the software sets this bit to 1 while the corresponding PID bits are set to BUF, this module finishes the control transfer stage. That is, this module sends an ACK handshake in response to OUT transactions from the USB host in the control read transfer, and sends a Zero-Length packet in response to IN transactions from the USB host in control write and no-data control transfers. However, a SET_ADDRESS request is detected, this module automatically sends responses from the SETUP stage until the end of the status stage irrespective of the setting of this bit. When this module receives the next setup packet, this module clears this bit to 0. When VALID = 1, the software cannot write 1 to this bit. When the host controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	Response PID Control responses of this module in control transfers. 00: NAK response 01: BUF response (depending on buffer state) 10: STALL response 11: STALL response (1) When the host controller function is selected Change these bits from NAK to BUF. When transmit direction is set Write all transmit data to the FIFO buffer when UACT = 1 and PID = NAK, and then set the PID bits to BUF. After BUF is set, this module executes OUT transactions (or PING transactions). When receive direction is set Check that the FIFO buffer is empty (or make it empty) when UACT = 1 and PID = NAK, and then set the PID bits to BUF. After BUF is set, this module executes IN transactions. This module modifies these bits in the following cases. When this module receives data with a size exceeding the MaxPacketSize value while these bits are set to BUF by the software, this module indicates PID = STALL (11). When this module detects a CRC error or another receive error three times in a row, this module indicates PID = NAK. When this module receives a STALL handshake, this module indicates PID = STALL (11). After this module sends S-SPLIT of split transactions for the selected pipe (indicating CSSTS = 1), this module executes the transaction until C-SPLIT is completed even if the software changed these bits to NAK. When C-SPLIT is completed, this module indicates PID = NAK.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	(2) When the function controller function is selected This module modifies these bits in the following cases. This module changes these bits to NAK upon receiving a SETUP packet. At this time, this module indicates VALID = 1. The software cannot modify these bits until the software sets VALID = 0. When this module receives data with a size exceeding the MaxPacketSize value while these bits are set to BUF by the software, this module indicates PID = STALL (11). When this module detects a control transfer sequence error, this module indicates PID = STALL (1x). When this module detects a USB bus reset, this module indicates PID = NAK. This module does not read the value of these bits during the SET_ADDRESS request processing (auto processing).

Notes: 1. These bits are always read as 0. Only writing 1 is enabled.
2. Only writing 1 is enabled.

32.3.30 Pipe Window Select Register (PIPESEL)

Make settings for pipes 1 to 9 using PIPESEL, PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN.

Specify a pipe to be used with PIPESEL, and then make function settings for each pipe in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI. The PIPEnCTR, PIPnTRE, and PIPnTRN registers can be set independently from pipe selection using PIPESEL.

Not only the selected pipe but also the corresponding bits in registers for all pipes are initialized by a power-on reset or USB bus reset.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	PIPESEL [3:0]	0000	R/W	Pipe Window Select Specify a pipe number corresponding to PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI to be read or written. 0000: No pipe is selected. 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 Other than above: Setting prohibited PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI corresponding to the pipe number specified by these bits can be read and written. When these bits are set to 0000, all bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI are read as 0 and cannot be modified.

32.3.31 Pipe Configuration Register (PIPECFG)

PIPECFG specifies the transfer type, buffer memory access direction, and endpoint number for pipes 1 to 9, selects continuous transfer mode or discontinuous transfer mode, and single buffer or double buffer, and also specifies whether to disable the operation of each pipe when data transfer finishes.

This register is initialized by a power-on reset. The TYPE1 and TYPE0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TYPE[1:0]		—	—	—	BFRE	DBLB	CNT MD	SHT NAK	—	—	DIR	EPNUM[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	TYPE[1:0]	00	R/W	Transfer Type Select the transfer type of the pipe specified by the PIPESEL bits (selected pipe). Pipes 1 and 2 00: No pipe is used. 01: Bulk transfer 10: Setting prohibited 11: Isochronous transfer Pipes 3 to 5 00: No pipe is used. 01: Bulk transfer 10: Setting prohibited 11: Setting prohibited Pipes 6 to 9 00: No pipe is used. 01: Setting prohibited 10: Interrupt transfer 11: Setting prohibited Before setting the selected pipe for PID = BUF (before starting USB communication using the selected pipe), be sure to set these bits to a value other than 00. Modify these bits when the PID bits of the selected pipe are set to NAK. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	BFRE	0	R/W	BRDY Interrupt Operation Specifies the BRDY interrupt output timing from this module to the CPU for the selected pipe. 0: At a BRDY interrupt timing during data transmission or reception 1: At a BRDY interrupt timing after reading data When this bit is set to 1 by the software and the selected pipe is used in the receive direction, this module detects the transfer end and outputs a BRDY interrupt when the packet is completely read. When a BRDY interrupt occurs with this setting, the software must set BCLR = 1. Unless BCLR = 1 is set, the FIFO buffer allocated to the selected pipe does not enter the receive ready state. When this bit is set to 1 by the software and the selected pipe is used in the transmit direction, this module generates no BRDY interrupt. For details, see section 32.4.2 (1), BRDY Interrupt. Modify this bit when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
9	DBLB	0	R/W	Double Buffer Mode Specifies a single buffer or double buffer for the FIFO buffer used in the selected pipe. 0: Single buffer 1: Double buffer This bit is valid when pipes 1 to 5 are selected. When this bit is set to 1 by the software, this module allocates the FIFO buffer size specified by the BUFSIZE bits in PIPEBUF to the selected pipe for two sides. Thus the size of the FIFO buffer that this module allocates to the selected pipe is as follows: (BUFSIZE + 1) * 64 * (DBLB + 1) [bytes] When this bit is set to 1 by the software and the selected pipe is used in the transmit direction, this module generates no BRDY interrupt. For details, see section 32.4.2 (1), BRDY Interrupt. Modify this bit when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
8	CNTMD	0	R/W	Continuous Transfer Mode Selects continuous transfer mode or discontinuous transfer mode to be used in communication for the selected pipe. 0: Discontinuous transfer mode 1: Continuous transfer mode This bit is valid when pipes 1 to 5 are selected by the PIPESEL bits and bulk transfer is selected (TYPE = 01). Modify this bit when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
7	SHTNAK	0	R/W	Pipe Disable at the Time of Transfer End Specifies whether to change the setting of the PID bits to NAK at the end of transfer when the selected pipe is in the receive direction. 0: The pipe is continued at the end of transfer. 1: The pipe is disabled at the end of transfer. This bit is valid when the selected pipe is either of pipes 1 to 5 and is in the receive direction. When the software sets this bit to 1 for a receive direction pipe, this module changes the setting of the PID bits corresponding to the selected pipe to NAK for the selected pipe when this module determines the transfer end. When the following conditions are satisfied, this module determines the transfer end. When short packet data (including a Zero-Length packet) is correctly received. When the transaction counter is used and packets with a size of the transaction counter are correctly received. Modify this bit when CSSTS = 0 and PID = NAK. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. For transmit direction pipes, set this bit to 0.
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	DIR	0	R/W	Transfer Direction Selects the transfer direction of the selected pipe. 0: Receive direction 1: Transmit direction When this bit is set to 0 by the software, this module uses the selected pipe in the receive direction. When this bit is set to 1, this module uses the selected pipe in the transmit direction. Modify this bit when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
3 to 0	EPNUM[3:0]	0000	R/W	Endpoint Number Specify the endpoint number of the selected pipe. The setting of 0000 means an unused pipe. Modify these bits when CSSTS = 0 and PID = NAK. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Set these bits so that the combination of the DIR setting and the EPNUM setting does not overlap the setting of other pipes (EPNUM = 0000 is allowed in this case.)

32.3.32 Pipe Buffer Register (PIPEBUF)

PIPEBUF specifies the buffer size and buffer number for pipes 1 to 9.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	BUFSIZE[4:0]					—	—	BUFNMB[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
14 to 10	BUFSIZE [4:0]	H'00	R/W	Buffer Size Specify the buffer size of the pipe specified by the PIPESEL bits (selected pipe) in units of blocks. One block is 64 bytes. 00000 (H'00): 64 bytes 00001 (H'01): 128 bytes : : 11111 (H'1F): 2 Kbytes When DBLB = 1 is set by the software, this module allocates the FIFO buffer size specified by these bits to the selected pipe for two sides. Thus the size of the FIFO buffer that this module allocates to the selected pipe is as follows: (BUFSIZE + 1) * 64 * (DBLB + 1) [bytes] A value that can be set in these bits varies depending on pipes selected. For pipes 1 to 5: Set BUFSIZE to H'00 to H'1F. For pipes 6 to 9: Set BUFSIZE to H'00. When using the buffer with CNTMD = 1, set a value in multiples of MaxPacketSize in these bits. Modify these bits when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	BUFNMB [7:0]	H'00	R/W	Buffer Number Specify the FIFO buffer number of the selected pipe with a value from H'04 to H'87. When the selected pipe is either of pipes 1 to 5, these bits can be set to a value according to user systems. Set BUFNMB to H'06 to H'4F. BUFNMB = 0 to 3 are for DCP only. BUFNMB = 4 is for pipe 6 only. However, when pipe 6 is not used, this is available for other pipes. When pipe 6 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 4. BUFNMB = 5 is for pipe 7 only. However, when pipe 7 is not used, this is available for other pipes. When pipe 7 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 5. BUFNMB = 6 is for pipe 8 only. However, when pipe 8 is not used, this is available for other pipes. When pipe 8 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 6. BUFNMB = 7 is for pipe 9 only. However, when pipe 9 is not used, this is available for other pipes. When pipe 9 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 7. Modify these bits when CSSTS = 0, PID = NAK, and no pipe number is set in the CURPIPE bits. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

32.3.33 Pipe Maximum Packet Size Register (PIPEMAXP)

PIPEMAXP specifies the maximum packet size for pipes 1 to 9.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DEVSEL[3:0]				—	MXPS[10:0]										
Initial value:	0	0	0	0	0	*	*	*	*	*	*	*	*	*	*	*
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	DEVSEL[3:0]	00	R/W	Device Select Specify the USB device address of the peripheral device that is a remote party for communication when the host controller function is selected. 0000: Address 0000 0001: Address 0001 0010: Address 0010 : : 1010: Address 1010 Other than above: Setting prohibited Set these bits after setting DEVADDn (n = 0 to A) corresponding to the value of these bits. When setting DEVSEL = 0010, for example, set the address in DEVADD2. To change these bits after changing the PID bits in DCP from BUF to NAK, check CSSTS = 0 and PBUSY = 0 and then change these bits. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. When the function controller function is selected, set these bits to B'0000.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10 to 0	MXPS[10:0]	*	R/W	Maximum Packet Size Specify the payload of data (maximum packet size) of the selected pipe. The settable value range for each pipe is as follows: Pipes 1 and 2: 1 byte (H'001) to 1024 bytes (H'400) Pipes 3 to 5: 8 (H'008), 16 (H'010), 32 (H'020), 64 (H'040), or 512 bytes (H'200) (MXPS2 to MXPS0 bits are not provided.) Pipes 6 to 9: 1 byte (H'001) to 64 bytes (H'040) Set a value in the MXPS bits based on the USB Specification for each transfer type. To transmit an isochronous pipe in split transactions, set a value of 188 bytes or less in the MXPS bits. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS = 0 or set the PID bits to BUF.

Note: * The initial value is H'000 (when no pipe is selected by the PIPESEL bits in PIPESEL) or H'040 (when a pipe is selected).

32.3.34 Pipe Cycle Control Register (PIPEPERI)

PIPEPERI specifies whether to activate the buffer flush function or not at the time of an interval error during the isochronous IN transfer, and also specifies the interval error detection interval for pipes 1 to 9.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	IFIS	0	R/W	Isochronous IN Buffer Flush Specifies whether to flush the FIFO buffer when the pipe specified by the PIPESEL bits (selected pipe) is isochronous IN transfer type. 0: The FIFO buffer is not flushed. 1: The FIFO buffer is flushed. Buffer flush is a function that this module automatically clears the FIFO buffer when this module does not receive IN-Token from the USB host in a (μ) frame for each interval specified in the IITV bits when the function controller function is selected and the selected pipe is isochronous IN transfer type. When double buffer is selected (DBLB = 1), this module clears data of only the older side. The FIFO buffer is cleared when an SOF packet is received immediately after the (μ) frame where IN-Token is to be received. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time when the SOF packet is to be received using the internal interpolation. When the host controller function is selected, set this bit to 0. When the selected pipe is not isochronous transfer type, set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
11 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	IITV[2:0]	000	R/W	Interval Error Detection Interval Specify the interval error detection interval of the selected pipe with a value of 2's n-th power of the frame timing. This function differs in detail between host controller function and function controller function as described later. Set these bits when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. To change the setting of these bits after USB communication, set PID = NAK and then set ACLRM = 1 to initialize the interval timer. These bits are not provided for pipes 3 to 5. Set 000 in the position of these bits corresponding to pipes 3 to 5.

32.3.35 Pipe n Control Register (PIPEnCTR) (n = 1 to 9)

PIPEnCTR monitors the buffer memory status, changes/checks the data PID sequence bits, selects whether to use auto-response mode and buffer auto-clear mode, and specifies a response PID for pipes 1 to 9. This register can be set independently of the pipe selection using PIPESEL.

This register is initialized by a power-on reset. The PID1 and PID0 bits are also initialized by a USB bus reset.

(1) PIPEnCTR (n = 1 to 5)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	INBUFM	CSCLR	CSSTS	—	ATREPM	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W*2	R	R	R/W	R/W	R/W*1	R/W*1	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	Buffer Status Indicates the FIFO buffer status of the pipe. 0: The buffer is not accessible from the CPU. 1: The buffer is accessible from the CPU. The meaning of this bit differs depending on the settings of the DIR, BFRE, and DCLRM bits as shown in Table 32.9.
14	INBUFM	0	R	Transmit Buffer Monitor Indicates the FIFO buffer status of the selected pipe in the transmit direction. 0: The buffer memory contains no transmittable data. 1: The buffer memory contains transmittable data. When transmit direction (DIR = 1) is set for the pipe, this module sets this bit to 1 when the software (or DMAC) finishes writing data to the FIFO buffer for at least one register set. When this module finishes sending all data on the register set (writing is completed) of the FIFO buffer, this bit indicates 0. In the case of a double buffer (DBLB = 1), when this module finishes sending all data on both register sets and the software (or DMAC) has not completed writing of data for one register set, this bit indicates 0. When receive direction (DIR = 0) is set for the selected pipe, this bit indicates the same value as the BSTS bit.

Bit	Bit Name	Initial Value	R/W	Description
13	CSCLR	0	R/W*2	CSPLIT Status Clear When the software sets this bit to 1 with the host controller function selected, this module clears the CSSTS bit to 0. 0: Invalid 1: Clears the CSSTS bit to 0. To forcibly restart the next transfer with S-SPLIT in data transfer using split transactions, set this bit to 1 by the software. Since this module automatically clears the CSSTS bit to 0 at the end of C-SPLIT in normal split transactions, the software needs not clear the CSSTS bit. Clear the CSSTS bit with this bit while communication is halted by clearing the UACT bit or when it is clarified that no data transfer is performed by detection of Detach mode. Even if this bit is set to 1 when CSSTS is 0, CSSTS remains 0. When the function controller function is selected, be sure to set this bit to 0.
12	CSSTS	0	R	CSSTS Status When the host controller function is selected, this bit indicates the C-SPLIT status of split transactions. 0: START-SPLIT (S-SPLIT) transaction is being processed or no split transaction is used. 1: C-SPLIT transaction is being processed. This module sets this bit to 1 when starting C-SPLIT, and clears this bit to 0 when C-SPLIT end is detected. The value of this bit is valid only when the host controller function is selected.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	ATREPM	0	R/W	Auto-Response Mode Enables or disables auto-response for the selected pipe. 0: Auto-response is disabled. 1: Auto-response is enabled. When the function controller function is selected and the transfer type of the selected pipe is set to bulk transfer, this bit can be set to 1. When this bit is 1, this module sends responses to tokens from the USB host as follows: (1) When the selected pipe is set for Bulk-IN transfer (TYPE = 01 and DIR = 1) When ATREPM = 1 and PID = BUF, this module sends a Zero-Length packet in response to the IN-Token. Each time this module receives ACK from the USB host (flow of one transaction: receiving IN-Token -> sending Zero Length packet -> receiving ACK), this module updates the sequence toggle bit (DATA-PID) by toggling it. No BRDY interrupt or BEMP interrupt is generated. (2) When the selected pipe is set for Bulk-OUT transfer (TYPE = 01 and DIR = 0) When ATREPM = 1 and PID = BUF, this module sends NAK in response to the OUT-Token (or PING-Token) and generates an NRDY interrupt. Modify this bit when CSSTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Be sure to set this bit to 1 for USB communication when the FIFO buffer is empty. Do not write data to the FIFO buffer during USB communication with this bit set to 1. When the selected pipe is set for isochronous transfer, be sure to set this bit to 0. When the host controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
9	ACLRM	0	R/W	Buffer Auto-Clear Mode Enables or disables buffer auto-clear mode for the selected pipe. 0: Buffer auto-clear mode is disabled. 1: Buffer auto-clear mode is enabled. (All buffers are initialized.) To completely delete the data in the FIFO buffer allocated to the pipe, write 1 and then 0 continuously to the ACLRM bit. Table 32.10 shows data cleared by this module when this bit is set to 1 and then 0 and cases where such data is cleared. Modify this bit when CSSTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
8	SQCLR	0	R/W*[1]	Toggle Bit Clear Set this bit to 1 to clear the expected value (in DATA0) of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is cleared in DATA0. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA0. This module always indicates SQCLR = 0. When this bit is set to 1 for a Bulk-Out transfer pipe with the host controller function selected, this module starts the next transfer with the PING-token for the pipe. Set the SQCLR bit to 1 when CSCTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
7	SQSET	0	R/W*[1]	Toggle Bit Set Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is set in DATA1. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA1. This module always indicates SQSET = 0. Set the SQSET bit to 1 when CSCTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
6	SQMON	0	R	Toggle Bit Check Indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: DATA0 1: DATA1 If the pipe is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.
5	PBUSY	0	R	Pipe Busy Indicates whether the pipe is currently used in the USB bus or not. 0: The selected pipe is not used in the USB bus. 1: The selected pipe is being used in the USB bus. When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.
4 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	Response PID Specify a response used in the next transaction for the selected pipe. 00: NAK response 01: BUF response (depending on buffer state) 10: STALL response 11: STALL response These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Tables 32.11 and 32.12 show the basic operation (with no error in packets) of this module in each setting of the PID bits. When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the pipe entered the NAK state. However, when this module changed these bits to NAK, the software does not have to check the PBUSY bit. This module modifies these bits in the following cases. • When the pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end. • When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11). • When this module detects a USB bus reset with the function control function selected, this module indicates PID = NAK. • When this module detects a CRC error or another receive error three times in a row with the host control function selected, this module indicates PID = NAK. • When this module receives a STALL handshake with the host control function selected, this module indicates PID = STALL (11). Set these bits as follows: • To change the state from NAK (00) to STALL, write 10. • To change the state from BUF (01) to STALL, write 11. • To change the state from STALL (11) to NAK, write 10 then 00. • To change the state from STALL to BUF, set these bits to NAK and then to BUF.

Notes: 1. Only reading 0 and writing 1 are enabled.
2. Only writing 1 is enabled.

Table 32.9 Operations of BSTS Bit

DIR Bit	BFRE Bit	DCLRM Bit	Meaning of BSTS Bit
0	0	0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
		1	Setting prohibited
	1	0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 when the software sets BCLR = 1 after the buffer data read.
		1	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
1	0	0	Indicates 1 when the FIFO buffer becomes ready to write transmit data to the buffer, and indicates 0 upon completion of the data write.
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

Table 32.10 Data Cleared by This Module when ACLRM = 1

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer (both sides for double FIFO buffer) allocated to the pipe	
2	Interval count value when the pipe is isochronous transfer type	When resetting the interval count value
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	FIFO buffer toggle control	When changing the DBLB setting
5	Internal flags related to the transaction count	When forcibly terminating the transaction count function

Table 32.11 Operations of This Module in Each Setting of PID Bits (when the Host Controller Function is Selected)

PID Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of This Module
00 (NAK)	Independent of the setting	Independent of the setting	Issues no token.
01 (BUF)	Bulk or interrupt	Independent of the setting	Issues tokens when UACT = 1 is set and the FIFO buffer for the pipe is ready to receive/transmit. Issues no token when UACT = 0 is set or the FIFO buffer is not ready to receive/transmit.
	Isochronous	Independent of the setting	Issues tokens irrespective of the state of the FIFO buffer for the pipe.
10 (STALL) or 11 (STALL)	Independent of the setting	Independent of the setting	Issues no token.

Table 32.12 Operations of This Module in Each Setting of PID Bits (when the Function Controller Function is Selected)

PID Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of This Module
00 (NAK)	Bulk or interrupt	Independent of the setting	Sends a NAK response to a token from the USB host. However, for the operation of this module when ATREPM = 1, see the description on the ATREPM bit.
	Isochronous	Independent of the setting	Sends no response to a token from the USB host.
01 (BUF)	Bulk	Receive direction (DIR = 0)	Receives data and sends an ACK response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, sends a NAK response. Sends an ACK response to the PING token from the USB host when the FIFO buffer for the selected pipe is ready to receive. Otherwise, sends a NYET response.
	Interrupt	Receive direction (DIR = 0)	Receives data and sends an ACK response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, sends a NAK response.
	Bulk or interrupt	Transmit direction (DIR = 1)	Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a NAK response.
	Isochronous	Receive direction (DIR = 0)	Receives data in response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, ignores the data.
		Transmit direction (DIR = 1)	Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a Zero-Length packet.
10 (STALL) or	Bulk or interrupt	Independent of the setting	Sends a STALL response to a token from the USB host.
11 (STALL)	Isochronous	Independent of the setting	Sends no response to a token from the USB host.

(2) PIPEnCTR (n = 6 to 9)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W:	R	R	R/W*1	R/W	R	R	R/W	R/W*1	R/W*1	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	Buffer Status Indicates the state of the FIFO buffer of the selected pipe. 0: The buffer is not accessible. 1: The buffer is accessible. The meaning of this bit differs as shown in Table 32.9 depending on the settings of the DIR, BFRE, and DCLRM bits.
14	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
13	CSCLR	0	R/W*1	CSPLIT Status Clear Setting this bit to 1 clears the CSSTS bit of the selected pipe. 0: Invalid 1: Clears the CSSTS bit. To forcibly restart the next transfer with S-SPLIT in data transfer using split transactions, set this bit to 1 by the software. Since this module automatically clears the CSSTS bit to 0 at the end of C-SPLIT in normal split transactions, the software does not have to clear the CSSTS bit. Control the CSSTS bit with this bit while communication is halted by clearing the UACT bit or when it is clarified that no data transfer is performed by detection of Detach mode. Even if this bit is set to 1 when CSSTS is 0, CSSTS remains 0. When the function controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
12	CSSTS	0	R/W	When the host controller function is selected, this bit indicates the C-SPLIT status of split transactions. 0: START-SPLIT (S-SPLIT) transaction is being processed or the transaction is transferred without split transaction. 1: C-SPLIT transaction is being processed. This module sets this bit to 1 when starting C-SPLIT, and clears this bit to 0 when C-SPLIT end is detected. When the function controller function is selected, the read value of this bit is invalid. This bit is valid only when the host controller function is selected.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	ACLRM	0	R/W	Buffer Auto-Clear Mode*3*4 Enables or disables buffer auto-clear mode for the selected pipe. 0: Buffer auto-clear mode is disabled. 1: Buffer auto-clear mode is enabled. (All buffers are initialized.) To completely delete the data in the FIFO buffer allocated to the pipe, write 1 and then 0 continuously to the ACLRM bit. Table 32.13 shows data cleared by this module when this bit is set to 1 and then 0 and cases where such data is cleared. Modify this bit when CSSTS = 0, PID = NAK, and the pipe is not set in the CURPIPE bits. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
8	SQCLR	0	R/W*[1]	Toggle Bit Clear*[3]*[4] Set this bit to 1 to clear the expected value (in DATA0) of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is cleared in DATA0. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA0. This module always indicates SQCLR = 0. When this bit is set to 1 for a Bulk-Out transfer pipe with the host controller function selected, this module starts the next transfer with the PING-token for the pipe. Set the SQCLR bit to 1 when CSCTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
7	SQSET	0	R/W*[1]	Toggle Bit Set*[3]*[4] Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is set in DATA1. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the selected pipe in DATA1. This module always indicates SQSET = 0. Set the SQSET bit to 1 when CSCTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
6	SQMON	0	R	Toggle Bit Check Indicates the expected value of the sequence toggle bit for the next transaction of the pipe. 0: DATA0 1: DATA1 If the selected pipe that is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.
5	PBUSY	0	R	Pipe Busy Indicates whether the selected pipe is currently used in the USB bus or not. 0: The selected pipe is not used in the USB bus. 1: The selected pipe is being used in the USB bus. When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.
4 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	Response PID Specify a response used in the next transaction for the selected pipe. 00: NAK response 01: BUF response (depending on buffer state) 10: STALL response 11: STALL response These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Tables 32.13 and 32.14 show the basic operation (with no error in packets) of this module in each setting of the PID bits. When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the selected pipe entered the NAK state. However, when this module changed these bits to NAK, the software needs not check the PBUSY bit. This module modifies these bits in the following cases. • When the selected pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end. • When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11). • When this module detects a USB bus reset with the function control function selected, this module indicates PID = NAK. • When this module detects a CRC error or another receive error three times in a row with the host control function selected, this module indicates PID = NAK. • When this module receives a STALL handshake with the host control function selected, this module indicates PID = STALL (11). Set these bits as follows: • To change the state from NAK (00) to STALL, write 10. • To change the state from BUF (01) to STALL, write 11. • To change the state from STALL (11) to NAK, write 10 then 00. • To change the state from STALL to BUF, set these bits to NAK and then to BUF.

Notes: 1. Only reading 0 and writing 1 are enabled.
2. Only writing 1 is enabled.
3. Set the ACLRM, SQCLR, or SQSET bit when CSSTS = 0, PID = NAK, and the selected pipe is not set in the CURPIPE bits.
4. When setting the ACLRM, SQCLR, or SQSET bit after changing the PID bits from BUF to NAK, check that CSSTS = 0 and PBUSY = 0 for the pipe. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Table 32.13 Data Cleared by This Module when ACLRM = 1

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer allocated to the selected pipe	
2	Interval count value when the host controller function is selected and the selected pipe is interrupt transfer type	When resetting the interval count value
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	Internal flags related to the transaction count	When forcibly terminating the transaction count function

32.3.36 Pipe n Transaction Counter Enable Register (PIPnTRE) (n = 1 to 5)

PIPnTRE enables or disables the transaction counter function and clears the counter for pipes 1 to 5.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	TRENB	0	R/W	Transaction Counter Enable Enables or disables the transaction counter function. 0: The transaction counter function is disabled. 1: The transaction counter function is enabled. When the software sets the number of total packets in the TRNCNT bits in PIPEnTRN for the receive pipe and then sets this bit to 1, this module controls the following when it received the same number of packets as the setting of the TRNCNT bits. When continuous communication mode is used (CNTMD = 1), this module toggles the received data to the CPU even if the FIFO buffer is not full at the end of reception. When SHTNAK = 1, this module changes the PID bits for the corresponding pipe to NAK when this module received the same number of packets as the setting of the TRNCNT bits. When BFRE = 1, this module asserts the BRDY interrupt when this module received the same number of packets as the setting of the TRNCNT bits and read the receeive data completely. For transmit pipes, set this bit to 0. When the transaction counter function is not used, set this bit to 0. When using the transaction counter function, set the TRNCNT bits and then set this bit to 1. Furthermore, set this bit to 1 before receiving the first packet that is included in the transaction count range.
8	TRCLR	0	R/W	Transaction Counter Clear Clears the current count value of the transaction counter for the pipe and indicates TRCLR = 0. 0: Invalid 1: The current count value is cleared.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: Change the bits in this register when CSSTS = 0 and PID = NAK.
When changing the bits in this register after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

32.3.37 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5)

PIPnTRE is a transaction counter for pipes 1 to 5.

This register is initialized by a power-on reset, but the setting of this register is retained through a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TRNCNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TRNCNT [15:0]	All 0	R/W	Transaction Counter Writing: Specify the number of transactions of DMA transfer. Reading: When TRENB = 0, the set number of transactions is indicated. When TRENB = 1, the number of current transactions is indicated. This module increments (+1) the value of these bits when the following conditions are all satisfied. TRENB = 1 TRCNT value ≠ current count value +1 when a packet is received. The payload of the received packet equals the value of the MXPS bits. This module clears these bits to 0 when any of the following is satisfied. When the following conditions are all satisfied - TRENB = 1 - TRCNT value = current count value +1 when a packet is received. - The payload of the received packet equals the value of the MXPS bits. When the following conditions are all satisfied - TRENB = 1 - A short packet is received. When the following conditions are all satisfied - TRENB = 1 - The software sets the TRCLR bit to 1.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TRNCNT [15:0]	All 0	R/W	For transmit pipes, set these bits to all 0. When the transaction counter function is not used, set these bits to all 0. Change these bits when CSSTS = 0, PID = NAK, and TRENB = 0. When setting these bits to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. When changing these bits, set TRCNT = 1 and then set TRENB = 1.

32.3.38 Device Address n Configuration Register (DEVADDn) (n = 0 to A)

DEVADDn specifies the address and port number of the HUB connected to a peripheral device as a communication target, as well as the transfer rate of the peripheral device, for pipes 0 to A.

When the host controller function is selected, be sure to set the bits in this register before starting communication for each pipe.

Change the bits in this register when there is no valid pipe that uses the setting of these bits. A valid pipe is defined as a pipe that meets the following two conditions.

1. The setting of the DEVSEL bits specifies this register.
2. The PID bits for the selected pipe are set to BUF or the selected pipe is the DCP with SUREQ = 1

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 11	UPPHUB [3:0]	0000	R/W	HUB Register Specify the USB address of the HUB connected to the peripheral device as a communication target. 0000: The peripheral device is connected directly to the port of this LSI. 0001 to 1010: USB address of the HUB 1011 to 1111: Setting prohibited When the host controller function is selected, this module reads these bits to generate packets when executing split transactions. When the function controller function is selected, set these bits to 0000.

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	HUBPORT [2:0]	000	R/W	HUB Port for Communication Target Device Specify the port number of the HUB connected to the peripheral device as a communication target. 000: The peripheral device is connected directly to the port of this LSI. 001 to 111: Port number of the HUB When the host controller function is selected, this module reads these bits to generate packets when executing split transactions. When the function controller function is selected, set these bits to 000.
7, 6	USBSPD [1:0]	00	R/W	Communication Target Device Transfer Rate Specify the USB transfer rate of the peripheral device as a communication target. 00: DEVADDn is not used. 01: Low speed 10: Full speed 11: High speed When the host controller function is selected, this module reads these bits to generate packets. When the function controller function is selected, set these bits to 00.
5 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

32.4 Operation

32.4.1 System Control and Oscillation Control

This section describes register operations required for the initial settings of this module and the registers required for the power consumption control.

(1) Reset

Table 32.14 lists the reset types of this module. For initialization states of registers after each reset, see section 32.3, Register Descriptions.

Table 32.14 Reset Types

Reset Name	Operation
Power-on reset	RESETP pin
AP system reset	RESETA pin
Power area reset	Register in the SYSC
Software reset	Register in the CPGA

(2) Setting Selection of Controller Functions

This module can select the host controller function or the function controller function. Select either of these functions by the DCFM bit in SYSCFG. Set the DCFM bit during the initial setting immediately after a power-on reset or in the D+ pull-up disabled state (DPRPU = 0) and D+/D- pull-down disabled state (DRPD = 0).

(3) Enabling High-Speed Operation

This module can set the USB transmission rate (communication bit rate) by the software.

When the host controller function is selected, high-speed operation or full-speed/low-speed operation is selectable. When the function controller function is selected, high-speed operation or full-speed operation is selectable. To enable high-speed operation with this module, set the HSE bit in SYSCFG to 1. When high-speed operation is enabled, this module executes the reset handshake protocol and automatically sets the USB transmission rate. The reset handshake result can be checked by the RHST bits in DVSTCTR.

When high-speed operation is disabled, this module operates in full speed or low speed when the host controller function is selected, and operates only in full speed when the function controller function is selected.

When the host controller function is selected, change the HSE bit during a period from ATTACH detection until a bus reset. When the host controller function is selected, change the HSE bit in the D+ pull-up disabled state (DPRPU = 0).

(4) USB Data Bus Resistor Control

Figure 32.1 shows the connection between this module and the USB connector.

This module incorporates a pull-up resistor of the D+ signal and pull-down resistors of the D+ and D- signals. Specify pull-up and pull-down for each signal using the DPRPU and DRPD bits in SYSCFG.

Furthermore, this module controls the terminating resistors of the D+ and D- signals in high-speed operation, and the output resistors in full-speed operation. This module automatically switches the on-chip resistors after connection to the host controller or the peripheral device upon detecting a reset handshake, suspended state, or resume.

When the function controller function is selected and the DPRPU bit in SYSCFG is set to 0 during communication with the host controller, this module disables the pull-up resistors (or terminating resistors) of the USB data line. Therefore, the USB host can be notified of a disconnection from the device.

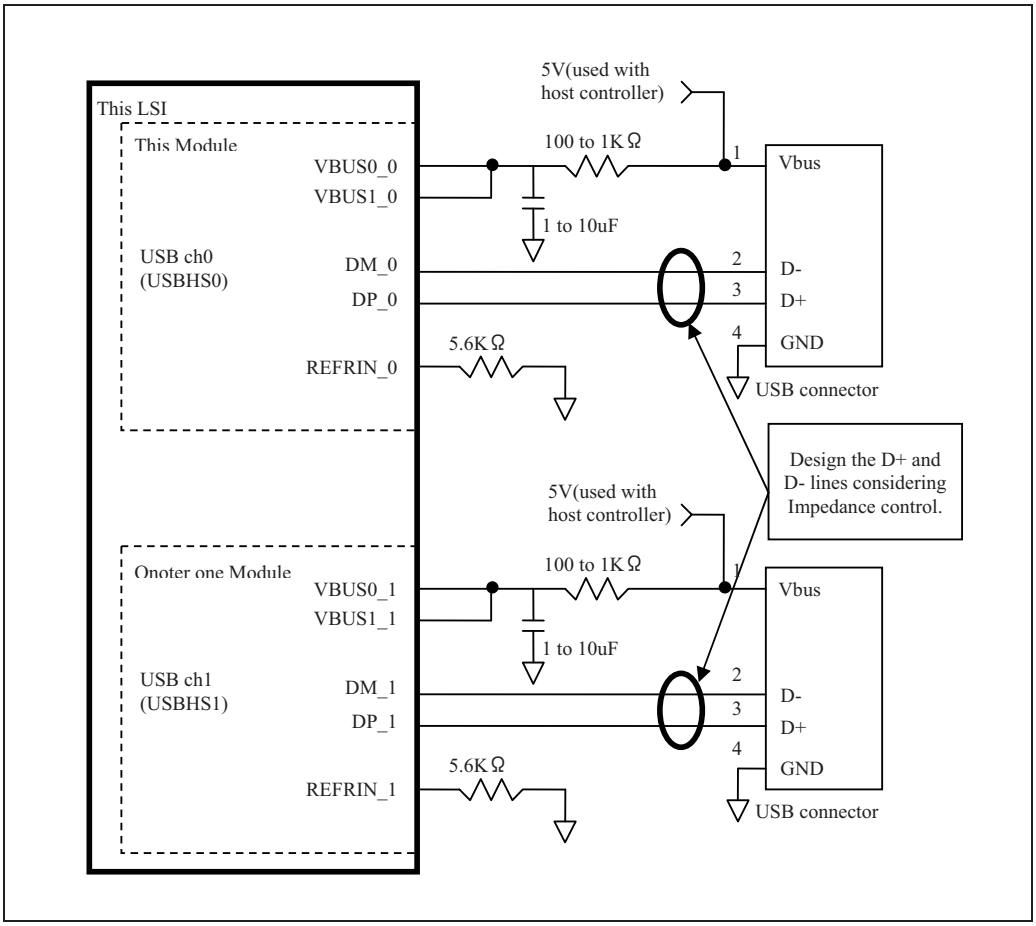

Figure 32.1 Connection to the USB Connector

(5) Software reset when the USB disconnection is detected

Issue a software reset of the USBHS module when the USB disconnection is detected. If the DMA interface is being used, issue a software reset of the USBHS-DMAC module as well. A software reset can be issued via a register in the CPGA.

Whether or not the USB disconnection is detected can be determined by the VBSTS in the INTSTS0 register when the function controller function is selected or the DTCH bit in the INTSTS1 register when the host controller function is selected.

32.4.2 Interrupt Function

Table 32.15 lists the interrupt generating conditions of this module.

When any of the following interrupt generating conditions are satisfied and the interrupt output is enabled by the corresponding interrupt enable register, this module outputs a USB interrupt request to the interrupt controller (INTC).

Table 32.15 Interrupt Generating Conditions

Bit	Interrupt Name	Interrupt Generating Conditions	Function	Related Status
VBINT	VBUS interrupt	When VBUS0_0 and VBUS1_0 input pin state change is detected (both L to H and H to L)	Host and function controller functions	VBSTS
RESM	Resume interrupt	When a USB bus state change is detected in the suspended state (J-State to K-State or J-State to SE0)	Function	—
SOFR	Frame number update interrupt	[When the host controller function is selected] When an SOF packet with a different frame number is sent [When the function controller function is selected] SOFRM = 0: When an SOF packet with a different frame number is received SOFRM = 1: When an SOF packet with a μ frame number of 0 cannot be received due to damage, etc.	Host and function controller functions	—
DVST	Device state transition interrupt	When a device state transition is detected USB bus reset detected Suspended state detected SET_ADDRESS request received SET_CONFIGURATION request received	Function	DVSQ

Bit	Interrupt Name	Interrupt Generating Conditions	Function	Related Status
CTRT	Control transfer stage transition interrupt	When a control transfer stage transition is detected Setup stage completed Control write transfer status stage shifted Control read transfer status stage shifted Control transfer completed Control transfer sequence error occurred	Function	CTSQ
BEMP	Buffer empty interrupt	When the buffer becomes empty after sending all buffer memory data When a packet with a size exceeding the maximum packet size is received	Host and function controller functions	BEMPSTS.PIPEBEMP
NRDY	Buffer not ready interrupt	[When the host controller function is selected] When STALL from the peripheral device in response to the issued token is received When a response from the peripheral device in response to the issued token cannot be received successfully (no response three times in a row or a packet receive error three times in a row) When an overrun or underrun error occurred during isochronous transfer [When the function controller function is selected] When NAK is sent in response to IN token, OUTtoken, or PING token When a CRC error or bit stuffing error occurred during data reception in isochronous transfer When an overrun or underrun error occurred during data reception in isochronous transfer	Host and function controller functions	NRDYSTS.PIPENRDY

Bit	Interrupt Name	Interrupt Generating Conditions	Function	Related Status
BRDY	Buffer ready interrupt	When the buffer becomes ready for reading or writing	Host and function controller functions	BRDYSTS. PIPEBRDY
OVRCR	OVRCR interrupt	When an OVCN_0/OVCN2 input pin state change is detected	Host and function controller functions	OVCMON
BCHG	Bus change interrupt	When a USB bus state change is detected	Host and function controller functions	—
DTCH	Disconnection in full-speed operation	When a disconnection from the peripheral device is detected during full-speed operation	Host controller function	—
ATTCH	Device connection	When J-STATE or K-STATE where USB bus state continues for 2.5 μs is detected This interrupt is available for detection of connection to a peripheral device.	Host controller function	—
EOFERR	EOF error	When an EOF error of the peripheral device is detected	Host controller function	—
SACK	SETUP	When an ACK response to the setup transaction is received	Host controller function	—
SIGN	SETUP error	When an error (no response or ACK packet damage) is detected three times in a row in the setup transaction	Host controller function	—

Note: These bits in this table are those of INTSTS0 if any register's name is not indicated.

Figure 32.2 shows a block diagram of the interrupt circuit of this module.

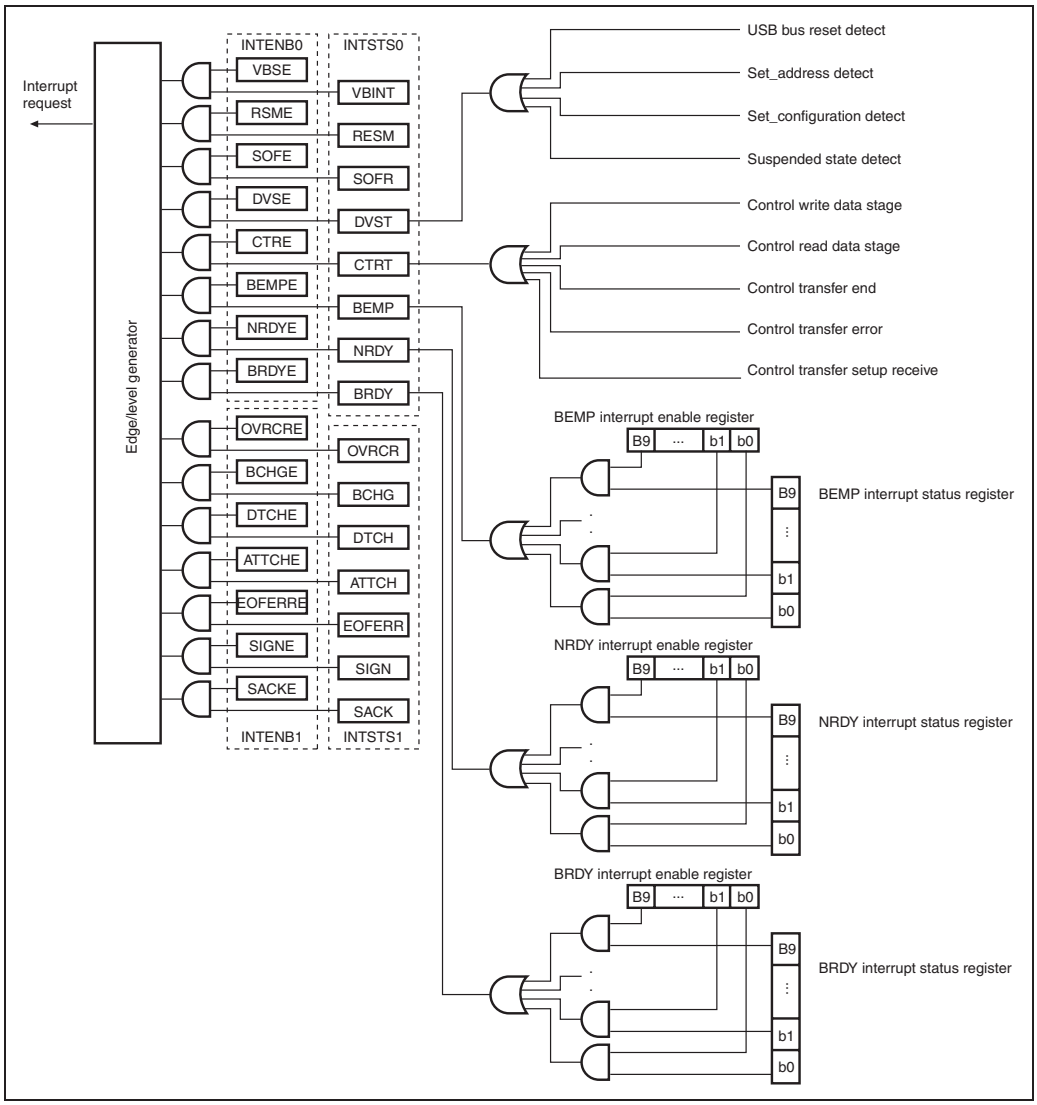

Figure 32.2 Block Diagram of Interrupt Circuit

(1) BRDY Interrupt

A BRDY interrupt can be generated when either of the host controller function and function controller functions is selected. When the following conditions in each pipe are satisfied, this module sets the corresponding bit in BRDYSTS to 1. At this time, when the PIPEBRDYE bit for the pipe in BRDYENB is set to 1 and the BRDYE bit in INTENB0 is set to 1 by the software, this module generates a BRDY interrupt.

BRDY interrupt generating conditions and clearing method depend on the settings of the BRDYM bit and the BFRE bit for each pipe.

(a) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified

With this setting, a BRDY interrupt indicates that the FIFO port is accessible.

This module generates an internal BRDY interrupt request trigger when the following conditions are satisfied, and sets the PIPEBRDY bit corresponding to the request trigger pipe to 1.

1. Pipes set for the transmit direction

- When the software changes the DIR bit from 0 to 1
- When this module finishes sending a packet of the pipe while data write from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)

  When continuous communication mode is selected, this module generates a BRDY interrupt request trigger upon completion of sending data for one side of the FIFO buffer.
- When a double FIFO buffer is specified and one side of the FIFO buffer is empty when data write to the other side of the FIFO buffer is completed

  Even if one side of the FIFO buffer becomes empty while the other side is in data write processing, no BRDY interrupt is generated until the ongoing data write finishes.
- When this module generates a buffer flush for a pipe of isochronous transfer type
- When the FIFO buffer becomes write enable state by writing 1 to the ACLRM bit

No BRDY interrupt request trigger is generated for the DCP (in data transmission of control transfer).

2. Pipes set for the receive direction

- When this module receives a packet successfully and the FIFO buffer becomes ready for reading while data read access from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)

  No BRDY interrupt request trigger is generated in transactions with incorrect data PID.

  When continuous communication mode is selected, no BRDY interrupt request trigger is generated for packets with a MaxPacketSize data size and when the FIFO buffer still has available space.

  When this module receives a short packet, this module generates a BRDY interrupt request trigger even if the buffer has available space.

  When a transaction counter is used, this module generates a BRDY interrupt request trigger when this module receives a packet with a size of the set value even if the FIFO buffer still has available space.

  When a double FIFO buffer is specified and one side of the FIFO buffer is ready for reading when data read from the other side of the FIFO buffer is completed

  Even if data read for one side of the FIFO buffer is completed while the other side is undergoing data read, no BRDY interrupt request trigger is generated until the ongoing data read finishes.

This interrupt is not generated in communication in the control transfer status stage when the function controller function is selected.

The software can clear the PIPEBRDY interrupt status of the pipe by writing 0 to the PIPEBRDY bit for the pipe in BRDYSTS. At this time, write 1 to the bits corresponding to other pipes.

Be sure to clear the BRDY interrupt status before accessing the FIFO buffer.

(b) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 1) at the end of data read are specified

With this setting, this module determines that a **BRDY** interrupt is generated upon completion of reading all data of one transfer in a receive pipe, and sets the bit for the pipe in this register to 1.

This module determines that the last data of a transfer was received in either of the following cases.

- A Zero-Length packet or another short packet is received.
- A transaction counter (TRNCNT bits) is used and a packet with a size of the value of the TRNCNT bits is received.

When either of these conditions is satisfied and the data read is completed, this module determines that reading all data for one transfer is completed.

When this module receives a Zero-Length packet with the FIFO buffer empty, this module determines that reading all data for one transfer is completed when the Zero-Length packet data is toggled to the CPU. In this case, write 1 to the BCLR bit in the corresponding FIFOCTR register by the software to start the next transfer.

With this setting, this module generates no BRDY interrupt for transmit pipes.

The software can clear the PIPEBRDY interrupt status of the pipe to 0 by writing 0 to the PIPEBRDY bit for the pipe. At this time, write 1 to the bits corresponding to other pipes.

When using this mode, do not change the BFRE setting until the processing for one transfer is completed.

To change the BFRE bit during processing, clear all FIFO buffers for the pipe by the ACLRM bit.

(c) When BRDY interrupt enable (BRDYM = 1) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified

With this setting, the value of the PIPEBRDY bit varies with the value of the **BSTS** bit for each pipe. That is, this module indicates 1 or 0 of the BRDY interrupt status according to the FIFO buffer status.

1. Pipes set for the transmit direction

   When the FIFO port is ready to write data, the PIPEBRDY bit indicates 1. When the FIFO port is not ready to write data, the PIPEBRDY bit indicates 0.

   However, even if the transmit pipe of the DCP is ready to write data, no BRDY interrupt is asserted.
2. Pipes set for the receive direction

   When the FIFO port is ready to read data, the PIPEBRDY bit indicates 1. When all data is read from the FIFO port (reading disabled), the PIPEBRDY bit indicates 0.

   When this module receives a Zero-Length packet with the FIFO buffer empty, this module indicates 1 with the corresponding bit until 1 is written to BCLR by the software, and continues to assert the BRDY interrupt.

   With this setting, the software cannot clear the PIPEBRDY bit to 0.

   When BRDYM = 1, set the BFRE bit to 0 for all pipes.

Figure 32.3 shows the BRDY interrupt generation timing.

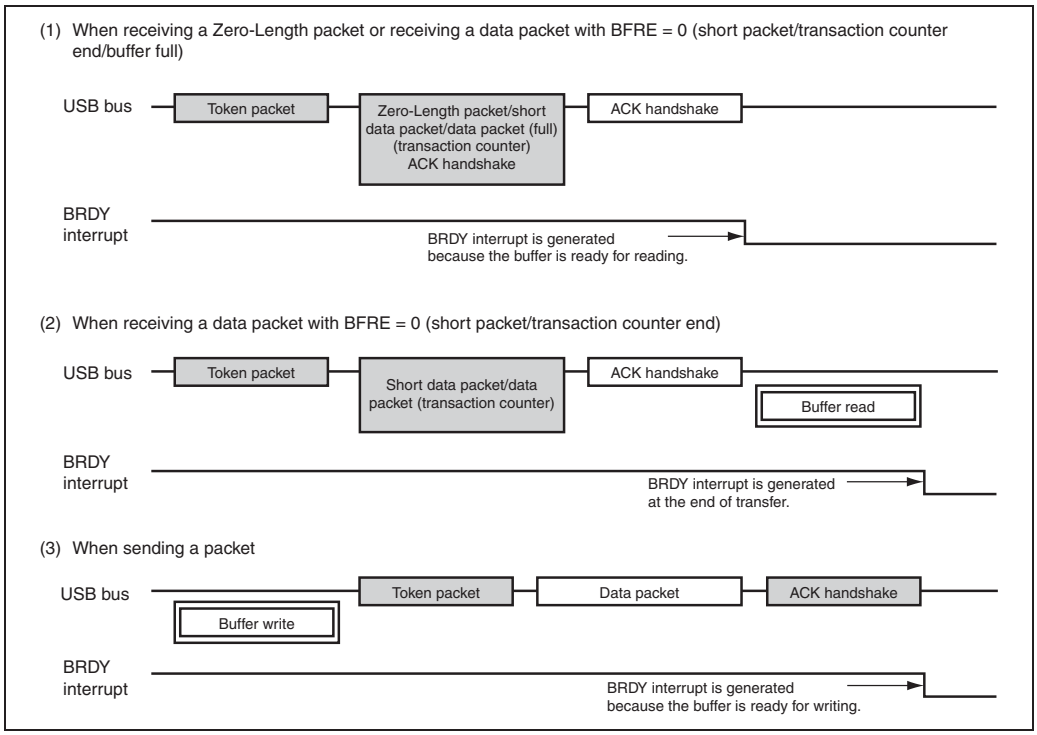

Figure 32.3 BRDY Interrupt Generation Timing

(2) NRDY Interrupt

When this module generates an internal NRDY interrupt request for the pipe in which PID = BUF is set by the software, this module indicates PIPENRDY = 1 for the pipe in NRDYSTS. At this time, when 1 is set in the corresponding bit in NRDYENB by the software, this module indicates NRDY = 1 in INTSTS0 and generates a USB interrupt.

The following shows the conditions for this module to generate an internal NRDY interrupt request for a pipe.

However, the execution of the SETUP transaction when the host controller function is selected is excluded from the following interrupt generation conditions. In the SETUP transaction when the host controller function is selected, this module detects an SACK interrupt or SIGN interrupt.

Furthermore, when executing the control transfer status stage with the function controller function selected, this module generates no interrupt request.

(a) When the host controller function is selected and no split transaction occurs

1. Pipes in the transmit direction

   This module detects an NRDY interrupt when either of the following conditions is satisfied.

   — When the OUT token transmit timing comes with no transmit data in the FIFO buffer in an isochronous transfer-type pipe

   At this time, this module sends a Zero-Length packet following the OUT token, and then indicates PIPENRDY = 1 for the pipe and OVRN = 1.

   — In communication other than SETUP transaction for a pipe of other than isochronous transfer type, when no response from the peripheral device (timeout is detected without detecting a handshake packet from the peripheral device) or an error in a packet from the peripheral device occurred three times in a row in an arbitrary combination

   At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to NAK.

   — When this module receives a STALL handshake from the peripheral device in communication other than the SETUP transaction (including STALL to PING as well as STALL to OUT)

   At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to STALL (11).

2. Pipes in the receive direction
   — When the IN token transmit timing comes with the FIFO buffer occupied in an isochronous transfer-type pipe

     At this time, this module ignores the receive data in response to the IN Token and indicates PIPENRDY = 1 for the pipe and OVRN = 1.

     Furthermore, when a packet error is detected in the receive data in response to the IN Token, this module also indicates CRCE = 1.

     In communication for a pipe of other than isochronous transfer type, when no response from the peripheral device to the IN token sent from this module (timeout is detected without detecting a data packet from the peripheral device) or an error in a packet from the peripheral device occurred three times in a row in an arbitrary combination

     At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to NAK.

     In communication for an isochronous transfer-type pipe, when this module receives no response from the peripheral device to the IN token sent from this module (timeout is detected without detecting a data packet from the peripheral device) or an error in a packet from the peripheral device is detected

     At this time, this module indicates PIPENRDY = 1 for the pipe but does not change the PID bits for the pipe.
   — In communication for an isochronous transfer-type pipe, when a CRC error or a bit stuffing error is detected in the received data packet

     At this time, this module indicates PIPENRDY = 1 for the pipe and CRCE = 1.
   — When this module receives a STALL handshake

     At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to STALL.

(b) When the host controller function is selected and split transactions occur

1. Pipes in the transmit direction
   — When the OUT token transmit timing comes with no transmit data in the FIFO buffer in an isochronous transfer-type pipe

     At this time, this module indicates PIPENRDY = 1 for the pipe and OVRN = 1 when it sends the Start-Split transaction (S-SPLIT). This module also sends a Zero-Length packet following the OUT token.
   — In the S-SPLIT or Complete-Sprit transaction (C-SPLIT) for a pipe of other than isochronous transfer type, when no response from the HUB (timeout is detected without detecting a handshake packet from the HUB) or an error in a packet from the HUB occurred three times in a row in an arbitrary combination

At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to NAK.

When this module detects an NRDY interrupt when sending C-SPLIT, this module clears the CSSTS bit to 0.

— When this module receives a STALL handshake in response to C-SPLIT

At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to STALL (11). This module also clears the CSSTS bit to 0.

However, this interrupt is not detected in the SETUP transaction.

— When this module receives NYET in response to C-SPLIT with microFrame = 4 in an interrupt transfer-type pipe

— At this time, this module indicates PIPENRDY = 1 for the pipe and clears the CSSTS bit to 0 but does not change the PID bits for the pipe.

2. Pipes in the receive direction

— When the IN token transmit timing comes with the FIFO buffer occupied in an isochronous transfer-type pipe

At this time, this module indicates PIPENRDY = 1 for the pipe and OVRN = 1 when it sends S-SPLIT. This module also ignores the receive data in response to the IN token.

— In a transfer for a bulk transfer-type pipe or in a transfer other than the SETUP transaction of the DCP, when no response from the HUB in response to the IN token from this module when sending S-SPLIT or C-SPLIT (timeout is detected without detecting a handshake packet from the HUB) or an error in a packet from the HUB occurred three times in a row in an arbitrary combination

At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to NAK. When this condition is generated in the C-SPLIT transaction, this module clears the CSSTS bit to 0.

— In the C-SPLIT transaction for a pipe of isochronous or interrupt type, when no response from the HUB in response to the IN token from this module (timeout is detected without detecting a data packet from the HUB) or an error in a packet from the HUB occurred three times in a row in an arbitrary combination

When this condition is generated in an interrupt transfer-type pipe, this module indicates PIPENRDY = 1 for the pipe, changes the PID bits for the pipe to NAK, and clears the CSSTS bit to 0.

When this condition is generated in an isochronous transfer-type pipe, this module indicates PIPENRDY = 1 for the pipe and CRCE = 1 and clears the CSSTS to 0, bit to 0 but does not change the PID bits for the pipe.

— When this module receives a STALL handshake response during the C-SPLIT transaction in a pipe of other than isochronous transfer type

At this time, this module indicates PIPENRDY = 1 for the pipe, changes the PID bits for the pipe to STALL (11), and clears the CSSTS bit to 0.

— When this module receives a NYET in response to C-SPLIT with microFrame = 4 in a pipe of isochronous or interrupt transfer type

At this time, this module indicates PIPENRDY = 1 for the pipe and CRCE = 1 and clears the CSSTS bit to 0, but does not change the PID bits for the pipe.

(c) When the function controller function is selected

1. Pipes in the transmit direction

— When this module receives an IN token with no transmit data in the FIFO buffer

This module generates an NRDY interrupt request and indicates PIPENRDY = 1.

When the pipe in which the interrupt is generated is isochronous transfer type, this module sends a Zero-Length packet and indicates OVRN = 1.

2. Pipes in the receive direction pipe

— When this module receives an OUT token with the FIFO buffer occupied

When the pipe in which the interrupt is generated is isochronous transfer type, this module generates an NRDY interrupt request when this module receives an OUT token, and indicates PIPENRDY = 1 and OVRN = 1.

When the pipe in which the interrupt is generated is not isochroous transfer type, this module generates an NRDY interrupt request when this module sends an NAK handshake response after receiving data following the OUT token, and indicates PIPENRDY = 1.

However, this module generates no NRDY interrupt when resending data (in the case of DATA-PID mismatch) or when an error occurs in a data packet.

— When this module receives a PING token with the FIFO buffer occupied

This module generates an NRDY interrupt request when this module receives a PING token and indicates PIPENRDY = 1.

— When a packet is not received correctly within the interval frame in an isochroous transfer-type pipe

This module generates an NRDY interrupt request when this module receives SOF and indicates PIPENRDY = 1.

Figure 32.4 shows the NRDY interrupt generation timing when the function controller function is selected.

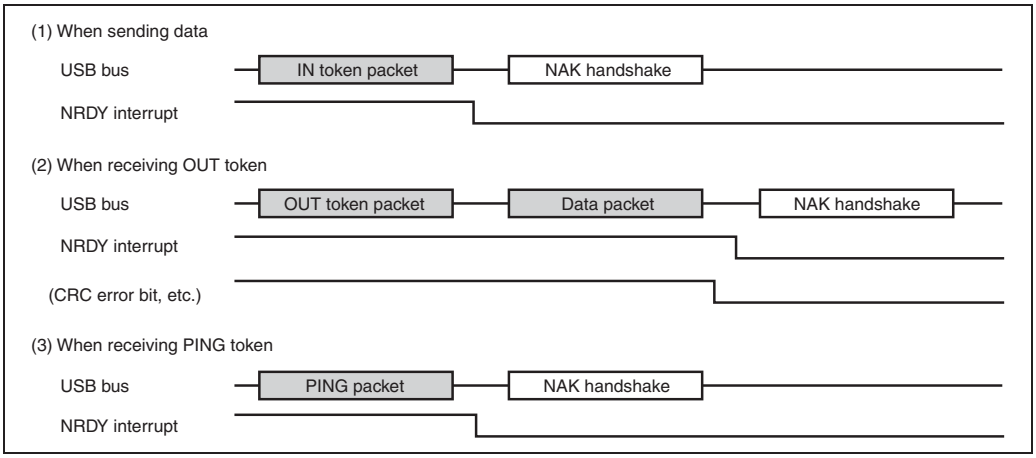

Figure 32.4 NRDY Interrupt Generation Timing when the Function Controller Function is Selected

(3) BEMP Interrupt

When this module detects a BEMP interrupt for the pipe in which PID = BUF is set by the software, this module indicates PIPEBEMP = 1 for the pipe in BEMPSTS. At this time, when 1 is set in the corresponding bit in BEMPENB by the software, this module indicates BEMP = 1 in INTSTS0 and generates a USB interrupt.

This module generates an internal BEMP interrupt request in the following cases.

1. Transmit direction pipes

   When the FIFO buffer for the pipe is empty at the end of transmission (including transmission of a Zero-Length packet)

   When single buffer is set for the FIFO buffer, this module generates an internal BEMP interrupt request concurrently with a BRDY interrupt for pipes other than DCP.
   However, this module generates no internal BEMP interrupt request in the following cases.

   — In the case of double buffer, when the software (DMAC) already started writing data to the FIFO buffer of the CPU at the end of transmission for one-side data
   — When the buffer is cleared (empty) by writing 1 to the ACLRM or BCLR bit.
   — When sending a Zero-Length packet (IN transfer) of the control transfer status stage when the function controller function is selected

2. Receive direction pipes

   When this module receives a packet with a data size exceeding the MaxPacketSize value

   In this case, this module generates a BEMP interrupt request and indicates the PIPEBEMP = 1 for the pipe, ignores the received data, and changes the PID bits for the pipe to STALL (11).

   At this time, this module sends no response when the host controller function is selected, and sends a STALL response when the function controller function is selected.

   However, this module generates no BEMP interrupt request in the following cases.

   — When this module detects a CRC error or bit stuffing error in the receive data

   — When executing the SETUP transaction

   Writing 0 to the PIPEBEMP bits clears the status.

   Writing 0 to the PIPEBEMP bits has no effect on the operation of this module.

Figure 32.5 shows the BEMP interrupt generation timing when the function controller function is selected.

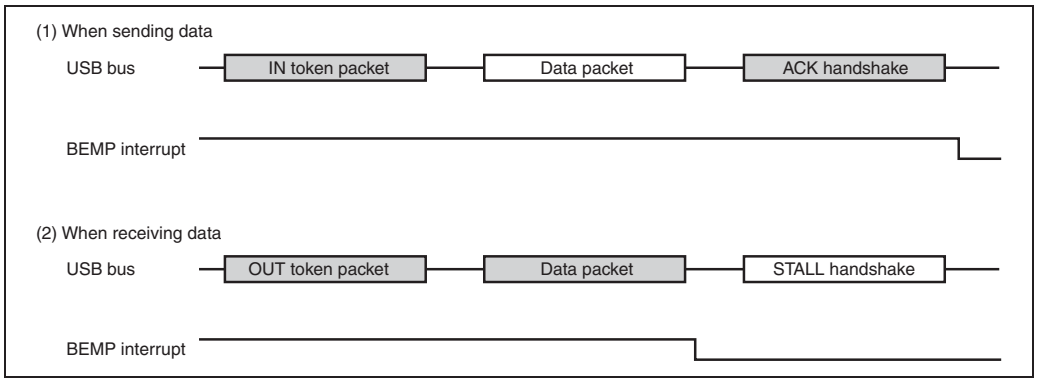

Figure 32.5 BEMP Interrupt Generation Timing when the Function Controller Function is Selected

(4) Device State Transition Interrupt

Figure 32.6 shows the device state transitions of this module. This module controls device states and generates device state transition interrupts. However, when returning from the suspended state (detecting the resume signal), this module detects the transition with a resume interrupt. The device state transition interrupt is enabled or disabled by setting INTENB0. The current device state can be monitored using the DVSQ bits in INTSTS0.

When this module shifts to the default state, a device state transition interrupt occurs after executing the reset handshake protocol.

This module controls the device states only when the function controller function is selected. In addition, device state transition interrupts are generated only when the function controller function is selected.

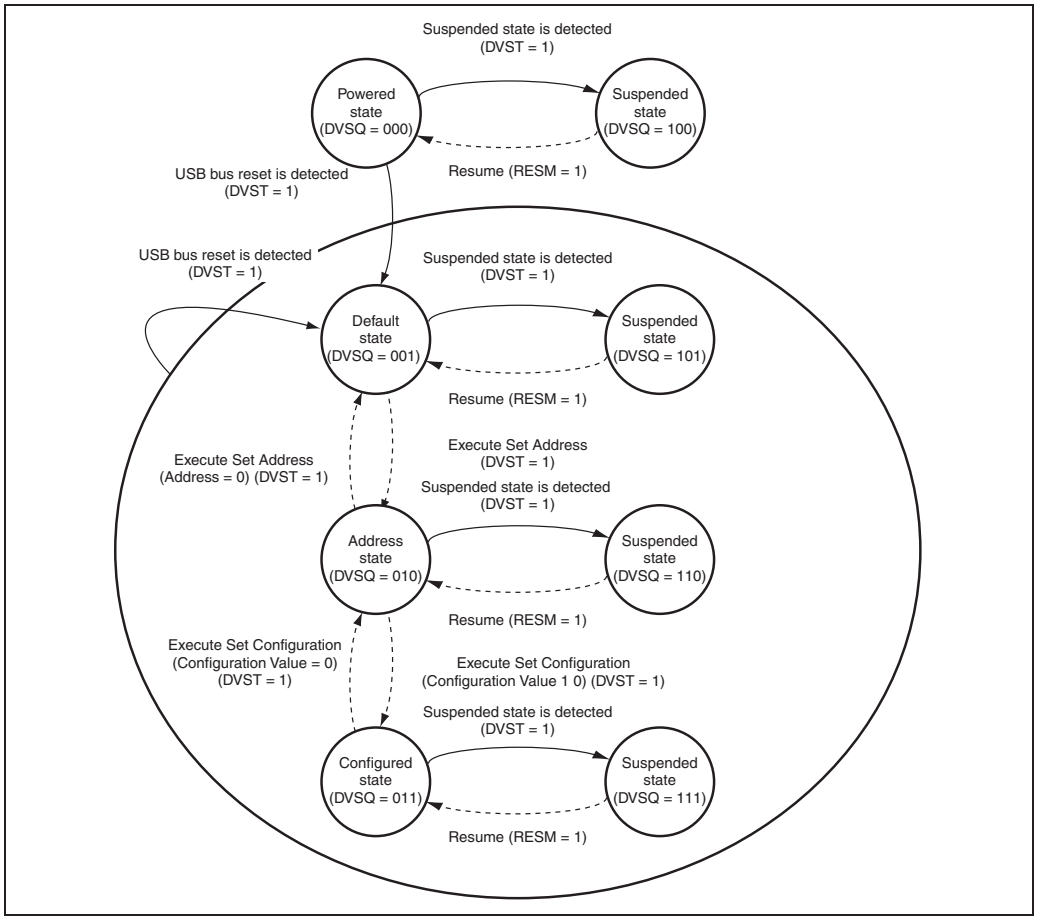

Figure 32.6 Device State Transitions

(5) Control Transfer Stage Transition Interrupt

Figure 32.7 shows control transfer stage transitions of this module. This module manages the sequence of control transfers and generates control transfer stage transition interrupts. Enabling or disabling each control transfer stage transition interrupt can be set by INTENB0. The current transfer stage after transition can be checked by the CTSQ bits in INTSTS0.

Control transfer stage transition interrupts are generated only when the function controller function is selected.

The following describes control transfer sequence errors. When an error occurs, the PID bits in DCPCTR indicate B'1x (STALL response).

1. Control read transfer
   - This module receives an OUT or PING token in response to the IN token in the data stage before starting data transfer.
   - This module receives an IN token in the status stage.
   - This module receives a packet with a data packet of DATAPID = DATA0 in the status stage.
2. Control write transfer
   - This module receives an IN token in response to the OUT token in the data stage before sending an ACK response.
   - This module receives a packet with the first data packet of DATAPID = DATA0.
   - This module receives an OUT or PING token in the status stage.
3. Control write no-data control transfer
   - This module receives an OUT or PING token in the status stage.

If the size of the receive data exceeds the wLength value of the USB request in the control write transfer data stage, this is not treated as a control transfer sequence error. This module sends ACK for normal end in response to a packet other than Zero-Length packet in the control read transfer status stage.

When a CTRT interrupt is generated (SERR = 1) due to a sequence error, CTSQ = 110 is retained until the interrupt status is cleared (CTRT = 0) by the system. For this reason, while CTSQ = 110, even if a new USB request is received, a CTRT interrupt at the end of the setup stage is not generated. (This module retains the setup stage end status and generates a setup stage end interrupt after the interrupt status is cleared by the software.)

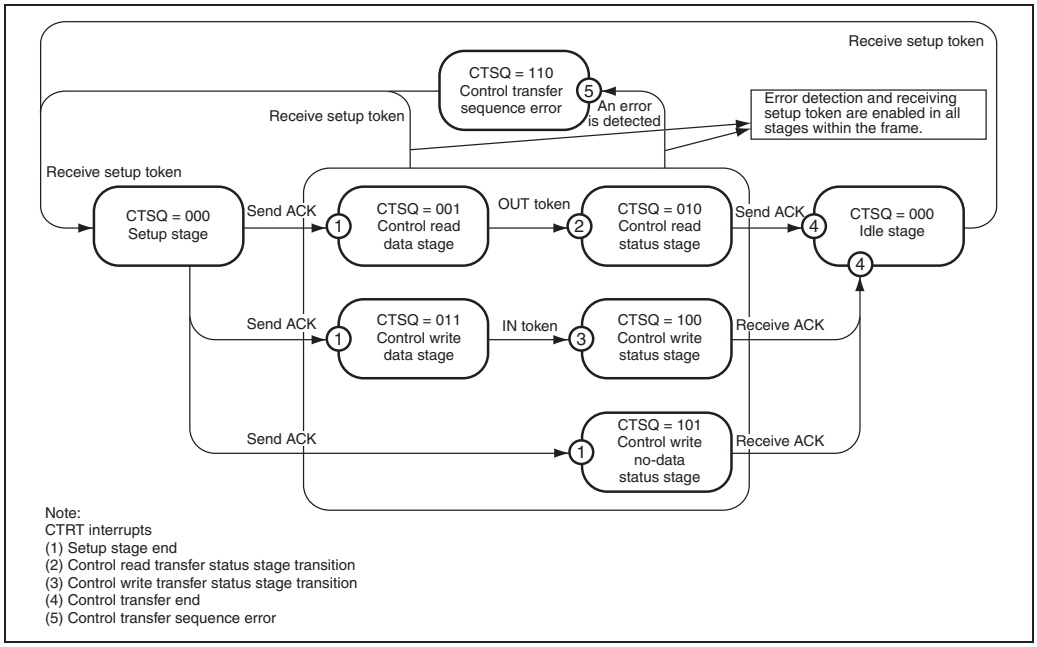

Figure 32.7 Control Transfer Stage Transitions

(6) Frame Update Interrupt

Figure 32.8 shows an example of the SOFR interrupt output timing of this module.

When the host controller function is selected, an SOFR interrupt is generated at the frame number update timing. When the function controller function is selected, an SOFR interrupt is generated immediately after the frame number is updated.

When this module detects a new SOF packet during the full-speed operation with the function controller function selected, this module updates the frame number and generates an SOFR interrupt. In the high-speed operation, however, the frame number is not updated or no SOFR interrupt is generated unless the module enters the μ SOF lock state. Furthermore, the SOF interpolation function is not activated. The μ SOF lock state occurs when this module receives a μ SOF packet twice in a row with different frame numbers without an error.

The μ SOF lock monitoring start and stop conditions are as follows:

1. µ SOF lock monitoring start conditions
   USBE = 1
2. µ SOF lock monitoring stop conditions
   USBE = 0, receiving USB bus reset, or detection of suspended state

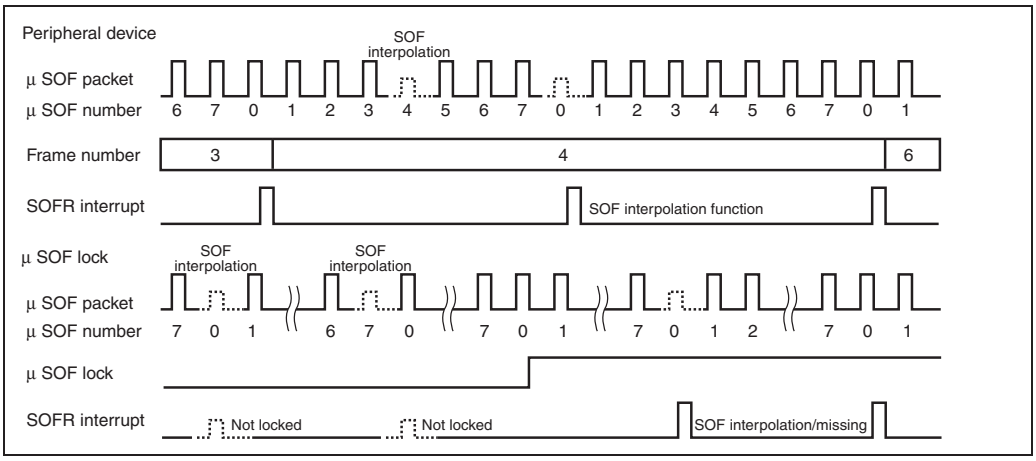

Figure 32.8 Example of SOFR Interrupt Output Timing

(7) VBUS Interrupt

When the VBUS pin state changes, a VBUS interrupt is generated. The VBUS pin level can be checked by the VBSTS bit in INTSTS0. The VBUS interrupt is used to check connection or disconnection to/from the host controller. However, when the system starts up with the host controller connected, the VBUS pin state remains unchanged, and therefore the first VBUS interrupt is not generated.

(8) Resume Interrupt

When the function controller function is selected and the USB bus state changes (J-State to K-State or J-State to SE0) with the device state suspended, a resume interrupt is generated. The resume interrupt is used to detect the return from the suspended state.

When the host controller function is selected, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

(9) BCHG Interrupt

When the USB bus state changes, a BCHG interrupt is generated. This interrupt is used to detect connection to a peripheral device and to detect remote wakeup when the host controller function is selected. This interrupt occurs when either of the host controller function or function controller function is selected.

(10) DTCH Interrupt

When a disconnection of the USB bus is detected with the host controller function selected, a DTCH interrupt is generated. This module detects a bus disconnection conforming to the USB Specification 2.0.

After detecting a DTCH interrupt, this module performs the following hardware control irrespective of the setting of the corresponding interrupt enable bit. The software must terminate the communication of all pipes with the port and drive this module into the state of waiting for connection to the port (ATTCH interrupt is generated).

- Change the UACT bit of the port that detected the DTCH interrupt to 0 and indicate UACT.
- Drive the port where the DTCH interrupt occurred into the idle state.

(11) SACK Interrupt

When this module receives ACK from the peripheral device in response to the transmitted setup packet with the host controller function selected, a SACK interrupt is generated. This interrupt indicates that a setup transaction is successfully completed.

(12) SIGN Interrupt

When this module cannot receive ACK successfully from the peripheral device in response to the transmitted setup packet three times in a row with the host controller function selected, a SIGN interrupt is generated. This interrupt is used to detect no ACK response from the peripheral device or ACK packet damage.

(13) ATTCH Interrupt

When J-State or K-State of the full-speed/low-speed signal level is detected for 2.5 μs in the USB port with the host controller function selected, an ATTCH interrupt is generated. This interrupt is detected in either of the following cases.

- When the signal level changed from K-State, SE0 or SE1 to J-State, and remains in J-State for 2.5 μs
- When the signal level changed from J-State, SE0 or SE1 to K-State, and remains in K-State for 2.5 μs

(14) EOFERR Interrupt

When this module detects that communication is not completed at the EOF2 timing specified in the USB Specification 2.0, an EOFERR interrupt is generated.

After detecting an EOFERR interrupt, this module performs the following hardware control irrespective of the setting of the corresponding interrupt enable bit. The software must terminate the communication of all pipes with the port and perform reenumeration for the port.

- Change the UACT bit of the port that detected the EOFERR interrupt to 0 and indicate UACT.
- Drive the port where the EOFERR interrupt occurred into the idle state.

32.4.3 Pipe Control

Table 32.16 lists the pipe settings of this module. In the USB data transfer, data must be transmitted or received using virtual pipes called “endpoint.” This module is provided with ten pipes for data transfer. Set each pipe according to system specifications.

Table 32.16 Pipe Settings

Register Name	Bit Name	Setting	Remarks
DCPCFG	TYPE	Transfer type	Pipes 1 to 9: Setting allowed
PIPECFG	BFRE	BRDY interrupt mode	Pipes 1 to 5: Setting allowed
	DBLB	Double buffer	Pipes 1 to 5: Setting allowed
	CNTMD	Continuous transfer or discontinuous transfer	Pipes 1, 2: Setting allowed only when bulk transfer is selected Pipes 3 to 5: Setting allowed
	DIR	Transfer direction	IN or OUT selectable
	EPNUM	Endpoint number	Pipes 1 to 9: Setting allowed Set a value other than 0000 when using pipes
	SHTNAK	Disabling pipes at the end of transfer	Pipes 1, 2: Setting allowed only when bulk transfer is selected Pipes 3 to 5: Setting allowed
PIPEBUF	BUFSIZE	Buffer memory size	DCP: Setting disallowed (256 bytes fixed) Pipes 1 to 5: Setting allowed (up to 2 Kbytes) Pipes 6 to 9: Setting disallowed (64 bytes fixed)
	BUFNMB	Buffer memory number	DCP: Setting disallowed (H'0 to H'3 fixed) Pipes 1 to 5: Setting allowed (H'8 to H'7F) Pipes 6 to 9: Setting disallowed (H'4 to H'7 fixed)
DCPMAXP PIPEMAXP	DEVSEL	Device select	Checked only when the host controller functions selected.
	MXPS	Maximum packet size	Setting conforming to the USB Specification

Register Name	Bit Name	Setting	Remarks
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to 5: Setting disallowed Pipes 6 to 9: Setting allowed only when the host control function is selected
	IITV	Interval counter	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to 5: Setting disallowed Pipes 6 to 9: Setting allowed only when the host control function is selected
DCPCTR PIPEnCTR	BSTS	Buffer status	For DCP, receive buffer status and transmit buffer status are switched by the ISEL bit.
	INBUFM	IN buffer monitor	Provided only for pipes 3 to 5.
	SUREQ	SETUP request	Setting allowed for DCP only Controlled only when the host controller function is selected.
	SUREQCLR	SUREQ clear	Setting allowed for DCP only Controlled only when the host controller function is selected.
	CSCLR	CSSTS clear	Controlled only when the host controller function is selected.
	CSSTS	SPLIT status	Monitored only when the host controller function is selected.
	ATREPM	Auto-response mode	Pipes 1 to 5: Setting allowed only when the function controller function is selected.
	ACLRM	Buffer auto-clear	Pipes 1 to 9: Setting allowed
	SQCLR	Sequence clear	Data toggle bit clear
	SQSET	Sequence setting	Data toggle bit setting
	SQMON	Sequence check	Data toggle bit check
	PBUSY	Pipe busy check	
	PID	Response PID	See section 32.4.3 (6), Response PID.

Register Name	Bit Name	Setting	Remarks
PIPEnTRE	TRENB	Transaction count enable	Pipes 1 to 5: Setting allowed
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Setting allowed
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5: Setting allowed

(1) Pipe Control Registers Switching Procedure

The following bits in the pipe control registers can be modified only when USB communication is set to disabled (PID = NAK).

Bits/registers that cannot be modified when USB communication is set to enabled (PID = BUF)

- Each bit in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPExCTR
- Each bit in PIPExTRE and PIPExTRN

When changing these bits from the state where USB communication is enabled (PID = BUF), follow the steps below.

1. Generate a pipe control register bit change request.
2. Change the PID bits for the pipe to NAK.
3. Wait until the CSSTS bit for the pipe is cleared to 0 (only when the host controller function is selected).
4. Wait until the PBUSY bit for the pipe is cleared to 0.
5. Change the bits in the pipe control registers.

The following bits in the pipe control registers can be modified only for pipe information that is not set in any of the CURPIPE bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Bits/registers that cannot be modified while the CURPIPE bits in FIFO-PORT are being set

- Each bit in DCPCFG and DCPMAXP
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI

Before changing the pipe information, set the CURPIPE bits to a pipe other than that to be changed. For the DCP, clear the buffer by the BCLR bit after modifying the pipe information.

(2) Transfer Type

Specify the transfer type of each pipe by the TYPE bits in PIPEPCFG as follows:

- DCP: Setting is not required (fixed to control transfer).
- Pipes 1, 2: Set bulk transfer or isochronous transfer.
- Pipes 3 to 5: Set bulk transfer.
- Pipes 6 to 9: Set interrupt transfer.

(3) Endpoint Number

Specify the endpoint number of each pipe by the EPNUM bits in PIPEPCFG. The endpoint number of the DCP is always 0. For other pipes, endpoint 1 to endpoint 15 are selectable.

- DCP: Setting is not required (fixed to endpoint 0).
- Pipes 1 to 9: Set an endpoint number by selecting a number 1 to 15.
  However, set an endpoint number so that combinations of the DIR bit and the EPNUM bits do not overlap.

(4) Maximum Packet Size

Specify the maximum packet size of each pipe by the MXPS bits in DCPMAXP and PIPEMAXP. For the DCP and pipes 1 to 5, any of the maximum packet sizes defined in the USB Specification can be set. For pipes 6 to 9, a maximum packet size up to 64 bytes can be set. Specify a maximum packet size as follows before starting transfer (PID = BUF):

- DCP: Set 64 for high-speed operation.
- DCP: Set 8, 16, 32, or 64 for full-speed operation.
- Pipes 1 to 5: Set 512 for high-speed bulk transfer.
- Pipes 1 to 5: Set 8, 16, 32, or 64 for full-speed bulk transfer.
- Pipes 1, 2: Set a value from 1 to 1024 for high-speed isochronous transfer.
- Pipes 1, 2: Set a value from 1 to 1023 for full-speed isochronous transfer.
- Pipes 6 to 9: Set a value from 1 to 64.

High Bandwidth in interrupt and isochronous transfers is not supported.

(5) Transaction Counter (Pipes 1 to 5: Read Direction)

When the specified number of transactions with data packet in the receive direction are completed, this module recognizes this as a transfer end. The transaction counter works when the pipe selected for the D0FIFO and D1FIFO ports is set for the data read (from the buffer memory) direction. The transaction counter is provided with the TRNCNT register to specify the number of transactions and the current counter to count transactions internally. When the current counter reaches the specified value, the buffer memory becomes ready for reading. The current counter of the transaction counter function can be initialized by the TRCLR bit to count transactions again from the beginning. The TRNCNT read data varies depending on the TRENB setting.

- TRENB = 0: The set transaction counter value is read.
- TRENB = 1: The internally counted current counter value is read.
- Change the CURPIPE bits according to the following.
- Do not change the CURPIPE bits until the transaction for the specified pipe finishes.
- Change the CURPIPE bits when the current counter is cleared.
- Control the TRCLR bit according to the following.
- Do not clear the current counter during transaction count and PID = BUF.
- Do not clear the current counter while data is remaining in the buffer.

(6) Response PID

Specify the response PID for each pipe by the PID bits in DCPCTR and PIPEnCTR.

This module operates as follows according to the response PID setting.

1. Setting the response PID when the host controller function is selected
   The response PID specifies the execution of transactions.
   — NAK setting: Pipes are disabled and no transaction is executed.
   — BUF setting: Transactions are executed according to the buffer memory status.
   When the buffer memory contains transmit data in the OUT direction, this module sends an OUT token.
   When the buffer memory has available space and is ready to receive data in the IN direction, this module sends an IN token.
   — STALL setting: Pipes are disabled and no transaction is executed.

Note: The DCP setup transaction is set by the SUREQ bit.

2. Setting the response PID when the function controller function is selected
   The response PID specifies a response to transactions from the host.
   — NAK setting: NAK is always sent in response to a transaction.
   — BUF setting: A response is sent to a transaction according to the buffer memory status.
   — STALL setting: STALL is always sent in response to a transaction.

Note: This module always sends ACK in response to a setup transaction irrespective of the PID setting, and stores a USB request in the register.

This module modifies the PID bits in the following cases depending on transaction results.

3. When the response PID is set by the hardware with the host controller function selected
   — NAK setting: This module sets PID = NAK and automatically stops sending tokens.

- When an NRDY interrupt is generated in a transfer other than isochronous transfer
- (For details, see 32.4.2(2) NRDY Interrupt.)
- When this module receives a short packet with the SHTNAK bit in PIPECFG set to 1 in the bulk transfer
- When the SHTNAK bit is set to 1 in the bulk transfer and the transaction counter stops counting
  — BUF setting: This module does not set the PID bits to BUF.
  — STALL setting: This module sets PID = STALL in the following cases and automatically stops sending tokens.
- When this module receives STALL in response to the transmitted token
- When the size of the received data packet is larger than the maximum packet size

4. When the response PID is set by the hardware with the function controller function selected
   — NAK setting: This module sets PID to NAK in the following cases and always sends NAK in response to a transaction.

- When a SETUP token is successfully received (DCP only)
- When the SHTNAK bit in PIPECFG is set to 1 in a bulk transfer and the transaction counter stops counting or this module receives a short packet
  — BUF setting: This module does not set the PID bits to BUF.
  — STALL setting: This module sets PID to STALL in the following cases and always sends STALL in response to a transaction.
- When a maximum packet size exceeded error is detected in a receive data packet
- When a control transfer sequence error is detected (DCP only)

(7) Data PID Sequence Bit

When data is successfully transferred in the control transfer data stage, bulk transfer, or interrupt transfer, this module automatically toggles the data PID sequence bit. The sequence bit of the data PID transmitted next can be monitored by the SQMON bit in DCPCTR and PIPEnCTR. In a data transmission period, the sequence bit switches at the ACK handshake receive timing. In a data reception period, the sequence bit switches at the ACK handshake transmit timing. The data PID sequence bit can also be changed by the SQCLR and SQSET bits in DCPCTR and PIPEnCTR.

In control transfers when the function controller function is selected, this module automatically sets the sequence bit during a stage transition. DATA0 is indicated at the end of the setup stage, and DATA1 is used for responses in the status stage. This does not require the setting of the sequence bit by the software. In control transfers when the host controller function is selected, the software must set the sequence bit during a stage transition.

Note that, when the host controller function or function controller function is selected, the software must also set the data PID sequence bit when sending or receiving a ClearFeature request.

The sequence bit cannot be modified by the SQSET bit for isochronous transfer pipes.

(8) Response PID = NAK Function

This module has a function to disable the pipe operation (Response PID = NAK) at the last data packet receive timing in a transfer (this module automatically identifies the last data packet receive timing at the short packet receive timing or using the transaction counter) by setting the SHTNAK bit in PIPECFG to 1.

This function allows reception of data packets in transfer units when the buffer memory is used as a double buffer. Furthermore, when the pipe operation is disabled, the software must set the response PID to BUF to enable the pipe operation.

This function is available only for bulk transfers.

(9) Auto-Response Mode

When the ATREPM bit in PIPEnCTR is set to 1 in a bulk transfer pipe (pipes 1 to 5), this module enters auto-response mode: OUT-NAK mode in OUT transfers (DIR = 0) or null auto-response mode in IN transfers (DIR = 1).

1. OUT-NAK mode

   When the ATREPM bit is set to 1 in a bulk OUT transfer pipe, this module sends NAK in response to an OUT token or PING token and outputs an NRDY interrupt. To change response mode from normal mode to OUT-NAK mode, specify OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, OUT-NAK mode is enabled. However, if an OUT token is received immediately before the pipe operation is disabled, this module receives the data of the token correctly and sends ACK to the host.

   To change response mode from OUT-NAK mode to normal mode, reset OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). In normal mode, this module can receive OUT data and sends ACK in response to a PING token when the buffer is ready for receiving.

2. Null auto-response mode

   When the ATREPM bit is set to 1 in a bulk IN transfer pipe, this module continues to send Zero-Length packets. To change response mode from normal mode to null auto-response mode, specify null auto-response mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, null auto-response mode is enabled. However, specify null auto-response mode while the buffer is empty. Verify this by checking INBUFM = 0. Since INBUFM = 1 indicates that the buffer contains data, clear the buffer by setting the ACLRM bit. Do not write data to the buffer from the FIFO port during setting to null auto-response mode.

To change response mode from null auto-response mode to normal mode, delay the pipe operation disabled state (Response PID = NAK) for a time period for sending a Zero-Length packet (full-speed: 10 μs, high-speed: 3 μs), and then reset null auto-response mode. Normal mode allows writing from the FIFO port, and also allows sending packets to the host by enabling the pipe operation (Response PID = BUF).

32.4.4 FIFO Buffer Memory

(1) Allocating FIFO Buffer Memory

Figure 32.9 shows an example of the FIFO buffer memory map of this module. The FIFO buffer memory is an area shared by the CPU and this module. There are two FIFO buffer memory states where the access right is given to the system (CPU) or to this module (SIE).

The FIFO buffer memory provides independent areas for each pipe. A memory area is set with the block start number and the number of blocks (BUFNMB and BUFSIZE bits in PIPEBUF) in 64-byte units as one block.

When continuous transfer mode is selected by the CNTMD bit in PIPEnCFG, be sure to set the BUFSIZE bits to a value in integral multiples of the maximum packet size. When double buffer is selected by the DBLB bit in PIPEnCFG, two sides of the memory area specified by the BUFSIZE bits in PIPEBUF are provided for the same pipe.

Furthermore, three FIFO ports are used for accesses (data read/write) to the buffer memory. The number of a pipe to be allocated to the FIFO ports is specified by the CURPIPE bits in CFIFOSEL and DnFIFOSEL.

The buffer status of each pipe can be monitored by the BSTS and INBUFM bits in DCPCTR and PIPEnCTR. The access right to the FIFO ports can be checked by the FRDY bit in CFIFOCTR and DnFIFOCTR.

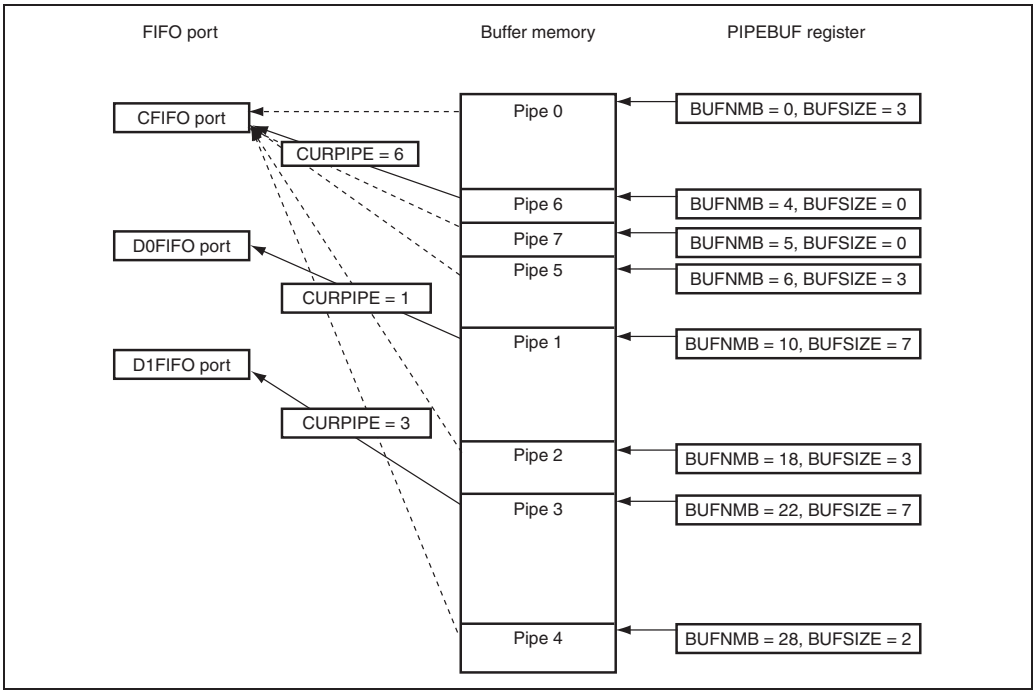

Figure 32.9 Example of Buffer Memory Map

- Buffer status

  Tables 32.17 and 32.18 show the buffer memory status of this module. The buffer memory status can be monitored by the BSTS bit in DCPCTR and the INBUFM bit in PIPEnCTR. The buffer memory access direction is specified by the DIR bit in PIPEnCFG or the ISEL bit in CFIFOSEL (when DCP is selected).

  The INBUFM bit is valid only for pipes 1 to 5 in the transmit direction.

  When a transfer pipe in the transmit direction is set to double buffer, the BSTS bit is used to monitor the buffer status on the CPU side, and the INBUFM bit is used to monitor the buffer status on the SIE side. When data write to the FIFO port by the CPU (DMAC) takes time and buffer empty cannot be checked by the BEMP interrupt, the INBUFM bit is available to check completion of transmission.

Table 32.17 Buffer Memory Status That Varies Depending on the BSTS Bit

ISEL or DIR	BSTS	Buffer Memory Status
0 (receive direction)	0	No receive data in the buffer memory or data is being received. Data cannot be read from the FIFO port.
0 (receive direction)	1	Receive data in the buffer memory or a Zero-Length packet is received. Data can be read from the FIFO port. However, the buffer must be cleared because the FIFO port cannot be read when this module receives a Zero-Length packet.
1 (transmit direction)	0	Transmission of data is not completed. Data cannot be written to the FIFO port.
1 (transmit direction)	1	Transmission of data is completed. The CPU can write data to the buffer memory.

Table 32.18 Buffer Memory Status That Varies Depending on the INBUFM Bit

DIR	INBUFM	Buffer Memory Status
0 (receive direction)	Invalid	Invalid
1 (transmit direction)	0	Transmittable data is completely sent. No transmittable data is in the buffer memory.
1 (transmit direction)	1	Transmittable data is written from the FIFO port. The buffer memory contains transmittable data.

- FIFO buffer clear

  Table 32.19 shows clearing of the FIFO buffer memory of this module. The buffer memory can be cleared by the BCLR, DCLRM, and ACLRM bits.

Table 32.19 Buffer Clear

Bit Name	BCLR	DCLRM	ACLRM
Register	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Function	Clears the buffer memory of the CPU.	Automatically clears the buffer memory after reading data of the specified pipe.	Automatically clears the buffer memory by ignoring all received packets.
Clearing method	Writing 1 to this bit clears the buffer memory.	1: This mode is enabled. 0: This mode is disabled.	1: This mode is enabled. 0: This mode is disabled.

- Buffer area

  Table 32.20 shows a buffer memory map of this module. The buffer memory includes a dedicated areas reserved beforehand for pipes and user areas provided for user settings.

  The buffer for DCP is a dedicated area commonly used in control read transfers and control write transfers.

  Areas for pipes 6 to 9 are allocated respectively in advance. However, when none of pipes 6 to 9 is used, the areas are available for pipes 1 to 5 as user areas.

  Allocate different areas of the buffer memory to each pipe. Note that, when double buffer is specified, the size of an area is twice of the set value.

  Do not set the buffer size to a value smaller than the maximum packet size.

Table 32.20 Buffer Memory Map

Buffer Memory Number	Buffer Size	Pipe Setting	Remarks
H'0	64 bytes	Fixed only for DCP	Single buffer
H'1 to H'3	—	Unavailable	—
H'4	64 bytes	Fixed only for pipe 6	Single buffer
H'5	64 bytes	Fixed only for pipe 7	Single buffer
H'6	64 bytes	Fixed only for pipe 8	Single buffer
H'7	64 bytes	Fixed only for pipe 9	Single buffer
H'8 to H'7F	Max. 7616 bytes	User area for pipes 1 to 5	Double buffer and continuous transfer can be set

- Buffer auto-clear mode function

  When the ACLRM bit PIPEnCTR is set to 1, this module discards all data packets received. However, when this module receives a data packet successfully, it sends ACK to the host controller. This function is available only for the buffer memory read direction.

  Writing 1 and then 0 continuously to the ACLRM bit clears the buffer memory of the selected pipe irrespective of the access direction.

  Take at least 100 ns between writing 1 and writing 0 for the sequence execution time of the hardware.

- Buffer memory specifications (single buffer/double buffer setting)

  Single buffer or double buffer is selectable for pipes 1 to 5 with the DBLB bit in PIPEnCFG. Double buffer is a function to provide two sides of the memory area specified by the BUFSIZE bits in PIPEBUF for the same pipe. Figure 32.10 shows an example of setting for the buffer memory of this module.

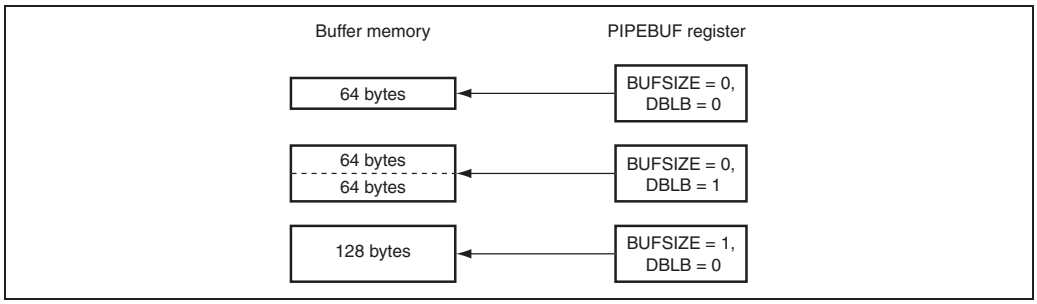

Figure 32.10 Example of Buffer Memory Setting

- Buffer memory operation (continuous transfer setting)

  Continuous transfer mode or discontinuous transfer mode is selectable with the CNTMD bit in PIPEnCFG. This selection is enabled for pipes 1 to 5.

  The continuous transfer mode function allows continuous transmission/reception of multiple transactions. When continuous transfer mode is selected, data up to the buffer size allocated to each pipe can be transferred without outputting an interrupt to the CPU.

  In continuous transmission mode, data in the buffer is divided by the maximum packet size and is then transmitted. To send data less than the buffer size (a short packet or a packet with a size of integral multiples of the maximum packet size and less than the buffer size), set BVAL = 1 after writing transmit data to the buffer.

  In continuous reception mode, no interrupt is generated until this module receives packets to the buffer size, the transaction count ends, or this module receives a short packet.

Table 32.21 shows the relationship between the CNTMD setting and determination of transmission/reception end of the FIFO buffer.

Table 32.21 Relationship between CNTMD Setting and Determination of Transmission/Reception End of FIFO Buffer

Transfer Mode	Determination of Buffer Readable State and Data Transmittable State
Discontinuous transfer (CNTMD = 0)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0):
	When this module receives one packet
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1):
	Any of the following cases:
	The software (or DMAC) writes data of the maximum packet size to the FIFO buffer.
	The software (or DMAC) writes data of a short packet (including 0 bytes) to the FIFO buffer, and then sets BVAL = 1.
Continuous transfer (CNTMD = 1)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0):
	When the bytes of data received in the FIFO buffer for the selected pipe equals the allocated bytes ((BUFSIZE + 1) * 64)
	When this module receives a short packet other than a Zero-Length packet
	When this module receives a Zero-Length packet when data is already stored in the FIFO buffer for the selected pipe
	When this module receives packets as large as the transaction counter value specified for the selected pipe by the software
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1):
	Any of the following cases:
	The volume of data written by the software (or DMAC) equals the size of one side of the FIFO buffer for the selected pipe.
	The software (or DMAC) writes data less than the size of one side of the FIFO buffer for the selected pipe to the FIFO buffer, and then sets BVAL = 1.

Figure 32.11 shows an example of buffer memory operation of this module.

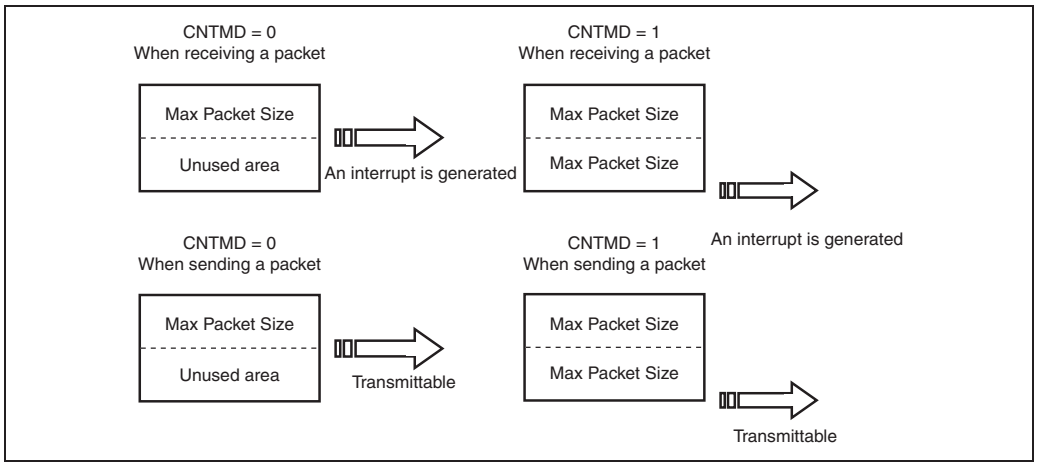

Figure 32.11 Example of Buffer Memory Operation

(2) FIFO Port Function

Table 32.22 lists the settings for the FIFO port functions of this module. During a data write access, when data up to buffer full (or up to the maximum packet size in discontinuous transfer) is written, the FIFO port automatically enters the data transmittable state. To make data less than buffer full (or the maximum packet size in discontinuous transfer) transmittable, set the BVAL bit in CFIFOCTR and DnFIFOCTR to 1 to set write end. For transmission of a Zero-Length packet, clear the buffer using the BCLR bit in these registers and then set the BVAL bit to 1.

During a data read access, when all data is read, the FIFO port automatically enters the new packet receivable state. However, when receiving a Zero-Length packet (DTLN = 0), no data can be read. Therefore, clear the buffer using the BCLR bit in these registers. The receive data length can be checked by the DTLN bits in CFIFOCTR and DnFIFOCTR.

Table 32.22 FIFO Port Function Settings

Register Name	Bit Name	Function	Remarks
CFIFOSEL	RCNT	Selects DTLN read mode.	
DnFIFOSEL	REW	Rewinds the buffer memory (reread/rewrite).	
	DCLRM	Reads and clears receive data of the specified pipe.	DnFIFO only
	DREQE	Enables DMA transfer.	DnFIFO only
	MBW	Specify FIFO port access bit width.	
	BIGEND	Selects FIFO port endian.	
	ISEL	Selects FIFO port access direction.	DCP only
	CURPIPE	Select the current pipe.	
CFIFOCTR	BVAL	Specifies buffer memory write end.	
DnFIFOCTR	BCLR	Clears the buffer memory of the CPU.	
	DTLN	Check receive data length.	

(a) FIFO Port Selection

Table 32.23 shows pipes that can be selected in each FIFO port. Select a pipe to be accessed by the CURPIPE bits in CFIFOSEL and DnFIFOSEL. After selecting a pipe, confirm that the set CURPIPE value is read correctly, check FRDY = 1, and then make an access to the FIFO port. (If the previous pipe number is read, this controller is changing a pipe.)

Also select the bus width to be accessed by the MBW bits. The buffer memory access direction is specified by the DIR bit in PIPEnCFG. However, only the access direction of DCP is determined by the ISEL bit.

Table 32.23 FIFO Port Access

Pipe	Access	Available port
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	CFIFO port register
	DMA access	D0FIFO port, D1FIFO port

(b) REW Bit

The current access to a pipe can be suspended temporarily, and it is also possible to make an access to another pipe to continue the ongoing pipe processing. This processing is allowed by using the REW bit in CFIFOSEL and DnFIFOSEL.

When the REW bit is set to 1 together with the CURPIPE bits in CFIFOSEL and DnFIFOSEL and a pipe is selected, the reading or writing pointer of the buffer memory is reset, which allows reading or writing data from the first byte. Furthermore, when a pipe is selected with the REW bit set to 0, data can be read or written following the data at the previous selection without resetting the reading or writing pointer of the buffer memory.

To make accesses to the FIFO port, select a pipe and check FRDY = 1.

(3) DMA Transfer (Dedicated DMA Interface)

(a) Overview of DMA Transfer

The FIFO port can be accessed by the DMAC for pipes 1 to 9. When the buffer of a pipe specified for DMA transfer becomes accessible, this module outputs a DMA transfer request.

Specify the data transfer unit to the FIFO port by the MBW bits in DnFIFOSEL, and select a pipe used for DMA transfer by the CURPIPE bits in DnFIFOSEL. Do not change the selected pipe during a DMA transfer.

(b) DMA Transfer End Auto-Recognition

This module can terminate writing of data by DMA transfer to the FIFO buffer by controlling the DMA transfer end signal input. After sampling the transfer end signal, this module drives the buffer memory into the transmittable state (same state as BVAL = 1).

(c) DnFIFO Auto-Clear Mode (D0FIFO/D1FIFO Port Read Direction)

By setting the DCLRM bit in DnFIFOSEL to 1, this module automatically clears the buffer memory for the selected pipe upon completion of data read from the buffer memory.

Table 32.24 shows the relationship between packet reception and buffer memory clear by the software. As shown in the table, buffer clearing conditions vary with the BFRE setting. However, in any state that needs clearing, using the DCLRM bit makes buffer clearing by the software unnecessary. Thus DMA transfer is enabled without requiring any software control.

- This function is available only for the buffer memory read direction.

Table 32.24 Relationship between Packet Reception and Buffer Memory Clear by the Software

Register Setting / Buffer Status When Receiving a Packet	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	Clearing not required	Clearing not required	Clearing not required	Clearing not required
Zero-Length packet reception	Clearing required	Clearing required	Clearing not required	Clearing not required
Normal short packet reception	Clearing not required	Clearing required	Clearing not required	Clearing not required
Transaction count end	Clearing not required	Clearing required	Clearing not required	Clearing not required

32.4.5 Control Transfer (DCP)

The default control pipe (DCP) is used for data transfer in the control transfer data stage. The buffer memory for the DCP is a 256-byte single buffer of a fixed area used for both control read and control write. The buffer memory can be accessed only by the CFIFO ports.

(1) Control Transfer when the Host Controller Function is Selected

(a) Setup Stage

USBREQ, USBVAL, USBINDX, and USBLENG are registers used to send USB requests in setup transactions. The specified data is sent as a setup transaction by writing the setup packet data in the register and writing 1 to the SUREQ bit in DCPCTR. The SUREQ bit is cleared to 0 when a transaction ends. Do not access the USB request registers while SUREQ = 1. The device address for a setup transaction is specified by the DEVSEL bits in DCPMAXP.

An interrupt is generated upon receiving a response from the peripheral device in response to the transmitted transaction (SIGN and SACK bits in INTSTS1). The setup transaction result can be checked at the timing of this interrupt request.

For data packets in setup transactions, a DATA0 data packet (USB request) is always sent irrespective of the SQMON setting in DCPCTR.

(b) Data Stage

This module transfers data using the DCP buffer memory in the data stage.

Specify the direction of accesses to the DCP buffer memory by the ISEL bit in CFIFOSEL. Also specify the transfer direction by the DIR bit in DCPCFG.

Transmit the first data packet in the data stage with data PID as DATA1. Set data PID = DATA1 by the SQSET bit in DCPCFG, and set PID = BUF to execute transactions. The completion of data transfer is detected by a BRDY interrupt and a BEMP interrupt.

In a control write transfer, when the transmit data is integral multiples of the maximum packet size, send a Zero-Length packet at the last by the software.

(c) Status Stage

In the status stage, data transfer of Zero-Length packets is performed in the reverse direction of the data stage. The same DCP buffer memory as in the data stage is used for data transfer. Transactions are executed using the same procedure as the data stage.

Send data packets in the data stage with data PID as DATA1. Set data PID = DATA1 by the SQSET bit in DCPCFG.

Furthermore, check the receive data length of a Zero-Length packet by the DTLN bits in CFIFOCTR after a BRDY interrupt is generated, and then clear the buffer memory by the BCLR bit.

(2) Control Transfer when the Function Controller Function is Selected

(a) Setup Stage

1. This module always sends ACK in response to a normal setup packet to this module. The following describes the operation of this module in the setup stage.
   When this module receives a new setup packet, this module sets the following bits.
   — The VALID bit in INTSTS0 to 1
   — The PID bits in DCPCTR to NAK
   — The CCPL bit in DCPCTR to 0
2. When this module receives a data packet following a setup packet, this module stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Be sure to process responses to control transfers while VALID = 0. The PID bits cannot be set to BUF when VALID = 1, and therefore the data stage cannot be completed.

With the VALID bit function, this module can suspend the ongoing request processing if this module receives a new USB request during a control transfer, and send a response to the latest request.

This module also determines the direction bit (bit 8 of bmRequestType) of the received USB request and the request data length (wLength), identifies a control read transfer, control write transfer, and control write no-data transfer, and controls stage transitions. For an incorrect sequence, a sequence error of the control transfer stage transition interrupt occurs, and the error is reported to the software. For the stage control of this module, see Figure 32.7.

(b) Data Stage

Transfer data in response to the received USB request using the DCP. Before making an access to the DCP buffer memory, specify the access direction by the ISEL bit in CFIFOSEL.

When the transfer data size is larger than the DCP buffer memory size, use a BRDY interrupt for control write transfers and a BEMP interrupt for control read transfers.

In the high-speed control write transfer, this module sends responses using the NYET handshake according to the buffer memory status.

(c) Status Stage

Setting the CCPL bit to 1 with the PID bits in DCPCTR set to BUF finishes a control transfer.

After these settings, this module executes the status stage as follows according to the data transfer direction determined in the setup stage:

- Control read transfer
  This module sends a Zero-Length packet and receives an ACK response from the USB host.
- Control write transfer, no-data control transfer
  This module receives a Zero-Length packet from the USB host and sends an ACK response.

(d) Control Transfer Auto-Response Function

This module automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, the software must respond to the error.

- Other than control read transfer: bmRequestType ≠ H'00
- Request errors: wIndex ≠ H'00
- Other than no-data control transfer: wLength ≠ H'00
- Request errors: wValue > H'7F

- Control transfer of device state errors: DVSQ = 011 (Configured)

All requests other than SET_ADDRESS require a response made by the software.

32.4.6 Bulk Transfer (Pipes 1 to 5)

The buffer memory usage (single buffer/double buffer setting or continuous/discontinuous transfer mode setting) can be selected for bulk transfers. The buffer memory size can be set to up to 2 Kbytes. This module manages the buffer memory status and automatically responds to a PING packet and an NYET handshake.

(1) PING Packet Control when the Host Controller Function is Selected

This module automatically sends a PING packet in the OUT direction.

As described below, this module sends an OUT packet upon receiving an ACK handshake with the initial state where a PING packet was transmitted. When this module receives NAK or NYET, it returns to the PING transmission state. This control is also effective for the control transfer data stage and status stage.

1. Set OUT data transmission.
2. Send a PING packet.
3. Receive an ACK handshake.
4. Send an OUT data packet.
5. Receive an ACK handshake.
   (Repeat steps 4 and 5.)
6. Send an OUT data packet.
7. Receive a NAK/NYET handshake.
8. Send a PING packet.

This module returns to the PING packet transmission state at the time of a power-on reset, receiving NYET/NAK handshake, setting the sequence toggle bit, setting clear (SQSET, SQCLR), and setting buffer clear (ACLRM).

(2) NYET Handshake Control when the Function Controller Function is Selected

Table 32.25 lists NYET handshake responses of this module. This module sends a NYET response under the following conditions. However, when this module receives a short packet, this module sends ACK instead of NYET. The same is true of the control write transfer data stage.

Table 32.25 NYET Handshake Responses

Setting of PID Bits in DCPCTR	Buffer Memory Status	Token	Response	Remarks
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY1	OUT/PING	ACK	Receives a data packet when receiving an OUT token.
	RCV-BRDY2	OUT	NYET	Receives a data packet. Sends a “reception disable” response.
	RCV-BRDY2	OUT (Short)	ACK	Receives a data packet. Sends a “reception enable” response.
	RCV-BRDY2	PING	ACK	Sends a “reception enable” response.
	RCV-NRDY	OUT/PING	NAK	Sends a “reception disable” response.
	TRN-BRDY	IN	DATA0/1	Sends a data packet.
	TRN-NRDY	IN	NAK	TRN-NRDY

[Legend]

RCV-BRDY1: The buffer memory has available space for two packets or more when receiving an OUT or PING token.

RCV-BRDY2: The buffer memory has available space for only one packet when receiving an OUT token.

RCV-NRDY: The buffer memory is occupied when receiving an PING token.

TRN-BRDY: The buffer memory contains transmit data when receiving an IN token.

TRN-NRDY: The buffer memory contains no transmit data when receiving an IN token.

32.4.7 Interrupt Transfer (Pipes 6 to 9)

When the function controller function is selected, this module performs interrupt transfer following the cycles controlled by the host controller. In interrupt transfers, this module ignores PING packets (no response), sends no NYET handshake, and sends ACK, NAK, and STALL responses.

When the host controller function is selected, the token output timing can be set using the interval counter. This module sends no PING token, but sends OUT tokens even in the OUT direction transfer.

This module does not support the High-Bandwidth interrupt transfer.

(1) Interval Counter in Interrupt Transfer when the Host Controller Function is Selected

To perform an interrupt transfer, set a transaction interval by the IITV bits in PIPEPERI. This controller sends tokens in the interrupt transfer at the specified intervals.

(a) Counter initialization

This controller initializes the interval counter under the following conditions.

- Power-on reset:
  The IITV bits are initialized.
- Buffer memory initialization by ACLRM
  The IITV bits are not initialized but the counter is initialized. The IITV value is counted from the beginning by clearing the ACLRM bit to 0.

Note that the interval counter is not initialized in the following cases.

- USB bus reset or USB suspended
  The IITV bits are not initialized. Setting the UACT bit to 1 causes the interval counter to start counting from the value before the USB bus reset or USB suspended state.

(b) Operation when this module cannot send/receive tokens at the token generation timing

This module generates no token in the following cases even at the token generation timing. In these cases, this module tries to execute the transaction in the next interval.

- When PID = NAK or STALL is set
- When the buffer memory is occupied at the token transmit timing in the IN direction (reception) transfer

- When the buffer memory contains no transmit data at the token transmit timing in the OUT direction (transmission) transfer

32.4.8 Isochronous Transfer (Pipes 1, 2)

This module is provided with the following functions for isochronous transfers.

- Reporting isochronous transfer error information
- Interval counter (IITV bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (IFIS bit)

This module does not support the isochronous High-Bandwidth transfer.

(1) Isochronous Transfer Error Detection

This module is provided with a function to detect the following error information so that the software can manage isochronous transfer errors. Tables 32.26 and 32.27 show the error detection priority of this module and interrupts generated as a result of error detection.

1. PID error
   — When the PID in a receive packet is invalid
2. CRC error, bit stuffing error
   — When a CRC error is found in a receive packet or bit stuffing is invalid
3. Maximum packet size exceeded error
   — When the data size of a receive packet is over the maximum packet size setting
4. Overrun/underrun error
   — When the host controller function is selected
   When the buffer memory is occupied at the token transmit timing in the IN direction (reception) transfer
   When the buffer memory contains no transmit data at the token transmit timing in the OUT direction (transmission) transfer
   — When the function controller function is selected
   When the buffer memory contains no data when this module receives an IN token in the IN direction (transmission) transfer
   When the buffer memory is occupied when this module receives an OUT token in the OUT direction (reception) transfer

5. Interval error

   When the function controller function is selected, this module generates an interval error in the following cases.

   — When no IN token can be received in interval frames in the isochronous IN transfer

   — When this module receives an OUT token other than interval frames in the isochronous OUT transfer

Table 32.26 Error Detection when Receiving Tokens

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet) when either of the host controller function or function controller function is selected.
2	CRC error, bit stuffing error	This module generates no interrupt (ignores as a damaged packet) when either of the host controller function or function controller function is selected.
3	Overrun error, underrun error	This module generates an NRDY interrupt and sets the OVRN bit when either of the host controller function or function controller function is selected. When the host controller function is selected, this module sends no token. When the function controller function is selected, this module sends a Zero-Length packet in response to the IN token. This module receives no data packet in response to the OUT token.
4	Interval error	When the function controller function is selected, this module generates an NRDY interrupt. When the host controller function is selected, this module generates no interrupt.

Table 32.27 Error Detection when Receiving Data Packets

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet).
2	CRC error, bit stuffing error	This module generates an NRDY interrupt and sets the CRCE bit when either of the host controller function or function controller function is selected.
3	Maximum packet size exceeded error	This module generates a BEMP interrupt and sets the PID bits to STALL when either of the host controller function or function controller function is selected.

(2) DATA-PID

This module does not support the High-Bandwidth transfer. The following lists responses to received PIDs when the function controller function is selected.

1. IN direction
   - DATA0: Sent correctly as the PID of data packet.
   - DATA1: Not sent
   - DATA2: Not sent
   - mDATA: Not sent
2. OUT direction (full-speed operation)
   - DATA0: Received correctly as the PID of a data packet.
   - DATA1: Received correctly as the PID of a data packet.
   - DATA2: The packet is ignored.
   - mDATA: The packet is ignored.
3. OUT direction (high-speed operation)
   - DATA0: Received correctly as the PID of a data packet.
   - DATA1: Received correctly as the PID of a data packet.
   - DATA2: Received correctly as the PID of a data packet.
   - mDATA: Received correctly as the PID of a data packet.

(3) Interval Counter

Intervals for isochronous transfers can be set by the IITV bits in PIPEPERI. When the function controller function is selected, the functions shown in Table 32.28 are made available with the interval counter. When the host controller function is selected, the interval counter generates the token transmit timing. When the host controller function is selected, the interval counter works in the same way as in the interrupt transfer.

Table 32.28 Interval Counter Functions when the Function Controller Function is Selected

Transfer Direction	Function	Detection Conditions
IN	Transmit buffer flush	No IN token can be successfully received in the interval frame during the isochronous IN transfer.
OUT	Reporting reception of no token	No OUT token can be successfully received in the interval frame during the isochronous OUT transfer.

Since the interval counter is counted upon receiving an SOF or using the interpolated SOF, the isochronism can be maintained even if the SOF is damaged. The specifiable frame interval is 2^{IITV} frames or 2^{IITV} μ frames.

(a) Counter initialization when the function controller function is selected

This module initializes the interval counter as follows:

- Power-on reset
  The IITV bits are initialized.
- Initializing buffer memory by ACLRM
  The IITV bits are not initialized but the interval counter is initialized. Clearing the ACLRM bit to 0 causes the counter to start counting from the set IITV value.

After the interval counter is initialized, the interval counter starts counting in either of the following cases after a packet is correctly transferred.

1. When this module receives an SOF after sending data in response to the IN token with PID = BUF
2. When this module receives an SOF after receiving the OUT token data with PID = BUF

The interval counter is not initialized under the following conditions.

1. When PID = NAK or STALL
   The interval timer does not stop. Try to execute the transaction in the next interval.
2. USB bus reset and USB suspended
   The IITV bits are not initialized. When this module receives an SOF, the interval counter starts counting from the value before receiving the SOF.

(b) Interval count and transfer control when the host controller function is selected

This module controls the token transmission intervals using the set IITV value. This module sends a token for the selected pipe once every 2^IITV times of (μ) frames.

This module counts the interval at every 1-ms frame for the pipe used for communication with the full-speed/low-speed peripheral device connected to the high-speed HUB.

This module starts counting the token transmission interval from the next (μ) frame where PID = BUF is specified by the software.

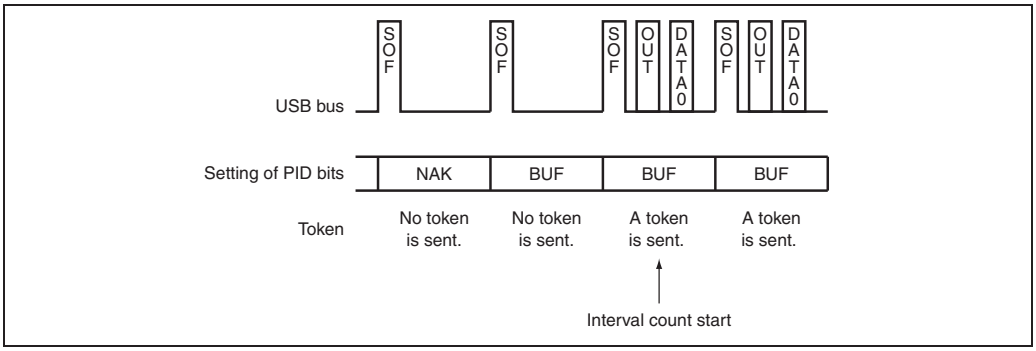

Figure 32.12 Transmission of Tokens when IITV = 0

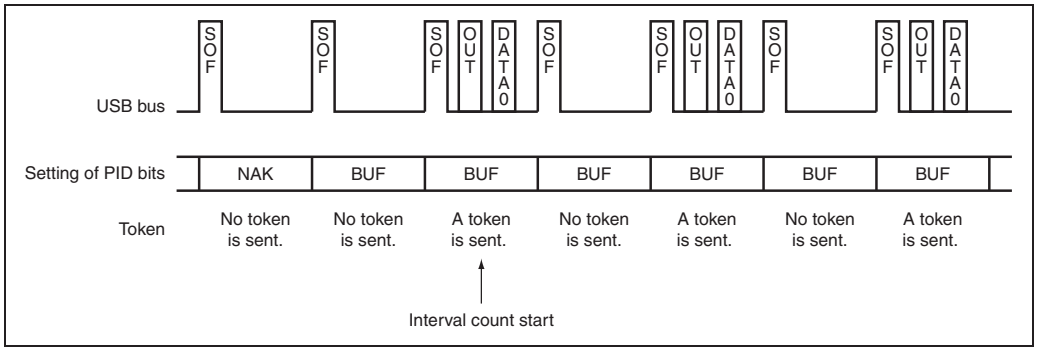

Figure 32.13 Transmission of Tokens when IITV = 1

When the selected pipe is isochronous transfer type, this module performs the following operations in connection with the token transmission interval control. Even if the NRDY interrupt generation conditions are satisfied, this module sends tokens.

1. When the selected pipe is Isochronous-IN transfer pipe

   This module sends an In-Token. When this module does not successfully receive a packet from the peripheral device (including no response and a packet error), this module generates an NRDY interrupt.

   When the IN-Token transmit timing comes before receiving data caused by the FIFO buffer full (due to a delay of reading data from the FIFO buffer by the software or DMAC), this module indicates OVRN = 1 and generates an NRDY interrupt.
2. When the selected pipe is Isochronous-OUT transfer pipe

   When the OUT-Token transmit timing comes with no transmittable data in the FIFO buffer (due to a delay of writing data to the FIFO buffer by the software or DMAC), this module indicates OVRN = 1, generates an NRDY interrupt, and sends a Zero-Length packet.

   The token transmission interval is reset in the following cases.

   — When this module is reset by the hardware (The set IITV value is also cleared to 0.)

   — When ACLRM is set to 1 by the software

(c) Interval count and transfer control when the function controller function is selected

1. When the selected pipe is Isochronous-OUT transfer pipe

   When this module receives no data packet in (μ) frames at the intervals specified by the IITV bits, this controller generates an NRDY interrupt.

   When this module cannot receive data due to a CRC error in the data packet, FIFO buffer full, or other reasons, this module also generates an NRDY interrupt.

   An NRDY interrupt is generated at the SOF packet receive timing. Even if the SOF packet is damaged, this module generates an NRDY interrupt at the SOF packet receive timing using the internal interpolation function.

   When IITV ≠ 0, however, this module generates an NRDY interrupt at the SOF packet receive timing in each interval after the interval count starts.

   When PID = NAK is set by the software after the interval timer is activated, this module generates no NRDY interrupt even when this module receives an SOF packet.

   The interval count start conditions vary with the set IITV value.

   — When IITV = 0: The interval count starts from the next (μ) frame where the PID bits for the selected pipe is changed to BUF.

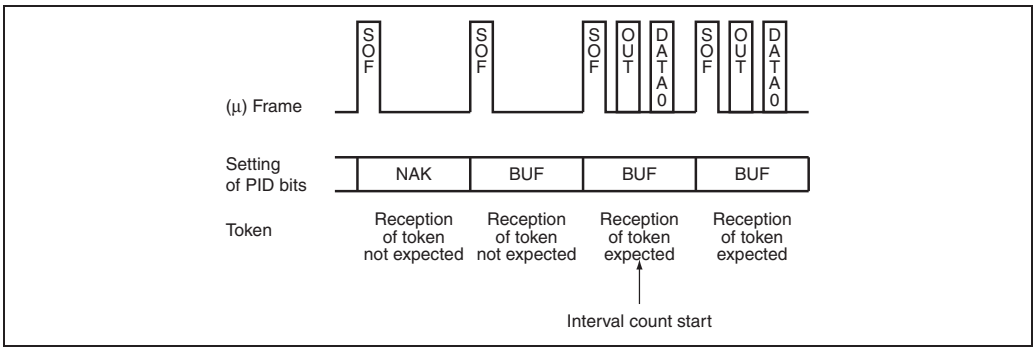

Figure 32.14 (μ) Frames and Expectation of Receiving a Token when IITV = 0

- When IITV ≠ 0: The interval count starts from the time when this module successfully receives the first data packet after the PID bits for the selected pipe is changed to BUF.

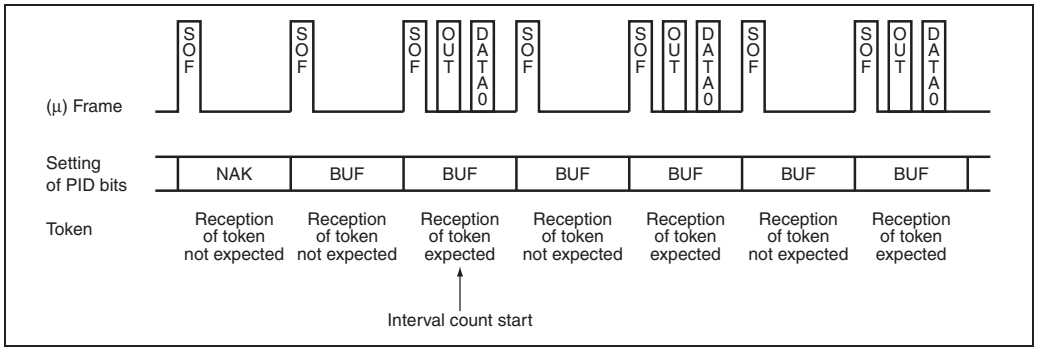

Figure 32.15 (μ) Frames and Expectation of Receiving a Token when IITV ≠ 0

2. When the selected pipe is Isochronous-IN transfer pipe

   Use the selected pipe by combining with the setting of IFIS = 1. When IFIS = 0, this module sends data packets in response to received tokens irrespective of the IITV value.

   When this module receives no IN-Token in (μ) frames at the intervals specified by the IITV bits with transmittable data stored in the FIFO buffer with IFIS = 1, this module clears the FIFO buffer.

   When this module cannot receive data due to a CRC error or another bus error in the IN-Token, this module also clears the FIFO buffer.

   The FIFO buffer is cleared at the SOF packet receive timing. Even if the SOF packet is damaged, this module clears the FIFO buffer at the SOF packet receive timing using the internal interpolation function.

   The interval count start conditions vary with the set IITV value (same as Isochronous-OUT transfer).

   When the function controller function is selected, the interval count start conditions are as follows:

   — When this module is reset by the hardware (The set IITV value is also cleared to 0.)
   — When ACLRM is set to 1 by the software
   — When this module detects a USB reset

(4) Transmit Data Setup in Isochronous Transfer when the Function Controller Function is Selected

In isochronous data transmission when the function controller function is selected, this module can send a data packet in the next frame after this module detects an SOF packet after writing data to the buffer. This function is referred to as the isochronous transfer transmit data setup function. With this function, the frame that started data transmission can be identified.

When the buffer memory is used as a double buffer, even if writing data to both buffers is completed, only one side that finished writing earlier becomes transferable. For this reason, even if multiple IN tokens are received in the same frame, only one packet of the buffer memory is sent.

When the buffer memory is ready for transmission in the IN token reception cycle, this module sends data and an ACK response. However, when the buffer memory is not ready for transmission, this module sends a Zero-Length packet and generates an underrun error.

Figure 32.16 shows an example of transmission using the isochronous transfer transmit data setup function of this module when IITV = 0 (each frame). Transmission of a Zero-Length packet is indicated as hatched “Null” in the figure.

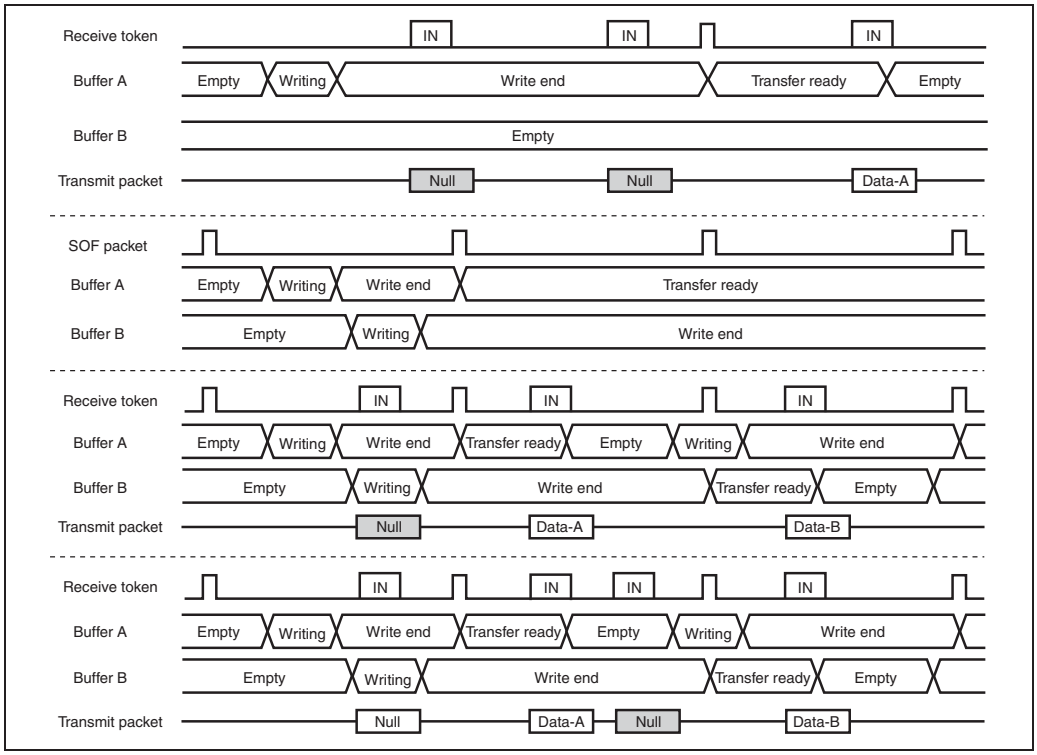

Figure 32.16 Example of Transmit Data Setup Function

(5) Transmit Buffer Flush in Isochronous Transfer when the Function Controller Function is Selected

In isochronous data transmission when the function controller function is selected, this module receives no IN token in the interval frame. When this module receives the SOF or μ SOF packet of the next frame, this module regards the IN token as damaged and clears the buffer that is ready for transmission to make it writable.

At this time, when the buffer memory is used as a double buffer and writing data to both buffers is completed, this module regards the discarded buffer memory data as transmitted in the same interval frame, and drives the buffer memory that is not discarded due to the reception of an SOF or μ SOF packet into the transmission ready state.

The buffer flush function activation timing varies depending on the IITV value.

- When IITV = 0
  This module activates the buffer flush function from the next frame after the pipe is enabled.
- When IITV ≠ 0
  This module activates the buffer flush function from the first normal transaction.

Figure 32.17 shows an example of the buffer flush function of this module. For tokens before the interval frame (outside the specified interval), however, this module sends the data stored in the buffer according to the data setup state or sends a Zero-Length packet as an underrun error.

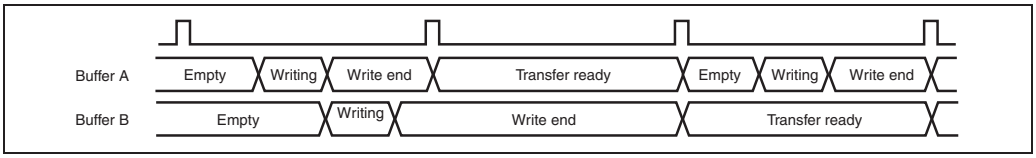

Figure 32.17 Example of Buffer Flush Function

Figure 32.18 shows an example of an interval error of this module. Interval errors are the following five. An interval error occurs at timing [1] in the figure, and the buffer flush function is activated.

When an interval error occurs, the buffer flush function is activated in the IN transfer and an NRDY interrupt occurs in the OUT transfer.

Discriminate an NRDY interrupt (including a receive packet error) from an overrun error with the OVRN bit.

This module sends a response to the hatched tokens in the figure according to the buffer memory status.

1. IN direction
   — When the buffer is ready to transmit data, this module sends the data and an ACK response.
   — When the buffer is not ready to transmit data, this module sends a Zero-Length packet and generates an underrun error.
2. OUT direction
   — When the buffer is ready to receive data, this module receives data and sends an ACK response.
   — When the buffer is not ready to receive data, this module discards the data and generates an overrun error.

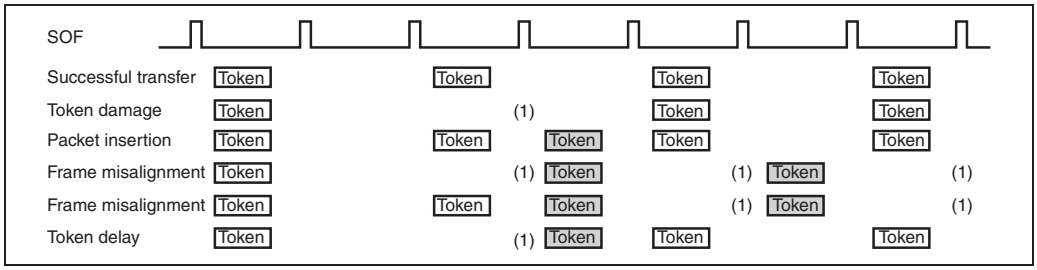

Figure 32.18 Example of Interval Error when IITV = 1

32.4.9 SOF Interpolation Function

When the function controller function is selected, in case this module cannot receive SOF packets at intervals of 1 ms (full-speed operation) or 125 μs (high-speed operation) due to damage or missing of SOF packets, this module interpolates the SOF. The SOF interpolation starts functioning when SYSCFG.USBE = 1, SYSCFG.SCKE = 1, and at the SOF packet receive timing. Furthermore, the interpolation function is initialized in the following cases.

- Power-on reset
- USB bus reset
- When the suspended state is detected

The SOF interpolation functions with the following specifications.

- The frame intervals (125 μs or 1 ms) conform to the result of the reset handshake protocol.
- The SOF interpolation does not function until this module receives an SOF packet.
- After receiving the first SOF packet, 125 μs or 1 ms is counted by the internal 48-MHz clock to interpolate the SOF.
- After receiving the second SOF packet or a following packet, the SOF is interpolated using the previous receive intervals.
- The SOF interpolation does not function in the suspended state and during a USB bus reset. (When this module enters the suspended state in high-speed operation, the SOF interpolation continues for 3 ms from the final packet.)

This module activates the following functions based on the reception of SOF packets. When one or more SOF packets are lost, normal operation can be continued to perform the SOF interpolation.

- Updating frame numbers and μ frame numbers
- SOFR interrupt timing and μ SOF lock

- Isochronous transfer interval count

When one or more SOF packets are lost in full-speed operation, the FRNM bits in FRMNUM are not updated. When one or more μ SOF packets are lost in high-speed operation, the FRNM bits are updated. However, when a μ SOF packet with UFRNM = 000 is lost, the FRNM bits are not updated even if following μ SOF packets with UFRNM ≠ 000 are successfully received.

32.4.10 Pipe Schedule

(1) Transaction Issuing Conditions

When the host controller function is selected, this module issues transactions after setting UACT = 1 according to the conditions in Table 32.29.

Table 32.29 Transaction Issuing Conditions

	Issuing Conditions				
Transaction	**DIR**	**PID**	**IITV0**	**Buffer Status**	**SUREQ**
Setup	—*1	—*1	—*1	—*1	Set to 1
Control transfer data stage, status stage, bulk transfer	IN	BUF	Disabled	Data receive area remaining	—*1
	OUT	BUF	Disabled	Transmit data stored	—*1
Interrupt transfer	IN	BUF	Enabled	Data receive area remaining	—*1
	OUT	BUF	Enabled	Transmit data stored	—*1
Isochronous transfer	IN	BUF	Enabled	*2	—*1
	OUT	BUF	Enabled	*3	—*1

Notes: 1. "—" means that the condition is not related to issuing tokens. "Enabled" shows that transactions are issued only in transfer frames by the interval counter in interrupt transfers and isochronous transfers. "Disabled" shows that transactions are issued irrespective of the interval counter.

2. Transactions are issued irrespective of whether the buffer has a data receive area or not. However, when the buffer has no data receive area, the receive data is discarded.

3. Transactions are issued irrespective of whether the buffer contains transmit data or not. However, when the buffer contains no transmit data, this module sends a Zero-Length packet.

(2) Transfer Schedule

The following describes the within-the-frame transfer scheduling of this module. This module transfers packets in the following procedure after sending the SOF.

1. Execute periodic transfer
   This module searches pipes in the order of pipe 1 -> pipe 2 -> pipe 6 -> pipe 7 -> pipe 8 -> pipe 9. When transactions can be issued in any of these pipes in isochronous transfers or interrupt transfers, this module issues transactions.
2. Control transfer setup transaction
   When the DCP indicates that the setup transaction is enabled, this module sends it.
3. Execute bulk transfer/control transfer data stage and status stage
   This module searches pipes in the order of pipe 1 -> pipe 2 -> pipe 3 -> pipe 4 -> pipe 5. When transactions can be issued in any of these pipes in the bulk transfer/control transfer data stage and control transfer status stage, this module executes transactions.
   When this module issued a transaction and received ACK or NAK from the peripheral device, this module shifts to the transactions for the next pipe. When there is time for transfer within the frame, this module repeats the operation in step 3.

(3) Enabling USB Communication

Setting the UACT bit in DVSTCTR to 1 starts transmission of an SOF or µ SOF, and issuing of transactions is enabled.

Setting the UACT bit to 0 stops transmission of an SOF or µ SOF, and issuing of transactions is suspended. When the UACT bit is changed from 1 to 0, the USB communication is halted after the next SOF or µ SOF is transmitted.

32.5 OTG Function

(1) Example of OTG Connection

The following shows an example of connection when MAX3355E is used as an OTG external device.

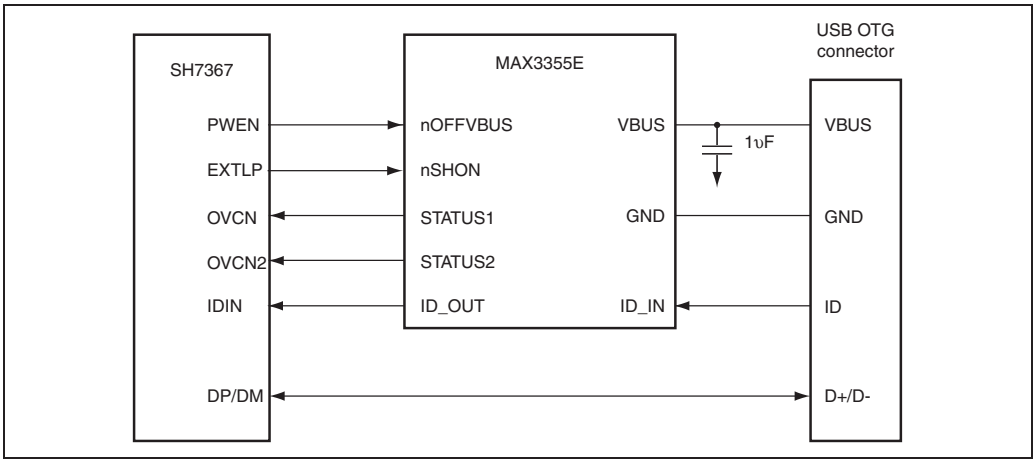

Figure 32.19 Example of OTG Connection

(2) Identifying Device ID

This module identifies either of the host controller function (device A) or function controller function (device B) using the IDMON bit. The IDIN pin state can be monitored with the IDMON bit. For the device ID specifications, see the OTG External Device Manual.

(3) HNP

The following shows a software processing flow for two transitions: (1) from the function controller function (device B) to the host controller function (device A), and (2) from the host controller function (device A) to the function controller function (device B).

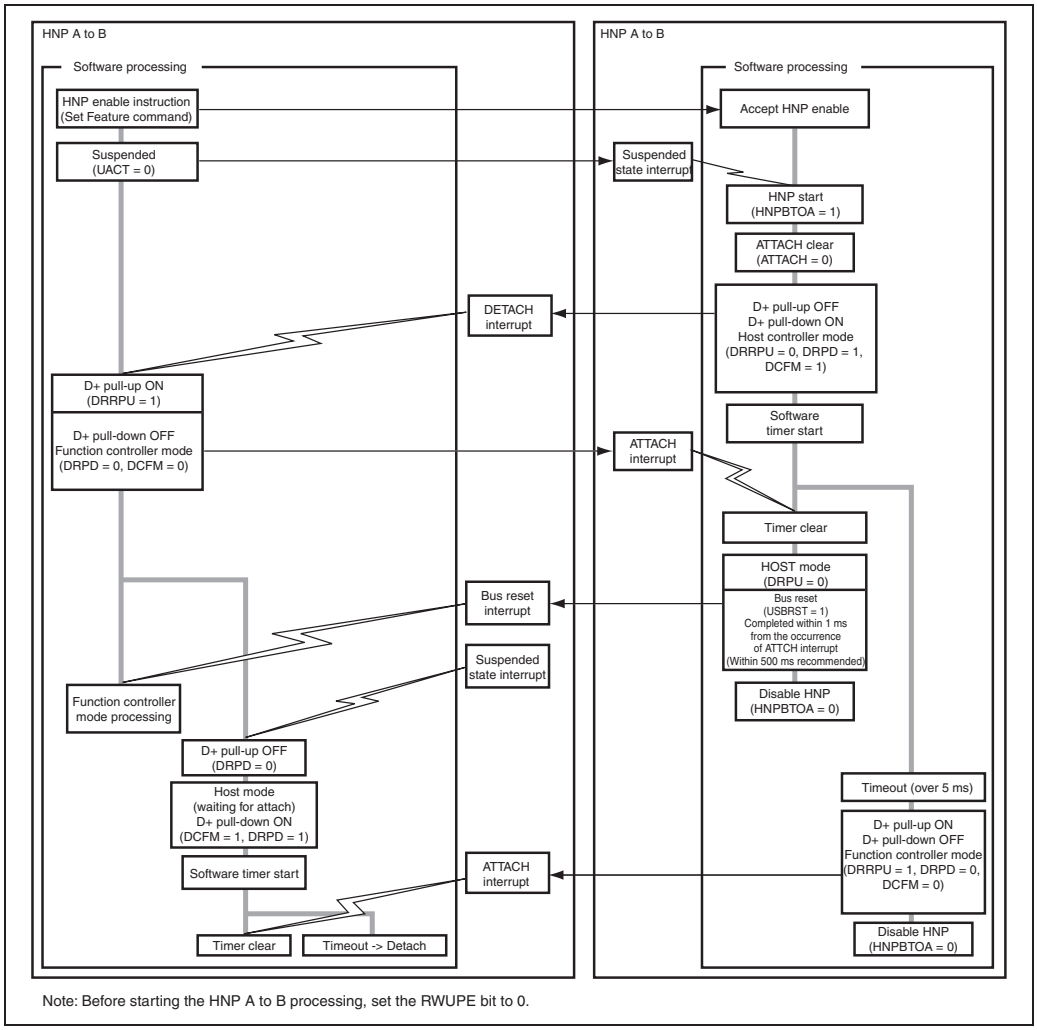

Figure 32.20 HNP Processing Flow

(4) SRP

The VBUS pin level can be sensed by the OVCMON1 and OVCMON0 bits. The values that are input to the OVCN_0 pin and OVCN2 pin are read from the OVCMON1 and OVCMON0 bits. For the VBUS level specifications, see the OTG External Device Manual.

32.6 Guidelines for Designing USB2.0 Hi-Speed Boards

32.6.1 USB Transmission Line

The USB transmission line indicates the pattern that connects the USB connector and this LSI's on-chip USB transceiver.

The USB2.0 has three communication modes: Hi-Speed, Full-Speed and Low-Speed modes. The transmission speed in the Hi-Speed mode is 480 Mbps. Therefore, the USB transmission line must be designed as a high-frequency circuit. Impedance control is required for the USB transmission line.

- The characteristic impedance required for the USB Hi-Speed transmission line is differential impedance 90Ω (±15%).
- The pattern width and pattern pitch for impedance control vary depending on the board thickness, material and layer configuration. For details, consult the board manufacturer.
- A maximum delay of 1 ns is allowed from the USB connector to this LSI. Therefore it is recommended that the pattern length from the USB device to the USB connector is less than 50 mm and the difference between the pattern lengths for D+ and D– is less than 2.5 mm for a generic PCB.
- The lower layer of the USB transmission line must be a solid ground plane. The ground must be wider than the USB transmission line by 2 mm or more. The power supply for a solid ground plane is DG33.
- Do not allocate other signal lines near to the USB transmission line. In particular, lines carrying widely fluctuating signals, such as clock and data bus lines, must be assigned far from the USB transmission line. Furthermore, layout of the USB transmission lines must be such that they do not cross with other signal lines.
- Locate the USB transmission line on the same layer without passing it through a through-hole. Do not create stubs.
- Place the USB transmission lines so that they are equally spaced from each other.
- Locate the USB transmission line as far as possible from the oscillator, power supply circuit, and other I/O connectors.
- Try to avoid bending the USB transmission line as far as possible. If it is absolutely necessary to bend it, do not bend it at acute or right angles. Bend it moderately, at not more than 45 degrees, or bend it into an arc.
- It is recommended to guard ring the clock, reset, read, write and chip select signals with grounds.

When a resistance is connected to the USB transmission line, locate it near to the USB transmission line. The connecting wire must be as short as possible.

32.6.2 Power Supply and Ground Pattern

Analog power supply: AV12 (1.2V), AV33 (3.3V)

Digital power supply: UV12 (1.2V), DV12 (1.2V), DV33 (3.3V)

Analog ground: AG12, AG33

Digital ground: UG12, DG12, DG33

- It is recommended to separate power supplies and ground patterns into digital and analog.
- Connect the power supplies and grounds firmly on wide areas.
- Tantalum solid electrolytic capacitors or ceramic capacitors having excellent high-frequency characteristics are recommended as capacitors for power supplies.
- Aluminum electrolytic capacitors affect the jitter value during measurement of EYE diagram. Use the capacitors after adequately designing and testing them.
- It is recommended to place decoupling capacitors with values of 0.1uF, 0.01uF, and 0.001uF as close as possible to the USB power supply.

32.6.3 Oscillation

- Provide an oscillation circuit near the clock input pin for USB (EXTAL2). It is recommended to guard ring EXTAL2 with a ground.
- When using a crystal resonator, consult its manufacturer to determine the circuit constant.

32.6.4 VBUS

- When this LSI is used as a host controller, it must supply the VBUS power. To do this it is recommended to use a power switch IC with an overcurrent limiter for the USB power bus (hereafter called USB power swtich IC). Current limits should be deteremined on the basis of the current values of the system power supply and the USB peripheral devices to be communicated with. For details on circuits, see the datasheet of your USB power switch IC. Input VBUS (5V) to the VBUS1_0 pin of this LSI. Provide the VBUS1_0 pin with a capacitance of 1uF and a resistance of 100Ω to 1000Ω (never exceeding 1000Ω) as a filter circuit. The potential of the VBUS is normally 5.0V, but when a cable is connected, overshoot may occur as a result of a reflection due to impedance mismatch between the VBUS power IC

and the VBUS in the cable. This overshoot can damage elements. For this reason, the element shown in Figure 32.1, Connection to the USB Connector, should be connected between the VBUS1_0 pin and the connector as a filter circuit.

32.6.5 REFRIN_0 Pin

- Provide a resistor (hereafter called reference resistor) of 5.6 kΩ ±1%, between the REFRIN_0 pin and AG33.
- Locate the reference resistor as close as possible to this LSI.
- The REFRIN_0 pin, the reference resistor and AG33 should be wired on wide areas and the shortest length.
- Use a wiring pattern for and only for the reference resistor and AG33. The pattern should be connected to the analog ground. The pattern should be designed avoiding the possibility for common impedance between REFRIN_0 and other signals.
- To prevent cross talk, very-frequently switched signals such as DP, DM, clocks, and control signals for addresses and data, should not be placed near to the reference resistor, and their patterns should neither get across nor go parallel to the wiring pattern between the reference resistor and the REFRIN_0 pin.

It is recommended to guard ring the reference resistor and its wiring pattern with ground.

Section 33 USB High-Speed 1 Module (USBHS1)

This module is a USB controller provided with the USB host controller function and the function controller function. When the host controller function is selected, high-speed transfer, full-speed transfer, and low-speed transfer conforming to the USB (universal serial bus) Specification 2.0 are available. When the function controller function is selected, high-speed transfer and full-speed transfer are available. Provided with an on-chip USB transceiver, this module also supports all transfer types defined by the USB Specification.

This module can use up to sixteen pipes when the function controller is selected. Furthermore, for pipes 1 to F(Pipe A to Pipe F are effective only when the function controller function is selected), arbitrary endpoint numbers can be allocated according to peripheral devices to be communicated and user systems.

33.1 Features

(1) Incorporates a host controller and a function controller conforming to USB High Speed. But, because the function when the function controller is selected is enhanced, this module is recommended to be selected as a function controller.

- On-chip USB host controller and function controller
- The USB host controller function and the function controller function are selectable by register setting.
- On-chip USB transceiver

(2) Achieves space-saving mount with less external elements.

- Direct connection of the VBUS0_1 and VBUS1_1 signal to the input pin of this module
- On-chip D+ pull-up resistor (function operation mode)
- On-chip D+/D- pull-down resistors (host operation mode)
- On-chip D+/D- terminating resistors (high-speed operation mode)
- On-chip D+/D- output resistors (full-speed operation mode)

(3) Supports all data transfer types for USB communication.

- Control transfer
- Bulk transfer
- Interrupt transfer (except for high bandwidth)
- Isochronous transfer (except for high bandwidth)

(4) Dedicated DMA interface

- On-chip 2-channel DMA interface

(5) Pipe configuration

- Up to twelve pipes are selectable (including the default control pipe)
- Programmable pipe configuration
- Arbitrary endpoint numbers can be allocated to pipes 1 to 9 when host controller function is selected. Arbitrary endpoint numbers can be allocated to pipes 1 to F when function controller function is selected.
- Settable transfer conditions for each pipe are as follows:

  Pipe 0: A pipe only for control transfer with a 64-byte (fixed) single buffer

  Pipes 1 and 2: Pipes that can select bulk transfer or isochronous transfer (Continuous transfer mode and buffer size are programmable.) (Double buffer can be specified with up to 2 Kbytes.)

  - When host controller function is selected:

  Pipes 3 to 5: Pipes only for bulk transfer (Continuous transfer mode and buffer size are programmable.) (Double buffer can be specified with up to 2 Kbytes.)

  Pipes 6 to 9: Pipes only for interrupt transfer with a 64-byte (fixed) single buffer

  - When function controller function is selected:

  Pipes 3 to 5 and 9 to F: Pipes only for bulk transfer (Continuous transfer mode and buffer size are programmable.) (Double buffer can be specified with up to 2 Kbytes.)

  Pipes 6 to 8: Pipes only for interrupt transfer with a 64-byte (fixed) single buffer

(6) Features with host controller function

- Supports high-speed transfer (480 Mbps), full-speed transfer (12 Mbps), and low-speed transfer (1.5 Mbps).
- Allows communication with multiple peripheral devices through a hub.
- Reset handshake auto-response
- Automated SOF/packet transmission schedule
- Isochronous transfer/interrupt transfer interval setting function

(7) Features with function controller function

- Supports high-speed transfer (480 Mbps) and full-speed transfer (12 Mbps).
- High-speed or full-speed automatic recognition of operation using the reset handshake auto-response function

- Control transfer stage management function
- Device state management function
- Auto-response to the SET_ADDRESS request
- NAK response interrupt function (NRDY)
- SOF interpolation function

(8) Other functions

- Transfer terminating function using transaction count
- SOF pulse output function
- BRDY interrupt event notification timing change function (BFRE)
- Buffer memory auto-clear function (DCLRM) after reading data of the pipe specified by the DnFIFO (n = 0, 1) port
- NAK setting function (SHTNAK) for the response PID due to the transfer end

33.2 Input/Output Pins

Table 33.1 lists the input and output pins of the USB.

Table 33.1 Pin Configuration of USB

Classification	Pin Name	Name	I/O	Description
USB bus interface	DP_1	USB D+ data	I/O	D+ Input/output of the On-chip Transceiver Connect this pin to the D+ pin of the USB bus.
	DM_1	USB D- data	I/O	D- Input/output of the On-chip Transceiver Connect this pin to the D- pin of the USB bus.
VBUS monitoring input	VBUS0_1	VBUS input	Input	USB Cable Connection Monitoring Pin Connect this pin directly to VBUS of the USB bus. This pin is used to detect VBUS connection or disconnection. When not connecting to VBUS of the USB bus, fix this pin to +5V. Also supply +5V to this pin when the host controller function is selected. However, VBUS cannot be supplied to devices to be connected.
	VBUS1_1	VBUS input	Input	USB Cable Connection Monitoring Pin Connect this pin directly to VBUS of the USB bus. This pin is used to detect VBUS connection or disconnection. When not connecting to VBUS of the USB bus, fix this pin to +5V. Also supply +5V to this pin when the host controller function is selected. However, VBUS cannot be supplied to devices to be connected.
Reference resistance	REFRIN_1	Reference input	Input	Reference Resistance Connecting Pin Connect this pin to the ground through a 5.6 kΩ ±1% resistor.

Classification	Pin Name	Name	I/O	Description
external device interface	PWEN_1	Power enable	Output	VBUS Supply ON/OFF Control Pin When using MAX3355E as an external device, connect this pin directly to the OFFVBUS0_1 and VBUS1_1 pin of the MAX3355E.
	EXTLP_1	external device low power	Output	External Device Power Shutdown Control Pin When using MAX3355E as an external device, connect this pin directly to the SHDN pin of the MAX3355E.
	OVCN_1	Overcurrent detection	Input	Overcurrent Status Monitoring Pin When using MAX3355E as an external device, connect this pin directly to the STATUS1 pin of the MAX3355E.
	OVCN2_1	Overcurrent detection 2	Input	Overcurrent Status Monitoring Pin When using MAX3355E as an external device, connect this pin directly to the STATUS2 pin of the MAX3355E.
	IDIN_1	Device ID	Input	Device ID Monitoring Pin When using MAX3355E as an external device, connect this pin directly to the ID_OUT pin of the MAX3355E.

33.3 Register Descriptions

Table 33.2 lists the registers used in this module. Table 33.3 list the register states in each processing mode.

Table 33.2 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
System configuration control register	SYSCFG	R/W	H'E68B 0000	16
CPU bus wait register	BUSWAIT	R/W	H'E68B 0002	16

33.3.1 System Configuration Control Register (SYSCFG)

SYSCFG enables or disables high-speed operation, selects the host controller function or function controller function, controls DP_1 and DM pins, and enables or disables the operation of this module.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SCKE	—	—	HSE	DCFM	DRPD	DPR PU	—	—	—	USBE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	SCKE	0	R/W	USB Module Clock Enable Enables or halts the supply of the 48-MHz clock to this module. 0: The clock supply to the USB module is halted. 1: The clock supply to the USB module is enabled. When this bit is 0, only this register and BUSWAIT are readable and writable. Other registers in the USB module are readable but not writable.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	HSE	0	R/W	High-Speed Operation Enable 0: High-speed operation is disabled. When the function controller function is selected: Full-speed operation only When host controller function is selected: Full-speed or low-speed operation 1: High-speed operation is enabled. (This module detects the transmission rate.) (1) When the host controller function is selected When HSE is 0, the USB port performs low-speed or full-speed operation. If the USB detects that a low-speed peripheral device is attached to the USB port, be sure to set the HSE bit to 0. When HSE is 1, this module executes the reset handshake protocol, and according to the result, the USB port is automatically driven to high-speed or full-speed operation mode. Change this bit after the ATTCH interrupt is detected and before resetting the USB bus (before setting USBRESET to 1). (2) When the function controller function is selected When HSE is 0, this module performs full-speed operation. When HSE is 1, this module executes the reset handshake protocol, and according to the result, this module automatically performs high-speed or full-speed operation. Change this bit while the DPRPU bit is 0.
6	DCFM	0	R/W	Controller Function Select Selects the function of this module. 0: The function controller function is selected. 1: The host controller function is selected. Change this bit while the DPRPU and DRPD bits are 0. During the HNP processing, however, this bit can be set according to the processing sequence.

Bit	Bit Name	Initial Value	R/W	Description
5	DRPD	0	R/W	D+ Line/D- Line Resistance Control Enables or disables pull-down of the D+ and D- lines when the host controller function is selected. 0: Pull-down is disabled. 1: Pull-down is enabled. Set this bit to 1 when the host controller function is selected. During the HNP processing, however, this bit can be set according to the processing sequence. Set this bit to 0 when the function controller function is selected.
4	DPRPU	0	R/W	D+ Line Resistance Control Enables or disables pull-up of the D+ line when the function controller function is selected. 0: Pull-up is disabled. 1: Pull-up is enabled. When this bit is set to 1 with the function controller function selected, this module pulls up the D+ line at 3.3V, and informs the USB host of ATTACH. Clearing this bit to 0 cancels the pull-up of the D+ line, and informs the USB host of DETACH. Set this bit to 1 when the function controller function is selected. During the HNP processing, however, this bit can be set according to the processing sequence. Set this bit to 0 when the host controller function is selected.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	USBE	0	R/W	USB Module Operation Enable Enables or disables the USB module operation. 0: The USB module operation is disabled. 1: The USB module operation is enabled. Tables 33.4 and 33.5 list the registers and bit names initialized when this bit is cleared to 0. Change this bit while the SCKE bit is 1. When the host controller function is selected, set the DPRD bit to 1, eliminate chattering with the LNST bit, confirm that the USB bus is stable, and then set this bit to 1.

Table 33.4 Registers Initialized by Writing 0 in the USBE Bit (When the function controller function is selected)

Register Name	Bit Name	Remarks
SYSSTS	LNST	The value is retained when the host controller function is selected.
DVSTCTR	RHST	
INTSTS0	DVSQ	The value is retained when the host controller function is selected.
USBADDR	USBADDR	The value is retained when the host controller function is selected.
USEREQ	BRequest, bmRequestType	The value is retained when the host controller function is selected.
USBVAL	wValue	The value is retained when the host controller function is selected.
USBINDX	wIndex	The value is retained when the host controller function is selected.
USBLENG	wLength	The value is retained when the host controller function is selected.

Table 33.5 Registers Initialized by Writing 0 in the USBE Bit (When the host controller function is selected)

Register Name	Bit Name	Remarks
DVSTCTR	RHST	
FRMNUM	FRNM	The value is retained when the function controller function is selected.
UFRMNUM	UFRNM	The value is retained when the function controller function is selected.

33.3.2 CPU Bus Wait Register (BUSWAIT)

BUSWAIT specifies the number of access waits from the CPU to this module.

This register is writable even if the SCKE bit in SYSCFG is 0.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	BWAIT[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	BWAIT[3:0]	1111	R/W	CPU Bus Wait Specify the number of access waits to this module. 0000: 0 waits (2 access cycles) 0001: 1 wait (3 access cycles) 0010 to 1110: 2 to 14 waits (4 to 16 access cycles) 1111: 15 waits (17 access cycles) initial value The following restriction is provided for access cycles to the registers of addresses beginning with H'04 of this controller. Restriction for wait: The cycle of continuous accesses to the registers of this controller must be 80 ns or more. To satisfy this restriction, control waits using the frequency of system clock HPϕ. Choose the best value within the initial value of 17 clock cycles (maximum). This setting is the same as the waits in accesses to the FIFO port register. The maximum speed of accesses to the FIFO port is as follows: MBW = 10 (32-bit width) : Max. 48 Mbytes/s MBW = 01 (16-bit width) : Max. 24 Mbytes/s MBW = 00 (8-bit width) : Max. 12 Mbytes/s

33.3.3 System Configuration Status Register (SYSSTS)

SYSSTS monitors the USB data bus line status (D+ and D- lines).

This register is initialized by a power-on reset or a USB reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVCMON[1:0]		—	—	—	—	—	—	—	HTACT	—	—	—	ID MON	LNST[1:0]	
Initial value:	—*	—*	0	0	0	1	0	0	0	0	0	0	0	—*	—*	—*
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15, 14	OVCMON [1:0]	Undefined*	R	OVCN_1/OVCN2_1 Pin Monitor Indicate the input state of the OVCN_1 and OVCN2_1 pins. 00: OVCN_1 = Low, OVCN2_1 = Low 01: OVCN_1 = Low, OVCN2_1 = High 10: OVCN_1 = High, OVCN2_1 = Low 11: OVCN_1 = High, OVCN2_1 = High Connection of an external device to the OVCN_1 and OVCN2_1 pins allows SRP.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
9 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	HTACT	0	R	Indicates that this module is processing when the host controller function is selected. 0: Idle state 1: Processing
5 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2	IDMON	Undefined*	R	Indicates the input state of the IDIN_1 pin. 0: IDIN_1 = Low 1: IDIN_1 = High Connection of an external device to the IDIN_1 pin allows a device ID to be reflected in this bit.
1, 0	LNST[1:0]	Undefined*	R	USB Data Line Status Monitor Indicate the USB data bus line (D+ and D- lines) status. Table 33.6 shows the USB data bus line status. Read these bits after the attach processing (DPRPU = 1) when the function controller function is selected or read them after enabling pull-down of the D+ and D- lines (DRPD = 1) when the host controller function is selected.

Note: * These bits depend on the state of the DP_1, DM_1, OVCN_1, OVCN2_1, and IDIN_1 pins.

Table 33.6 USB Data Bus Line Status

LNST[1]	LNST[0]	Low-Speed Operation (only when host controller function is selected)	Full-Speed Operation	High-Speed Operation	Chirp Operation
0	0	SE0	SE0	Squelch	Squelch
0	1	K-State	J-State	UnSquelch	Chirp J
1	0	J-State	K-State	Invalid	Chirp K
1	1	SE1	SE1	Invalid	Invalid

Legend:

Chirp: The reset handshake protocol (RHSP) is being executed with high-speed operation is enabled (HSE = 1 in SYSCFG).
Squelch: SE0 or idle state
UnSquelch: High-speed J-State or high-speed K-State
Chirp J: Chirp J-State
Chirp K: Chirp K-State
Invalid: Invalid

33.3.4 Device State Control Register (DVSTCTR)

DVSTCTR controls and monitors the USB data bus state.

This register is initialized by a power-on reset. The WKUP bit is initialized and the RESUME bit becomes undefined by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	HNP BTOA	EXT LP	PWEN	WKUP	RWU PE	USB RST	RES UME	UACT	—	RHST[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W*	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	HNPBTOA	0	R/W	Switches HNP (Host Negotiation Protocol) From B (Device) to A (Host). This bit is used to switch the function controller function (device B) to the host controller function (device A) the HNP. 0: Normal operation 1: Switching B to A is enabled. When this bit is 1, the internal function controller remains suspended until the HNP processing finishes even when DPRPU = 0 or DCFM = 1. Furthermore, even if the falling edge of the D+ signal is detected, the resume (RESM) interrupt is not generated. When the HOST ATTACH (pull-up at the other side) is detected or the HNP processing timeout occurs, write 0 in this bit. Write 1 in this bit only in the suspended state with the function controller function selected.
10	EXTLP_1	0	R/W	Controls the EXTLP_1 pin output state. 0: EXTLP_1 Low output 1: EXTLP_1 High output
9	PWEN_1	0	R/W	Controls the PWEN_1 pin output state. 0: PWEN_1 Low output 1: PWEN_1 High output

Bit	Bit Name	Initial Value	R/W	Description
8	WKUP	0	R/W*	Wakeup Output Enables or disables the remote wakeup (resume signal output) to the USB bus when the function controller function is selected. 0: The remote wakeup signal is not output. 1: The remote wakeup signal is output. This module controls the remote wakeup signal output time. When this bit is set to 1, this module outputs 10 ms K-State and then clears this bit. The USB Specification requires the USB bus idle state to be maintained for at least 5 ms before transmitting the remote wakeup signal. For this reason, this module outputs K-State after waiting for 2 ms even if 1 is written in this bit immediately after the suspended state is detected. Write 1 in this bit only when the device is in the suspended state (DVSQ = 1xx in INTSTS0) and remote wakeup is enabled by the USB host. When setting this bit to 1, do not stop the internal clock even in the suspended state (Write 1 in this bit with SCKE set to 1). Write 0 in this bit when the host controller function is selected.
7	RWUPE	0	R/W	Wakeup Detection Enable Enables or disables remote wakeup (resume signal output) for the peripheral device of the down port when the host controller function is selected. 0: Remote wakeup output to the down port is disabled. 1: Remote wakeup output to the down port is enabled. When the remote wakeup signal is detected while this bit is 1, this module detects the resume signal (2.5 μs K-State) for the down port and performs resume processing to drive K-State. When this bit is set to 0, the remote wakeup signal (K-State) from the peripheral device connected to the selected port is ignored even if it is detected by this module. While this bit is 1, do not halt any internal clocks even in the suspended state (keep SCKE = 1). Also do not reset the USB bus from the suspended state by writing 1 in the USBRST bit. This is prohibited by USB Specification 2.0. Set this bit to 0 when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
6	USBRST	0	R/W	Bus Reset Output Controls the USB bus reset signal output when the host controller function is selected. 0: The USB bus reset signal is not output. 1: The USB bus reset signal is output. When this bit is set to 1 with the host controller function selected, this module drives SE0 of the USB port to perform the USB bus reset processing. When the HSE bit is 1 at this time, this module executes the reset handshake protocol. While USBRST is 1 (until the software writes 0 in this bit), this module continues the SE0 output. Secure the time specified in the USB Specification 2.0 for the USB bus reset time period (USBRST = 1). If 1 is written in this bit during communication (UACT = 1) or during resume (RESUME = 1), this module does not reset the USB bus until the UACT and RESUME bits are cleared to 0. Immediately after this bit is cleared to cancel a USB bus reset, write 1 in the UACT bit. Set this bit to 0 when the function controller function is selected.
5	RESUME	0	R/W	Resume Output Controls the resume signal output when the host controller function is selected. 0: The resume signal is not output. 1: The resume signal is output. When this bit is set to 1, this module drives the port into K-State to output the resume signal. While RESUME is 1 (until the software writes 0 in this bit), this module continues the K-State output. Secure the time specified in the USB Specification 2.0 for the resume time period (RESUME = 1). Write 1 in this bit only in the suspended state. Immediately after this bit is cleared to cancel the resume, write 1 in the UACT bit. Set this bit to 0 when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
4	UACT	0	R/W	USB Bus Enable Enables or disables the USB bus operation (output control of the SOF or μSOF packet to the USB bus) when the host controller function is selected. 0: Down port operation is disabled. (SOF/μSOF packets are not sent.) 1: Down port operation is enabled. (SOF/μSOF packets are sent.) When this bit is set to 1, this module drives the USB port into the USB bus enable state, sends the SOF packet, and performs data communication. The SOF or μSOF packet is sent within one (micro) frame time period after the software writes 1 in this bit. When this bit is set to 0, this module enters the idle state after the SOF or μSOF packet is sent. This module sets this bit to 0 in the following cases: When the DTCH interrupt is detected during communication (UACT = 1) When the EOFERR interrupt is detected during communication (UACT = 1) Write 1 in this bit at the end of USB reset processing (clearing the USBRST bit) or at the end of resume processing from the suspended state (clearing the RESUME bit). Set this bit to 0 when the function controller function is selected.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	RHST[2:0]	000	R	Reset Handshake Indicate the reset handshake state. (1) When the host controller function is selected: 000: Transmission rate is undefined (when powered or not connected). 1xx: The reset handshake processing is in progress. 001: Low-speed connection 010: Full-speed connection 011: High-speed connection After the software writes 1 in USBRST, these bits become 100. When HSE is set to 1 for the port, these bits become 111 when this module detects ChirpK from the peripheral device. When the software writes 0 in USBRST of the selected port and this module finishes driving SE0, this module determines the value of the RHST bits. (2) When the function controller function is selected: 000: Transmission rate is undefined. 100: The reset handshake processing is in progress. 010: Full-speed connection 011: High-speed connection When this module detects a USB bus reset with the HSE bit set to 1 for the port, these bits become 100. After that, when this module outputs ChirpK and detects ChirpJK from the USB host three times, these bits become 011. Unless high-speed mode is fixed within 2.5 ms after the ChirpK output, these bits become 010. When this module detects a USB bus reset with the HSE bit set to 0 for the port, these bits become 010. When the RHST bits are fixed to 010 or 011 after this module detected a USB bus reset, the DVST interrupt occurs.

33.3.5 Test Mode Register (TESTMODE)

TESTMODE controls the USB test signal output in high-speed operation mode.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	UTST[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	UTST[3:0]	0000	R/W	Test Mode Table 33.7 shows the test mode operation of this module. Control the USB test signal output in high-speed operation mode. These bits are valid only in high-speed operation mode. Use this test mode when the RHST bits in DVSTCTR are 011. Since bit 3 (UTST3) of these bits depends on the DCFM bit (controller function select), set these bits according to the DCFM bit. Furthermore, after the test with these bits, cancel this test mode by a power-on reset. When the host controller function is selected: Set these bits after setting DRPD to 1. This module outputs waveforms to the USB port for which DRPD = 1 and UACT = 1 are set. This module also performs high-speed termination for the USB port. Set the UTST bits using the following steps. 1. System reset 2. Clock initiation 3. DCFM = 1, DPRD = 1 (Setting HSE to 1 is not needed.) 4. USBE = 1 5. Set the UTST bits to a value according to the test content. 6. Set the UACT bit to 1.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	UTST[3:0]	0000	R/W	Change the UTST bits using the following steps. 1. UACT = 0, USBE = 0 2. USBE = 1 3. Set the UTST bits to a value according to the test content. 4. Set the UACT bit to 1. When Test_SE0_NAK (1011) is set, this module does not output the SOF packet to the port for which UACT is set to 1. When Test_Force_Enable (1101) is set, this module outputs the SOF packet to the port for which UACT is set to 1. Furthermore in this test mode, even if this module detects a high-speed disconnection (DTCH interrupt), this module does not control the hardware related to the detection. Before setting the UTST bits, set the PID bit of all pipes to NAK. When performing normal USB communication after setting test mode, issue a system reset. When the function controller function is selected: Set these bits according to the SetFeature request from the USB host during high-speed communication. While these bits are 0001 to 0100, this module does not enter the suspended state.

Table 33.7 Test Mode Operation

	UTST Bits Setting	
Test Mode	**When function controller function is selected**	**When host controller function is selected**
Normal operation	0000	0000
Test_J	0001	1001
Test_K	0010	1010
Test_SE0_NAK	0011	1011
Test_Packet	0100	1100
Test_Force_Enable	—	1101
Reserved	0101 to 0111	1110 to 1111

33.3.6 CFIFO Port Register

CFIFO is a port register to read data from or write data to the FIFO buffer memory.

Each FIFO port consists of this register (CFIFO) for data read/write from/to the FIFO buffer memory, the select registers (CFIFOSEL, D0FIFOSEL, and D1FIFOSEL) to select pipes to be allocated to a FIFO port, and the control registers (CFIFOCTR, D0FIFOCTR, and D1FIFOCTR).

Each FIFO port provides the following features.

- Make accesses to the FIFO buffer for DCP through the CFIFO port.
- Make accesses to the FIFO buffer with DMA transfers through the DMAC module for USB high-speed only.
- When using a function specific to FIFO ports (DMA transfer function, etc.), the pipe number (selected pipe) specified by the CURPIPE bits cannot be changed.
- Register groups of a FIFO port do not affect other FIFO ports.
- Do not allocate the same pipe number to different FIFO ports.
- There are two FIFO buffer states where the access mastership is on the CPU side and on the SIE side. When the FIFO buffer access mastership is on the SIE side, the CPU cannot make an access to the FIFO buffer.

This register is initialized by a power-on reset.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FIFOPORT[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FIFOPORT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	FIFOPORT [31:0]	All 0	R/W	FIFO Port Read receive data from the FIFO buffer or write transmit data to the FIFO buffer using these bits. Access to this register is enabled only when the FRDY bit in each control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is set to 1. Valid bits in this register vary with the value of the MBW bits. Table 33.8 shows the valid bits in this register.

Table 33.8 Operation of This Register when Accessed

Access Size	Bits 31 to 24	Bits 23 to 16	Bits 15 to 8	Bits 7 to 0
32 bits	N + 3 address	N + 2 address	N + 1 address	N + 0 address
16 bits	Write: Invalid, Read: Prohibited*		N + 1 address	N + 0 address
8 bits	Write: Invalid, Read: Prohibited*			N + 0 address

Note: * Reading an invalid register with word access or byte access is prohibited.

33.3.7 FIFO Port Select Registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL)

CFIFOSEL, D0FIFOSEL, and D1FIFOSEL select pipes to be allocated to FIFO ports and control accesses to each FIFO port.

Do not specify the same pipe number for the CURPIPE bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL. When the CURPIPE bits in D0FIFOSEL and D1FIFOSEL are set to B'000, no pipe is specified.

Do not change any pipe number when DMA transfer is enabled.

This register is initialized by a power-on reset.

(1) CFIFOSEL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCNT	REW	—	—	MBW[1:0]		—	—	—	—	ISEL	—	CURPIPE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	RCNT	0	R/W	Read Count Mode Specifies read mode of the DTLN bits in CFIFOCTR. 0: Clears the DTLN bits after reading all receive data in the CFIFO (or after reading receive data of one side of the double buffer). 1: Counts down the DTLN bits at each reading of CFIFO receive data.
14	REW	0	R/W	Buffer Pointer Rewind Specifies whether to rewind the buffer pointer or not. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound. When the selected pipe is in the receive direction and this bit is set to 1 during FIFO buffer reading, the FIFO buffer can be read from the first data. (In the case of a double buffer, the first data of one side that is being read can be read again.) Do not set this bit to 1 concurrently with the CURPIPE setting change. Be sure to confirm that the FRDY bit is 1 when setting this bit to 1. To rewrite the FIFO buffer data from the first data for a pipe in the transmit direction, use the BCLR bit.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11, 10	MBW[1:0]	00	R/W	CFIFO Port Access Bit Width Specify the bit width for accesses to the CFIFO port. 00: 8 bits 01: 16 bits 10: 32 bits 11: Setting prohibited When the selected pipe is in the receive direction and data read is started after these bits are set, do not change these bits until all data is completely read. When the selected pipe is in the receive direction, set the CURPIPE and MBW bits at the same time. When the selected pipe is in the transmit direction, no bit width can be changed (from 8 bits to 16/32 bits or from 16 bits to 32 bits) during data write to the buffer memory. When 8-bit width or 16-bit width is selected, data of odd bytes can also be written by controlling the byte access.
9 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	ISEL	0	R/W	CFIFO Port Access Direction when DCP is Selected 0: Buffer memory read is selected. 1: Buffer memory write is selected. To change this bit when the selected pipe is DCP, write 1 or 0 in this bit, read the value of this bit, confirm that the write value equals the read value, and then proceed with the next processing. If this bit is changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of this bit is rewritten, and then further access is enabled. Set this bit concurrently with the CURPIPE bits.

Bit	Bit Name	Initial Value	R/W	Description
4	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
3 to 0	CURPIPE [3:0]	0000	R/W	CFIFO Port Access Pipe Select Set the number of pipe to be used for data read or write through the CFIFO port. 0000: DCP 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 1010: Pipe A*2 1011: Pipe B*2 1100: Pipe C*2 1101: Pipe D*2 1110: Pipe E*2 1111: Pipe F*2 To change these bits, write a value in these bits, read the value of these bits, confirm that the write value equals the read value, and then proceed with the next processing. Do not write the same pipe number in the CURPIPE bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL. If these bits are changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of these bits is rewritten, and then further access is enabled.

Note: * Only reading 0 is enabled.
*2 Pipe A to Pipe F are effective only when the function controller function is selected.

(2) D0FIFOSEL, D1FIFOSEL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCNT	REW	DCLRM	DREQE	MBW[1:0]		—	—	DEZPM	—	—	—	CURPIPE[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W*	R/W	R/W	R/W	R/W	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	RCNT	0	R/W	Read Count Mode Specifies read mode of the DTLN bits in DnFIFOCTR. 0: Clears the DTLN bits after reading all receive data in the DnFIFO (or after reading receive data of one side of the double buffer). 1: Counts down the DTLN bits at each reading of DnFIFO receive data. When making an access to the DnFIFO with the BFRE bit set to 1, set this bit to 0.
14	REW	0	R/W*	Buffer Pointer Rewind Specifies whether to rewind the buffer pointer or not. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound. When the selected pipe is in the receive direction and this bit is set to 1 during FIFO buffer reading, the FIFO buffer can be read from the first data. (In the case of a double buffer, the first data of one side that is being read can be read again.) Do not set this bit to 1 concurrently with the CURPIPE setting change. Be sure to confirm that the FRDY bit is 1 when setting this bit to 1. When making an access to the DnFIFO with the BFRE bit set to 1, do not set this bit to 1 when the short packet data is completely read. To rewrite the FIFO buffer data from the first data for a pipe in the transmit direction, use the BCLR bit.

Bit	Bit Name	Initial Value	R/W	Description
13	DCLRM	0	R/W	Buffer Memory Auto-Clear Mode after Reading Data of Selected Pipe Enables or disables buffer memory auto-clear mode after reading data of the selected pipe. 0: Buffer memory auto-clear mode is disabled. 1: Buffer memory auto-clear mode is enabled. When this bit is 1 and a Zero-Length packet is received while the FIFO buffer allocated to the selected pipe is empty or when a short packet is received with the BFRE bit set to 1 and the packet data is completely read, this module performs buffer clear (BCLR = 1 processing) of the FIFO buffer. When using this module with the BRDYM bit set to 1, be sure to set this bit to 0.
12	DREQE	0	R/W	DMA Transfer Request Enable Enables or disables making a DMA transfer request. 0: DMA transfer request is disabled. 1: DMA transfer request is enabled. To enable a DMA transfer request, set the CURPIPE bits and then set this bit to 1. Set this bit to 0 before changing the CURPIPE setting.
11, 10	MBW[1:0]	00	R/W	FIFO Port Access Bit Width Specify the bit width for accesses to the DnFIFO port. 00: 8 bits 01: 16 bits 10: 32 bits 11: Setting prohibited When the selected pipe is in the receive direction and data read is started after these bits are set, do not change these bits until all data is completely read. When the selected pipe is in the receive direction, set the CURPIPE and MBW bits at the same time. When the selected pipe is in the transmit direction, no bit width can be changed (from 8 bits to 16/32 bits or from 16 bits to 32 bits) during data write to the buffer memory. When 8-bit width or 16-bit width is selected, data of odd bytes can also be written by controlling the byte access.

Bit	Bit Name	Initial Value	R/W	Description
9 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	DEZPM	0	R/W	DEZPM: Zero-Length Packet Addition Mode If the DMA transfer size that is set for the the USBHS-DMAC modules is an integral multiple of the maximum packet size, a null packet is added after all of the data has been sent. 0: Disables addition of packets. 1: Enables addition of packets. This bit is applied to pipes used to write to the FIFO buffer. DEZPM must be set before starting DMA transfers. If the DEZPM bit is set after DMA transfers complete, no null packets are added. Note : This mode depends on the buffer size(PIPEBUF.BUFSIZE[4:0]). A null packet is added after transferring data up to buffer size which is defined by PIPEBUF.BUFSIZE[4:0]. When transfer data size is over 2Kbytes, this mode must not be used because max size of buffer is 2Kbytes. In that case, please add the null packet by SW with BVAL bit of FIFO Port Control Registers.
6 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CURPIPE [3:0]	0000	R/W	FIFO Port Access Pipe Select Set the number of pipe to be used for data read or write through the D0FIFO and D1FIFO ports. 0000: No pipe 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 1010: Pipe A*2 1011: Pipe B*2 1100: Pipe C*2 1101: Pipe D*2 1110: Pipe E*2 1111: Pipe F*2 To change these bits, write a value in these bits, read the value of these bits, confirm that the write value equals the read value, and then proceed with the next processing. Do not write the same pipe number in the CURPIPE bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL. If these bits are changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of these bits is rewritten, and then further access is enabled.

Note: * Only reading 0 is enabled.
*2 Pipe A to Pipe F are effective only when the function controller function is selected.

33.3.8 FIFO Port Control Registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR)

CFIFOCTR, D0FIFOCTR, and D1FIFOCTR specify buffer memory write end and CPU buffer clear, as well as indicate whether the FIFO port is accessible or not. These registers correspond to each FIFO port.

These registers are initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BVAL	BCLR	FRDY	—	DTLN[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*1	R/W*2	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	BVAL	0	R/W*1	Buffer Memory Enable Flag This flag is set to 1 upon completion of data write in the FIFO buffer of the CPU of the pipe selected by the CURPIPE bits. 0: Invalid 1: Write end When the selected pipe is in the transmit direction, set this bit to 1 in the following cases. This module sets the FIFO buffer of the CPU to the SIE side to enable data transmission. To send a short packet, set this bit to 1 upon completion of data write. To send a Zero-Length packet, set this bit to 1 before writing data to the FIFO buffer. For pipes of continuous transfer mode, set this bit to 1 after writing data that is a positive integer multiple of MaxPacketSize and less than the BufferSize value. When data with the size specified by MaxPacketSize is written to a pipe of continuous transfer mode, this module writes 1 in this bit and sets the FIFO buffer of the CPU to the SIE side to enable data transmission. Set this bit to 1 when this module shows FRDY = 1. When the selected pipe is in the receive direction, do not set this bit to 1.

Bit	Bit Name	Initial Value	R/W	Description
14	BCLR	0	R/W*2	CPU buffer clear Clears the CPU side FIFO buffer of the selected pipe. 0: Invalid 1: Clears the CPU side FIFO buffer. When the FIFO buffer assigned to the selected pipe is set to a double buffer, and even when both sides of the buffer are readable, this module clears only one side of the FIFO buffer. When the selected pipe is DCP, this module clears the FIFO buffer when this bit is set to 1 irrespective of whether the FIFO buffer is on the CPU side or SIE side. When clearing the SIE side FIFO buffer, be sure to set the PID bits in DCP to NAK and then set the BCLR bit to 1. When the selected pipe is in the transmit direction, and if 1 is written in the BVAL and BCLR bits at the same time, this module clears the previously written data, and makes a Zero-Length packet transmittable. When the selected pipe is not DCP, write 1 in this bit while the FRDY flag indicates 1.
13	FRDY	0	R	FIFO Port Ready Indicates whether the CPU (DMAC) can access the FIFO port. 0: The FIFO port is not accessible. 1: The FIFO port is accessible. This module indicates FRDY = 1 in the following cases. However, since there is no data to read, no data can be read from the FIFO port. In these cases, set the BCLR bit to 1 to clear the FIFO buffer to make transmission/reception of the next data available. When a Zero-Length packet is received with the FIFO buffer assigned to the selected pipe empty When a short packet is received with BFRE set to 1 and the packet data is completely read
12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11 to 0	DTLN[11:0]	H'000	R	Receive Data Length Indicate the receive data length. The value of these bits during FIFO buffer reading varies as follows depending on the setting of the RCNT bit. When RCNT = 0: This module indicates the reecive data length with these bits until the CPU (DMAC) finishes reading one side of the FIFO buffer. When BFRE is 1, this module retains the reecive data length until the BCLR bit is set to 1 after the FIFO buffer read is completed. When RCNT = 1: This module decrements the value of the DTLN bits in each read cycle (-1 when MBW = 0, and -2 when MBW = 1) When reading out from a single FIFO buffer is complete, DTLN = 0 for this module. However, the behavior is different when double-buffering has been specified. If reading out of data from one side is not finished before the other side is full of received data, when all data have been read out from the first side, the DTLN bits reflect the amount of data received in the other side. When reading these bits during FIFO buffer reading while the RCNT bit is 1, note that this module updates the value in these bits within 150 ns after each FIFO port read cycle.

Notes: 1. Only writing 1 is enabled.
2. Only reading 0 and writing 1 are enabled.

33.3.9 Interrupt Enable Register 0 (INTENB0)

INTENB0 specifies masking of each interrupt when selection for function controller. When this module detects an interrupt for which 1 is written in the corresponding bit in this register by the software, this module generates a USB interrupt.

When interrupt source detection conditions are satisfied irrespective of the register setting (interrupt enable/disable), this module sets the corresponding status bit in INTSTS0 to 1.

When the software changes an interrupt enable bit (0 to 1) whose interrupt source status bit in INTSTS0 is set to 1, this module generates a USB interrupt. Only when the function controller is selected, the interrupt permission by INTENB0 register can be set. Please do not permit when you select the host controller.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VBSE	RSME	SOFE	DVSE	CTRE	BEMPE	NRDYE	BRDYE	—	—	—	—	—	—	—	—

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	VBSE	0	R/W	VBUS0_1 and VBUS1_1 Interrupt Enable Enables or disables USB interrupt outputs when the VBINT interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
14	RSME	0	R/W	Resume Interrupt Enable Enables or disables USB interrupt outputs when the RESM interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
13	SOFE	0	R/W	Frame Number Update Interrupt Enable Enables or disables USB interrupt outputs when the SOFR interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
12	DVSE	0	R/W	Device State Transition Interrupt Enable* Enables or disables USB interrupt outputs when the DVST interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
11	CTRE	0	R/W	Control Transfer Stage Transition Interrupt Enable* Enables or disables USB interrupt outputs when the CTRT interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
10	BEMPE	0	R/W	Buffer Empty Interrupt Enable Enables or disables USB interrupt outputs when the BEMP interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
9	NRDYE	0	R/W	Buffer Not Ready Response Interrupt Enable Enables or disables USB interrupt outputs when the NRDY interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
8	BRDYE	0	R/W	Buffer Ready Interrupt Enable Enables or disables USB interrupt outputs when the BRDY interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: * The RSME, DVSE, and CTRE bits can be set to 1 only when the function controller function is selected. Do not enable interrupts of these bits when the host controller function is selected.

33.3.10 Interrupt Enable Register 1 (INTENB1)

INTENB1 specifies masking of each interrupt when the host controller function is selected. When this module detects an interrupt for which 1 is written in the corresponding bit in this register by the software, this module generates a USB interrupt.

When interrupt source detection conditions are satisfied irrespective of the register setting (interrupt enable/disable), this module sets the corresponding status bit in INTSTS1 to 1.

When the software changes an interrupt enable bit (0 to 1) whose interrupt source status bit in INTSTS1 is set to 1, this module outputs a USB interrupt.

When the function controller function is selected, do not allow any interrupt.

This register is initialized by a power-on reset.

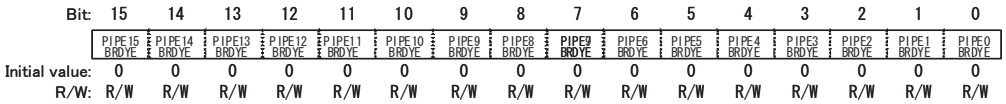
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
12	DTCHE	0	R/W	Disconnection Detect Interrupt Enable Enables or disables USB interrupt outputs when the DTCH interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
11	ATTCHE	0	R/W	Connection Detect Interrupt Enable Enables or disables USB interrupt outputs when the ATTCH interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
10 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	EOFERRE	0	R/W	EOF Error Detect Interrupt Enable Enables or disables USB interrupt outputs when the EOFERR interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
5	SIGNE	0	R/W	Setup Transaction Error Interrupt Enable Enables or disables USB interrupt outputs when the SIGN interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
4	SACKE	0	R/W	Setup Transaction ACK Interrupt Enable Enables or disables USB interrupt outputs when the SACK interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

33.3.11 BRDY Interrupt Enable Register (BRDYENB)



BRDYENB enables or disables the BRDY bit to be set to 1 when the BRDY interrupt of a pipe is detected.

When this module detects the BRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBRDY bit of the pipe in BRDYSTS and also sets the BRDY bit in INTSTS0 to 1 and generates the BRDY interrupt.

When one or more PIPEBRDY bits in BRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BRDY interrupt.

This register is initialized by a power-on reset.

Pipe A to Pipe F are effective only when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEF BRDYE	0	R/W	Pipe F BRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
14	PIPEE BRDYE	0	R/W	Pipe E BRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
13	PIPED BRDYE	0	R/W	Pipe D BRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

4	PIPE4 BRDYE	0	R/W	Pipe 4 BRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
3	PIPE3 BRDYE	0	R/W	Pipe 3 BRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
2	PIPE2 BRDYE	0	R/W	Pipe 2 BRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
1	PIPE1 BRDYE	0	R/W	Pipe 1 BRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
0	PIPE0 BRDYE	0	R/W	Pipe 0 BRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

33.3.12 NRDY Interrupt Enable Register (NRDYENB)

NRDYENB enables or disables the NRDY bit to be set to 1 when the NRDY interrupt of a pipe is detected.

When this module detects the NRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPENRDY bit of the pipe in NRDYSTS and also sets the NRDY bit in INTSTS0 to 1 and generates an NRDY interrupt.

When one or more PIPENRDY bits in NRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates an NRDY interrupt.

This register is initialized by a power-on reset.

Pipe A to Pipe F are effective only when the function controller function is selected.

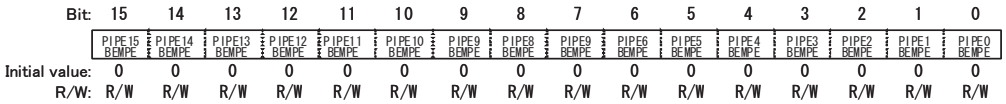
1	PIPE1 NRDYE	0	R/W	Pipe 1 NRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
0	PIPE0 NRDYE	0	R/W	Pipe 0 NRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

33.3.13 BEMP Interrupt Enable Register (BEMPENB)



BEMPENB enables or disables the BEMP bit to be set to 1 when the BEMP interrupt of a pipe is detected.

When this module detects the BEMP interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBEMP bit of the pipe in BEMPSTS and the BEMP bit in INTSTS0 to 1 and generates the BEMP interrupt.

When one or more PIPEBEMP bits in BEMPSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BEMP interrupt.

This register is initialized by a power-on reset.

Pipe A to Pipe F are effective only when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEF BEMPE	0	R/W	Pipe F BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
14	PIPEE BEMPE	0	R/W	Pipe E BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
13	PIPED BEMPE	0	R/W	Pipe D BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
12	PIPEC BEMPE	0	R/W	Pipe C BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
11	PIPEB BEMPE	0	R/W	Pipe B BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
10	PIPEA BEMPE	0	R/W	Pipe A BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
9	PIPE9 BEMPE	0	R/W	Pipe 9 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
8	PIPE8 BEMPE	0	R/W	Pipe 8 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
7	PIPE7 BEMPE	0	R/W	Pipe 7 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
6	PIPE6 BEMPE	0	R/W	Pipe 6 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
5	PIPE5 BEMPE	0	R/W	Pipe 5 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
4	PIPE4 BEMPE	0	R/W	Pipe 4 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
3	PIPE3 BEMPE	0	R/W	Pipe 3 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
2	PIPE2 BEMPE	0	R/W	Pipe 2 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
1	PIPE1 BEMPE	0	R/W	Pipe 1 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
0	PIPE0 BEMPE	0	R/W	Pipe 0 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

33.3.14 SOF Output Configuration Register (SOFCFG)

SOFCFG specifies an effective period of transactions, the BRDY interrupt status clear timing, and others.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TRNENSEL	—	BRDYM	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R/W	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	TRNENSEL	0	R/W	Transaction Effective Period Switching Specifies a transaction effective period where this module sends a token in one frame in a port in full-speed or low-speed communication. 0: Low-speed is not supported. 1: Low-speed is supported. This bit is valid only when the host controller function is selected. This bit does not affect the high-speed transaction effective period even when the host controller function is selected. Set this bit to 0 when the function controller function is selected.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	BRDYM	0	R/W	Status Clear Timing of Each Pipe BRDY Interrupt Specifies the timing to clear the BRDY interrupt status of each pipe. 0: The software clears the status. 1: This module clears the status by reading or writing the FIFO buffer.

Bit	Bit Name	Initial Value	R/W	Description
5	—	0	R	Reserved This bit is reserved. Write the value that was read immediately before. Note: The initial value of this bit is 0 immediately after a power-on reset. Be sure to set this bit to 1 during the initialization routine of this module.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

33.3.15 Interrupt Status Register 0 (INTSTS0)

INTSTS0 can know the interrupt generation by referring to the register when the function controller is selected.

Please permit interrupt by the status change that each bit of this register shows only when you select the function.

This register is initialized by a power-on reset. The DVSQ2 to DVSQ0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Initial value:	0	0	0	*1	0	0	0	0	*3	*2	*2	*2	0	0	0	0
R/W:	R/W*7	R/W*7	R/W*7	R/W*7	R/W*7	R	R	R	R	R	R	R	R/W*7	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	VBINT	0	R/W*7	VBUS0_1 and VBUS1_1 Interrupt Status*4*5 0: No VBUS0_1 and VBUS1_1 interrupt is generated. 1: A VBUS0_1 and VBUS1_1 interrupt is generated. This bit indicates 1 when this module detects a change in the VBUS0_1 and VBUS1_1 pin input level (high to low or low to high level). This module indicates the VBUS0_1 and VBUS1_1 pin input value using the VBSTS bit. When a VBINT interrupt occurs, read the VBSTS bit several times by the software and confirm that the read value is equal each time to eliminate chattering.
14	RESM	0	R/W*7	Resume Interrupt Status*4*5*6 0: No resume interrupt is generated. 1: A resume interrupt is generated. This bit indicates 1 when this module detects a falling of the DP pin level in the suspended state (DVSQ = 1XX) with the function controller function selected. The read value is invalid when the host controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
13	SOFR	0	R/W*7	Frame Number Update Interrupt Status*4 0: No SOF interrupt is generated. 1: An SOF interrupt is generated. (1) When the host controller function is selected When the UACT bit is set to 1 by the software, this bit is set to 1 at the frame number update timing. (This interrupt is detected every millisecond.) (2) When the function controller function is selected This module indicates SOFR = 1 at the frame number update timing. (This interrupt is detected every millisecond.) Even when an SOF packet from the USB host is corrupted, this module detects an SOFR interrupt using the internal interpolation.
12	DVST	0/1*1	R/W*7	Device State Transition Interrupt Status*4*6 0: No device state transition interrupt is generated. 1: A device state transition interrupt is generated. When this module detects a change in device state with the function controller function selected, this module updates the DVSQ value and set this bit to 1. When this interrupt occurred, clear the status before this module detects the next device state transition. The read value is invalid when the host controller function is selected.
11	CTRT	0	R/W*7	Control Transfer Stage Transition Interrupt Status*4*6 0: No control transfer stage transition interrupt is generated. 1: A control transfer stage transition interrupt is generated. When this module detects a control transfer stage transition with the function controller function selected, this module updates the CTSQ value and set this bit to 1. When this interrupt occurred, clear the status before this module detects the next stage transition in control transfers. The read value is invalid when the host controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
10	BEMP	0	R	Buffer Empty Interrupt Status 0: No BEMP interrupt is generated. 1: A BEMP interrupt is generated. This module indicates BEMP = 1 when at least one of the PIPEBEMP bits in BEMPSTS corresponding to the pipes for which 1 is set in the PIPEBEMPE bits in BEMPENB is set to 1 (when this module detects a BEMP interrupt of one or more pipes for which BEMP interrupts are enabled by the software). For PIPEBEMP status assertion conditions, see section 33.4.2 (3), BEMP Interrupt. When the software writes 0 to all PIPEBEMP bits corresponding to the pipes for which interrupts are enabled by the PIPEBEMPE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.
9	NRDY	0	R	Buffer Not Ready Interrupt Status 0: No NRDY interrupt is generated. 1: An NRDY interrupt is generated. This module indicates NRDY = 1 when at least one of the PIPENRDY bits in NRDYSTS corresponding to the pipes for which 1 is set in the PIPENRDYE bits in NRDYENB is set to 1 (when this module detects an NRDY interrupt of one or more pipes for which NRDY interrupts are enabled by the software). For PIPENRDY status assertion conditions, see section 33.4.2 (2), NRDY Interrupt. When the software writes 0 to all PIPENRDY bits corresponding to the pipes for which interrupts are enabled by the PIPENRDYE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.

Bit	Bit Name	Initial Value	R/W	Description
8	BRDY	0	R	Buffer Ready Interrupt Status Indicates the BRDY interrupt status. 0: No BRDY interrupt is generated. 1: A BRDY interrupt is generated. This module indicates BRDY = 1 when at least one of the PIPEBRDY bits in BRDYSTS corresponding to the pipes for which 1 is set in the PIPEBRDYE bits in BRDYENB is set to 1 (when this module detects a BRDY interrupt of one or more pipes for which BRDY interrupts are enabled by the software). For PIPEBRDY status assertion conditions, see section 33.4.2 (1), BRDY Interrupt. When the software writes 0 to all PIPEBRDY bits corresponding to the pipes for which interrupts are enabled by the PIPEBRDYE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.
7	VBSTS	0/1*[3]	R	VBUS0_1 and VBUS1_1 Input Status 0: The VBUS0_1 and VBUS1_1 pin is low level. 1: The VBUS0_1 and VBUS1_1 pin is high level.
6 to 4	DVSQ[2:0]	000/001*[2]	R	Device State 000: Powered state 001: Default state 010: Address state 011: Configuration state 1xx: Suspended state The read value is invalid when the host controller function is selected.
3	VALID	0	R/W*[7]	USB Request Receive 0: Not detected 1: A setup packet is received. The read value is invalid when the host controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	CTSQ[2:0]	000	R	Control Transfer Stage 000: Idle stage or setup stage 001: Control read data stage 010: Control read status stage 011: Control write data stage 100: Control write status stage 101: Control write (NoData) status stage 110: Control transfer sequence error 111: Setting prohibited The read value is invalid when the host controller function is selected.

Notes:
1. The initial value is B'0 after a power-on reset, and B'1 after a USB bus reset.
2. The initial value is B'000 after a power-on reset, and B'001 after a USB bus reset.
3. The initial value is 1 when the VBUS0_1 and VBUS1_1 pin is high level, and is 0 when the VBUS0_1 and VBUS1_1 pin is low level.
4. To clear the VBINT, RESM, SOFR, DVST, or CTRT bit, write 0 only to bits to be cleared and write 1 to the other bits. Do not write 0 to status bits that indicate 0.
5. When a status change shown in the VBINT or RESM bit is detected while the clock is halted (SCKE = 0) and the corresponding interrupt is enabled, the interrupt is output. Clear the interrupt status of these bits by the software after the clock is enabled.
6. A status change of the RESM, DVST, or CTRT bit occurs only when the function controller function is selected. When the function controller function is selected, disable the corresponding interrupt enable bits to 0 (disabled).
7. Only writing 0 is enabled.

33.3.16 Interrupt Status Register 1 (INTSTS1)

INTSTS1 can know the interrupt generation by referring to the register when the host controller is selected.

By using INTSTS0 when the function controller function is selected or INTSTS1 when the host controller function is selected, occurrence of interrupts can be monitored with either of these registers.

Enable interrupts generated due to a status change shown by each bit in this register only when the host controller function is selected.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVRCR	BCHG	—	DTCH	ATTCH	—	—	—	—	EOFERR	SIGN	SACK	—	—	—	—
Initial value:	—	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W*1	R	R/W*1	R/W*1	R	R	R	R	R/W*1	R/W*1	R/W*1	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	OVRCR	Undefined	R/W	OVRCR Interrupt Status This interrupt is generated when the OVCN_1 or OVCN2_1 pin input status changes. 0: No OVRCR interrupt is generated. 1: An OVRCR interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
14	BCHG	0	R/W*[1]	USB Bus Change Interrupt Status Indicates the USB bus change interrupt status. 0: No BCHG interrupt is generated. 1: A BCHG interrupt is generated. When a full-speed or low-speed signal level change occurs in the USB port (from J-State, K-State, or SE0 to J-State, K-State, or SE0), this module detects a BCHG interrupt and indicates BCHG = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates an interrupt. The current input state of the USB port is indicated by the LNST bits in SYSSTS. When a BCHG interrupt occurs, read the LNST bits several times by the software and confirm that the read value is equal each time to eliminate chattering. A USB bus change can also be detected while the internal clock is halted. The read value is invalid when the function controller function is selected.
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
12	DTCH	0	R/W*[1]	USB Disconnection Detect Interrupt Status Indicates the USB disconnection detect interrupt status when the host controller function is selected. 0: No DTCH interrupt is generated. 1: A DTCH interrupt is generated. When a USB bus disconnection is detected, this module detects a DTCH interrupt and indicates DTCH = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates an interrupt. This module detects a USB bus disconnection based on the USB 2.0 Specification. After detecting a DTCH interrupt, this module performs the following hardware control irrespective of the setting of the corresponding interrupt enable bit. The software must terminate communication of all pipes with the USB port and drives this module into a state of waiting for ATTACH to the USB port (an ATTCH interrupt is generated). Clears the UACT bit of the port in which a DTCH interrupt is detected to 0 and indicates the UACT bit. Drives the port in which a DTCH interrupt is detected into the idle state. The read value is invalid when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
11	ATTCH	0	R/W*[1]	ATTCH Interrupt Status Indicates the ATTCH interrupt status when the host controller function is selected. 0: No ATTCH interrupt is generated. 1: An ATTCH interrupt is generated. When this module detects J-State or K-State of full-speed or low-speed signal level for 2.5 μs in the USB port, this module detects an ATTCH interrupt and indicates ATTCH = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates an interrupt. Conditions for this module to detect an ATTCH interrupt are as follows: When K-State, SE0 or SE1 changes to J-State and then J-State continues for 2.5 μs When J-State, SE0 or SE1 changes to K-State and then K-State continues for 2.5 μs The read value is invalid when the function controller function is selected.
10 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
6	EOFERR	0	R/W*[1]	EOF Error Detect Interrupt Status Indicates the EOFERR interrupt status when the host controller function is selected. 0: No EOFERR interrupt is generated. 1: An EOFERR interrupt is generated. When this module detects that communication is not completed at the EOF2 timing specified in the USB 2.0 Specification, this module detects an EOFERR interrupt and indicates EOFERR = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates an EOFERR interrupt. After detecting an EOFERR interrupt, this module performs the following hardware control irrespective of the setting of the corresponding interrupt enable bit. The software must terminate communication of all pipes with the USB port and perform reenumeration for the USB port. Clears the UACT bit of the port in which an EOFERR interrupt is detected to 0 and indicates the UACT bit. Drives the port in which an EOFERR interrupt is detected into the idle state. The read value is invalid when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
5	SIGN	0	R/W*[1]	Setup Transaction Error Interrupt Status Indicates the setup transaction error interrupt status when the host controller function is selected. 0: No SIGN interrupt is generated. 1: A SIGN interrupt is generated. When a peripheral device does not send an ACK response three times in a row in the SETUP transaction issued by this module, this module detects a SIGN interrupt and indicates SIGN = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates a SIGN interrupt. This module detects a SIGN interrupt when any of the following response is generated to SETUP transactions (three times in a row). When the peripheral device sends no response and therefore this module detects a timeout When the ACK packet is corrupted When a handshake signal (NAK, NYET, or STALL) other than ACK is received The read value is invalid when the function controller function is selected.

Bit	Bit Name	Initial Value	R/W	Description
4	SACK	0	R/W*[1]	Setup Transaction ACK Response Interrupt Status Indicates the setup transaction ACK response interrupt status when the host controller function is selected. 0: No SACK interrupt is generated. 1: A SACK interrupt is generated. When this module receives an ACK response from a peripheral device in the SETUP transaction issued by this module, this module detects a SACK interrupt and indicates SACK = 1. At this time, when the corresponding interrupt enable bit is set to 1 by the software, this module generates a SACK interrupt.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Notes: 1. To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

2. When a status change shown in the BCHG bit is detected while the clock is halted (SCKE = 0) and the corresponding interrupt is enabled, the interrupt is output. Clear the BCHG interrupt status by the software after the clock is enabled.

   Any interrupts other than the BCHG bit are not detected while the clock is halted (SCKE = 0).

33.3.17 BRDY Interrupt Status Register (BRDYSTS)

BRDYSTS indicates the BRDY interrupt status of each pipe.

This register is initialized by a power-on reset.

Pipe A to Pipe F are effective only when the function controller function is selected.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPE15 BRDY	PIPE14 BRDY	PIPE13 BRDY	PIPE12 BRDY	PIPE11 BRDY	PIPE10 BRDY	PIPE9 BRDY	PIPE8 BRDY	PIPE9 BRDY	PIPE6 BRDY	PIPE5 BRDY	PIPE4 BRDY	PIPE3 BRDY	PIPE2 BRDY	PIPE1 BRDY	PIPE0 BRDY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFBRDY	0	R/W*1	Pipe A BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEEBRDY	0	R/W*1	Pipe A BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDBRDY	0	R/W*1	Pipe A BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECBRDY	0	R/W*1	Pipe A BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBBRDY	0	R/W*1	Pipe A BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEABRDY	0	R/W*1	Pipe A BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9BRDY	0	R/W*1	Pipe 9 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
8	PIPE8BRDY	0	R/W*[1]	Pipe 8 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7BRDY	0	R/W*[1]	Pipe 7 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6BRDY	0	R/W*[1]	Pipe 6 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5BRDY	0	R/W*[1]	Pipe 5 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
4	PIPE4BRDY	0	R/W*[1]	Pipe 4 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3BRDY	0	R/W*[1]	Pipe 3 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2BRDY	0	R/W*[1]	Pipe 2 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1BRDY	0	R/W*[1]	Pipe 1 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0BRDY	0	R/W*[1]	Pipe 0 BRDY Interrupt Status*[2] 0: No interrupt is generated. 1: An interrupt is generated.

Notes: 1. To clear the status of each bit in this register when BRDYM is 0, write 0 only to bits to be cleared and write 1 to the other bits.
2. When BRDYM is 0, be sure to clear this interrupt before making an access to the FIFO.

33.3.18 NRDY Interrupt Status Register (NRDYSTS)

NRDYSTS indicates the NRDY interrupt status of each pipe.

This register is initialized by a power-on reset.

Pipe A to Pipe F are effective only when the function controller function is selected.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPE15 NRDY	PIPE14 NRDY	PIPE13 NRDY	PIPE12 NRDY	PIPE11 NRDY	PIPE10 NRDY	PIPE9 NRDY	PIPE8 NRDY	PIPE9 NRDY	PIPE6 NRDY	PIPE5 NRDY	PIPE4 NRDY	PIPE3 NRDY	PIPE2 NRDY	PIPE1 NRDY	PIPE0 NRDY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFNRDY	0	R/W*	Pipe F NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEENRDY	0	R/W*	Pipe E NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDNRDY	0	R/W*	Pipe D NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECNRDY	0	R/W*	Pipe C NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBNRDY	0	R/W*	Pipe B NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEANRDY	0	R/W*	Pipe A NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9NRDY	0	R/W*	Pipe 9 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
8	PIPE8NRDY	0	R/W*	Pipe 8 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7NRDY	0	R/W*	Pipe 7 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6NRDY	0	R/W*	Pipe 6 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5NRDY	0	R/W*	Pipe 5 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
4	PIPE4NRDY	0	R/W*	Pipe 4 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3NRDY	0	R/W*	Pipe 3 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2NRDY	0	R/W*	Pipe 2 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1NRDY	0	R/W*	Pipe 1 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0NRDY	0	R/W*	Pipe 0 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: * To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

33.3.19 BEMP Interrupt Status Register (BEMPSTS)

BEMPSTS indicates the BEMP interrupt status of each pipe.

This register is initialized by a power-on reset.

Pipe A to Pipe F are effective only when the function controller function is selected.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPE15 BEMP	PIPE14 BEMP	PIPE13 BEMP	PIPE12 BEMP	PIPE11 BEMP	PIPE10 BEMP	PIPE9 BEMP	PIPE8 BEMP	PIPE9 BEMP	PIPE6 BEMP	PIPE5 BEMP	PIPE4 BEMP	PIPE3 BEMP	PIPE2 BEMP	PIPE1 BEMP	PIPE0 BEMP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFBEMP	0	R/W*	Pipe F BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEEBEMP	0	R/W*	Pipe E BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDBEMP	0	R/W*	Pipe D BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECBEMP	0	R/W*	Pipe C BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBBEMP	0	R/W*	Pipe B BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEABEMP	0	R/W*	Pipe A BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9BEMP	0	R/W*	Pipe 9 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
8	PIPE8BEMP	0	R/W*	Pipe 8 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7BEMP	0	R/W*	Pipe 7 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6BEMP	0	R/W*	Pipe 6 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5BEMP	0	R/W*	Pipe 5 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
4	PIPE4BEMP	0	R/W*	Pipe 4 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3BEMP	0	R/W*	Pipe 3 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2BEMP	0	R/W*	Pipe 2 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1BEMP	0	R/W*	Pipe 1 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0BEMP	0	R/W*	Pipe 0 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: * To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

33.3.20 Frame Number Register (FRMNUM)

FRMNUM indicates the sources of isochronous errors and a frame number.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	OVRN	0	R/W*	Overrun/Underrun Detect Status Indicates whether an overrun or underrun error is detected or not in a pipe that is performing isochronous transfer. 0: No error is detected. 1: An error is detected. Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register. (1) When the host controller function is selected This module indicates OVRN =1 in any of the following cases. When the OUT token transmit timing comes when transmit data write to the FIFO buffer is not completed in a transmit direction pipe of isochronous transfer type When the IN token transmit timing comes with no side of the FIFO buffer empty in a receive direction pipe of isochronous transfer type (2) When the function controller function is selected This module indicates OVRN =1 in any of the following cases. When the IN token is received when transmit data write to the FIFO buffer is not completed in a transmit direction pipe of isochronous transfer type When the OUT token is received with no side of the FIFO buffer empty in a receive direction pipe of isochronous transfer type

Bit	Bit Name	Initial Value	R/W	Description
14	CRCE	0	R/W*	Receive Data Error Indicates whether a CRC error or bit stuffing error is detected or not in a pipe that is performing isochronous transfer. 0: No error is detected. 1: An error is detected. Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register. (1) When the host controller function is selected When a CRC error is detected, this module generates an internal NRDY interrupt request. (2) When the function controller function is selected When a CRC error is detected, this module does not generate an internal NRDY interrupt request.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	FRNM [10:0]	H'000	R	Frame Number This module modifies this bit at the SOF transmit timing (every 1 ms) or when an SOF is received and indicates the latest frame number. Read these bits twice and confirm that the read value is equal each time.

Note: * Only writing 0 is enabled.

33.3.21 μ Frame Number Register (UFRMNUM)

UFRMNUM indicates a μ frame number.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	UFRNM[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	UFRNM[2:0]	000	R	μ Frame Indicate a μ frame number. In high-speed operating mode, these bits indicate a μ frame number. In other operating modes, these bits indicate B'000. Read these bits twice and confirm that the read value is equal each time.

33.3.22 USB Address Register (USBADDR)

USBADDR indicates a USB address.

This register is valid only when the function controller function is selected. To set the address of a peripheral device when the host controller function is selected, use the DEVSEL bits in PIPEMAXP.

This register is initialized by a power-on reset or USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	USBADDR[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	USBADDR[6:0]	H'00	R	USB Address Indicate the USB address allocated by the host when the SET_ADRESS request is successfully processed with the function controller function selected. When this module detects a USB reset, these bits indicate H'00. When the host controller function is selected, these bits are invalid.

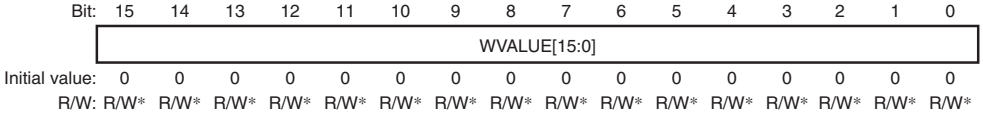
33.3.23 USB Request Type Register (USBREQ)

USBREQ stores the setup request for control transfers.

When the function controller function is selected, USBREQ stores the values of received bRequest and bmRequestType. When the host controller function is selected, USBREQ sets the values of bRequest and bmRequestType to be sent.

This register is initialized by a power-on reset or USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BREQUEST[7:0]								BMREQUESTTYPE[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*



Bit	Bit Name	Initial Value	R/W	Description
15 to 8	BREQUEST [7:0]	H'00	R/W*	Request Store the value of USB request bRequest. (1) When the host controller function is selected Set the value of USB request data of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.
7 to 0	BMREQUEST TYPE[7:0]	H'00	R/W*	Request Type Store the value of USB request bmRequestType. (1) When the host controller function is selected: Set the value of USB request data of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected: Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.

Note: * When the function controller function is selected, these are read-only bits and cannot be modified. When the host controller function is selected, these are readable/writable bits.

33.3.24 USB Request Value Register (USBVAL)

When the function controller function is selected, USBVAL stores the value of received wValue. When the host controller function is selected, USBVAL sets the value of wValue to be sent.

This register is initialized by a power-on reset or USB bus reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WVALUE [15:0]	H'0000	R/W*	Value Store the value of USB request wValue. (1) When the host controller function is selected Set the value of USB request wValue of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected Indicate the value of USB request wValue received in the SETUP transaction. These bits cannot be modified.

Note: * When the function controller function is selected, these are read-only bits and cannot be modified. When the host controller function is selected, these are readable/writable bits.

33.3.25 USB Request Index Register (USBINDX)

USBINDX stores the setup request for control transfers.

When the function controller function is selected, USBINDX stores the value of received wIndex. When the host controller function is selected, USBINDX sets the value of wIndex to be sent.

This register is initialized by a power-on reset or USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WINDEX[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WINDEX [15:0]	H'0000	R/W*	Index Store the value of USB request wIndex. (1) When the host controller function is selected Set the value of USB request wIndex of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected Indicate the value of USB request wIndex received in the SETUP transaction. These bits cannot be modified.

Note: * When the function controller function is selected, these are read-only bits and cannot be modified. When the host controller function is selected, these are readable/writable bits.

33.3.26 USB Request Length Register (USBLENG)

USBLENG stores the setup request of control transfers.

When the function controller function is selected, USBLENG stores the value of received wLength. When the host controller function is selected, USBLENG sets the value of wLength to be sent.

This register is initialized by a power-on reset or USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WLENGTH[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WLENGTH [15:0]	H'0000	R/W*	Length Store the value of USB request wLength. (1) When the host controller function is selected Set the value of USB request wLength of the SETUP transaction to be sent. Do not modify these bits when the SUREQ bit is 1. (2) When the function controller function is selected Indicate the value of USB request wLength received in the SETUP transaction. These bits cannot be modified.

Note: * When the function controller function is selected, these are read-only bits and cannot be modified. When the host controller function is selected, these are readable/writable bits.

33.3.27 DCP Configuration Register (DCPCFG)

DCPCFG specifies the data transfer direction of the default control pipe (DCP).

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	DIR	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	DIR	0	R/W	Transfer Direction Specifies the data stage and status stage transfer direction of control transfers when the host controller function is selected. 0: Data receive direction 1: Data transmit direction When the function controller function is selected, set this bit to 0.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

33.3.28 DCP Maximum Packet Size Register (DCPMAXP)

DCPMAXP specifies the maximum packet size of the DCP.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DEVSEL[3:0]				—	—	—	—	—	MXPS[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	DEVSEL [3:0]	0000	R/W	Device Select Specify the address of the peripheral device that is a remote party for control transfers when the host controller function is selected. 0000: Address 0000 0001: Address 0001 : : 1001: Address 1001 1010: Address 1010 Other than above: Setting prohibited Set DEVADDn corresponding to the value of these bits, and then set these bits. When setting DEVSEL = 0010, for example, set the address in DEVADD2. Set these bits when CSSTS = 0, PID = NAK, and the SUREQ bit is 0. To change these bits after changing the PID bits in DCP from BUF to NAK, check CSSTS = 0 and PBUSY = 0 and then change these bits. However, the software does not have to check the PBUSY bit when this module changed the PID bit to NAK. When the function controller function is selected, set these bits to B'0000.
11 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
6 to 0	MXPS [6:0]	H'40	R/W	Maximum Packet Size Set the payload of DCP data (maximum DCP packet size) in these bits. The initial value of these bits is H'40 (64 bytes). Set a value in the MXPS bits based on the USB Specification. Set the MXPS bits when CSSTS = 0, PID = NAK, and the CURPIPE bits are not set. When setting these bits to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS bits are 0 or set the PID bits to BUF.

33.3.29 DCP Control Register (DCPCTR)

DCPCTR is used to monitor the buffer memory status, change/check the data PID sequence bit, and set the response PID for a DCP.

This register is initialized by a power-on reset. The PID2 to PID0 bits in CCPL are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	SUREQ	CSCLR	CSSTS	SUREQCLR	—	—	SQCLR	SQSET	SQMON	PBUSY	PINGE	—	CCPL	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R	R/W*2	R/W*1	R	R/W*1	R	R	R/W*1	R/W*1	R	R	R/W	R	R/W*1	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	Buffer Status Indicates whether the DCP FIFO buffer is accessible or not. 0: The buffer is not accessible. 1: The buffer is accessible. This bit indicates as follows depending on the ISEL value. When ISEL = 0, this bit indicates whether the buffer is ready to read receive data. When ISEL = 1, this bit indicates whether the buffer is ready to write transmit data.

Bit	Bit Name	Initial Value	R/W	Description
14	SUREQ	0	R/W*[2]	Sending SETUP Token When the host controller function is selected, a setup packet is sent by writing 1 to this bit. 0: Invalid 1: A setup packet is sent. After processing the SETUP transaction, this module generates a SACK interrupt or SIGN interrupt and clears this bit to 0. When the SUREQCLR bit is set to 1 by the software, this module clears this bit to 0. Set this bit to 1 after setting the USB request to be sent in the SETUP transaction in the DEVSEL bits, USBREQ, USBVAL, USBINDX, and USBLENG registers. Check that PID bits in DCP are set to NAK before setting the SUREQ bit to 1. Furthermore, do not change the values of the DEVSEL bits, USBREQ, USBVAL, USBINDX, and USBLENG registers after setting this bit to 1 until the SETUP transaction is completed (while SUREQ = 1). Set this bit to 1 only when sending a SETUP token. In other cases, be sure to set this bit to 0. When the function controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
13	CSCLR	0	R/W*[1]	Split Transactions C-SPLIT Status Clear When the host controller function is selected, the CSSTS bit can be cleared to 0 by writing 1 to this bit for data transfer using split transactions. In this case, the next transfer of DCP restarts with S-SPLIT. 0: Invalid 1: Clears the CSSTS bit to 0. When this bit is set to 1 by the software, this module clears the CSSTS bit to 0. To forcibly restart the next transfer with S-SPLIT in data transfer using split transactions, set this bit to 1 by the software. Since this module automatically clears the CSSTS bit to 0 at the end of C-SPLIT in normal split transactions, the software needs not clear the CSSTS bit. Control the CSSTS bit with this bit while communication is halted by clearing the UACT bit or when it is clarified that no data transfer is performed by detection of DETACH. Even if this bit is set to 1 when CSSTS is 0, CSSTS remains 0. When the function controller function is selected, be sure to set this bit to 0.
12	CSSTS	0	R	Split Transactions COMPLETE SPLIT (C-SPLIT) Status When the host controller function is selected, the C-SPLIT status of split transactions is indicated. 0: START-SPLIT (S-SPLIT) transaction is being processed or a device that is not used in split transactions is being processed. 1: C-SPLIT transaction is being processed. This module sets this bit to 1 when starting C-SPLIT, and clears this bit to 0 when C-SPLIT end is detected. When the function controller function is selected, the read value of this bit is invalid.

Bit	Bit Name	Initial Value	R/W	Description
11	SUREQCLR	0	R/W*[1]	SUREQ Bit Clear When the host controller function is selected, the SUREQ bit can be cleared to 0 by writing 1 to this bit. 0: Invalid 1: Clears the SUREQ bit. This bit always indicates 0. When communication is halted with the SUREQ bit set to 1 in the SETUP transaction, set this bit to 1 by the software. Since this module automatically clears the SUREQ bit to 0 at the end of normal SETUP transaction, the software needs not clear the SUREQ bit. Control the SUREQ bit with this bit while communication is halted by clearing the UACT bit or when it is clarified that no data transfer is performed by detection of DETACH. When the function controller function is selected, be sure to set this bit to 0.
10, 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SQCLR	0	R/W*[1]	Toggle Bit Clear The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA0. 0: Invalid 1: The expected value is set in DATA0. This bit always indicates 0. Do not set the SQCLR and SQSET bits to 1 at the same time. Set this bit to 1 when CSCTS = 0, PID = NAK, and the CURPIPE bits are not set. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
7	SQSET	0	R/W*[1]	Toggle Bit Set The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA1. 0: Invalid 1: The expected value is set in DATA1. Do not set the SQCLR and SQSET bits to 1 at the same time. Set this bit to 1 when CSCTS = 0, PID = NAK, and the CURPIPE bits are not set. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
6	SQMON	1	R	Sequence Toggle Bit Monitor Indicates the expected value of the sequence toggle bit for the next transaction in DCP transfer. 0: DATA0 1: DATA1 When the transaction is successfully completed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled. When the function controller function is selected, this module sets this bit to 1 (sets the expected value in DATA1) when the setup packet is successfully received. When the function controller function is selected, this module does not read this bit in IN transactions or OUT transactions in the status stage.

Bit	Bit Name	Initial Value	R/W	Description
5	PBUSY	0	R	Pipe Busy Indicates whether the DCP communication state is shifted to the NAK state or not when the DCP changed the PID bits from BUF to NAK. 0: Transition to the NAC state is not completed. 1: Transition to the NAC state is completed. When this module starts the USB transaction for the corresponding pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to check whether changing the pipe setting is enabled or not.
4	PINGE	0	R/W	PING Token Output Enable When this bit is set to 1 with the host controller function selected, this module sends the PING token in the transmit direction transfer. The transmit direction transfer is started with the PING transaction. 0: Sending the PING token is disabled. 1: Normal PING operation When an ACK handshake is detected in the PING transaction, this module executes an OUT transaction for the next transaction. When a NAK handshake is detected in an OUT transaction, this module executes a PING transaction for the next transaction. When the software sets this bit to 0 with the host controller function selected, this module does not send the PING token in the transmit direction transfer. The transmit direction transfer is always performed in OUT transactions. Change this bit when CSSTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. When the function controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	CCPL	0	R/W*[1]	Control Transfer End Enable Enables the status stage end of control transfers when the function controller function is selected. 0: Invalid 1: The control transfer end is enabled. When the software sets this bit to 1 while the corresponding PID bits are set to BUF, this module finishes the control transfer stage. That is, this module sends an ACK handshake in response to OUT transactions from the USB host in the control read transfer, and sends a Zero-Length packet in response to IN transactions from the USB host in control write and no-data control transfers. However, a SET_ADDRESS request is detected, this module automatically sends responses from the SETUP stage until the end of the status stage irrespective of the setting of this bit. When this module receives the next setup packet, this module clears this bit to 0. When VALID = 1, the software cannot write 1 to this bit. When the host controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	Response PID Control responses of this module in control transfers. 00: NAK response 01: BUF response (depending on buffer state) 10: STALL response 11: STALL response (1) When the host controller function is selected Change these bits from NAK to BUF. When transmit direction is set Write all transmit data to the FIFO buffer when UACT = 1 and PID = NAK, and then set the PID bits to BUF. After BUF is set, this module executes OUT transactions (or PING transactions). When receive direction is set Check that the FIFO buffer is empty (or make it empty) when UACT = 1 and PID = NAK, and then set the PID bits to BUF. After BUF is set, this module executes IN transactions. This module modifies these bits in the following cases. When this module receives data with a size exceeding the MaxPacketSize value while these bits are set to BUF by the software, this module indicates PID = STALL (11). When this module detects a CRC error or another receive error three times in a row, this module indicates PID = NAK. When this module receives a STALL handshake, this module indicates PID = STALL (11). After this module sends S-SPLIT of split transactions for the selected pipe (indicating CSSTS = 1), this module executes the transaction until C-SPLIT is completed even if the software changed these bits to NAK. When C-SPLIT is completed, this module indicates PID = NAK.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	(2) When the function controller function is selected This module modifies these bits in the following cases. This module changes these bits to NAK upon receiving a SETUP packet. At this time, this module indicates VALID = 1. The software cannot modify these bits until the software sets VALID = 0. When this module receives data with a size exceeding the MaxPacketSize value while these bits are set to BUF by the software, this module indicates PID = STALL (11). When this module detects a control transfer sequence error, this module indicates PID = STALL (1x). When this module detects a USB bus reset, this module indicates PID = NAK. This module does not read the value of these bits during the SET_ADDRESS request processing (auto processing).

Notes: 1. These bits are always read as 0. Only writing 1 is enabled.
2. Only writing 1 is enabled.

33.3.30 Pipe Window Select Register (PIPESEL)

Make settings for pipes 1 to F (1 to 9 when the function controller function is selected) using PIPESEL, PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN.

Specify a pipe to be used with PIPESEL, and then make function settings for each pipe in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI. The PIPEnCTR, PIPnTRE, and PIPnTRN registers can be set independently from pipe selection using PIPESEL.

Not only the selected pipe but also the corresponding bits in registers for all pipes are initialized by a power-on reset or USB bus reset.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	PIPESEL [3:0]	0000	R/W	Pipe Window Select Specify a pipe number corresponding to PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI to be read or written. 0000: No pipe is selected. 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 1010: Pipe A* 1010: Pipe B* 1010: Pipe C* 1010: Pipe D* 1010: Pipe E* 1010: Pipe F* PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI corresponding to the pipe number specified by these bits can be read and written. When these bits are set to 0000, all bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI are read as 0 and cannot be modified.

Note * Pipe A to Pipe F are effective only when the function controller function is selected.

33.3.31 Pipe Configuration Register (PIPECFG)

PIPECFG specifies the transfer type, buffer memory access direction, and endpoint number for pipes 1 to F(Pipe A to Pipe F are effective only when the function controller function is selected), selects continuous transfer mode or discontinuous transfer mode, and single buffer or double buffer, and also specifies whether to disable the operation of each pipe when data transfer finishes.

This register is initialized by a power-on reset. The TYPE1 and TYPE0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TYPE[1:0]		—	—	—	BFRE	DBLB	CNT MD	SHT NAK	—	—	DIR	EPNUM[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	TYPE[1:0]	00	R/W	Transfer Type Select the transfer type of the pipe specified by the PIPESEL bits (selected pipe). Pipes 1 and 2 00: No pipe is used. 01: Bulk transfer 10: Setting prohibited 11: Isochronous transfer Pipes 3 to 5, and 9 to F when the function controller function is selected 00: No pipe is used. 01: Bulk transfer 10: Setting prohibited 11: Setting prohibited Pipes 6 to 8, and 9 when the host controller function is selected 00: No pipe is used. 01: Setting prohibited 10: Interrupt transfer 11: Setting prohibited Before setting the selected pipe for PID = BUF (before starting USB communication using the selected pipe), be sure to set these bits to a value other than 00. Modify these bits when the PID bits of the selected pipe are set to NAK. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	BFRE	0	R/W	BRDY Interrupt Operation Specifies the BRDY interrupt output timing from this module to the CPU for the selected pipe. 0: At a BRDY interrupt timing during data transmission or reception 1: At a BRDY interrupt timing after reading data When this bit is set to 1 by the software and the selected pipe is used in the receive direction, this module detects the transfer end and outputs a BRDY interrupt when the packet is completely read. When a BRDY interrupt occurs with this setting, the software must set BCLR = 1. Unless BCLR = 1 is set, the FIFO buffer allocated to the selected pipe does not enter the receive ready state. When this bit is set to 1 by the software and the selected pipe is used in the transmit direction, this module generates no BRDY interrupt. For details, see section 33.4.2 (1), BRDY Interrupt. Modify this bit when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
9	DBLB	0	R/W	Double Buffer Mode Specifies a single buffer or double buffer for the FIFO buffer used in the selected pipe. 0: Single buffer 1: Double buffer This bit is valid when pipes 1 to 5, 9 to F are selected. When this bit is set to 1 by the software, this module allocates the FIFO buffer size specified by the BUFSIZE bits in PIPEBUF to the selected pipe for two sides. Thus the size of the FIFO buffer that this module allocates to the selected pipe is as follows: (BUFSIZE + 1) * 64 * (DBLB + 1) [bytes] When this bit is set to 1 by the software and the selected pipe is used in the transmit direction, this module generates no BRDY interrupt. For details, see section 33.4.2 (1), BRDY Interrupt. Modify this bit when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
8	CNTMD	0	R/W	Continuous Transfer Mode Selects continuous transfer mode or discontinuous transfer mode to be used in communication for the selected pipe. 0: Discontinuous transfer mode 1: Continuous transfer mode This bit is valid when pipes 1 to 5 (and 9 to F when the function controller function is selected) are selected by the PIPESEL bits and bulk transfer is selected (TYPE = 01). Modify this bit when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
7	SHTNAK	0	R/W	Pipe Disable at the Time of Transfer End Specifies whether to change the setting of the PID bits to NAK at the end of transfer when the selected pipe is in the receive direction. 0: The pipe is continued at the end of transfer. 1: The pipe is disabled at the end of transfer. This bit is valid when the selected pipe is either of pipes 1 to 5 (and 9 to F when the function controller function is selected) and is in the receive direction. When the software sets this bit to 1 for a receive direction pipe, this module changes the setting of the PID bits corresponding to the selected pipe to NAK for the selected pipe when this module determines the transfer end. When the following conditions are satisfied, this module determines the transfer end. When short packet data (including a Zero-Length packet) is correctly received. When the transaction counter is used and packets with a size of the transaction counter are correctly received. Modify this bit when CSSTS = 0 and PID = NAK. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. For transmit direction pipes, set this bit to 0.
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	DIR	0	R/W	Transfer Direction Selects the transfer direction of the selected pipe. 0: Receive direction 1: Transmit direction When this bit is set to 0 by the software, this module uses the selected pipe in the receive direction. When this bit is set to 1, this module uses the selected pipe in the transmit direction. Modify this bit when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
3 to 0	EPNUM[3:0]	0000	R/W	Endpoint Number Specify the endpoint number of the selected pipe. The setting of 0000 means an unused pipe. Modify these bits when CSSTS = 0 and PID = NAK. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Set these bits so that the combination of the DIR setting and the EPNUM setting does not overlap the setting of other pipes (EPNUM = 0000 is allowed in this case.)

33.3.32 Pipe Buffer Register (PIPEBUF)

PIPEBUF specifies the buffer size and buffer number for pipes 1 to F(Pipe A to Pipe F are effective only when the function controller function is selected).

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	BUFSIZE[4:0]					—	—	BUFNMB[7:0]

R/W:	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
14 to 10	BUFSIZE [4:0]	H'00	R/W	Buffer Size Specify the buffer size of the pipe specified by the PIPESEL bits (selected pipe) in units of blocks. One block is 64 bytes. 00000 (H'00): 64 bytes 00001 (H'01): 128 bytes : : 11111 (H'1F): 2 Kbytes When DBLB = 1 is set by the software, this module allocates the FIFO buffer size specified by these bits to the selected pipe for two sides. Thus the size of the FIFO buffer that this module allocates to the selected pipe is as follows: (BUFSIZE + 1) * 64 * (DBLB + 1) [bytes] A value that can be set in these bits varies depending on pipes selected. For pipes 1 to 5 (and 9 to F when the function controller function is selected): Set BUFSIZE to H'00 to H'1F. For pipes 6 to 8 (and 9 when the host controller function is selected): Set BUFSIZE to H'00. When using the buffer with CNTMD = 1, set a value in multiples of MaxPacketSize in these bits. Modify these bits when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	BUFNMB [7:0]	H'00	R/W	Buffer Number Specify the FIFO buffer number of the selected pipe with a value from H'04 to H'87. When the selected pipe is either of pipes 1 to 5, 9 to F, these bits can be set to a value according to user systems. Set BUFNMB to H'06 to H'4F. BUFNMB = 0 to 3 are for DCP only. BUFNMB = 4 is for pipe 6 only. However, when pipe 6 is not used, this is available for other pipes. When pipe 6 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 4. BUFNMB = 5 is for pipe 7 only. However, when pipe 7 is not used, this is available for other pipes. When pipe 7 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 5. BUFNMB = 6 is for pipe 8 only. However, when pipe 8 is not used, this is available for other pipes. When pipe 8 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 6. Modify these bits when CSSTS = 0, PID = NAK, and no pipe number is set in the CURPIPE bits. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

33.3.33 Pipe Maximum Packet Size Register (PIPEMAXP)

PIPEMAXP specifies the maximum packet size for pipes 1 to F (Pipe A to Pipe F are effective only when the function controller function is selected).

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DEVSEL[3:0]				—	MXPS[10:0]										
Initial value:	0	0	0	0	0	*	*	*	*	*	*	*	*	*	*	*
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	DEVSEL[3:0]	00	R/W	Device Select Specify the USB device address of the peripheral device that is a remote party for communication when the host controller function is selected. 0000: Address 0000 0001: Address 0001 0010: Address 0010 : : 1010: Address 1010 Other than above: Setting prohibited Set these bits after setting DEVADDn (n = 0 to A) corresponding to the value of these bits. When setting DEVSEL = 0010, for example, set the address in DEVADD2. To change these bits after changing the PID bits in DCP from BUF to NAK, check CSSTS = 0 and PBUSY = 0 and then change these bits. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. When the function controller function is selected, set these bits to B'0000.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10 to 0	MXPS[10:0]	*	R/W	Maximum Packet Size Specify the payload of data (maximum packet size) of the selected pipe. The settable value range for each pipe is as follows: Pipes 1 and 2: 1 byte (H'001) to 1024 bytes (H'400) Pipes 3 to 5, and 9 to F when the function controller function is selected: 8 (H'008), 16 (H'010), 32 (H'020), 64 (H'040), or 512 bytes (H'200) (MXPS2 to MXPS0 bits are not provided.) Pipes 6 to 8, and 9 when the host controller function is selected: 1 byte (H'001) to 64 bytes (H'040) Set a value in the MXPS bits based on the USB Specification for each transfer type. To transmit an isochronous pipe in split transactions, set a value of 188 bytes or less in the MXPS bits. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS = 0 or set the PID bits to BUF.

Note: * The initial value is H'000 (when no pipe is selected by the PIPESEL bits in PIPESEL) or H'040 (when a pipe is selected).

33.3.34 Pipe Cycle Control Register (PIPEPERI)

PIPEPERI specifies whether to activate the buffer flush function or not at the time of an interval error during the isochronous IN transfer, and also specifies the interval error detection interval for pipes 1 to F (Pipe A to Pipe F are effective only when the function controller function is selected).

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	IFIS	0	R/W	Isochronous IN Buffer Flush Specifies whether to flush the FIFO buffer when the pipe specified by the PIPESEL bits (selected pipe) is isochronous IN transfer type. 0: The FIFO buffer is not flushed. 1: The FIFO buffer is flushed. Buffer flush is a function that this module automatically clears the FIFO buffer when this module does not receive IN-Token from the USB host in a (μ) frame for each interval specified in the IITV bits when the function controller function is selected and the selected pipe is isochronous IN transfer type. When double buffer is selected (DBLB = 1), this module clears data of only the older side. The FIFO buffer is cleared when an SOF packet is received immediately after the (μ) frame where IN-Token is to be received. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time when the SOF packet is to be received using the internal interpolation. When the host controller function is selected, set this bit to 0. When the selected pipe is not isochronous transfer type, set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
11 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	IITV[2:0]	000	R/W	Interval Error Detection Interval Specify the interval error detection interval of the selected pipe with a value of 2's n-th power of the frame timing. This function differs in detail between host controller function and function controller function as described later. Set these bits when CSSTS = 0, PID = NAK, and no pipe number is specified by the CURPIPE bits. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. To change the setting of these bits after USB communication, set PID = NAK and then set ACLRM = 1 to initialize the interval timer. These bits are not provided for pipes 3 to 5, and 9 to F when the function controller function is selected. Set 000 in the position of these bits corresponding to pipes 3 to 5, and 9 to F when the function controller function is selected.

33.3.35 Pipe n Control Register (PIPEnCTR) (n = 1 to F (Pipe A to Pipe F are effective only when the function controller function is selected.))

PIPEnCTR monitors the buffer memory status, changes/checks the data PID sequence bits, selects whether to use auto-response mode and buffer auto-clear mode, and specifies a response PID for pipes 1 to F(Pipe A to Pipe F are effective only when the function controller function is selected). This register can be set independently of the pipe selection using PIPESEL.

This register is initialized by a power-on reset. The PID1 and PID0 bits are also initialized by a USB bus reset.

(1) PIPEnCTR (n = 1 to 5, and 9 to F when the function controller function is selected)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	INBUFM	CSCLR	CSSTS	—	ATREPM	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W*2	R	R	R/W	R/W	R/W*1	R/W*1	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	Buffer Status Indicates the FIFO buffer status of the pipe. 0: The buffer is not accessible from the CPU. 1: The buffer is accessible from the CPU. The meaning of this bit differs depending on the settings of the DIR, BFRE, and DCLRM bits as shown in Table 33.9.

Bit	Bit Name	Initial Value	R/W	Description
14	INBUFM	0	R	Transmit Buffer Monitor Indicates the FIFO buffer status of the selected pipe in the transmit direction. 0: The buffer memory contains no transmittable data. 1: The buffer memory contains transmittable data. When transmit direction (DIR = 1) is set for the pipe, this module sets this bit to 1 when the software (or DMAC) finishes writing data to the FIFO buffer for at least one register set. When this module finishes sending all data on the register set (writing is completed) of the FIFO buffer, this bit indicates 0. In the case of a double buffer (DBLB = 1), when this module finishes sending all data on both register sets and the software (or DMAC) has not completed writing of data for one register set, this bit indicates 0. When receive direction (DIR = 0) is set for the selected pipe, this bit indicates the same value as the BSTS bit.

Bit	Bit Name	Initial Value	R/W	Description
13	CSCLR	0	R/W*[2]	CSPLIT Status Clear When the software sets this bit to 1 with the host controller function selected, this module clears the CSSTS bit to 0. 0: Invalid 1: Clears the CSSTS bit to 0. To forcibly restart the next transfer with S-SPLIT in data transfer using split transactions, set this bit to 1 by the software. Since this module automatically clears the CSSTS bit to 0 at the end of C-SPLIT in normal split transactions, the software needs not clear the CSSTS bit. Clear the CSSTS bit with this bit while communication is halted by clearing the UACT bit or when it is clarified that no data transfer is performed by detection of Detach mode. Even if this bit is set to 1 when CSSTS is 0, CSSTS remains 0. When the function controller function is selected, be sure to set this bit to 0.
12	CSSTS	0	R	CSSTS Status When the host controller function is selected, this bit indicates the C-SPLIT status of split transactions. 0: START-SPLIT (S-SPLIT) transaction is being processed or no split transaction is used. 1: C-SPLIT transaction is being processed. This module sets this bit to 1 when starting C-SPLIT, and clears this bit to 0 when C-SPLIT end is detected. The value of this bit is valid only when the host controller function is selected.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	ATREPM	0	R/W	Auto-Response Mode Enables or disables auto-response for the selected pipe. 0: Auto-response is disabled. 1: Auto-response is enabled. When the function controller function is selected and the transfer type of the selected pipe is set to bulk transfer, this bit can be set to 1. When this bit is 1, this module sends responses to tokens from the USB host as follows: (1) When the selected pipe is set for Bulk-IN transfer (TYPE = 01 and DIR = 1) When ATREPM = 1 and PID = BUF, this module sends a Zero-Length packet in response to the IN-Token. Each time this module receives ACK from the USB host (flow of one transaction: receiving IN-Token -> sending Zero Length packet -> receiving ACK), this module updates the sequence toggle bit (DATA-PID) by toggling it. No BRDY interrupt or BEMP interrupt is generated. (2) When the selected pipe is set for Bulk-OUT transfer (TYPE = 01 and DIR = 0) When ATREPM = 1 and PID = BUF, this module sends NAK in response to the OUT-Token (or PING-Token) and generates an NRDY interrupt. Modify this bit when CSSTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Be sure to set this bit to 1 for USB communication when the FIFO buffer is empty. Do not write data to the FIFO buffer during USB communication with this bit set to 1. When the selected pipe is set for isochronous transfer, be sure to set this bit to 0. When the host controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
9	ACLRM	0	R/W	Buffer Auto-Clear Mode Enables or disables buffer auto-clear mode for the selected pipe. 0: Buffer auto-clear mode is disabled. 1: Buffer auto-clear mode is enabled. (All buffers are initialized.) To completely delete the data in the FIFO buffer allocated to the pipe, write 1 and then 0 continuously to the ACLRM bit. Table 33.10 shows data cleared by this module when this bit is set to 1 and then 0 and cases where such data is cleared. Modify this bit when CSSTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
8	SQCLR	0	R/W*[1]	Toggle Bit Clear Set this bit to 1 to clear the expected value (in DATA0) of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is cleared in DATA0. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA0. This module always indicates SQCLR = 0. When this bit is set to 1 for a Bulk-Out transfer pipe with the host controller function selected, this module starts the next transfer with the PING-token for the pipe. Set the SQCLR bit to 1 when CSCTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
7	SQSET	0	R/W*[1]	Toggle Bit Set Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is set in DATA1. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA1. This module always indicates SQSET = 0. Set the SQSET bit to 1 when CSCTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
6	SQMON	0	R	Toggle Bit Check Indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: DATA0 1: DATA1 If the pipe is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.
5	PBUSY	0	R	Pipe Busy Indicates whether the pipe is currently used in the USB bus or not. 0: The selected pipe is not used in the USB bus. 1: The selected pipe is being used in the USB bus. When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.
4 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	Response PID Specify a response used in the next transaction for the selected pipe. 00: NAK response 01: BUF response (depending on buffer state) 10: STALL response 11: STALL response These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Tables 33.11 and 33.12 show the basic operation (with no error in packets) of this module in each setting of the PID bits. When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the pipe entered the NAK state. However, when this module changed these bits to NAK, the software does not have to check the PBUSY bit. This module modifies these bits in the following cases. • When the pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end. • When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11). • When this module detects a USB bus reset with the function control function selected, this module indicates PID = NAK. • When this module detects a CRC error or another receive error three times in a row with the host control function selected, this module indicates PID = NAK. • When this module receives a STALL handshake with the host control function selected, this module indicates PID = STALL (11). Set these bits as follows: • To change the state from NAK (00) to STALL, write 10. • To change the state from BUF (01) to STALL, write 11. • To change the state from STALL (11) to NAK, write 10 then 00. • To change the state from STALL to BUF, set these bits to NAK and then to BUF.

Notes: 1. Only reading 0 and writing 1 are enabled.
2. Only writing 1 is enabled.

Table 33.9 Operations of BSTS Bit

DIR Bit	BFRE Bit	DCLRM Bit	Meaning of BSTS Bit
0	0	0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
		1	Setting prohibited
	1	0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 when the software sets BCLR = 1 after the buffer data read.
		1	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
1	0	0	Indicates 1 when the FIFO buffer becomes ready to write transmit data to the buffer, and indicates 0 upon completion of the data write.
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

Table 33.10 Data Cleared by This Module when ACLRM = 1

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer (both sides for double FIFO buffer) allocated to the pipe	
2	Interval count value when the pipe is isochronous transfer type	When resetting the interval count value
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	FIFO buffer toggle control	When changing the DBLB setting
5	Internal flags related to the transaction count	When forcibly terminating the transaction count function

Table 33.11 Operations of This Module in Each Setting of PID Bits (when the Host Controller Function is Selected)

PID Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of This Module
00 (NAK)	Independent of the setting	Independent of the setting	Issues no token.
01 (BUF)	Bulk or interrupt	Independent of the setting	Issues tokens when UACT = 1 is set and the FIFO buffer for the pipe is ready to receive/transmit. Issues no token when UACT = 0 is set or the FIFO buffer is not ready to receive/transmit.
	Isochronous	Independent of the setting	Issues tokens irrespective of the state of the FIFO buffer for the pipe.
10 (STALL) or 11 (STALL)	Independent of the setting	Independent of the setting	Issues no token.

Table 33.12 Operations of This Module in Each Setting of PID Bits (when the Function Controller Function is Selected)

PID Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of This Module
00 (NAK)	Bulk or interrupt	Independent of the setting	Sends a NAK response to a token from the USB host. However, for the operation of this module when ATREPM = 1, see the description on the ATREPM bit.
	Isochronous	Independent of the setting	Sends no response to a token from the USB host.
01 (BUF)	Bulk	Receive direction (DIR = 0)	Receives data and sends an ACK response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, sends a NAK response. Sends an ACK response to the PING token from the USB host when the FIFO buffer for the selected pipe is ready to receive. Otherwise, sends a NYET response.
	Interrupt	Receive direction (DIR = 0)	Receives data and sends an ACK response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, sends a NAK response.
	Bulk or interrupt	Transmit direction (DIR = 1)	Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a NAK response.
	Isochronous	Receive direction (DIR = 0)	Receives data in response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, ignores the data.
		Transmit direction (DIR = 1)	Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a Zero-Length packet.
10 (STALL) or	Bulk or interrupt	Independent of the setting	Sends a STALL response to a token from the USB host.
11 (STALL)	Isochronous	Independent of the setting	Sends no response to a token from the USB host.

(2) PIPEnCTR (n = 6 to 8 , 9 when the host controller function is selected)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	Buffer Status Indicates the state of the FIFO buffer of the selected pipe. 0: The buffer is not accessible. 1: The buffer is accessible. The meaning of this bit differs as shown in Table 33.9 depending on the settings of the DIR, BFRE, and DCLRM bits.
14	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
13	CSCLR	0	R/W*1	CSPLIT Status Clear Setting this bit to 1 clears the CSSTS bit of the selected pipe. 0: Invalid 1: Clears the CSSTS bit. To forcibly restart the next transfer with S-SPLIT in data transfer using split transactions, set this bit to 1 by the software. Since this module automatically clears the CSSTS bit to 0 at the end of C-SPLIT in normal split transactions, the software does not have to clear the CSSTS bit. Control the CSSTS bit with this bit while communication is halted by clearing the UACT bit or when it is clarified that no data transfer is performed by detection of Detach mode. Even if this bit is set to 1 when CSSTS is 0, CSSTS remains 0. When the function controller function is selected, be sure to set this bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
12	CSSTS	0	R/W	When the host controller function is selected, this bit indicates the C-SPLIT status of split transactions. 0: START-SPLIT (S-SPLIT) transaction is being processed or the transaction is transferred without split transaction. 1: C-SPLIT transaction is being processed. This module sets this bit to 1 when starting C-SPLIT, and clears this bit to 0 when C-SPLIT end is detected. When the function controller function is selected, the read value of this bit is invalid. This bit is valid only when the host controller function is selected.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	ACLRM	0	R/W	Buffer Auto-Clear Mode*3*4 Enables or disables buffer auto-clear mode for the selected pipe. 0: Buffer auto-clear mode is disabled. 1: Buffer auto-clear mode is enabled. (All buffers are initialized.) To completely delete the data in the FIFO buffer allocated to the pipe, write 1 and then 0 continuously to the ACLRM bit. Table 33.13 shows data cleared by this module when this bit is set to 1 and then 0 and cases where such data is cleared. Modify this bit when CSSTS = 0, PID = NAK, and the pipe is not set in the CURPIPE bits. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
8	SQCLR	0	R/W*[1]	Toggle Bit Clear*[3]*[4] Set this bit to 1 to clear the expected value (in DATA0) of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is cleared in DATA0. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA0. This module always indicates SQCLR = 0. When this bit is set to 1 for a Bulk-Out transfer pipe with the host controller function selected, this module starts the next transfer with the PING-token for the pipe. Set the SQCLR bit to 1 when CSCTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
7	SQSET	0	R/W*[1]	Toggle Bit Set*[3]*[4] Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is set in DATA1. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the selected pipe in DATA1. This module always indicates SQSET = 0. Set the SQSET bit to 1 when CSCTS = 0 and PID = NAK. When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
6	SQMON	0	R	Toggle Bit Check Indicates the expected value of the sequence toggle bit for the next transaction of the pipe. 0: DATA0 1: DATA1 If the selected pipe that is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.
5	PBUSY	0	R	Pipe Busy Indicates whether the selected pipe is currently used in the USB bus or not. 0: The selected pipe is not used in the USB bus. 1: The selected pipe is being used in the USB bus. When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.
4 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	Response PID Specify a response used in the next transaction for the selected pipe. 00: NAK response 01: BUF response (depending on buffer state) 10: STALL response 11: STALL response These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Tables 33.13 and 33.14 show the basic operation (with no error in packets) of this module in each setting of the PID bits. When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the selected pipe entered the NAK state. However, when this module changed these bits to NAK, the software needs not check the PBUSY bit. This module modifies these bits in the following cases. • When the selected pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end. • When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11). • When this module detects a USB bus reset with the function control function selected, this module indicates PID = NAK. • When this module detects a CRC error or another receive error three times in a row with the host control function selected, this module indicates PID = NAK. • When this module receives a STALL handshake with the host control function selected, this module indicates PID = STALL (11). Set these bits as follows: • To change the state from NAK (00) to STALL, write 10. • To change the state from BUF (01) to STALL, write 11. • To change the state from STALL (11) to NAK, write 10 then 00. • To change the state from STALL to BUF, set these bits to NAK and then to BUF.

Notes: 1. Only reading 0 and writing 1 are enabled.
2. Only writing 1 is enabled.
3. Set the ACLRM, SQCLR, or SQSET bit when CSSTS = 0, PID = NAK, and the selected pipe is not set in the CURPIPE bits.
4. When setting the ACLRM, SQCLR, or SQSET bit after changing the PID bits from BUF to NAK, check that CSSTS = 0 and PBUSY = 0 for the pipe. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Table 33.13 Data Cleared by This Module when ACLRM = 1

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer allocated to the selected pipe	
2	Interval count value when the host controller function is selected and the selected pipe is interrupt transfer type	When resetting the interval count value
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	Internal flags related to the transaction count	When forcibly terminating the transaction count function

33.3.36 Pipe n Transaction Counter Enable Register (PIPnTRE) (n = 1 to 5, and 9 to F when the function controller function is selected)

PIPnTRE enables or disables the transaction counter function and clears the counter for pipes 1 to 5, and 9 to F when the function controller function is selected.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	TRENB	0	R/W	Transaction Counter Enable Enables or disables the transaction counter function. 0: The transaction counter function is disabled. 1: The transaction counter function is enabled. When the software sets the number of total packets in the TRNCNT bits in PIPEnTRN for the receive pipe and then sets this bit to 1, this module controls the following when it received the same number of packets as the setting of the TRNCNT bits. When continuous communication mode is used (CNTMD = 1), this module toggles the received data to the CPU even if the FIFO buffer is not full at the end of reception. When SHTNAK = 1, this module changes the PID bits for the corresponding pipe to NAK when this module received the same number of packets as the setting of the TRNCNT bits. When BFRE = 1, this module asserts the BRDY interrupt when this module received the same number of packets as the setting of the TRNCNT bits and read the receeive data completely. For transmit pipes, set this bit to 0. When the transaction counter function is not used, set this bit to 0. When using the transaction counter function, set the TRNCNT bits and then set this bit to 1. Furthermore, set this bit to 1 before receiving the first packet that is included in the transaction count range.
8	TRCLR	0	R/W	Transaction Counter Clear Clears the current count value of the transaction counter for the pipe and indicates TRCLR = 0. 0: Invalid 1: The current count value is cleared.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: Change the bits in this register when CSSTS = 0 and PID = NAK.
When changing the bits in this register after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

33.3.37 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5, and 9 to F when the function controller function is selected)

PIPnTRE is a transaction counter for pipes 1 to 5, and 9 to F when the function controller function is selected.

This register is initialized by a power-on reset, but the setting of this register is retained through a USB bus reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TRNCNT [15:0]	All 0	R/W	Transaction Counter Writing: Specify the number of transactions of DMA transfer. Reading: When TRENB = 0, the set number of transactions is indicated. When TRENB = 1, the number of current transactions is indicated. This module increments (+1) the value of these bits when the following conditions are all satisfied. TRENB = 1 TRCNT value ≠ current count value +1 when a packet is received. The payload of the received packet equals the value of the MXPS bits. This module clears these bits to 0 when any of the following is satisfied. When the following conditions are all satisfied - TRENB = 1 - TRCNT value = current count value +1 when a packet is received. - The payload of the received packet equals the value of the MXPS bits. When the following conditions are all satisfied - TRENB = 1 - A short packet is received. When the following conditions are all satisfied - TRENB = 1 - The software sets the TRCLR bit to 1.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TRNCNT [15:0]	All 0	R/W	For transmit pipes, set these bits to all 0. When the transaction counter function is not used, set these bits to all 0. Change these bits when CSSTS = 0, PID = NAK, and TRENB = 0. When setting these bits to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. When changing these bits, set TRCNT = 1 and then set TRENB = 1.

33.3.38 Device Address n Configuration Register (DEVADDn) (n = 0 to A)

DEVADDn specifies the address and port number of the HUB connected to a peripheral device as a communication target, as well as the transfer rate of the peripheral device, for pipes 0 to 9, and A to F when the function controller function is selected.

When the host controller function is selected, be sure to set the bits in this register before starting communication for each pipe.

Change the bits in this register when there is no valid pipe that uses the setting of these bits. A valid pipe is defined as a pipe that meets the following two conditions.

1. The setting of the DEVSEL bits specifies this register.
2. The PID bits for the selected pipe are set to BUF or the selected pipe is the DCP with SUREQ = 1

This register is initialized by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 11	UPPHUB [3:0]	0000	R/W	HUB Register Specify the USB address of the HUB connected to the peripheral device as a communication target. 0000: The peripheral device is connected directly to the port of this LSI. 0001 to 1010: USB address of the HUB 1011 to 1111: Setting prohibited When the host controller function is selected, this module reads these bits to generate packets when executing split transactions. When the function controller function is selected, set these bits to 0000.

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	HUBPORT [2:0]	000	R/W	HUB Port for Communication Target Device Specify the port number of the HUB connected to the peripheral device as a communication target. 000: The peripheral device is connected directly to the port of this LSI. 001 to 111: Port number of the HUB When the host controller function is selected, this module reads these bits to generate packets when executing split transactions. When the function controller function is selected, set these bits to 000.
7, 6	USBSPD [1:0]	00	R/W	Communication Target Device Transfer Rate Specify the USB transfer rate of the peripheral device as a communication target. 00: DEVADDn is not used. 01: Low speed 10: Full speed 11: High speed When the host controller function is selected, this module reads these bits to generate packets. When the function controller function is selected, set these bits to 00.
5 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

33.4 Operation

33.4.1 System Control and Oscillation Control

This section describes register operations required for the initial settings of this module and the registers required for the power consumption control.

(1) Reset

Table 33.14 lists the reset types of this module. For initialization states of registers after each reset, see section 33.3, Register Descriptions.

Table 33.14 Reset Types

Reset Name	Operation
Power-on reset	RESETP pin
AP system reset	RESETA pin
Power area reset	Register in the SYSC
Software reset	Register in the CPGA

(2) Setting Selection of Controller Functions

This module can select the host controller function or the function controller function. Select either of these functions by the DCFM bit in SYSCFG. Set the DCFM bit during the initial setting immediately after a power-on reset or in the D+ pull-up disabled state (DPRPU = 0) and D+/D- pull-down disabled state (DRPD = 0).

(3) Enabling High-Speed Operation

This module can set the USB transmission rate (communication bit rate) by the software.

When the host controller function is selected, high-speed operation or full-speed/low-speed operation is selectable. When the function controller function is selected, high-speed operation or full-speed operation is selectable. To enable high-speed operation with this module, set the HSE bit in SYSCFG to 1. When high-speed operation is enabled, this module executes the reset handshake protocol and automatically sets the USB transmission rate. The reset handshake result can be checked by the RHST bits in DVSTCTR.

When high-speed operation is disabled, this module operates in full speed or low speed when the host controller function is selected, and operates only in full speed when the function controller function is selected.

When the host controller function is selected, change the HSE bit during a period from ATTACH detection until a bus reset. When the host controller function is selected, change the HSE bit in the D+ pull-up disabled state (DPRPU = 0).

(4) USB Data Bus Resistor Control

Figure 33.1 shows the connection between this module and the USB connector.

This module incorporates a pull-up resistor of the D+ signal and pull-down resistors of the D+ and D- signals. Specify pull-up and pull-down for each signal using the DPRPU and DRPD bits in SYSCFG.

Furthermore, this module controls the terminating resistors of the D+ and D- signals in high-speed operation, and the output resistors in full-speed operation. This module automatically switches the on-chip resistors after connection to the host controller or the peripheral device upon detecting a reset handshake, suspended state, or resume.

When the function controller function is selected and the DPRPU bit in SYSCFG is set to 0 during communication with the host controller, this module disables the pull-up resistors (or terminating resistors) of the USB data line. Therefore, the USB host can be notified of a disconnection from the device.

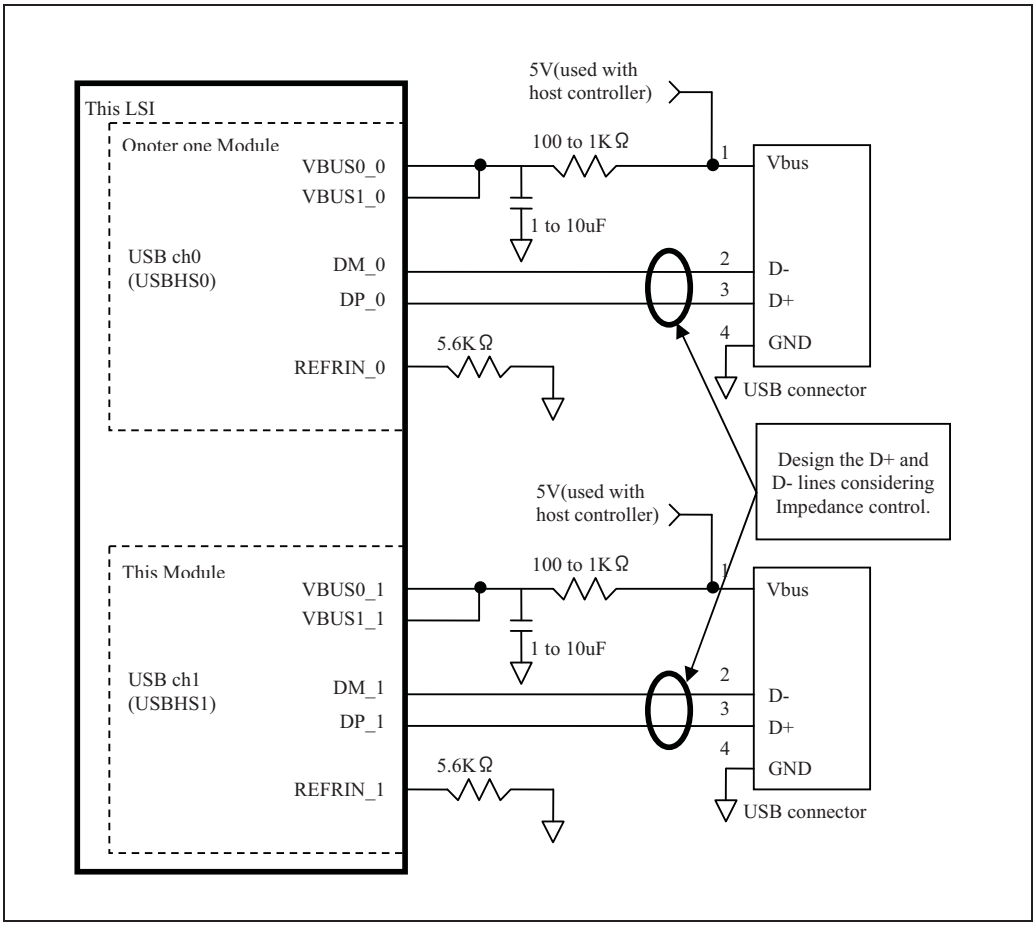

Figure 33.1 Connection to the USB Connector

(5) Software reset when the USB disconnection is detected

Issue a software reset of the USBHS module when the USB disconnection is detected. If the DMA interface is being used, issue a software reset of the USBHS-DMAC module as well. A software reset can be issued via a register in the CPGA.

Whether or not the USB disconnection is detected can be determined by the VBSTS in the INTSTS0 register when the function controller function is selected or the DTCH bit in the INTSTS1 register when the host controller function is selected.

33.4.2 Interrupt Function

Table 33.15 lists the interrupt generating conditions of this module.

When any of the following interrupt generating conditions are satisfied and the interrupt output is enabled by the corresponding interrupt enable register, this module outputs a USB interrupt request to the interrupt controller (INTC).

Table 33.15 Interrupt Generating Conditions

Bit	Interrupt Name	Interrupt Generating Conditions	Function	Related Status
VBINT	VBUS interrupt	When VBUS0_1 and VBUS1_1 input pin state change is detected (both L to H and H to L)	Host and function controller functions	VBSTS
RESM	Resume interrupt	When a USB bus state change is detected in the suspended state (J-State to K-State or J-State to SE0)	Function	—
SOFR	Frame number update interrupt	[When the host controller function is selected] When an SOF packet with a different frame number is sent [When the function controller function is selected] SOFRM = 0: When an SOF packet with a different frame number is received SOFRM = 1: When an SOF packet with a μ frame number of 0 cannot be received due to damage, etc.	Host and function controller functions	—
DVST	Device state transition interrupt	When a device state transition is detected USB bus reset detected Suspended state detected SET_ADDRESS request received SET_CONFIGURATION request received	Function	DVSQ

Bit	Interrupt Name	Interrupt Generating Conditions	Function	Related Status
CTRT	Control transfer stage transition interrupt	When a control transfer stage transition is detected	Function	CTSQ
		Setup stage completed		
		Control write transfer status stage shifted		
		Control read transfer status stage shifted		
		Control transfer completed		
		Control transfer sequence error occurred		
BEMP	Buffer empty interrupt	When the buffer becomes empty after sending all buffer memory data	Host and function controller functions	BEMPSTS.PIPEBEMP
		When a packet with a size exceeding the maximum packet size is received		
NRDY	Buffer not ready interrupt	[When the host controller function is selected]	Host and function controller functions	NRDYSTS.PIPENRDY
		When STALL from the peripheral device in response to the issued token is received		
		When a response from the peripheral device in response to the issued token cannot be received successfully (no response three times in a row or a packet receive error three times in a row)		
		When an overrun or underrun error occurred during isochronous transfer		
		[When the function controller function is selected]		
		When NAK is sent in response to IN token, OUTtoken, or PING token		
		When a CRC error or bit stuffing error occurred during data reception in isochronous transfer		
		When an overrun or underrun error occurred during data reception in isochronous transfer		

Bit	Interrupt Name	Interrupt Generating Conditions	Function	Related Status
BRDY	Buffer ready interrupt	When the buffer becomes ready for reading or writing	Host and function controller functions	BRDYSTS. PIPEBRDY
OVRCR	OVRCR interrupt	When an OVCN_1/OVCN2_1 input pin state change is detected	Host and function controller functions	OVCMON
BCHG	Bus change interrupt	When a USB bus state change is detected	Host and function controller functions	—
DTCH	Disconnection in full-speed operation	When a disconnection from the peripheral device is detected during full-speed operation	Host controller function	—
ATTCH	Device connection	When J-STATE or K-STATE where USB bus state continues for 2.5 μs is detected This interrupt is available for detection of connection to a peripheral device.	Host controller function	—
EOFERR	EOF error	When an EOF error of the peripheral device is detected	Host controller function	—
SACK	SETUP	When an ACK response to the setup transaction is received	Host controller function	—
SIGN	SETUP error	When an error (no response or ACK packet damage) is detected three times in a row in the setup transaction	Host controller function	—

Note: These bits in this table are those of INTSTS0 if any register's name is not indicated.

Figure 33.2 shows a block diagram of the interrupt circuit of this module.

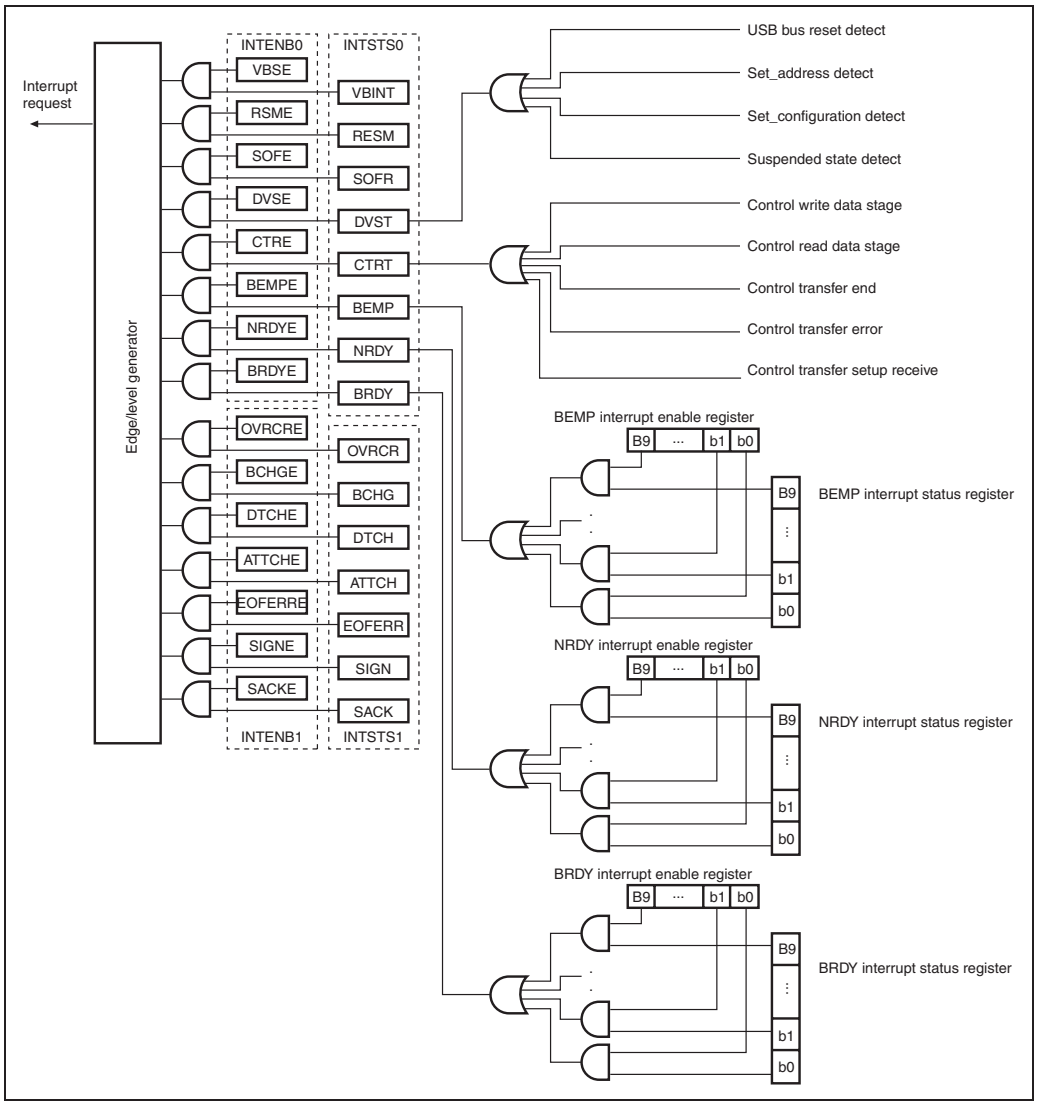

Figure 33.2 Block Diagram of Interrupt Circuit

(1) BRDY Interrupt

A BRDY interrupt can be generated when either of the host controller function and function controller functions is selected. When the following conditions in each pipe are satisfied, this module sets the corresponding bit in BRDYSTS to 1. At this time, when the PIPEBRDYE bit for the pipe in BRDYENB is set to 1 and the BRDYE bit in INTENB0 is set to 1 by the software, this module generates a BRDY interrupt.

BRDY interrupt generating conditions and clearing method depend on the settings of the BRDYM bit and the BFRE bit for each pipe.

(a) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified

With this setting, a BRDY interrupt indicates that the FIFO port is accessible.

This module generates an internal BRDY interrupt request trigger when the following conditions are satisfied, and sets the PIPEBRDY bit corresponding to the request trigger pipe to 1.

1. Pipes set for the transmit direction

- When the software changes the DIR bit from 0 to 1
- When this module finishes sending a packet of the pipe while data write from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)

  When continuous communication mode is selected, this module generates a BRDY interrupt request trigger upon completion of sending data for one side of the FIFO buffer.
- When a double FIFO buffer is specified and one side of the FIFO buffer is empty when data write to the other side of the FIFO buffer is completed

  Even if one side of the FIFO buffer becomes empty while the other side is in data write processing, no BRDY interrupt is generated until the ongoing data write finishes.
- When this module generates a buffer flush for a pipe of isochronous transfer type
- When the FIFO buffer becomes write enable state by writing 1 to the ACLRM bit

No BRDY interrupt request trigger is generated for the DCP (in data transmission of control transfer).

2. Pipes set for the receive direction

- When this module receives a packet successfully and the FIFO buffer becomes ready for reading while data read access from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)

  No BRDY interrupt request trigger is generated in transactions with incorrect data PID.

  When continuous communication mode is selected, no BRDY interrupt request trigger is generated for packets with a MaxPacketSize data size and when the FIFO buffer still has available space.

  When this module receives a short packet, this module generates a BRDY interrupt request trigger even if the buffer has available space.

  When a transaction counter is used, this module generates a BRDY interrupt request trigger when this module receives a packet with a size of the set value even if the FIFO buffer still has available space.

  When a double FIFO buffer is specified and one side of the FIFO buffer is ready for reading when data read from the other side of the FIFO buffer is completed

  Even if data read for one side of the FIFO buffer is completed while the other side is undergoing data read, no BRDY interrupt request trigger is generated until the ongoing data read finishes.

This interrupt is not generated in communication in the control transfer status stage when the function controller function is selected.

The software can clear the PIPEBRDY interrupt status of the pipe by writing 0 to the PIPEBRDY bit for the pipe in BRDYSTS. At this time, write 1 to the bits corresponding to other pipes.

Be sure to clear the BRDY interrupt status before accessing the FIFO buffer.

(b) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 1) at the end of data read are specified

With this setting, this module determines that a **BRDY** interrupt is generated upon completion of reading all data of one transfer in a receive pipe, and sets the bit for the pipe in this register to 1.

This module determines that the last data of a transfer was received in either of the following cases.

- A Zero-Length packet or another short packet is received.
- A transaction counter (TRNCNT bits) is used and a packet with a size of the value of the TRNCNT bits is received.

When either of these conditions is satisfied and the data read is completed, this module determines that reading all data for one transfer is completed.

When this module receives a Zero-Length packet with the FIFO buffer empty, this module determines that reading all data for one transfer is completed when the Zero-Length packet data is toggled to the CPU. In this case, write 1 to the BCLR bit in the corresponding FIFOCTR register by the software to start the next transfer.

With this setting, this module generates no BRDY interrupt for transmit pipes.

The software can clear the PIPEBRDY interrupt status of the pipe to 0 by writing 0 to the PIPEBRDY bit for the pipe. At this time, write 1 to the bits corresponding to other pipes.

When using this mode, do not change the BFRE setting until the processing for one transfer is completed.

To change the BFRE bit during processing, clear all FIFO buffers for the pipe by the ACLRM bit.

(c) When BRDY interrupt enable (BRDYM = 1) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified

With this setting, the value of the PIPEBRDY bit varies with the value of the **BSTS** bit for each pipe. That is, this module indicates 1 or 0 of the BRDY interrupt status according to the FIFO buffer status.

1. Pipes set for the transmit direction
   When the FIFO port is ready to write data, the PIPEBRDY bit indicates 1. When the FIFO port is not ready to write data, the PIPEBRDY bit indicates 0.
   However, even if the transmit pipe of the DCP is ready to write data, no BRDY interrupt is asserted.
2. Pipes set for the receive direction
   When the FIFO port is ready to read data, the PIPEBRDY bit indicates 1. When all data is read from the FIFO port (reading disabled), the PIPEBRDY bit indicates 0.
   When this module receives a Zero-Length packet with the FIFO buffer empty, this module indicates 1 with the corresponding bit until 1 is written to BCLR by the software, and continues to assert the BRDY interrupt.

   With this setting, the software cannot clear the PIPEBRDY bit to 0.
   When BRDYM = 1, set the BFRE bit to 0 for all pipes.

Figure 33.3 shows the BRDY interrupt generation timing.

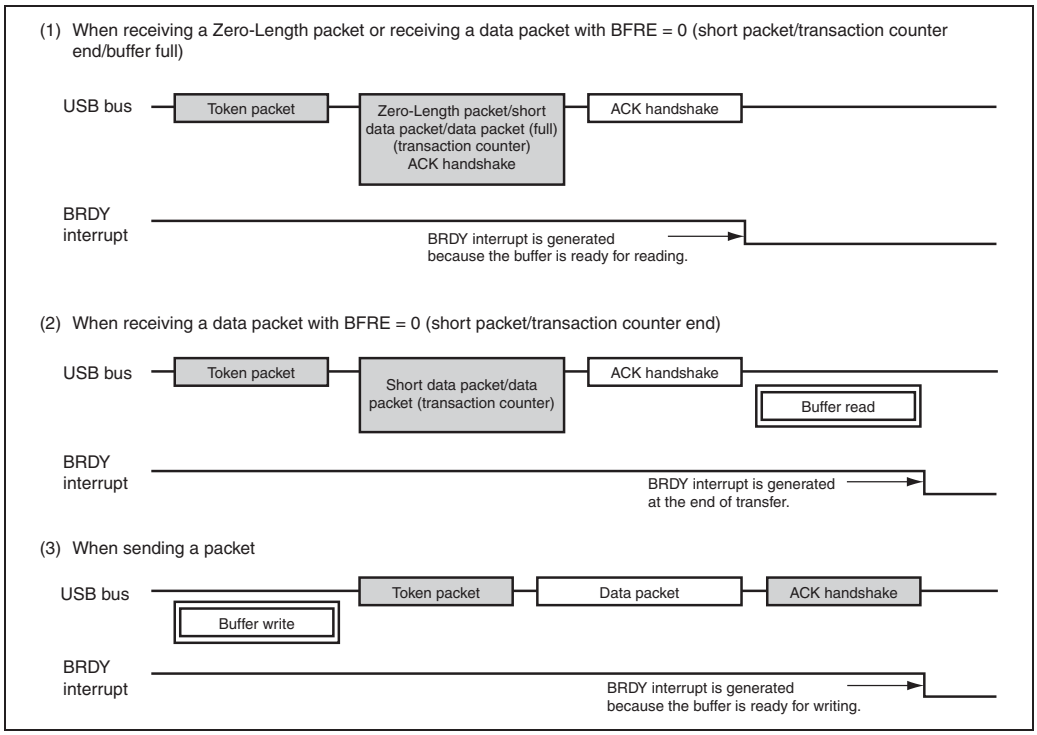

Figure 33.3 BRDY Interrupt Generation Timing

(2) NRDY Interrupt

When this module generates an internal NRDY interrupt request for the pipe in which PID = BUF is set by the software, this module indicates PIPENRDY = 1 for the pipe in NRDYSTS. At this time, when 1 is set in the corresponding bit in NRDYENB by the software, this module indicates NRDY = 1 in INTSTS0 and generates a USB interrupt.

The following shows the conditions for this module to generate an internal NRDY interrupt request for a pipe.

However, the execution of the SETUP transaction when the host controller function is selected is excluded from the following interrupt generation conditions. In the SETUP transaction when the host controller function is selected, this module detects an SACK interrupt or SIGN interrupt.

Furthermore, when executing the control transfer status stage with the function controller function selected, this module generates no interrupt request.

(a) When the host controller function is selected and no split transaction occurs

1. Pipes in the transmit direction

   This module detects an NRDY interrupt when either of the following conditions is satisfied.

   — When the OUT token transmit timing comes with no transmit data in the FIFO buffer in an isochronous transfer-type pipe

   At this time, this module sends a Zero-Length packet following the OUT token, and then indicates PIPENRDY = 1 for the pipe and OVRN = 1.

   — In communication other than SETUP transaction for a pipe of other than isochronous transfer type, when no response from the peripheral device (timeout is detected without detecting a handshake packet from the peripheral device) or an error in a packet from the peripheral device occurred three times in a row in an arbitrary combination

   At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to NAK.

   — When this module receives a STALL handshake from the peripheral device in communication other than the SETUP transaction (including STALL to PING as well as STALL to OUT)

   At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to STALL (11).

2. Pipes in the receive direction
   — When the IN token transmit timing comes with the FIFO buffer occupied in an isochronous transfer-type pipe

     At this time, this module ignores the receive data in response to the IN Token and indicates PIPENRDY = 1 for the pipe and OVRN = 1.

     Furthermore, when a packet error is detected in the receive data in response to the IN Token, this module also indicates CRCE = 1.

     In communication for a pipe of other than isochronous transfer type, when no response from the peripheral device to the IN token sent from this module (timeout is detected without detecting a data packet from the peripheral device) or an error in a packet from the peripheral device occurred three times in a row in an arbitrary combination

     At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to NAK.

     In communication for an isochronous transfer-type pipe, when this module receives no response from the peripheral device to the IN token sent from this module (timeout is detected without detecting a data packet from the peripheral device) or an error in a packet from the peripheral device is detected

     At this time, this module indicates PIPENRDY = 1 for the pipe but does not change the PID bits for the pipe.
   — In communication for an isochronous transfer-type pipe, when a CRC error or a bit stuffing error is detected in the received data packet

     At this time, this module indicates PIPENRDY = 1 for the pipe and CRCE = 1.
   — When this module receives a STALL handshake

     At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to STALL.

(b) When the host controller function is selected and split transactions occur

1. Pipes in the transmit direction
   — When the OUT token transmit timing comes with no transmit data in the FIFO buffer in an isochronous transfer-type pipe

     At this time, this module indicates PIPENRDY = 1 for the pipe and OVRN = 1 when it sends the Start-Split transaction (S-SPLIT). This module also sends a Zero-Length packet following the OUT token.
   — In the S-SPLIT or Complete-Sprit transaction (C-SPLIT) for a pipe of other than isochronous transfer type, when no response from the HUB (timeout is detected without detecting a handshake packet from the HUB) or an error in a packet from the HUB occurred three times in a row in an arbitrary combination

At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to NAK.

When this module detects an NRDY interrupt when sending C-SPLIT, this module clears the CSSTS bit to 0.

— When this module receives a STALL handshake in response to C-SPLIT

At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to STALL (11). This module also clears the CSSTS bit to 0.

However, this interrupt is not detected in the SETUP transaction.

— When this module receives NYET in response to C-SPLIT with microFrame = 4 in an interrupt transfer-type pipe

— At this time, this module indicates PIPENRDY = 1 for the pipe and clears the CSSTS bit to 0 but does not change the PID bits for the pipe.

2. Pipes in the receive direction

— When the IN token transmit timing comes with the FIFO buffer occupied in an isochronous transfer-type pipe

At this time, this module indicates PIPENRDY = 1 for the pipe and OVRN = 1 when it sends S-SPLIT. This module also ignores the receive data in response to the IN token.

— In a transfer for a bulk transfer-type pipe or in a transfer other than the SETUP transaction of the DCP, when no response from the HUB in response to the IN token from this module when sending S-SPLIT or C-SPLIT (timeout is detected without detecting a handshake packet from the HUB) or an error in a packet from the HUB occurred three times in a row in an arbitrary combination

At this time, this module indicates PIPENRDY = 1 for the pipe and changes the PID bits for the pipe to NAK. When this condition is generated in the C-SPLIT transaction, this module clears the CSSTS bit to 0.

— In the C-SPLIT transaction for a pipe of isochronous or interrupt type, when no response from the HUB in response to the IN token from this module (timeout is detected without detecting a data packet from the HUB) or an error in a packet from the HUB occurred three times in a row in an arbitrary combination

When this condition is generated in an interrupt transfer-type pipe, this module indicates PIPENRDY = 1 for the pipe, changes the PID bits for the pipe to NAK, and clears the CSSTS bit to 0.

When this condition is generated in an isochronous transfer-type pipe, this module indicates PIPENRDY = 1 for the pipe and CRCE = 1 and clears the CSSTS to 0, bit to 0 but does not change the PID bits for the pipe.

— When this module receives a STALL handshake response during the C-SPLIT transaction in a pipe of other than isochronous transfer type

At this time, this module indicates PIPENRDY = 1 for the pipe, changes the PID bits for the pipe to STALL (11), and clears the CSSTS bit to 0.

— When this module receives a NYET in response to C-SPLIT with microFrame = 4 in a pipe of isochronous or interrupt transfer type

At this time, this module indicates PIPENRDY = 1 for the pipe and CRCE = 1 and clears the CSSTS bit to 0, but does not change the PID bits for the pipe.

(c) When the function controller function is selected

1. Pipes in the transmit direction

— When this module receives an IN token with no transmit data in the FIFO buffer

This module generates an NRDY interrupt request and indicates PIPENRDY = 1.

When the pipe in which the interrupt is generated is isochronous transfer type, this module sends a Zero-Length packet and indicates OVRN = 1.

2. Pipes in the receive direction pipe

— When this module receives an OUT token with the FIFO buffer occupied

When the pipe in which the interrupt is generated is isochronous transfer type, this module generates an NRDY interrupt request when this module receives an OUT token, and indicates PIPENRDY = 1 and OVRN = 1.

When the pipe in which the interrupt is generated is not isochroous transfer type, this module generates an NRDY interrupt request when this module sends an NAK handshake response after receiving data following the OUT token, and indicates PIPENRDY = 1.

However, this module generates no NRDY interrupt when resending data (in the case of DATA-PID mismatch) or when an error occurs in a data packet.

— When this module receives a PING token with the FIFO buffer occupied

This module generates an NRDY interrupt request when this module receives a PING token and indicates PIPENRDY = 1.

— When a packet is not received correctly within the interval frame in an isochroous transfer-type pipe

This module generates an NRDY interrupt request when this module receives SOF and indicates PIPENRDY = 1.

Figure 33.4 shows the NRDY interrupt generation timing when the function controller function is selected.

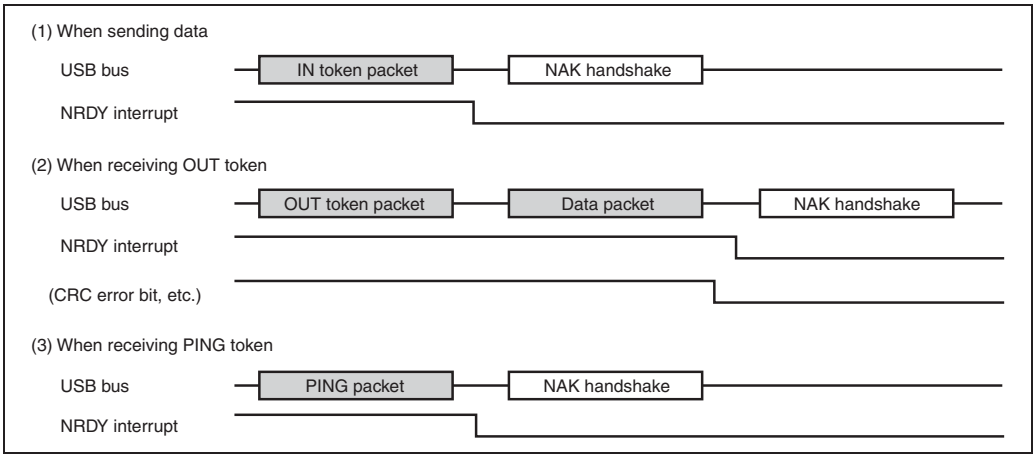

Figure 33.4 NRDY Interrupt Generation Timing when the Function Controller Function is Selected

(3) BEMP Interrupt

When this module detects a BEMP interrupt for the pipe in which PID = BUF is set by the software, this module indicates PIPEBEMP = 1 for the pipe in BEMPSTS. At this time, when 1 is set in the corresponding bit in BEMPENB by the software, this module indicates BEMP = 1 in INTSTS0 and generates a USB interrupt.

This module generates an internal BEMP interrupt request in the following cases.

1. Transmit direction pipes

   When the FIFO buffer for the pipe is empty at the end of transmission (including transmission of a Zero-Length packet)

   When single buffer is set for the FIFO buffer, this module generates an internal BEMP interrupt request concurrently with a BRDY interrupt for pipes other than DCP.
   However, this module generates no internal BEMP interrupt request in the following cases.

   — In the case of double buffer, when the software (DMAC) already started writing data to the FIFO buffer of the CPU at the end of transmission for one-side data
   — When the buffer is cleared (empty) by writing 1 to the ACLRM or BCLR bit.
   — When sending a Zero-Length packet (IN transfer) of the control transfer status stage when the function controller function is selected

2. Receive direction pipes

   When this module receives a packet with a data size exceeding the MaxPacketSize value

   In this case, this module generates a BEMP interrupt request and indicates the PIPEBEMP = 1 for the pipe, ignores the received data, and changes the PID bits for the pipe to STALL (11).

   At this time, this module sends no response when the host controller function is selected, and sends a STALL response when the function controller function is selected.

   However, this module generates no BEMP interrupt request in the following cases.

   — When this module detects a CRC error or bit stuffing error in the receive data

   — When executing the SETUP transaction

   Writing 0 to the PIPEBEMP bits clears the status.

   Writing 0 to the PIPEBEMP bits has no effect on the operation of this module.

Figure 33.5 shows the BEMP interrupt generation timing when the function controller function is selected.

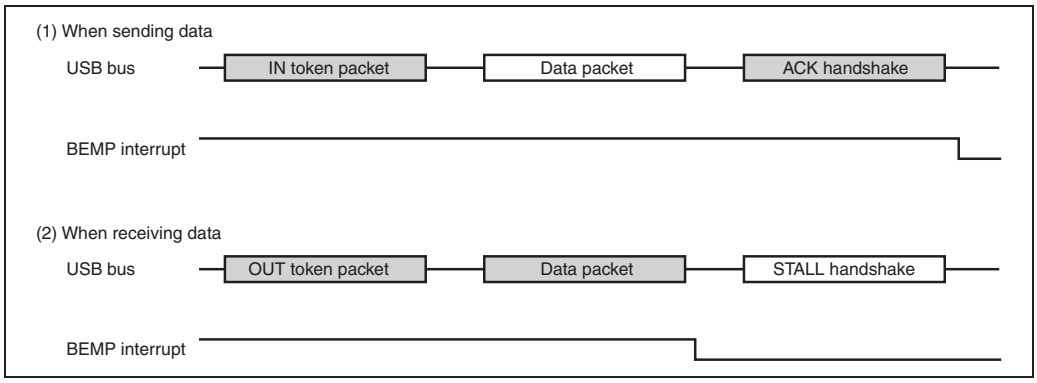

Figure 33.5 BEMP Interrupt Generation Timing when the Function Controller Function is Selected

(4) Device State Transition Interrupt

Figure 33.6 shows the device state transitions of this module. This module controls device states and generates device state transition interrupts. However, when returning from the suspended state (detecting the resume signal), this module detects the transition with a resume interrupt. The device state transition interrupt is enabled or disabled by setting INTENB0. The current device state can be monitored using the DVSQ bits in INTSTS0.

When this module shifts to the default state, a device state transition interrupt occurs after executing the reset handshake protocol.

This module controls the device states only when the function controller function is selected. In addition, device state transition interrupts are generated only when the function controller function is selected.

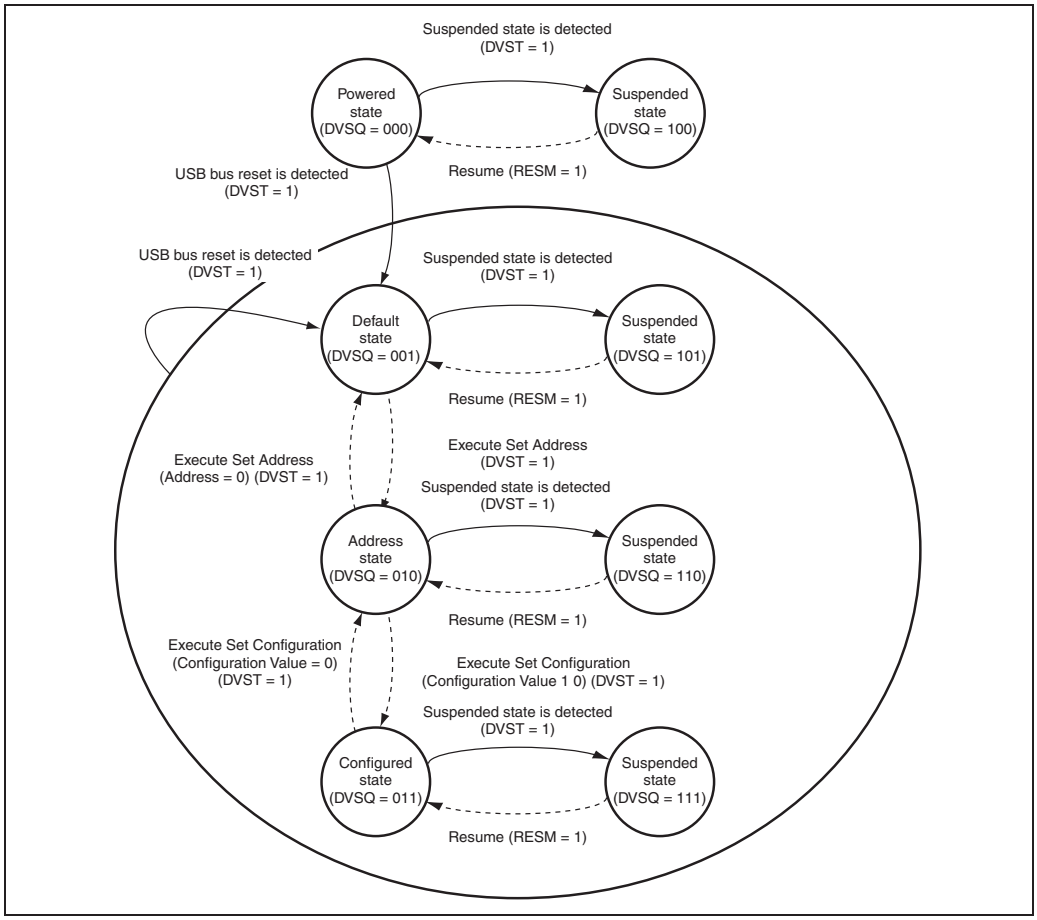

Figure 33.6 Device State Transitions

(5) Control Transfer Stage Transition Interrupt

Figure 33.7 shows control transfer stage transitions of this module. This module manages the sequence of control transfers and generates control transfer stage transition interrupts. Enabling or disabling each control transfer stage transition interrupt can be set by INTENB0. The current transfer stage after transition can be checked by the CTSQ bits in INTSTS0.

Control transfer stage transition interrupts are generated only when the function controller function is selected.

The following describes control transfer sequence errors. When an error occurs, the PID bits in DCPCTR indicate B'1x (STALL response).

1. Control read transfer
   - This module receives an OUT or PING token in response to the IN token in the data stage before starting data transfer.
   - This module receives an IN token in the status stage.
   - This module receives a packet with a data packet of DATAPID = DATA0 in the status stage.
2. Control write transfer
   - This module receives an IN token in response to the OUT token in the data stage before sending an ACK response.
   - This module receives a packet with the first data packet of DATAPID = DATA0.
   - This module receives an OUT or PING token in the status stage.
3. Control write no-data control transfer
   - This module receives an OUT or PING token in the status stage.

If the size of the receive data exceeds the wLength value of the USB request in the control write transfer data stage, this is not treated as a control transfer sequence error. This module sends ACK for normal end in response to a packet other than Zero-Length packet in the control read transfer status stage.

When a CTRT interrupt is generated (SERR = 1) due to a sequence error, CTSQ = 110 is retained until the interrupt status is cleared (CTRT = 0) by the system. For this reason, while CTSQ = 110, even if a new USB request is received, a CTRT interrupt at the end of the setup stage is not generated. (This module retains the setup stage end status and generates a setup stage end interrupt after the interrupt status is cleared by the software.)

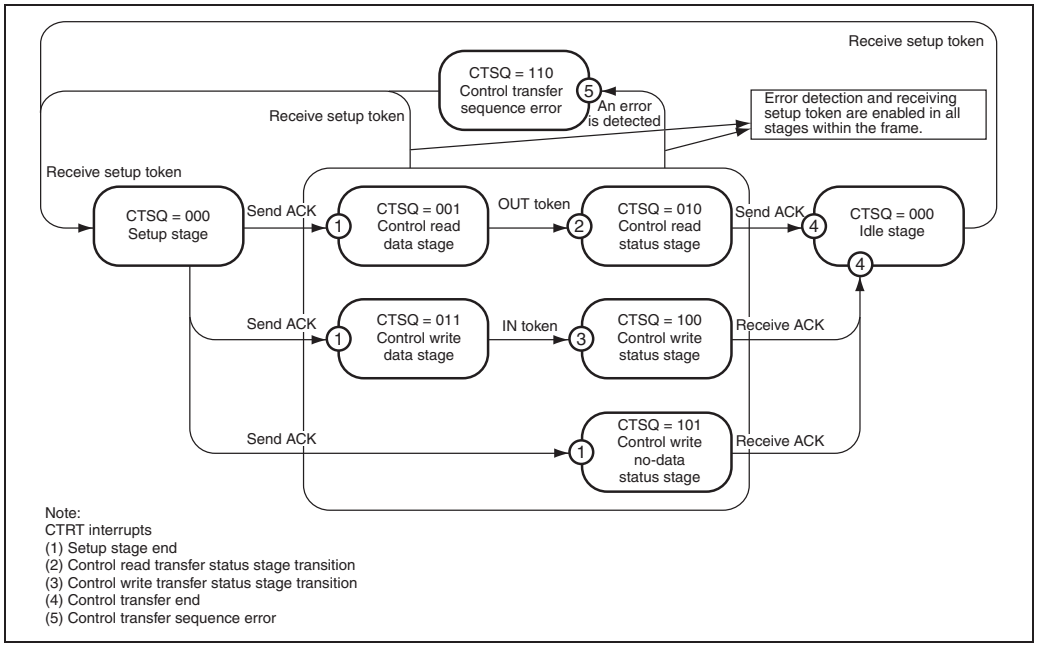

Figure 33.7 Control Transfer Stage Transitions

(6) Frame Update Interrupt

Figure 33.8 shows an example of the SOFR interrupt output timing of this module.

When the host controller function is selected, an SOFR interrupt is generated at the frame number update timing. When the function controller function is selected, an SOFR interrupt is generated immediately after the frame number is updated.

When this module detects a new SOF packet during the full-speed operation with the function controller function selected, this module updates the frame number and generates an SOFR interrupt. In the high-speed operation, however, the frame number is not updated or no SOFR interrupt is generated unless the module enters the μ SOF lock state. Furthermore, the SOF interpolation function is not activated. The μ SOF lock state occurs when this module receives a μ SOF packet twice in a row with different frame numbers without an error.

The μ SOF lock monitoring start and stop conditions are as follows:

1. µ SOF lock monitoring start conditions
   USBE = 1
2. µ SOF lock monitoring stop conditions
   USBE = 0, receiving USB bus reset, or detection of suspended state

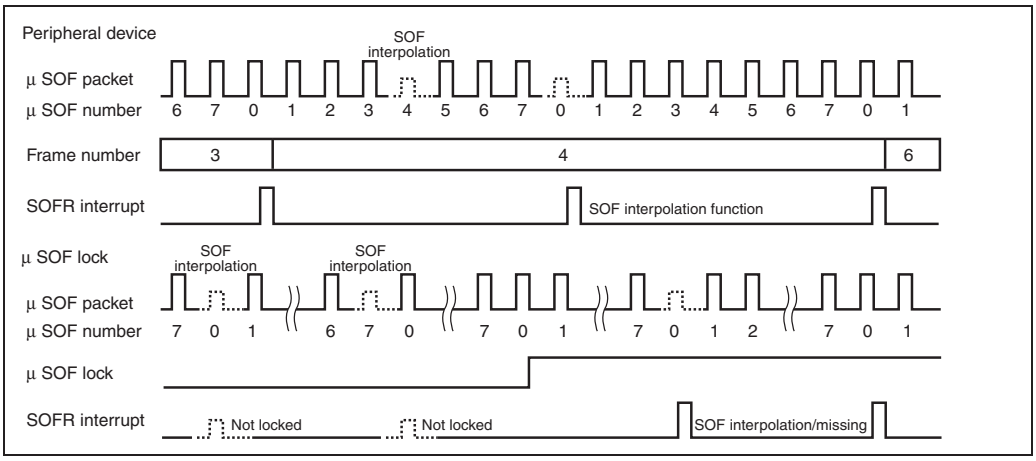

Figure 33.8 Example of SOFR Interrupt Output Timing

(7) VBUS Interrupt

When the VBUS pin state changes, a VBUS interrupt is generated. The VBUS pin level can be checked by the VBSTS bit in INTSTS0. The VBUS interrupt is used to check connection or disconnection to/from the host controller. However, when the system starts up with the host controller connected, the VBUS pin state remains unchanged, and therefore the first VBUS interrupt is not generated.

(8) Resume Interrupt

When the function controller function is selected and the USB bus state changes (J-State to K-State or J-State to SE0) with the device state suspended, a resume interrupt is generated. The resume interrupt is used to detect the return from the suspended state.

When the host controller function is selected, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

(9) BCHG Interrupt

When the USB bus state changes, a BCHG interrupt is generated. This interrupt is used to detect connection to a peripheral device and to detect remote wakeup when the host controller function is selected. This interrupt occurs when either of the host controller function or function controller function is selected.

(10) DTCH Interrupt

When a disconnection of the USB bus is detected with the host controller function selected, a DTCH interrupt is generated. This module detects a bus disconnection conforming to the USB Specification 2.0.

After detecting a DTCH interrupt, this module performs the following hardware control irrespective of the setting of the corresponding interrupt enable bit. The software must terminate the communication of all pipes with the port and drive this module into the state of waiting for connection to the port (ATTCH interrupt is generated).

- Change the UACT bit of the port that detected the DTCH interrupt to 0 and indicate UACT.
- Drive the port where the DTCH interrupt occurred into the idle state.

(11) SACK Interrupt

When this module receives ACK from the peripheral device in response to the transmitted setup packet with the host controller function selected, a SACK interrupt is generated. This interrupt indicates that a setup transaction is successfully completed.

(12) SIGN Interrupt

When this module cannot receive ACK successfully from the peripheral device in response to the transmitted setup packet three times in a row with the host controller function selected, a SIGN interrupt is generated. This interrupt is used to detect no ACK response from the peripheral device or ACK packet damage.

(13) ATTCH Interrupt

When J-State or K-State of the full-speed/low-speed signal level is detected for 2.5 μs in the USB port with the host controller function selected, an ATTCH interrupt is generated. This interrupt is detected in either of the following cases.

- When the signal level changed from K-State, SE0 or SE1 to J-State, and remains in J-State for 2.5 μs
- When the signal level changed from J-State, SE0 or SE1 to K-State, and remains in K-State for 2.5 μs

(14) EOFERR Interrupt

When this module detects that communication is not completed at the EOF2 timing specified in the USB Specification 2.0, an EOFERR interrupt is generated.

After detecting an EOFERR interrupt, this module performs the following hardware control irrespective of the setting of the corresponding interrupt enable bit. The software must terminate the communication of all pipes with the port and perform reenumeration for the port.

- Change the UACT bit of the port that detected the EOFERR interrupt to 0 and indicate UACT.
- Drive the port where the EOFERR interrupt occurred into the idle state.

33.4.3 Pipe Control

Table 33.16 lists the pipe settings of this module. In the USB data transfer, data must be transmitted or received using virtual pipes called “endpoint.” This module is provided with ten pipes for data transfer. Set each pipe according to system specifications.

Table 33.16 Pipe Settings

For when the host controller function is selected

Register Name	Bit Name	Setting	Remarks
DCPCFG	TYPE	Transfer type	Pipes 1 to 9: Setting allowed
PIPECFG	BFRE	BRDY interrupt mode	Pipes 1 to 5: Setting allowed
	DBLB	Double buffer	Pipes 1 to 5: Setting allowed
	CNTMD	Continuous transfer or discontinuous transfer	Pipes 1, 2: Setting allowed only when bulk transfer is selected Pipes 3 to 5: Setting allowed
	DIR	Transfer direction	IN or OUT selectable
	EPNUM	Endpoint number	Pipes 1 to 9: Setting allowed Set a value other than 0000 when using pipes
	SHTNAK	Disabling pipes at the end of transfer	Pipes 1, 2: Setting allowed only when bulk transfer is selected Pipes 3 to 5: Setting allowed
PIPEBUF	BUFSIZE	Buffer memory size	DCP: Setting disallowed (256 bytes fixed) Pipes 1 to 5: Setting allowed (up to 2 Kbytes) Pipes 6 to 9: Setting disallowed (64 bytes fixed)
	BUFNMB	Buffer memory number	DCP: Setting disallowed (H'0 to H'3 fixed) Pipes 1 to 5: Setting allowed (H'8 to H'7F) Pipes 6 to 9: Setting disallowed (H'4 to H'7 fixed)
DCPMAXP PIPEMAXP	DEVSEL	Device select	Checked only when the host controller functions selected.
	MXPS	Maximum packet size	Setting conforming to the USB Specification

Register Name	Bit Name	Setting	Remarks
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to 5: Setting disallowed Pipes 6 to 9 Setting allowed only when the host control function is selected
	IITV	Interval counter	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to 5: Setting disallowed Pipes 6 to 9 Setting allowed only when the host control function is selected
DCPCTR PIPEnCTR	BSTS	Buffer status	For DCP, receive buffer status and transmit buffer status are switched by the ISEL bit.
	INBUFM	IN buffer monitor	Provided only for pipes 3 to 5.
	SUREQ	SETUP request	Setting allowed for DCP only Controlled only when the host controller function is selected.
	SUREQCLR	SUREQ clear	Setting allowed for DCP only Controlled only when the host controller function is selected.
	CSCLR	CSSTS clear	Controlled only when the host controller function is selected.
	CSSTS	SPLIT status	Monitored only when the host controller function is selected.
	ATREPM	Auto-response mode	Pipes 1 to 5 setting allowed only when the function controller function is selected.
	ACLRM	Buffer auto-clear	Pipes 1 to 9 Setting allowed
	SQCLR	Sequence clear	Data toggle bit clear
	SQSET	Sequence setting	Data toggle bit setting
	SQMON	Sequence check	Data toggle bit check
	PBUSY	Pipe busy check	
	PID	Response PID	See section 33.4.3 (6), Response PID.

Register Name	Bit Name	Setting	Remarks
PIPEnTRE	TRENB	Transaction count enable	Pipes 1 to 5: Setting allowed
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Setting allowed
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5: Setting allowed

For when the function controller function is selected

Register Name	Bit Name	Setting	Remarks
DCPCFG	TYPE	Transfer type	Pipes 1 to F: Setting allowed
PIPECFG	BFRE	BRDY interrupt mode	Pipes 1 to 5, 9 to F: Setting allowed
	DBLB	Double buffer	Pipes 1 to 5, 9 to F: Setting allowed
	CNTMD	Continuous transfer or discontinuous transfer	Pipes 1, 2: Setting allowed only when bulk transfer is selected Pipes 3 to 5, 9 to F: Setting allowed
	DIR	Transfer direction	IN or OUT selectable
	EPNUM	Endpoint number	Pipes 1 to F: Setting allowed Set a value other than 0000 when using pipes
	SHTNAK	Disabling pipes at the end of transfer	Pipes 1, 2: Setting allowed only when bulk transfer is selected Pipes 3 to 5, 9 to F: Setting allowed
PIPEBUF	BUFSIZE	Buffer memory size	DCP: Setting disallowed (256 bytes fixed) Pipes 1 to 5, 9 to F: Setting allowed (up to 2 Kbytes) Pipes 6 to 8: Setting disallowed (64 bytes fixed)
	BUFNMB	Buffer memory number	DCP: Setting disallowed (H'0 to H'3 fixed) Pipes 1 to 5, 9 to F: Setting allowed (H'8 to H'7F) Pipes 6 to 8: Setting disallowed (H'4 to H'7 fixed)
DCPMAXP PIPEMAXP	DEVSEL	Device select	Checked only when the host controller functions selected.
	MXPS	Maximum packet size	Setting conforming to the USB Specification

Register Name	Bit Name	Setting	Remarks
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to 5, 9 to F: Setting disallowed Pipes 6 to 8 Setting allowed only when the host control function is selected
	IITV	Interval counter	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to 5, 9 to F: Setting disallowed Pipes 6 to 8 Setting allowed only when the host control function is selected
DCPCTR PIPEnCTR	BSTS	Buffer status	For DCP, receive buffer status and transmit buffer status are switched by the ISEL bit.
	INBUFM	IN buffer monitor	Provided only for pipes 3 to 5, 9 to F.
	SUREQ	SETUP request	Setting allowed for DCP only Controlled only when the host controller function is selected.
	SUREQCLR	SUREQ clear	Setting allowed for DCP only Controlled only when the host controller function is selected.
	CSCLR	CSSTS clear	Controlled only when the host controller function is selected.
	CSSTS	SPLIT status	Monitored only when the host controller function is selected.
	ATREPM	Auto-response mode	Pipes 1 to 5, 9 to F etting allowed only when the function controller function is selected.
	ACLRM	Buffer auto-clear	Pipes 1 to F Setting allowed
	SQCLR	Sequence clear	Data toggle bit clear
	SQSET	Sequence setting	Data toggle bit setting
	SQMON	Sequence check	Data toggle bit check
	PBUSY	Pipe busy check	
	PID	Response PID	See section 33.4.3 (6), Response PID.

Register Name	Bit Name	Setting	Remarks
PIPEnTRE	TRENB	Transaction count enable	Pipes 1 to 5, 9 to F: Setting allowed
	TRCLR	Current transaction counter clear	Pipes 1 to 5, 9 to F: Setting allowed
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5, 9 to F: Setting allowed

(1) Pipe Control Registers Switching Procedure

The following bits in the pipe control registers can be modified only when USB communication is set to disabled (PID = NAK).

Bits/registers that cannot be modified when USB communication is set to enabled (PID = BUF)

- Each bit in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPExCTR
- Each bit in PIPExTRE and PIPExTRN

When changing these bits from the state where USB communication is enabled (PID = BUF), follow the steps below.

1. Generate a pipe control register bit change request.
2. Change the PID bits for the pipe to NAK.
3. Wait until the CSSTS bit for the pipe is cleared to 0 (only when the host controller function is selected).
4. Wait until the PBUSY bit for the pipe is cleared to 0.
5. Change the bits in the pipe control registers.

The following bits in the pipe control registers can be modified only for pipe information that is not set in any of the CURPIPE bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Bits/registers that cannot be modified while the CURPIPE bits in FIFO-PORT are being set

- Each bit in DCPCFG and DCPMAXP
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI

Before changing the pipe information, set the CURPIPE bits to a pipe other than that to be changed. For the DCP, clear the buffer by the BCLR bit after modifying the pipe information.

(2) Transfer Type

Specify the transfer type of each pipe by the TYPE bits in PIPEPCFG as follows:

- DCP: Setting is not required (fixed to control transfer).
- Pipes 1, 2: Set bulk transfer or isochronous transfer.

When host controller function is selected:

- Pipes 3 to 5: Set bulk transfer.
- Pipes 6 to 9 Set interrupt transfer.

When function controller function is selected:

- Pipes 3 to 5, 9 to F: Set bulk transfer.
- Pipes 6 to 8 Set interrupt transfer.

(3) Endpoint Number

Specify the endpoint number of each pipe by the EPNUM bits in PIPEPCFG. The endpoint number of the DCP is always 0. For other pipes, endpoint 1 to endpoint 15 are selectable.

- DCP: Setting is not required (fixed to endpoint 0).
- Pipes 1 to 9 Set an endpoint number by selecting a number 1 to 9 when host controller function is selected.
- Pipes 1 to F Set an endpoint number by selecting a number 1 to 15 when function controller function is selected.

  However, set an endpoint number so that combinations of the DIR bit and the EPNUM bits do not overlap.

(4) Maximum Packet Size

Specify the maximum packet size of each pipe by the MXPS bits in DCPMAXP and PIPEMAXP. For the DCP and pipes 1 to 5, and 9 to F when function controller function is selected, any of the maximum packet sizes defined in the USB Specification can be set. For pipes 6 to 8, and 9 when host controller function is selected, a maximum packet size up to 64 bytes can be set. Specify a maximum packet size as follows before starting transfer (PID = BUF):

- DCP: Set 64 for high-speed operation.
- DCP: Set 8, 16, 32, or 64 for full-speed operation.

- Pipes 1 to 5, and 9 to F when function controller function is selected: Set 512 for high-speed bulk transfer.
- Pipes 1 to 5, and 9 to F when function controller function is selected: Set 8, 16, 32, or 64 for full-speed bulk transfer.
- Pipes 1, 2: Set a value from 1 to 1024 for high-speed isochronous transfer.
- Pipes 1, 2: Set a value from 1 to 1023 for full-speed isochronous transfer.
- Pipes 6 to 8, 9 and when function controller function is selected, set a value from 1 to 64.

High Bandwidth in interrupt and isochronous transfers is not supported.

(5) Transaction Counter (Pipes 1 to 5, and 9 to F when function controller function is selected : Read Direction)

When the specified number of transactions with data packet in the receive direction are completed, this module recognizes this as a transfer end. The transaction counter works when the pipe selected for the D0FIFO and D1FIFO ports is set for the data read (from the buffer memory) direction. The transaction counter is provided with the TRNCNT register to specify the number of transactions and the current counter to count transactions internally. When the current counter reaches the specified value, the buffer memory becomes ready for reading. The current counter of the transaction counter function can be initialized by the TRCLR bit to count transactions again from the beginning. The TRNCNT read data varies depending on the TRENB setting.

- TRENB = 0: The set transaction counter value is read.
- TRENB = 1: The internally counted current counter value is read.
- Change the CURPIPE bits according to the following.
- Do not change the CURPIPE bits until the transaction for the specified pipe finishes.
- Change the CURPIPE bits when the current counter is cleared.
- Control the TRCLR bit according to the following.
- Do not clear the current counter during transaction count and PID = BUF.
- Do not clear the current counter while data is remaining in the buffer.

(6) Response PID

Specify the response PID for each pipe by the PID bits in DCPCTR and PIPEnCTR.

This module operates as follows according to the response PID setting.

1. Setting the response PID when the host controller function is selected
   The response PID specifies the execution of transactions.
   — NAK setting: Pipes are disabled and no transaction is executed.
   — BUF setting: Transactions are executed according to the buffer memory status.
   When the buffer memory contains transmit data in the OUT direction, this module sends an OUT token.
   When the buffer memory has available space and is ready to receive data in the IN direction, this module sends an IN token.
   — STALL setting: Pipes are disabled and no transaction is executed.

Note: The DCP setup transaction is set by the SUREQ bit.

2. Setting the response PID when the function controller function is selected
   The response PID specifies a response to transactions from the host.
   — NAK setting: NAK is always sent in response to a transaction.
   — BUF setting: A response is sent to a transaction according to the buffer memory status.
   — STALL setting: STALL is always sent in response to a transaction.

Note: This module always sends ACK in response to a setup transaction irrespective of the PID setting, and stores a USB request in the register.

This module modifies the PID bits in the following cases depending on transaction results.

3. When the response PID is set by the hardware with the host controller function selected
   — NAK setting: This module sets PID = NAK and automatically stops sending tokens.
- When an NRDY interrupt is generated in a transfer other than isochronous transfer
- (For details, see 33.4.2(2) NRDY Interrupt.)
- When this module receives a short packet with the SHTNAK bit in PIPECFG set to 1 in the bulk transfer
- When the SHTNAK bit is set to 1 in the bulk transfer and the transaction counter stops counting
  — BUF setting: This module does not set the PID bits to BUF.
  — STALL setting: This module sets PID = STALL in the following cases and automatically stops sending tokens.
- When this module receives STALL in response to the transmitted token
- When the size of the received data packet is larger than the maximum packet size

4. When the response PID is set by the hardware with the function controller function selected
   — NAK setting: This module sets PID to NAK in the following cases and always sends NAK in response to a transaction.
- When a SETUP token is successfully received (DCP only)
- When the SHTNAK bit in PIPECFG is set to 1 in a bulk transfer and the transaction counter stops counting or this module receives a short packet
  — BUF setting: This module does not set the PID bits to BUF.
  — STALL setting: This module sets PID to STALL in the following cases and always sends STALL in response to a transaction.
- When a maximum packet size exceeded error is detected in a receive data packet
- When a control transfer sequence error is detected (DCP only)

(7) Data PID Sequence Bit

When data is successfully transferred in the control transfer data stage, bulk transfer, or interrupt transfer, this module automatically toggles the data PID sequence bit. The sequence bit of the data PID transmitted next can be monitored by the SQMON bit in DCPCTR and PIPEnCTR. In a data transmission period, the sequence bit switches at the ACK handshake receive timing. In a data reception period, the sequence bit switches at the ACK handshake transmit timing. The data PID sequence bit can also be changed by the SQCLR and SQSET bits in DCPCTR and PIPEnCTR.

In control transfers when the function controller function is selected, this module automatically sets the sequence bit during a stage transition. DATA0 is indicated at the end of the setup stage, and DATA1 is used for responses in the status stage. This does not require the setting of the sequence bit by the software. In control transfers when the host controller function is selected, the software must set the sequence bit during a stage transition.

Note that, when the host controller function or function controller function is selected, the software must also set the data PID sequence bit when sending or receiving a ClearFeature request.

The sequence bit cannot be modified by the SQSET bit for isochronous transfer pipes.

(8) Response PID = NAK Function

This module has a function to disable the pipe operation (Response PID = NAK) at the last data packet receive timing in a transfer (this module automatically identifies the last data packet receive timing at the short packet receive timing or using the transaction counter) by setting the SHTNAK bit in PIPECFG to 1.

This function allows reception of data packets in transfer units when the buffer memory is used as a double buffer. Furthermore, when the pipe operation is disabled, the software must set the response PID to BUF to enable the pipe operation.

This function is available only for bulk transfers.

(9) Auto-Response Mode

When the ATREPM bit in PIPEnCTR is set to 1 in a bulk transfer pipe (pipes 1 to 5 , and 9 to F when the function controller function is selected), this module enters auto-response mode: OUT-NAK mode in OUT transfers (DIR = 0) or null auto-response mode in IN transfers (DIR = 1).

1. OUT-NAK mode

   When the ATREPM bit is set to 1 in a bulk OUT transfer pipe, this module sends NAK in response to an OUT token or PING token and outputs an NRDY interrupt. To change response mode from normal mode to OUT-NAK mode, specify OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, OUT-NAK mode is enabled. However, if an OUT token is received immediately before the pipe operation is disabled, this module receives the data of the token correctly and sends ACK to the host.

   To change response mode from OUT-NAK mode to normal mode, reset OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). In normal mode, this module can receive OUT data and sends ACK in response to a PING token when the buffer is ready for receiving.

2. Null auto-response mode

   When the ATREPM bit is set to 1 in a bulk IN transfer pipe, this module continues to send Zero-Length packets. To change response mode from normal mode to null auto-response mode, specify null auto-response mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, null auto-response mode is enabled. However, specify null auto-response mode while the buffer is empty. Verify this by checking INBUFM = 0. Since INBUFM = 1 indicates that the buffer contains data, clear the buffer by setting the ACLRM bit. Do not write data to the buffer from the FIFO port during setting to null auto-response mode.

To change response mode from null auto-response mode to normal mode, delay the pipe operation disabled state (Response PID = NAK) for a time period for sending a Zero-Length packet (full-speed: 10 μs, high-speed: 3 μs), and then reset null auto-response mode. Normal mode allows writing from the FIFO port, and also allows sending packets to the host by enabling the pipe operation (Response PID = BUF).

33.4.4 FIFO Buffer Memory

(1) Allocating FIFO Buffer Memory

Figure 33.9 shows an example of the FIFO buffer memory map of this module. The FIFO buffer memory is an area shared by the CPU and this module. There are two FIFO buffer memory states where the access right is given to the system (CPU) or to this module (SIE).

The FIFO buffer memory provides independent areas for each pipe. A memory area is set with the block start number and the number of blocks (BUFNMB and BUFSIZE bits in PIPEBUF) in 64-byte units as one block.

When continuous transfer mode is selected by the CNTMD bit in PIPEnCFG, be sure to set the BUFSIZE bits to a value in integral multiples of the maximum packet size. When double buffer is selected by the DBLB bit in PIPEnCFG, two sides of the memory area specified by the BUFSIZE bits in PIPEBUF are provided for the same pipe.

Furthermore, three FIFO ports are used for accesses (data read/write) to the buffer memory. The number of a pipe to be allocated to the FIFO ports is specified by the CURPIPE bits in CFIFOSEL and DnFIFOSEL.

The buffer status of each pipe can be monitored by the BSTS and INBUFM bits in DCPCTR and PIPEnCTR. The access right to the FIFO ports can be checked by the FRDY bit in CFIFOCTR and DnFIFOCTR.

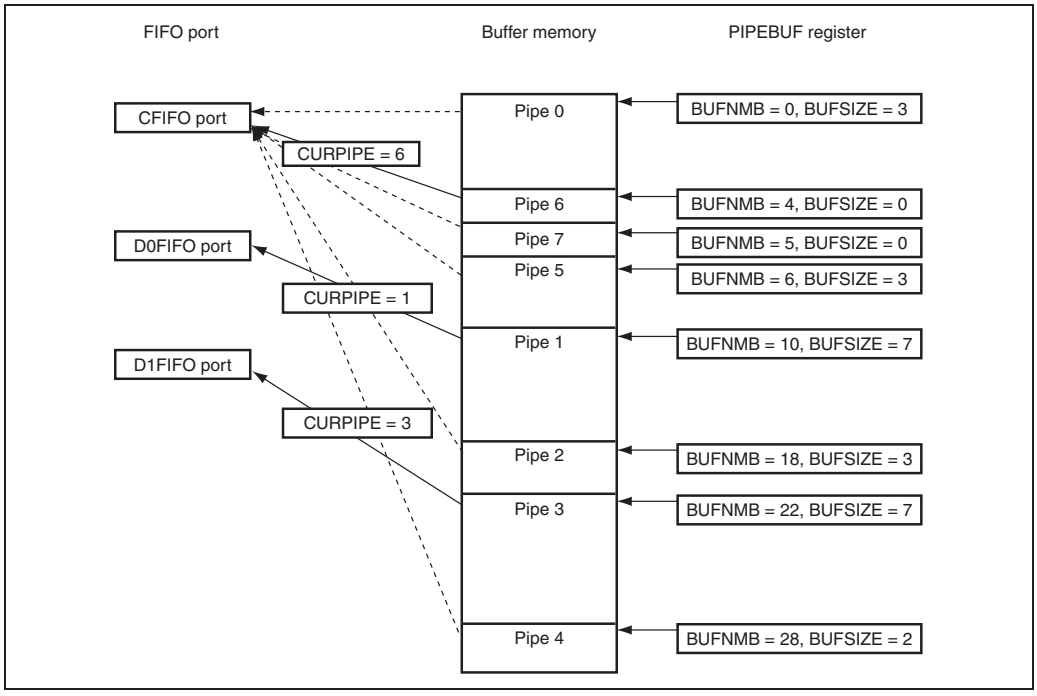

Figure 33.9 Example of Buffer Memory Map

- Buffer status

  Tables 33.17 and 33.18 show the buffer memory status of this module. The buffer memory status can be monitored by the BSTS bit in DCPCTR and the INBUFM bit in PIPEnCTR. The buffer memory access direction is specified by the DIR bit in PIPEnCFG or the ISEL bit in CFIFOSEL (when DCP is selected).

  The INBUFM bit is valid only for pipes 1 to 5, and 9 to F when function controller function is selected in the transmit direction.

  When a transfer pipe in the transmit direction is set to double buffer, the BSTS bit is used to monitor the buffer status on the CPU side, and the INBUFM bit is used to monitor the buffer status on the SIE side. When data write to the FIFO port by the CPU (DMAC) takes time and buffer empty cannot be checked by the BEMP interrupt, the INBUFM bit is available to check completion of transmission.

Table 33.17 Buffer Memory Status That Varies Depending on the BSTS Bit

ISEL or DIR	BSTS	Buffer Memory Status
0 (receive direction)	0	No receive data in the buffer memory or data is being received. Data cannot be read from the FIFO port.
0 (receive direction)	1	Receive data in the buffer memory or a Zero-Length packet is received. Data can be read from the FIFO port. However, the buffer must be cleared because the FIFO port cannot be read when this module receives a Zero-Length packet.
1 (transmit direction)	0	Transmission of data is not completed. Data cannot be written to the FIFO port.
1 (transmit direction)	1	Transmission of data is completed. The CPU can write data to the buffer memory.

Table 33.18 Buffer Memory Status That Varies Depending on the INBUFM Bit

DIR	INBUFM	Buffer Memory Status
0 (receive direction)	Invalid	Invalid
1 (transmit direction)	0	Transmittable data is completely sent. No transmittable data is in the buffer memory.
1 (transmit direction)	1	Transmittable data is written from the FIFO port. The buffer memory contains transmittable data.

- FIFO buffer clear

  Table 33.19 shows clearing of the FIFO buffer memory of this module. The buffer memory can be cleared by the BCLR, DCLRM, and ACLRM bits.

Table 33.19 Buffer Clear

Bit Name	BCLR	DCLRM	ACLRM
Register	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Function	Clears the buffer memory of the CPU.	Automatically clears the buffer memory after reading data of the specified pipe.	Automatically clears the buffer memory by ignoring all received packets.
Clearing method	Writing 1 to this bit clears the buffer memory.	1: This mode is enabled. 0: This mode is disabled.	1: This mode is enabled. 0: This mode is disabled.

- Buffer area

  Table 33.20 shows a buffer memory map of this module. The buffer memory includes a dedicated areas reserved beforehand for pipes and user areas provided for user settings.

  The buffer for DCP is a dedicated area commonly used in control read transfers and control write transfers.

  Areas for pipes 6 to 8, and 9 when host controller function is selected, are allocated respectively in advance. However, when none of pipes 6 to 8, and 9 when host controller function is selected, is used, the areas are available for pipes 1 to 5, 9 to F when function controller function is selected, as user areas.

  Allocate different areas of the buffer memory to each pipe. Note that, when double buffer is specified, the size of an area is twice of the set value.

  Do not set the buffer size to a value smaller than the maximum packet size.

Table 33.20 Buffer Memory Map

Buffer Memory Number	Buffer Size	Pipe Setting	Remarks
H'0	64 bytes	Fixed only for DCP	Single buffer
H'1 to H'3	—	Unavailable	—
H'4	64 bytes	Fixed only for pipe 6	Single buffer
H'5	64 bytes	Fixed only for pipe 7	Single buffer
H'6	64 bytes	Fixed only for pipe 8	Single buffer

Buffer Memory Number	Buffer Size	Pipe Setting	Remarks
H'7	64 bytes	Fixed only for pipe 9	Single buffer when host controller function is selected
H'8to H'7F,and H'7 when function controller function is selected.	Max. 7616 bytes	User area for pipes 1 to 5, and 9 to F when function controller function is selected	Double buffer and continuous transfer can be set

- Buffer auto-clear mode function

  When the ACLRM bit PIPEnCTR is set to 1, this module discards all data packets received. However, when this module receives a data packet successfully, it sends ACK to the host controller. This function is available only for the buffer memory read direction.

  Writing 1 and then 0 continuously to the ACLRM bit clears the buffer memory of the selected pipe irrespective of the access direction.

  Take at least 100 ns between writing 1 and writing 0 for the sequence execution time of the hardware.

- Buffer memory specifications (single buffer/double buffer setting)

  Single buffer or double buffer is selectable for pipes 1 to 5, and 9 to F when function controller function is selected, with the DBLB bit in PIPEnCFG. Double buffer is a function to provide two sides of the memory area specified by the BUFSIZE bits in PIPEBUF for the same pipe. Figure 33.10 shows an example of setting for the buffer memory of this module.

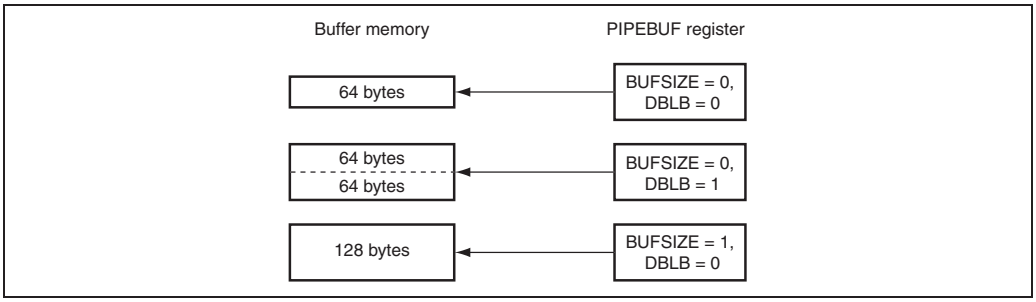

Figure 33.10 Example of Buffer Memory Setting

- Buffer memory operation (continuous transfer setting)

  Continuous transfer mode or discontinuous transfer mode is selectable with the CNTMD bit in PIPEnCFG. This selection is enabled for pipes 1 to 5, 9 to F when function controller function is selected.

The continuous transfer mode function allows continuous transmission/reception of multiple transactions. When continuous transfer mode is selected, data up to the buffer size allocated to each pipe can be transferred without outputting an interrupt to the CPU.

In continuous transmission mode, data in the buffer is divided by the maximum packet size and is then transmitted. To send data less than the buffer size (a short packet or a packet with a size of integral multiples of the maximum packet size and less than the buffer size), set BVAL = 1 after writing transmit data to the buffer.

In continuous reception mode, no interrupt is generated until this module receives packets to the buffer size, the transaction count ends, or this module receives a short packet.

Table 33.21 shows the relationship between the CNTMD setting and determination of transmission/reception end of the FIFO buffer.

Table 33.21 Relationship between CNTMD Setting and Determination of Transmission/Reception End of FIFO Buffer

Transfer Mode	Determination of Buffer Readable State and Data Transmittable State
Discontinuous transfer (CNTMD = 0)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0):
	When this module receives one packet
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1):
	Any of the following cases:
	The software (or DMAC) writes data of the maximum packet size to the FIFO buffer.
	The software (or DMAC) writes data of a short packet (including 0 bytes) to the FIFO buffer, and then sets BVAL = 1.
Continuous transfer (CNTMD = 1)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0):
	When the bytes of data received in the FIFO buffer for the selected pipe equals the allocated bytes ((BUFSIZE + 1) * 64)
	When this module receives a short packet other than a Zero-Length packet
	When this module receives a Zero-Length packet when data is already stored in the FIFO buffer for the selected pipe
	When this module receives packets as large as the transaction counter value specified for the selected pipe by the software
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1):
	Any of the following cases:
	The volume of data written by the software (or DMAC) equals the size of one side of the FIFO buffer for the selected pipe.
	The software (or DMAC) writes data less than the size of one side of the FIFO buffer for the selected pipe to the FIFO buffer, and then sets BVAL = 1.

Figure 33.11 shows an example of buffer memory operation of this module.

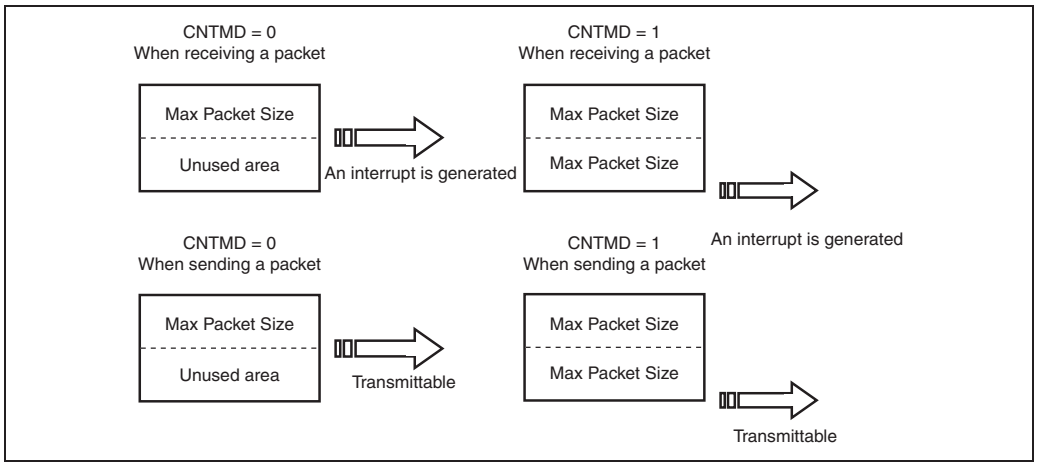

Figure 33.11 Example of Buffer Memory Operation

(2) FIFO Port Function

Table 33.22 lists the settings for the FIFO port functions of this module. During a data write access, when data up to buffer full (or up to the maximum packet size in discontinuous transfer) is written, the FIFO port automatically enters the data transmittable state. To make data less than buffer full (or the maximum packet size in discontinuous transfer) transmittable, set the BVAL bit in CFIFOCTR and DnFIFOCTR to 1 to set write end. For transmission of a Zero-Length packet, clear the buffer using the BCLR bit in these registers and then set the BVAL bit to 1.

During a data read access, when all data is read, the FIFO port automatically enters the new packet receivable state. However, when receiving a Zero-Length packet (DTLN = 0), no data can be read. Therefore, clear the buffer using the BCLR bit in these registers. The receive data length can be checked by the DTLN bits in CFIFOCTR and DnFIFOCTR.

Table 33.22 FIFO Port Function Settings

Register Name	Bit Name	Function	Remarks
CFIFOSEL	RCNT	Selects DTLN read mode.	
DnFIFOSEL	REW	Rewinds the buffer memory (reread/rewrite).	
	DCLRM	Reads and clears receive data of the specified pipe.	DnFIFO only
	DREQE	Enables DMA transfer.	DnFIFO only
	MBW	Specify FIFO port access bit width.	
	BIGEND	Selects FIFO port endian.	
	ISEL	Selects FIFO port access direction.	DCP only
	CURPIPE	Select the current pipe.	
CFIFOCTR	BVAL	Specifies buffer memory write end.	
DnFIFOCTR	BCLR	Clears the buffer memory of the CPU.	
	DTLN	Check receive data length.	

(a) FIFO Port Selection

Table 33.23 shows pipes that can be selected in each FIFO port. Select a pipe to be accessed by the CURPIPE bits in CFIFOSEL and DnFIFOSEL. After selecting a pipe, confirm that the set CURPIPE value is read correctly, check FRDY = 1, and then make an access to the FIFO port. (If the previous pipe number is read, this controller is changing a pipe.)

Also select the bus width to be accessed by the MBW bits. The buffer memory access direction is specified by the DIR bit in PIPEnCFG. However, only the access direction of DCP is determined by the ISEL bit.

Table 33.23 FIFO Port Access

Pipe	Access	Available port
DCP	CPU access	CFIFO port register
Pipes 1 to 9, and A to F when the function controller function is selected	CPU access	CFIFO port register
	DMA access	D0FIFO port, D1FIFO port

(b) REW Bit

The current access to a pipe can be suspended temporarily, and it is also possible to make an access to another pipe to continue the ongoing pipe processing. This processing is allowed by using the REW bit in CFIFOSEL and DnFIFOSEL.

When the REW bit is set to 1 together with the CURPIPE bits in CFIFOSEL and DnFIFOSEL and a pipe is selected, the reading or writing pointer of the buffer memory is reset, which allows reading or writing data from the first byte. Furthermore, when a pipe is selected with the REW bit set to 0, data can be read or written following the data at the previous selection without resetting the reading or writing pointer of the buffer memory.

To make accesses to the FIFO port, select a pipe and check FRDY = 1.

(3) DMA Transfer (Dedicated DMA Interface)

(a) Overview of DMA Transfer

The FIFO port can be accessed by the DMAC for pipes 1 to 9, and A to F when function controller function is selected, When the buffer of a pipe specified for DMA transfer becomes accessible, this module outputs a DMA transfer request.

Specify the data transfer unit to the FIFO port by the MBW bits in DnFIFOSEL, and select a pipe used for DMA transfer by the CURPIPE bits in DnFIFOSEL. Do not change the selected pipe during a DMA transfer.

(b) DMA Transfer End Auto-Recognition

This module can terminate writing of data by DMA transfer to the FIFO buffer by controlling the DMA transfer end signal input. After sampling the transfer end signal, this module drives the buffer memory into the transmittable state (same state as BVAL = 1).

(c) DnFIFO Auto-Clear Mode (D0FIFO/D1FIFO Port Read Direction)

By setting the DCLRM bit in DnFIFOSEL to 1, this module automatically clears the buffer memory for the selected pipe upon completion of data read from the buffer memory.

Table 33.24 shows the relationship between packet reception and buffer memory clear by the software. As shown in the table, buffer clearing conditions vary with the BFRE setting. However, in any state that needs clearing, using the DCLRM bit makes buffer clearing by the software unnecessary. Thus DMA transfer is enabled without requiring any software control.

- This function is available only for the buffer memory read direction.

Table 33.24 Relationship between Packet Reception and Buffer Memory Clear by the Software

Register Setting / Buffer Status When Receiving a Packet	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	Clearing not required	Clearing not required	Clearing not required	Clearing not required
Zero-Length packet reception	Clearing required	Clearing required	Clearing not required	Clearing not required
Normal short packet reception	Clearing not required	Clearing required	Clearing not required	Clearing not required
Transaction count end	Clearing not required	Clearing required	Clearing not required	Clearing not required

33.4.5 Control Transfer (DCP)

The default control pipe (DCP) is used for data transfer in the control transfer data stage. The buffer memory for the DCP is a 256-byte single buffer of a fixed area used for both control read and control write. The buffer memory can be accessed only by the CFIFO ports.

(1) Control Transfer when the Host Controller Function is Selected

(a) Setup Stage

USBREQ, USBVAL, USBINDX, and USBLENG are registers used to send USB requests in setup transactions. The specified data is sent as a setup transaction by writing the setup packet data in the register and writing 1 to the SUREQ bit in DCPCTR. The SUREQ bit is cleared to 0 when a transaction ends. Do not access the USB request registers while SUREQ = 1. The device address for a setup transaction is specified by the DEVSEL bits in DCPMAXP.

An interrupt is generated upon receiving a response from the peripheral device in response to the transmitted transaction (SIGN and SACK bits in INTSTS1). The setup transaction result can be checked at the timing of this interrupt request.

For data packets in setup transactions, a DATA0 data packet (USB request) is always sent irrespective of the SQMON setting in DCPCTR.

(b) Data Stage

This module transfers data using the DCP buffer memory in the data stage.

Specify the direction of accesses to the DCP buffer memory by the ISEL bit in CFIFOSEL. Also specify the transfer direction by the DIR bit in DCPCFG.

Transmit the first data packet in the data stage with data PID as DATA1. Set data PID = DATA1 by the SQSET bit in DCPCFG, and set PID = BUF to execute transactions. The completion of data transfer is detected by a BRDY interrupt and a BEMP interrupt.

In a control write transfer, when the transmit data is integral multiples of the maximum packet size, send a Zero-Length packet at the last by the software.

(c) Status Stage

In the status stage, data transfer of Zero-Length packets is performed in the reverse direction of the data stage. The same DCP buffer memory as in the data stage is used for data transfer. Transactions are executed using the same procedure as the data stage.

Send data packets in the data stage with data PID as DATA1. Set data PID = DATA1 by the SQSET bit in DCPCFG.

Furthermore, check the receive data length of a Zero-Length packet by the DTLN bits in CFIFOCTR after a BRDY interrupt is generated, and then clear the buffer memory by the BCLR bit.

(2) Control Transfer when the Function Controller Function is Selected

(a) Setup Stage

1. This module always sends ACK in response to a normal setup packet to this module. The following describes the operation of this module in the setup stage.
   When this module receives a new setup packet, this module sets the following bits.
   — The VALID bit in INTSTS0 to 1
   — The PID bits in DCPCTR to NAK
   — The CCPL bit in DCPCTR to 0
2. When this module receives a data packet following a setup packet, this module stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Be sure to process responses to control transfers while VALID = 0. The PID bits cannot be set to BUF when VALID = 1, and therefore the data stage cannot be completed.

With the VALID bit function, this module can suspend the ongoing request processing if this module receives a new USB request during a control transfer, and send a response to the latest request.

This module also determines the direction bit (bit 8 of bmRequestType) of the received USB request and the request data length (wLength), identifies a control read transfer, control write transfer, and control write no-data transfer, and controls stage transitions. For an incorrect sequence, a sequence error of the control transfer stage transition interrupt occurs, and the error is reported to the software. For the stage control of this module, see Figure 33.7.

(b) Data Stage

Transfer data in response to the received USB request using the DCP. Before making an access to the DCP buffer memory, specify the access direction by the ISEL bit in CFIFOSEL.

When the transfer data size is larger than the DCP buffer memory size, use a BRDY interrupt for control write transfers and a BEMP interrupt for control read transfers.

In the high-speed control write transfer, this module sends responses using the NYET handshake according to the buffer memory status.

(c) Status Stage

Setting the CCPL bit to 1 with the PID bits in DCPCTR set to BUF finishes a control transfer.

After these settings, this module executes the status stage as follows according to the data transfer direction determined in the setup stage:

- Control read transfer
  This module sends a Zero-Length packet and receives an ACK response from the USB host.
- Control write transfer, no-data control transfer
  This module receives a Zero-Length packet from the USB host and sends an ACK response.

(d) Control Transfer Auto-Response Function

This module automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, the software must respond to the error.

- Other than control read transfer: bmRequestType ≠ H'00
- Request errors: wIndex ≠ H'00
- Other than no-data control transfer: wLength ≠ H'00
- Request errors: wValue > H'7F

- Control transfer of device state errors: DVSQ = 011 (Configured)

All requests other than SET_ADDRESS require a response made by the software.

33.4.6 Bulk Transfer (Pipes 1 to 5, and 9 to F when the function controller function is selected)

The buffer memory usage (single buffer/double buffer setting or continuous/discontinuous transfer mode setting) can be selected for bulk transfers. The buffer memory size can be set to up to 2 Kbytes. This module manages the buffer memory status and automatically responds to a PING packet and an NYET handshake.

(1) PING Packet Control when the Host Controller Function is Selected

This module automatically sends a PING packet in the OUT direction.

As described below, this module sends an OUT packet upon receiving an ACK handshake with the initial state where a PING packet was transmitted. When this module receives NAK or NYET, it returns to the PING transmission state. This control is also effective for the control transfer data stage and status stage.

1. Set OUT data transmission.
2. Send a PING packet.
3. Receive an ACK handshake.
4. Send an OUT data packet.
5. Receive an ACK handshake.
   (Repeat steps 4 and 5.)
6. Send an OUT data packet.
7. Receive a NAK/NYET handshake.
8. Send a PING packet.

This module returns to the PING packet transmission state at the time of a power-on reset, receiving NYET/NAK handshake, setting the sequence toggle bit, setting clear (SQSET, SQCLR), and setting buffer clear (ACLRM).

(2) NYET Handshake Control when the Function Controller Function is Selected

Table 33.25 lists NYET handshake responses of this module. This module sends a NYET response under the following conditions. However, when this module receives a short packet, this module sends ACK instead of NYET. The same is true of the control write transfer data stage.

Table 33.25 NYET Handshake Responses

Setting of PID Bits in DCPCTR	Buffer Memory Status	Token	Response	Remarks
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY1	OUT/PING	ACK	Receives a data packet when receiving an OUT token.
	RCV-BRDY2	OUT	NYET	Receives a data packet. Sends a “reception disable” response.
	RCV-BRDY2	OUT (Short)	ACK	Receives a data packet. Sends a “reception enable” response.
	RCV-BRDY2	PING	ACK	Sends a “reception enable” response.
	RCV-NRDY	OUT/PING	NAK	Sends a “reception disable” response.
	TRN-BRDY	IN	DATA0/1	Sends a data packet.
	TRN-NRDY	IN	NAK	TRN-NRDY

[Legend]

RCV-BRDY1: The buffer memory has available space for two packets or more when receiving an OUT or PING token.

RCV-BRDY2: The buffer memory has available space for only one packet when receiving an OUT token.

RCV-NRDY: The buffer memory is occupied when receiving an PING token.

TRN-BRDY: The buffer memory contains transmit data when receiving an IN token.

TRN-NRDY: The buffer memory contains no transmit data when receiving an IN token.

33.4.7 Interrupt Transfer (Pipes 6 to 8, and 9 when function controller function is selected)

When the function controller function is selected, this module performs interrupt transfer following the cycles controlled by the host controller. In interrupt transfers, this module ignores PING packets (no response), sends no NYET handshake, and sends ACK, NAK, and STALL responses.

When the host controller function is selected, the token output timing can be set using the interval counter. This module sends no PING token, but sends OUT tokens even in the OUT direction transfer.

This module does not support the High-Bandwidth interrupt transfer.

(1) Interval Counter in Interrupt Transfer when the Host Controller Function is Selected

To perform an interrupt transfer, set a transaction interval by the IITV bits in PIPEPERI. This controller sends tokens in the interrupt transfer at the specified intervals.

(a) Counter initialization

This controller initializes the interval counter under the following conditions.

- Power-on reset:
  The IITV bits are initialized.
- Buffer memory initialization by ACLRM
  The IITV bits are not initialized but the counter is initialized. The IITV value is counted from the beginning by clearing the ACLRM bit to 0.

Note that the interval counter is not initialized in the following cases.

- USB bus reset or USB suspended
  The IITV bits are not initialized. Setting the UACT bit to 1 causes the interval counter to start counting from the value before the USB bus reset or USB suspended state.

(b) Operation when this module cannot send/receive tokens at the token generation timing

This module generates no token in the following cases even at the token generation timing. In these cases, this module tries to execute the transaction in the next interval.

- When PID = NAK or STALL is set

- When the buffer memory is occupied at the token transmit timing in the IN direction (reception) transfer
- When the buffer memory contains no transmit data at the token transmit timing in the OUT direction (transmission) transfer

33.4.8 Isochronous Transfer (Pipes 1, 2)

This module is provided with the following functions for isochronous transfers.

- Reporting isochronous transfer error information
- Interval counter (IITV bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (IFIS bit)

This module does not support the isochronous High-Bandwidth transfer.

(1) Isochronous Transfer Error Detection

This module is provided with a function to detect the following error information so that the software can manage isochronous transfer errors. Tables 33.26 and 33.27 show the error detection priority of this module and interrupts generated as a result of error detection.

1. PID error
   — When the PID in a receive packet is invalid
2. CRC error, bit stuffing error
   — When a CRC error is found in a receive packet or bit stuffing is invalid
3. Maximum packet size exceeded error
   — When the data size of a receive packet is over the maximum packet size setting
4. Overrun/underrun error
   — When the host controller function is selected
     When the buffer memory is occupied at the token transmit timing in the IN direction (reception) transfer
     When the buffer memory contains no transmit data at the token transmit timing in the OUT direction (transmission) transfer
   — When the function controller function is selected
     When the buffer memory contains no data when this module receives an IN token in the IN direction (transmission) transfer
     When the buffer memory is occupied when this module receives an OUT token in the OUT direction (reception) transfer

5. Interval error

   When the function controller function is selected, this module generates an interval error in the following cases.

   — When no IN token can be received in interval frames in the isochronous IN transfer

   — When this module receives an OUT token other than interval frames in the isochronous OUT transfer

Table 33.26 Error Detection when Receiving Tokens

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet) when either of the host controller function or function controller function is selected.
2	CRC error, bit stuffing error	This module generates no interrupt (ignores as a damaged packet) when either of the host controller function or function controller function is selected.
3	Overrun error, underrun error	This module generates an NRDY interrupt and sets the OVRN bit when either of the host controller function or function controller function is selected. When the host controller function is selected, this module sends no token. When the function controller function is selected, this module sends a Zero-Length packet in response to the IN token. This module receives no data packet in response to the OUT token.
4	Interval error	When the function controller function is selected, this module generates an NRDY interrupt. When the host controller function is selected, this module generates no interrupt.

Table 33.27 Error Detection when Receiving Data Packets

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet).
2	CRC error, bit stuffing error	This module generates an NRDY interrupt and sets the CRCE bit when either of the host controller function or function controller function is selected.
3	Maximum packet size exceeded error	This module generates a BEMP interrupt and sets the PID bits to STALL when either of the host controller function or function controller function is selected.

(2) DATA-PID

This module does not support the High-Bandwidth transfer. The following lists responses to received PIDs when the function controller function is selected.

1. IN direction
   - DATA0: Sent correctly as the PID of data packet.
   - DATA1: Not sent
   - DATA2: Not sent
   - mDATA: Not sent
2. OUT direction (full-speed operation)
   - DATA0: Received correctly as the PID of a data packet.
   - DATA1: Received correctly as the PID of a data packet.
   - DATA2: The packet is ignored.
   - mDATA: The packet is ignored.
3. OUT direction (high-speed operation)
   - DATA0: Received correctly as the PID of a data packet.
   - DATA1: Received correctly as the PID of a data packet.
   - DATA2: Received correctly as the PID of a data packet.
   - mDATA: Received correctly as the PID of a data packet.

(3) Interval Counter

Intervals for isochronous transfers can be set by the IITV bits in PIPEPERI. When the function controller function is selected, the functions shown in Table 33.28 are made available with the interval counter. When the host controller function is selected, the interval counter generates the token transmit timing. When the host controller function is selected, the interval counter works in the same way as in the interrupt transfer.

Table 33.28 Interval Counter Functions when the Function Controller Function is Selected

Transfer Direction	Function	Detection Conditions
IN	Transmit buffer flush	No IN token can be successfully received in the interval frame during the isochronous IN transfer.
OUT	Reporting reception of no token	No OUT token can be successfully received in the interval frame during the isochronous OUT transfer.

Since the interval counter is counted upon receiving an SOF or using the interpolated SOF, the isochronism can be maintained even if the SOF is damaged. The specifiable frame interval is 2^{IITV} frames or 2^{IITV} μ frames.

(a) Counter initialization when the function controller function is selected

This module initializes the interval counter as follows:

- Power-on reset
  The IITV bits are initialized.
- Initializing buffer memory by ACLRM
  The IITV bits are not initialized but the interval counter is initialized. Clearing the ACLRM bit to 0 causes the counter to start counting from the set IITV value.

After the interval counter is initialized, the interval counter starts counting in either of the following cases after a packet is correctly transferred.

1. When this module receives an SOF after sending data in response to the IN token with PID = BUF
2. When this module receives an SOF after receiving the OUT token data with PID = BUF

The interval counter is not initialized under the following conditions.

1. When PID = NAK or STALL
   The interval timer does not stop. Try to execute the transaction in the next interval.
2. USB bus reset and USB suspended
   The IITV bits are not initialized. When this module receives an SOF, the interval counter starts counting from the value before receiving the SOF.

(b) Interval count and transfer control when the host controller function is selected

This module controls the token transmission intervals using the set IITV value. This module sends a token for the selected pipe once every 2^IITV times of (μ) frames.

This module counts the interval at every 1-ms frame for the pipe used for communication with the full-speed/low-speed peripheral device connected to the high-speed HUB.

This module starts counting the token transmission interval from the next (μ) frame where PID = BUF is specified by the software.

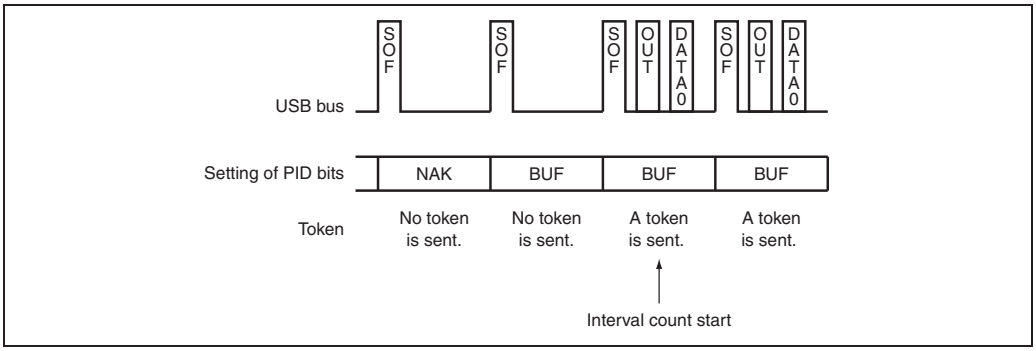

Figure 33.12 Transmission of Tokens when IITV = 0

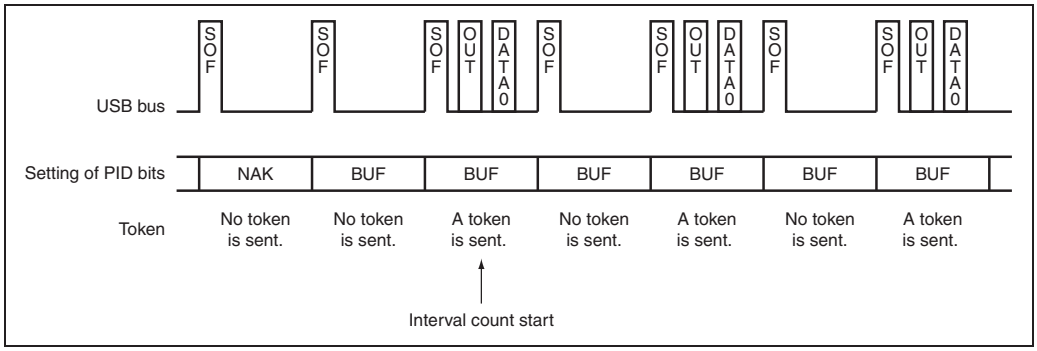

Figure 33.13 Transmission of Tokens when IITV = 1

When the selected pipe is isochronous transfer type, this module performs the following operations in connection with the token transmission interval control. Even if the NRDY interrupt generation conditions are satisfied, this module sends tokens.

1. When the selected pipe is Isochronous-IN transfer pipe

   This module sends an In-Token. When this module does not successfully receive a packet from the peripheral device (including no response and a packet error), this module generates an NRDY interrupt.

   When the IN-Token transmit timing comes before receiving data caused by the FIFO buffer full (due to a delay of reading data from the FIFO buffer by the software or DMAC), this module indicates OVRN = 1 and generates an NRDY interrupt.
2. When the selected pipe is Isochronous-OUT transfer pipe

   When the OUT-Token transmit timing comes with no transmittable data in the FIFO buffer (due to a delay of writing data to the FIFO buffer by the software or DMAC), this module indicates OVRN = 1, generates an NRDY interrupt, and sends a Zero-Length packet.

   The token transmission interval is reset in the following cases.

   — When this module is reset by the hardware (The set IITV value is also cleared to 0.)

   — When ACLRM is set to 1 by the software

(c) Interval count and transfer control when the function controller function is selected

1. When the selected pipe is Isochronous-OUT transfer pipe

   When this module receives no data packet in (μ) frames at the intervals specified by the IITV bits, this controller generates an NRDY interrupt.

   When this module cannot receive data due to a CRC error in the data packet, FIFO buffer full, or other reasons, this module also generates an NRDY interrupt.

   An NRDY interrupt is generated at the SOF packet receive timing. Even if the SOF packet is damaged, this module generates an NRDY interrupt at the SOF packet receive timing using the internal interpolation function.

   When IITV ≠ 0, however, this module generates an NRDY interrupt at the SOF packet receive timing in each interval after the interval count starts.

   When PID = NAK is set by the software after the interval timer is activated, this module generates no NRDY interrupt even when this module receives an SOF packet.

   The interval count start conditions vary with the set IITV value.

   — When IITV = 0: The interval count starts from the next (μ) frame where the PID bits for the selected pipe is changed to BUF.

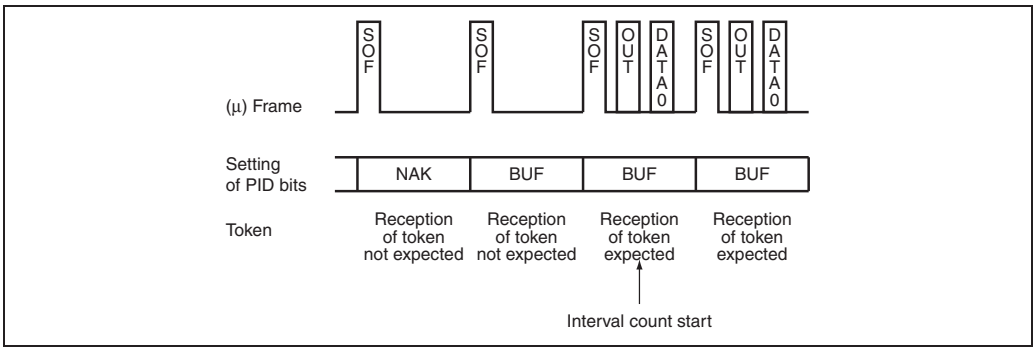

Figure 33.14 (μ) Frames and Expectation of Receiving a Token when IITV = 0

- When IITV ≠ 0: The interval count starts from the time when this module successfully receives the first data packet after the PID bits for the selected pipe is changed to BUF.

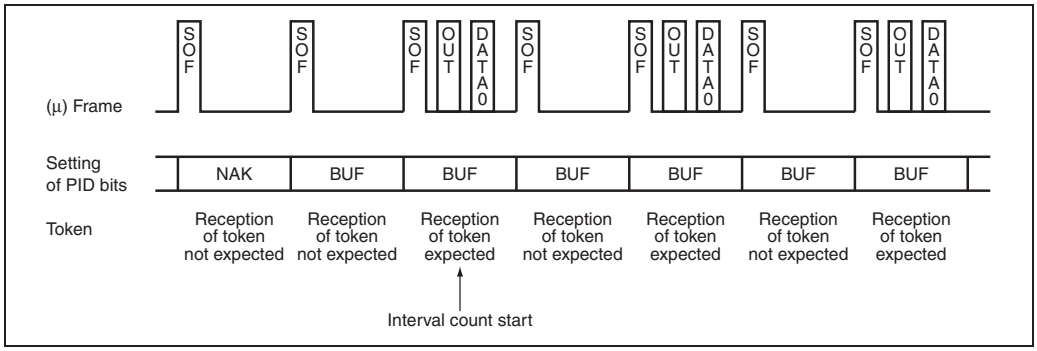

Figure 33.15 (μ) Frames and Expectation of Receiving a Token when IITV ≠ 0

2. When the selected pipe is Isochronous-IN transfer pipe

   Use the selected pipe by combining with the setting of IFIS = 1. When IFIS = 0, this module sends data packets in response to received tokens irrespective of the IITV value.

   When this module receives no IN-Token in (μ) frames at the intervals specified by the IITV bits with transmittable data stored in the FIFO buffer with IFIS = 1, this module clears the FIFO buffer.

   When this module cannot receive data due to a CRC error or another bus error in the IN-Token, this module also clears the FIFO buffer.

   The FIFO buffer is cleared at the SOF packet receive timing. Even if the SOF packet is damaged, this module clears the FIFO buffer at the SOF packet receive timing using the internal interpolation function.

   The interval count start conditions vary with the set IITV value (same as Isochronous-OUT transfer).

   When the function controller function is selected, the interval count start conditions are as follows:

   — When this module is reset by the hardware (The set IITV value is also cleared to 0.)
   — When ACLRM is set to 1 by the software
   — When this module detects a USB reset

(4) Transmit Data Setup in Isochronous Transfer when the Function Controller Function is Selected

In isochronous data transmission when the function controller function is selected, this module can send a data packet in the next frame after this module detects an SOF packet after writing data to the buffer. This function is referred to as the isochronous transfer transmit data setup function. With this function, the frame that started data transmission can be identified.

When the buffer memory is used as a double buffer, even if writing data to both buffers is completed, only one side that finished writing earlier becomes transferable. For this reason, even if multiple IN tokens are received in the same frame, only one packet of the buffer memory is sent.

When the buffer memory is ready for transmission in the IN token reception cycle, this module sends data and an ACK response. However, when the buffer memory is not ready for transmission, this module sends a Zero-Length packet and generates an underrun error.

Figure 33.16 shows an example of transmission using the isochronous transfer transmit data setup function of this module when IITV = 0 (each frame). Transmission of a Zero-Length packet is indicated as hatched “Null” in the figure.

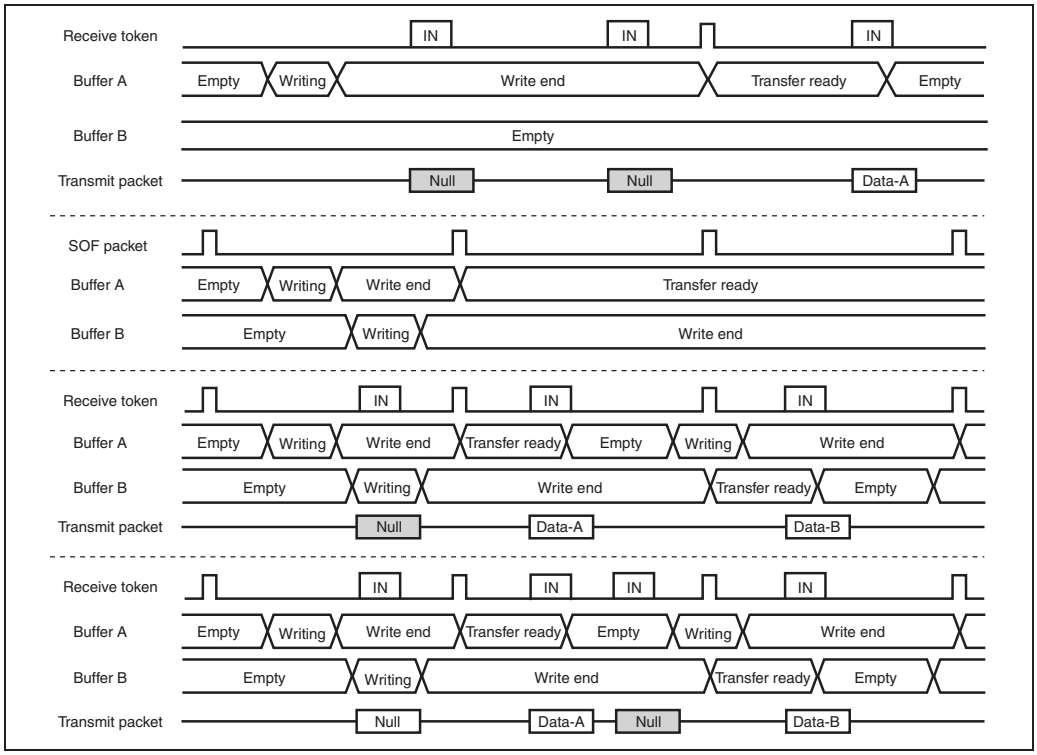

Figure 33.16 Example of Transmit Data Setup Function

(5) Transmit Buffer Flush in Isochronous Transfer when the Function Controller Function is Selected

In isochronous data transmission when the function controller function is selected, this module receives no IN token in the interval frame. When this module receives the SOF or μ SOF packet of the next frame, this module regards the IN token as damaged and clears the buffer that is ready for transmission to make it writable.

At this time, when the buffer memory is used as a double buffer and writing data to both buffers is completed, this module regards the discarded buffer memory data as transmitted in the same interval frame, and drives the buffer memory that is not discarded due to the reception of an SOF or μ SOF packet into the transmission ready state.

The buffer flush function activation timing varies depending on the IITV value.

- When IITV = 0
  This module activates the buffer flush function from the next frame after the pipe is enabled.
- When IITV ≠ 0
  This module activates the buffer flush function from the first normal transaction.

Figure 33.17 shows an example of the buffer flush function of this module. For tokens before the interval frame (outside the specified interval), however, this module sends the data stored in the buffer according to the data setup state or sends a Zero-Length packet as an underrun error.

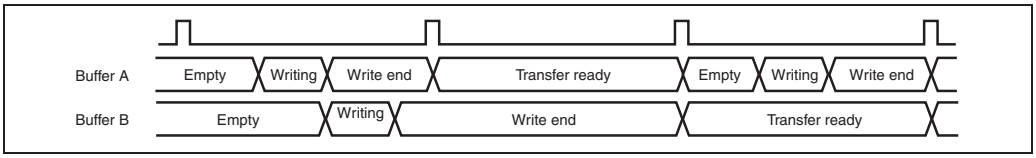

Figure 33.17 Example of Buffer Flush Function

Figure 33.18 shows an example of an interval error of this module. Interval errors are the following five. An interval error occurs at timing [1] in the figure, and the buffer flush function is activated.

When an interval error occurs, the buffer flush function is activated in the IN transfer and an NRDY interrupt occurs in the OUT transfer.

Discriminate an NRDY interrupt (including a receive packet error) from an overrun error with the OVRN bit.

This module sends a response to the hatched tokens in the figure according to the buffer memory status.

1. IN direction
   — When the buffer is ready to transmit data, this module sends the data and an ACK response.
   — When the buffer is not ready to transmit data, this module sends a Zero-Length packet and generates an underrun error.
2. OUT direction
   — When the buffer is ready to receive data, this module receives data and sends an ACK response.
   — When the buffer is not ready to receive data, this module discards the data and generates an overrun error.

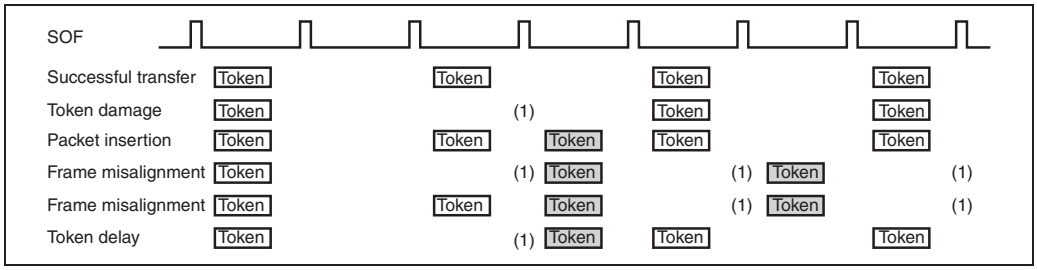

Figure 33.18 Example of Interval Error when IITV = 1

33.4.9 SOF Interpolation Function

When the function controller function is selected, in case this module cannot receive SOF packets at intervals of 1 ms (full-speed operation) or 125 μs (high-speed operation) due to damage or missing of SOF packets, this module interpolates the SOF. The SOF interpolation starts functioning when SYSCFG.USBE = 1, SYSCFG.SCKE = 1, and at the SOF packet receive timing. Furthermore, the interpolation function is initialized in the following cases.

- Power-on reset
- USB bus reset
- When the suspended state is detected

The SOF interpolation functions with the following specifications.

- The frame intervals (125 μs or 1 ms) conform to the result of the reset handshake protocol.
- The SOF interpolation does not function until this module receives an SOF packet.
- After receiving the first SOF packet, 125 μs or 1 ms is counted by the internal 48-MHz clock to interpolate the SOF.
- After receiving the second SOF packet or a following packet, the SOF is interpolated using the previous receive intervals.
- The SOF interpolation does not function in the suspended state and during a USB bus reset. (When this module enters the suspended state in high-speed operation, the SOF interpolation continues for 3 ms from the final packet.)

This module activates the following functions based on the reception of SOF packets. When one or more SOF packets are lost, normal operation can be continued to perform the SOF interpolation.

- Updating frame numbers and μ frame numbers
- SOFR interrupt timing and μ SOF lock

- Isochronous transfer interval count

When one or more SOF packets are lost in full-speed operation, the FRNM bits in FRMNUM are not updated. When one or more μ SOF packets are lost in high-speed operation, the FRNM bits are updated. However, when a μ SOF packet with UFRNM = 000 is lost, the FRNM bits are not updated even if following μ SOF packets with UFRNM ≠ 000 are successfully received.

33.4.10 Pipe Schedule

(1) Transaction Issuing Conditions

When the host controller function is selected, this module issues transactions after setting UACT = 1 according to the conditions in Table 33.29.

Table 33.29 Transaction Issuing Conditions

	Issuing Conditions				
Transaction	**DIR**	**PID**	**IITV0**	**Buffer Status**	**SUREQ**
Setup	—*1	—*1	—*1	—*1	Set to 1
Control transfer data stage, status stage, bulk transfer	IN	BUF	Disabled	Data receive area remaining	—*1
	OUT	BUF	Disabled	Transmit data stored	—*1
Interrupt transfer	IN	BUF	Enabled	Data receive area remaining	—*1
	OUT	BUF	Enabled	Transmit data stored	—*1
Isochronous transfer	IN	BUF	Enabled	*2	—*1
	OUT	BUF	Enabled	*3	—*1

Notes: 1. "—" means that the condition is not related to issuing tokens. "Enabled" shows that transactions are issued only in transfer frames by the interval counter in interrupt transfers and isochronous transfers. "Disabled" shows that transactions are issued irrespective of the interval counter.

2. Transactions are issued irrespective of whether the buffer has a data receive area or not. However, when the buffer has no data receive area, the receive data is discarded.

3. Transactions are issued irrespective of whether the buffer contains transmit data or not. However, when the buffer contains no transmit data, this module sends a Zero-Length packet.

(2) Transfer Schedule

The following describes the within-the-frame transfer scheduling of this module. This module transfers packets in the following procedure after sending the SOF.

1. Execute periodic transfer
   This module searches pipes in the order of pipe 1 -> pipe 2 -> pipe 6 -> pipe 7 -> pipe 8 -> pipe 9. When transactions can be issued in any of these pipes in isochronous transfers or interrupt transfers, this module issues transactions.
2. Control transfer setup transaction
   When the DCP indicates that the setup transaction is enabled, this module sends it.
3. Execute bulk transfer/control transfer data stage and status stage
   This module searches pipes in the order of pipe 1 -> pipe 2 -> pipe 3 -> pipe 4 -> pipe 5. When transactions can be issued in any of these pipes in the bulk transfer/control transfer data stage and control transfer status stage, this module executes transactions.
   When this module issued a transaction and received ACK or NAK from the peripheral device, this module shifts to the transactions for the next pipe. When there is time for transfer within the frame, this module repeats the operation in step 3.

(3) Enabling USB Communication

Setting the UACT bit in DVSTCTR to 1 starts transmission of an SOF or µ SOF, and issuing of transactions is enabled.

Setting the UACT bit to 0 stops transmission of an SOF or µ SOF, and issuing of transactions is suspended. When the UACT bit is changed from 1 to 0, the USB communication is halted after the next SOF or µ SOF is transmitted.

33.5 Guidelines for Designing USB2.0 Hi-Speed Boards

33.5.1 USB Transmission Line

The USB transmission line indicates the pattern that connects the USB connector and the USB transceiver with built-in this LSI.

The USB2.0 has three communication modes: Hi-Speed, Full-Speed and Low-Speed modes. The transmission speed in the Hi-Speed mode is 480 Mbps. Therefore, the USB transmission line must be designed as a high-frequency circuit. Impedance control is required for the USB transmission line.

- The characteristic impedance required for the USB Hi-Speed transmission line is differential impedance 90Ω (±15%).
- The pattern width and pattern pitch for impedance control vary depending on the board thickness, material and layer configuration. For details, consult the board manufacturer.
- A maximum delay of 1 ns is allowed from the USB connector to this LSI. Therefore it is recommended that the pattern length from the USB device to the USB connector is less than 50 mm and the difference between the pattern lengths for D+ and D– is less than 2.5 mm for a generic PCB.
- The lower layer of the USB transmission line must be a solid ground plane. The ground must be wider than the USB transmission line by 2 mm or more. The power supply for a solid ground plane is DG33.
- Do not allocate other signal lines near to the USB transmission line. In particular, lines carrying widely fluctuating signals, such as clock and data bus lines, must be assigned far from the USB transmission line. Furthermore, layout of the USB transmission lines must be such that they do not cross with other signal lines.
- Locate the USB transmission line on the same layer without passing it through a through-hole. Do not create stubs.
- Place the USB transmission lines so that they are equally spaced from each other.
- Locate the USB transmission line as far as possible from the oscillator, power supply circuit, and other I/O connectors.
- Try to avoid bending the USB transmission line as far as possible. If it is absolutely necessary to bend it, do not bend it at acute or right angles. Bend it moderately, at not more than 45 degrees, or bend it into an arc.
- It is recommended to guard ring the clock, reset, read, write and chip select signals with grounds.

When a resistance is connected to the USB transmission line, locate it near to the USB transmission line. The connecting wire must be as short as possible.

33.5.2 Power Supply and Ground Pattern

Analog power supply: AV12 (1.2V), AV33 (3.3V)

Digital power supply: UV12 (1.2V), DV12 (1.2V), DV33 (3.3V)

Analog ground: AG12, AG33

Digital ground: UG12, DG12, DG33

- It is recommended to separate power supplies and ground patterns into digital and analog.
- Connect the power supplies and grounds firmly on wide areas.
- Tantalum solid electrolytic capacitors or ceramic capacitors having excellent high-frequency characteristics are recommended as capacitors for power supplies.
- Aluminum electrolytic capacitors affect the jitter value during measurement of EYE diagram. Use the capacitors after adequately designing and testing them.
- It is recommended to place decoupling capacitors with values of 0.1uF, 0.01uF, and 0.001uF as close as possible to the USB power supply.

33.5.3 Oscillation

- Provide an oscillation circuit near the clock input pin for USB (EXTAL2). It is recommended to guard ring EXTAL2 with a ground.
- When using a crystal resonator, consult its manufacturer to determine the circuit constant.

33.5.4 VBUS

- When this LSI is used as a host controller, it must supply the VBUS power. To do this it is recommended to use a power switch IC with an overcurrent limiter for the USB power bus (hereafter called USB power swtich IC). Current limits should be deteremined on the basis of the current values of the system power supply and the USB peripheral devices to be communicated with. For details on circuits, see the datasheet of your USB power switch IC. Input VBUS (5V) to the VBUS1_1 pin of this LSI. Provide the VBUS1_1 pin with a capacitance of 1uF and a resistance of 100Ω to 1000Ω (never exceeding 1000Ω) as a filter circuit. The potential of the VBUS is normally 5.0V, but when a cable is connected, overshoot may occur as a result of a reflection due to impedance mismatch between the VBUS power IC

and the VBUS in the cable. This overshoot can damage elements. For this reason, the element shown in Figure 33.1, Connection to the USB Connector, should be connected between the VBUS1_1 pin and the connector as a filter circuit.

33.5.5 REFRIN_1 Pin

- Provide a resistor (hereafter called reference resistor) of 5.6 kΩ ±1%, between the REFRIN_1 pin and AG33.
- Locate the reference resistor as close as possible to this LSI.
- The REFRIN_1 pin, the reference resistor and AG33 should be wired on wide areas and the shortest length.
- Use a wiring pattern for and only for the reference resistor and AG33. The pattern should be connected to the analog ground. The pattern should be designed avoiding the possibility for common impedance between REFRIN_1 and other signals.
- To prevent cross talk, very-frequently switched signals such as DP_1, DM_1, clocks, and control signals for addresses and data, should not be placed near to the reference resistor, and their patterns should neither get across nor go parallel to the wiring pattern between the reference resistor and the REFRIN_1 pin.

It is recommended to guard ring the reference resistor and its wiring pattern with ground.

Section 34 Capture Engine Unit (CEU)

The CEU is a capture module that fetches image data externally input and transfers it to the memory. The CEU is connected to the system bus via bus bridge modules.

34.1 Features

Lists the fetures of CEU as follows.

(1) Image data fetch

- Captures an image output from an external module and writes YCbCr data to the memory with it separated into Y data and CbCr data.
- Fetches image data other than YCbCr data, e.g. JPEG data, from an externally connected module, such as a camera, and sequentially writes the image data to the memory.
- Fetches an interlace source image in both-field units or one-field units and writes it to the memory. In both-field capture, an image can be stored in the memory as a frame image.

(2) Filter processing

- Performs scale-down and removal of high-frequency components (only in the horizontal direction) for an image using internal filters. Note that the scaled-down image must not exceed VGA. The filter processing can be applied to only YCbCr input data.

(3) Display information acquisition

- Acquires the complexity level of the captured display and writes it to the memory. This information output at MPEG-4 encoding is useful for determining the scene change.

(4) Format conversion

- Converts image data input in the YCbCr 4:2:2 format into the YCbCr 4:2:0 format and writes it to the memory.Note that the conversion algorithm is simple skipping in which the chrominance component (CbCr) of the even-numbered lines is skipped.

The functional overview of the CEU is shown in table 34.1.

List the two homologous series for the interface connecting to camera as follows.

- 16-bit input for parallel-I/F camera.
- 32-bit input from CSI2C.

This LSI does not support strobe function. Do not attempt to write to the register that controls strobe function.

Table 34.1 Functional Overview of CEU

Classification	Item	Function	Description	Note
Connectable camera	Size	Maximum	8188 pixels × 8188 lines	Horizontal: 4-pixel units
		64M pixels		Vertical: 4-line units
		Minimum	48 pixels × 48 lines	

Classification	Item	Function	Description	Note
Connectable camera	Input format	YCbCr 4:2:2 8 bits	Cb_0, Y_0, Cr_0, $Y_{1...}$	Supports clock ratio of 1:1.
			Cr_0, Y_0, Cb_0, $Y_{1...}$	
			Y_0, Cb_0, Y_1, $Cr_{0...}$	
			Y_0, Cr_0, Y_1, $Cb_{0...}$	
		YCbCr 4:2:2 16 bits	{Y0, Cb0}, {Y1, Cr0}, …	
			{Y0, Cr0}, {Y1, Cb0}, …	
		Binary data	Binary data such as JPEG	Written sequentially
	Horizontal and vertical sync signal polarities	Arbitrary	High-active and low-active	
	Capture start location	Arbitrary	Can be specified in camera input clock units.	Horizontal: 1-cycle units Vertical: 1-HD (horizontal sync signal) units
	Number of captured pixels	Arbitrary	Can be specified in 4-pixel units horizontally and in 4-line units vertically.	
	Interlace	Both-field capture	Stored as a field image	Capture: 2-VD (vertical sync signal period) units
			Stored as a frame image	
		One-field capture	Top field or bottom field can be specified	Capture: 1-VD units
Memory write	Output format	YCbCr 4:2:2 YCbCr 4:2:0	YCbCr 4:2:0 is realized by simple skipping.	

Classification	Item	Function	Description	Note
Strobe function (not supported in this LSI)	Strobe control	Automatic mode	Emission time is controlled by to the emission start counter, strobe exposed signal, or vertical sync signal.	Emission start = Register setting Emission stop = Strobe exposed signal Emission start = Register setting Emission stop = Register setting Emission start = Vertical sync signal Emission stop = Vertical sync signal
		Manual mode	Emission pin is controlled by modifying the register.	Emission start = Modifying the register Emission stop = Clearing the register
Filter function	No scaling or scale-down	Scale-down of captured display	Desired scaling factor from 1/16 to 1 (scaled-down display-width must be 2048 pixels or less horizontally)	
	Low-pass filter		Removal of high-frequency components	Only in the horizontal direction
Display information acquisition	Complexity level	Acquisition of complexity level of captured display	Variation of pixel values is indicated	Used for MPEG-4 16-line units, 8-line units, or 1-display units can be selected

Figure 34.1 shows a block diagram of the CEU.

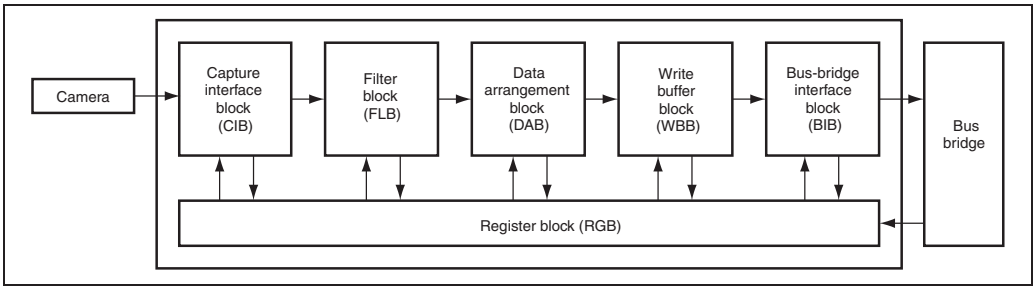

Figure 34.1 Block Diagram of CEU

34.2 Pin Configuration of CEU

The pin configuration of the CEU is shown in table 34.2. And, connected image is shown in Figure 34.2.

Table 34.2 Pin Configuration of CEU

Pin Name	Function	I/O	Description
VIO_D15 to VIO_D0	Main camera data bus	Input	Camera image data input from the main camera
VIO_CLK	Main camera clock	Input	Camera clock input from the main camera
VIO_VD	Main camera vertical sync	Input	Camera vertical sync signal input from the main camera
VIO_HD	Main camera horizontal sync	Input	Camera horizontal sync signal input from the main camera
VIO_FLD	Field signal	Input	Field identification signal
VIO_CKO	Camera clock output	Output	Clock output to the camera

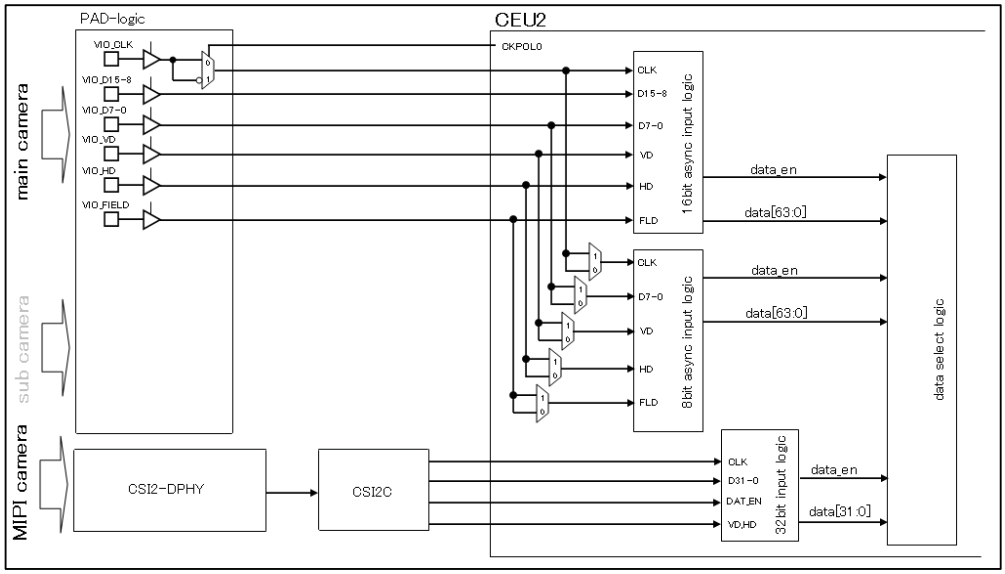

Figure 34.2 shows a connection image

34.3 Description of CEU Registers

The register configuration of the CEU is shown in table 34.3. The register states in each processing mode are shown in table 34.3.

Most CEU registers have a 2-plane configuration (plane A and plane B). The CEU switches the planes when using these 2-plane registers. A mirror address, which is an address that can always access the register on the unused plane, is provided for each 2-plane register. Figure 34.3 shows the timing to switch the register planes. The CEU switches the register planes at the same time a VD interrupt is asserted.

In the following register descriptions, "during operation" indicates the period that begins when the CEU is activated by the CE bit in the capture start register (CAPSR) and ends when a capture end interrupt (CPE) of the capture event flag clear register (CETCR) occurs. In the read-only bits in each register, the write value should always be 0. If a value other than 0 is written to any of these bits, correct operation cannot be guaranteed.

Table 34.3 Register Configuration of CEU

			Addresses			
Register Name	Abbr.	R/W	Address (Plane A)	Address (Plane B)	Mirror Address	Access Size
Capture start register	CAPSR	R/W	H'FE91 0000	—	—	32

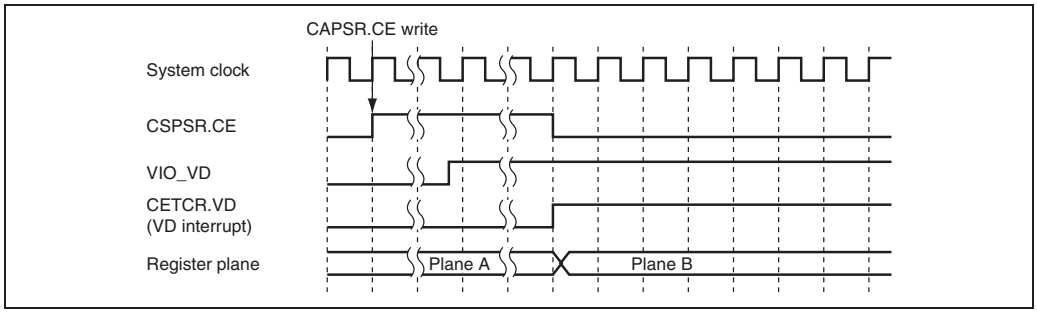

Figure 34.3 Register Plane Switching Timing (VD Polarity is High-Active)

34.3.1 Capture Start Register (CAPSR)

CAPSR captures data input to the CEU from an external module.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPKIL
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	CPKIL	0	R/W	Write 1 to this bit to perform a software reset of capturing. At a software reset, capturing ends immediately without completing capture operation until the end of a frame. Clear the CE bit to 0 when writing 1 to this bit. Processing of the capture software reset is indicated by this bit being set to 1. When this bit is 1, do not start capturing since reset processing is in progress. When restarting capture operations, after referring to the CPTON bit in CSTSR to ensure that the CEU is halted (in the idle state), wait until this bit is cleared to 0. The timing of restarting capture operations is shown in figure 34.7. When a software reset is generated by this bit, a capture end interrupt (CPE bit in CETCR) may be output immediately after the software reset. However, such kind of interrupt should be ignored. Also, even if the capture end interrupt is not output, the interrupt source (CPE bit) must be cleared before capturing of the next frame. 0: Normal state 1: Software reset of capturing
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	CE	0	R/W	• Single-capture This bit reserves capturing of the next frame. When 1 is written to this bit, the capture of one frame starts from the next VD input, and stops when the one-frame capture end interrupt (CPE bit in CETCR) is asserted (figure 34.8). To perform capture again, write 1 to this bit. After the VD or HD polarity is changed, do not write 1 to this bit until the next VD interrupt is asserted. As this bit indicates the capture reserve state, this bit is read as 1 after it is set to 1 and until VD is input. When VD is input, this bit returns to 0 and so is read as 0. The capture end is determined by the one-frame capture end interrupt (CPE bit). This is similar in data fetch mode. Registers should be set before the VD interrupt of the frame where capture starts next. The new register settings take effect at the next VD input. When registers are modified during capturing, the register settings take effect from the capture operations of the next VD input. If a setting register to which writing during capturing is prohibited is modified during capturing, an interrupt source (IGRW bit in CETCR) is generated. For details on the interrupt source, see the description on CETCR. • Continuous capture When this bit is set to 1 while the CTNCP bit in CAPCR is set to 1, continuous capture starts from the next frame (figure 34.9). Note that this bit is not cleared to 0 but remains as 1. To stop capturing, clear this bit to 0; capturing stops after the current frame is completed. Continuous capture operations are possible in only image capture mode. The start address of the memory to which the captured data is written to must be set for each frame. 0: Stops capturing. 1: Starts capturing.

When both the VD (vertical sync signal) and HD (horizontal sync signal) polarities are high-active, one frame is defined as a period from a VD rising edge to the next VD rising edge, and one line as a period from an HD rising edge to the next HD rising edge. Figure 34.4 shows the timing of one frame (when both the VD and HD polarities are high-active).

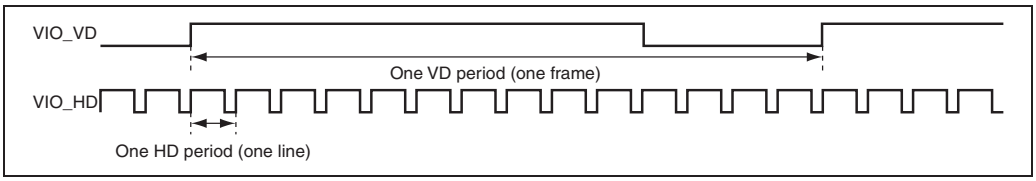

Figure 34.4 Frame Timing

When both the VD and HD polarities are high-active, similar to one frame, one field is defined as follows:

- Period from a VD rising edge to the next VD rising edge
- One line is a period from an HD rising edge to the next HD rising edge.

The field identification signal FLD should be fixed for at least 1-HD period from a VD input. Figure 34.5shows the timing of one field (when both the VD and HD polarities are high-active).

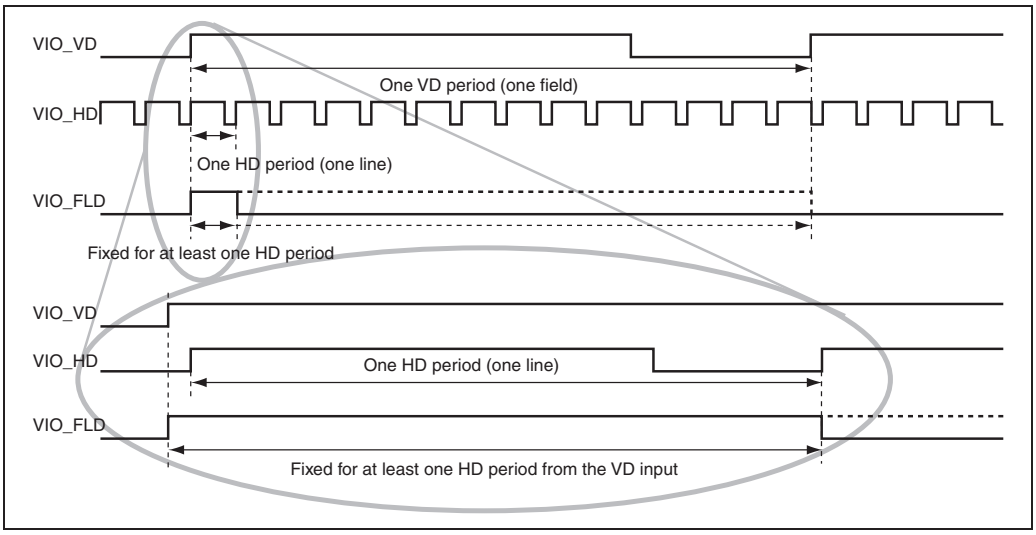

Figure 34.5 One Field Timing

In data enable fetch, one frame is defined as a period from a VD rising edge to the VD falling edge. With the HD as an enable signal (positive polarity), data of a cycle in which the HD is asserted is fetched while the VD is high. Figure 34.6 shows the timing of one frame for data enable fetch.

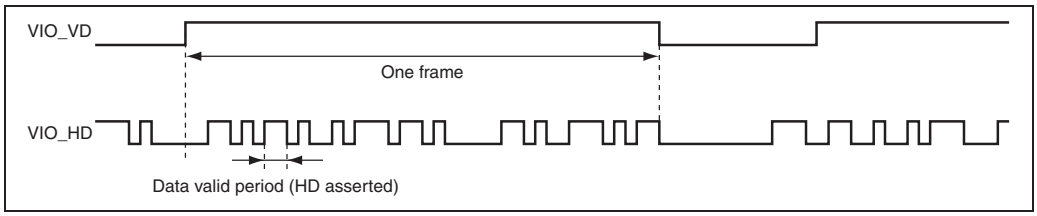

Figure 34.6 Frame Timing (Data Enable Fetch)

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	FDRP[7:0]	H'00	R/W	These bits set the frame drop interval in continuous-frame capture. When these bits are cleared to 0, frame drop is not performed, and all frames are captured. Figure 34.10 shows the value set in these bits and the timing of captured frames. The frame drop interval unit differs according to the capture setting. Table 34.5shows the relationship between the capture setting and frame drop interval unit. The image of the frame drop timing for each capture setting when these bits are set to 2 is shown in figure 34.11. In both-field capture, capturing is performed continuously for 2-VD periods, regardless of whether the second field is the top field or bottom field. In addition, in both-field capture, the frame drop counter is incremented when the first field has been identified as the top field or bottom field, regardless of whether the second field is the top field or bottom field.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	FDRP[7:0]	H'00	R/W	When 0 is written to the CE bit in CAPSR, capturing terminates after the current frame has been captured for a capture frame. However, for a drop frame, capturing is forcibly terminated in the CEU so no capture end interrupt (CPE bit in CETCR) is output. Note: Do not change the setting of these bits during continuous capture operations. To change the setting of these bits, stop continuous capture (CE bit = 0), clear the CTNCP bit (continuous capture) in CAPCR to 0, and then restart continuous capture. Continuous capture is performed during the period of CAPSR.CE = 1 shown in figure 34.10.
23, 22	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	MTCM[1:0]	00	R/W	These bits specify the unit for transferring data to a bus bridge module. The access efficiency of SDRAM where the image data is to be stored can be improved by continuously accessing the addresses. To improve the write efficiency, set these bits to 11. The setting of these bits appears to be unchanged from the outside. 00: Transferred to the bus in 4-burst 1-transfer (4QW × 1) units 01: Transferred to the bus in 4-burst 2-transfer (4QW × 2) units 10: Transferred to the bus in 4-burst 4-transfer (4QW × 4) units 11: Transferred to the bus in 4-burst 8-transfer (4QW × 8) units (1) Image capture 00: Y data and C data are transferred in 4QW units. 01: Y data and C data are transferred in 4QW × 2 units. 10: Y data and C data are transferred in 4QW × 4 units. 11: Y data and C data are transferred in 4QW × 8 units. (2) Data fetch 00: Data is transferred in 4QW units. 01: Data is transferred in 4QW × 2 units. 10: Data is transferred in 4QW × 4 units. 11: Data is transferred in 4QW × 8 units.

Bit	Bit Name	Initial Value	R/W	Description
19 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	CTNCP	0	R/W	When capturing is started with this bit set to 1, capturing continues until the CE bit in CAPSR is cleared to 0 or a software reset is initiated by the CPKIL bit in CAPSR (see figure 34.10). Continuous capture must be set before capturing is started. This bit is modified only after 0 is written to the CE bit to stop capturing. If this bit is modified during capturing, correct operation cannot be guaranteed. In data fetch mode, clear this bit to 0. 0: One-frame capture when the CE bit is 1 1: Continuous capture until the CE bit is cleared to 0
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

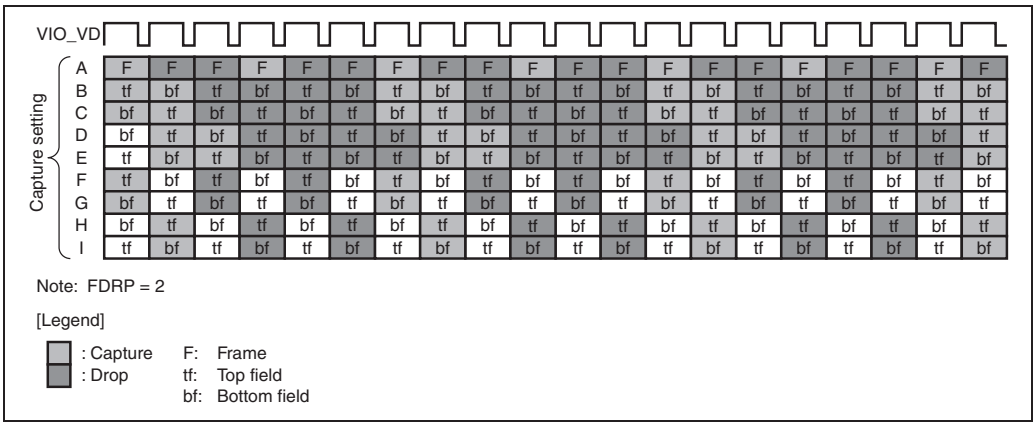

Figure 34.11 Image of Frame Drop Timing for Capture Settings (FDRP Bits = 2)

34.3.3 Capture Interface Control Register (CAMCR)

CAMCR sets the capture interface.

The following items are set by CAMCR.

- Selection between image capture operation or data fetch operation
- Polarities of the vertical and horizontal sync signals
- Input order of image data components (Y, Cb, and Cr) (only for image capture mode)
- Selection of digital image input pins (8 bits or 16 bits)
- Polarity of the field identification signal

CAMCR must be set according to the module connected. In data fetch mode, set the DTARY bits to B'0. Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to B'1.

Note: After changing the setting of this register, do not start capture until at least 10 external input clock cycles have elapsed.

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
16	FLDPOL	0	R/W	Sets the polarity of the field identification signal (FLD) from an external module. 0: When the FLD signal is high-active, the field is detected as the top field and when low-active, the field is detected as the bottom field. 1: When the FLD signal is low-active, the field is detected as the top field and when high-active, the field is detected as the bottom field.
15 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13, 12	DTIF[1:0]	00	R/W	00: Sub camera 8-bit input 01: Main camera 16-bit input 10: Main camera 8-bit input 11: CSI2 32-bit input
11, 10	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9, 8	DTARY[1:0]	00	R/W	These bits set the input order of the luminance component and chrominance component. The order in which the luminance component (Y) and chrominance component (Cb and Cr) are input from an external module differs among modules. The CEU supports the input orders shown in figure 34.12. Set the corresponding value in these bits. In data fetch mode, set these bits to 00. (1) 8-bit interface 00: Image input data is fetched in the order of Cb_0, Y_0, Cr_0, and Y_1. 01: Image input data is fetched in the order of Cr_0, Y_0, Cb_0, and Y_1. 10: Image input data is fetched in the order of Y_0, Cb_0, Y_1, and Cr_0. 11: Image input data is fetched in the order of Y_0, Cr_0, Y_1, and Cb_0. (2) 16-bit interface 00: Image input data is fetched in the order of {Cb0, Y0}, {Cr0, Y1}. 01: Image input data is fetched in the order of {Cr0, Y0}, {Cb0, Y1}. 10: Image input data is fetched in the order of {Y0, Cb0}, {Y1, Cr0}. 11: Image input data is fetched in the order of {Y0, Cr0}, {Y1, Cb0}.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	JPG[1:0]	00	R/W	Selects the fetched data type. 00 Image capture mode (input data is separated into Y data and CbCr data when stored in the memory) 01 Data fetch mode (input data is written to the specified memory addresses in the input order) 10: Data enable fetch mode (Fetch the input data by enabling HD and output to the designated address in the input order) 11: Setting prohibited
3, 2	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
1	VDPOL	0	R/W	Sets the polarity for detection of the vertical sync signal input from an external module. Figure 34.15 shows the relationship between the VD and VD interrupt when high-active is selected. Since a VD interrupt may occur when this bit value is modified, the VD bit in CETCR must always be cleared to 0 when this bit value is changed. This bit cannot be used in data enable fetch mode. 0: Vertical sync signal (VD) from an external module is detected as high-active. 1: Vertical sync signal (VD) from an external module is detected as low-active.

Bit	Bit Name	Initial Value	R/W	Description
0	HDPOL	0	R/W	Sets the polarity for detection of the horizontal sync signal input from an external module. Figure 34.16 shows the relationship between the HD and HD interrupt when high-active is selected. Since an HD interrupt may occur when this bit value is modified, the HD bit in CETCR must always be cleared to 0 when this bit value is changed. Set to 0 in data enable fetch mode. 0: Horizontal sync signal (HD) from an external module is detected as high-active. 1: Horizontal sync signal (HD) from an external module is detected as low-active.

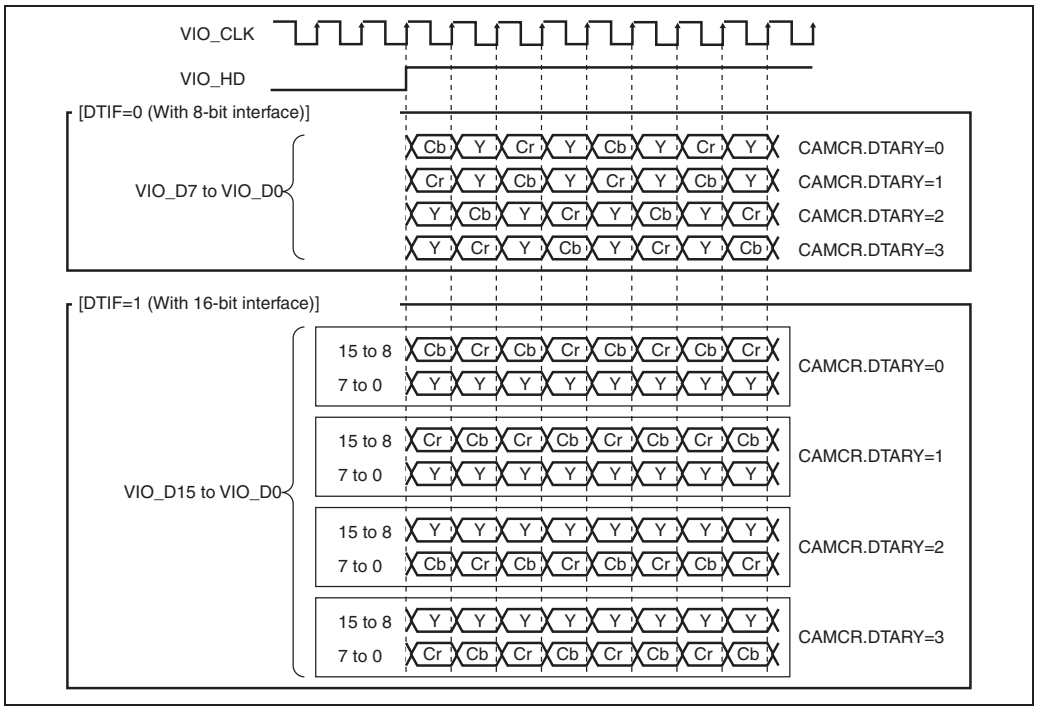

Figure 34.12 Input Order of Image Data

The JPG bit in CAMCR selects whether digital image data is fetched or data such as JPEG is fetched. In addition, when data such as JPEG is fetched, select whether the specified amount of data is continuously fetched in synchronization with the sync signal or data is fetched while the horizontal sync signal is enabled.

In data enable fetch mode, one frame is defined as a period from the rising edge to the falling edge of the vertical sync signal (VD) for data fetching. The horizontal sync signal (HD) is enabled only when the VD is high and treated as an enable signal. Data input in the cycle in which the HD is asserted (high) is fetched and output to the memory continuously.

Figures 34.13 and 34.14 show the interface timing in data enable fetch mode.

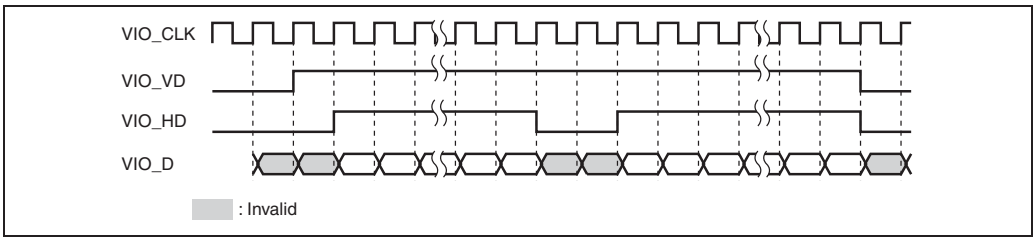

Figure 34.13 Data Enable Fetch Timing (HD Asserted (High) While VD is High)

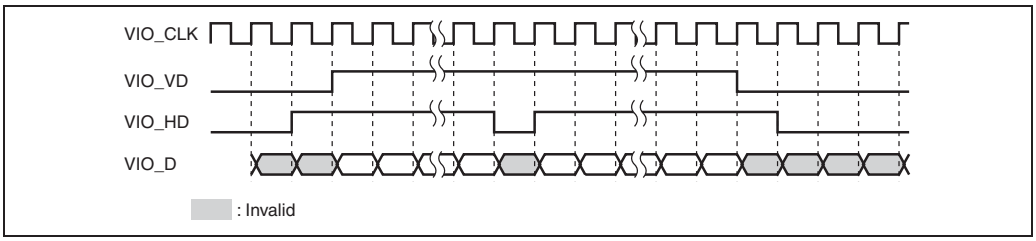

Figure 34.14 Data Enable Fetch Timing (HD Asserted (High) When VD is Not High)

This module starts fetching data at the rising edge of the VD and stops fetching data at the falling edge of the VD in data enable fetch mode. Thus, if the VD remains high and does not go low, end processing does not start. In addition, if the VD remains high and the HD also remains asserted, data continues to be fetched.

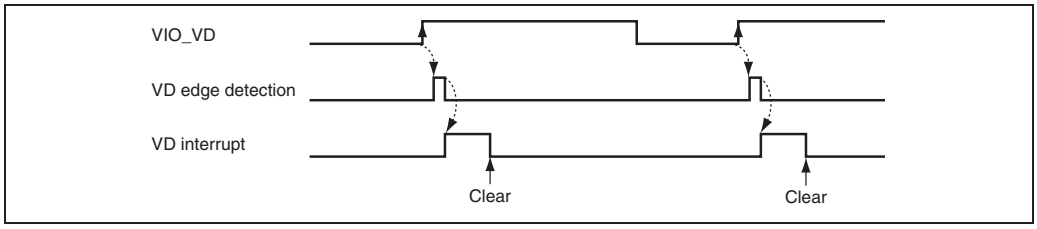

Figure 34.15 Relationship between VIO_VD and VD Interrupt when VD is High-Active

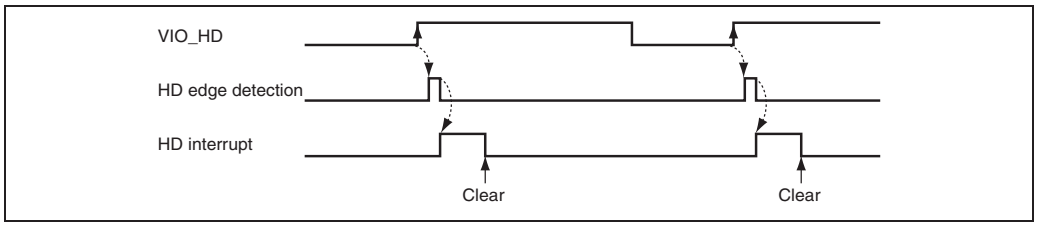

Figure 34.16 Relationship between VIO_HD and HD Interrupt when HD is High-Active

34.3.4 Capture Interface Cycle Register (CMCYR)

CMCYR is used to detect an illegal VD and an illegal HD. For HD, the number of cycles from a rising edge of HD to the next rising edge is set (falling edges when low-active is selected for HD). For VD, the number of HD inputs from a rising edge of VD to the next rising edge is set (falling edges when low-active is selected for VD).

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to B'1.

In data enable fetch mode, set 0 to all the bits in CMCYR register.

Note: After changing the setting of this register, do not start capture until at least 10 external input clock cycles have elapsed.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	VCYL[13:0]	H'0000	R/W	Vertical HD Count of External Module These bits set the number of VD cycles of an external module with the number of HD inputs. The interrupt source bit IGVS in CETCR is set to 1 when the actual number of VD cycles input from the external module differs from this setting. Set these bits for detecting an illegal VD. When these bits are all cleared to 0, the interrupt source bit IGVS in CETCR is not set to 1. Though the interrupt source bit IGVS in CETCR may be set to 1 after the VDPOL bit (VD polarity) in CAMCR is changed, this interrupt should be ignored.
15	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 0	HCYL[14:0]	H'0000	R/W	Horizontal Cycle Count of External Module These bits set the number of HD cycles of an external module. The interrupt source bit IGHS in CETCR is set to 1 when the actual number of HD cycles input from the external module differs from this setting. Set these bits for detecting an illegal HD. When these bits are all cleared to 0, the interrupt source bit IGHS in CETCR is not set to 1. Though the interrupt source bit IGHS in CETCR may be set to 1 after the HDPOL bit (HD polarity) in CAMCR is changed, this interrupt should be ignored.

34.3.5 Capture Interface Offset Register (CAMOR)

CAMOR sets the location to start capturing when capturing images.

Since the number of HD (horizontal sync signal) inputs from a VD (vertical sync signal) input to the start of a valid image period, and the number of clock cycles from an HD input to the start of a valid image period differ among external modules, these must be set in CAMOR. By setting a value greater than the valid image area, part of the image can be clipped for capture. When fetching data, the setting of this register becomes the number of cycles (HD count) up to the start of a valid data period.

* Caution: using of CSI2 connection mode is need special setting. Please refer to detail “34.4.4 CSI2 connetion special setting “.

This register cannot be used in data enable fetch mode.

R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 16	VOFST[11:0]	H'000	R/W	These bits specify the capture start location in terms of the HD count from a vertical sync signal (1-HD units). The blanking period from a vertical sync signal differs among external modules. Therefore, the vertical capture start location must be specified by these bits in terms of the HD count from a vertical sync signal so that an image can be captured from the valid image area (see figure 34.17). Some external modules output a vertical sync signal as a data enable signal. In this case, there is no blanking period so these bits must be cleared to 0 (see figure 34.17).

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	HOFST[12:0]	H'0000	R/W	These bits specify the capture start location in terms of the number of clock cycles from a horizontal sync signal (1-cycle units). The blanking period from a horizontal sync signal differs among external modules. Therefore, the horizontal capture start location must be specified by these bits in terms of external input clock cycles from a horizontal sync signal so that an image can be captured from the valid image area. This is similar in data fetch mode (see figure 34.19). Some external modules output a horizontal sync signal as a data enable signal. In this case, there is no blanking period so these bits must be cleared to 0 (see figure 34.19). Note: The first HD (horizontal sync signal) being input simultaneously or after the first VD (vertical sync signal) is the operating condition of the CEU. These inputs are affected by the polarities (set by the VDPOL and HDPOL bits in CAMCR).

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	IFS	0	R/W	Sets the input mode for capturing images. 0: Progressive 1: Interlace
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CIM	0	R/W	Sets the images to be captured. Clear this bit to 0 when the input mode for image capture is progressive (frame image) or when the input mode for image capture is interlace for continuous capture of both the top and bottom fields. Set this bit to 1 when the input mode for image capture is interlace for capture of only a one-field image. 0: Capture of frame image (1 VD) or both-field image (2 VD) 1: Capture of one-field image (1 VD)

Bit	Bit Name	Initial Value	R/W	Description
3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	CKPOL0	0	R/W	Main Camera Clock Edge Select 0: Input signals (VIO_D0 to D15, VIO_VD, VIO_HD, VIO_FLD) are captured using the rising edge of the sub camera clock (VIO_CLK). 1: Input signals (VIO_D0 to D15, VIO_VD, VIO_HD, VIO_FLD) are captured using the falling edge of the sub camera clock (VIO_CLK).
1, 0	FCI[1:0]	00	R/W	These bits set the timing to start capturing. The timing to start capturing is set by specifying the image to be captured first. Set these bits to 00 when the input mode is progressive. 00: Capture starts from the VD input immediately after the CEU activation regardless of it being a top or bottom field. 01: After the CEU activation, input of a top-field image is waited, and then capture starts from the top field. 10: After the CEU activation, input of a bottom-field image is waited, and then capture starts from the bottom field. 11: Setting prohibited

Table 34.7 CAIFR Setting Items

Input Mode	IFS Bit	Captured Image	CIM Bit	Image to Start Capture	FCI Bits
Progressive	B'0	Frame	B'0	Frame immediately after activation	B'00
Interlace	B'1	Both-field (2-VD capture)	B'0	Field immediately after activation	B'00
				Top field	B'01
				Bottom field	B'10
				Setting prohibited	B'11
		One-field (1-VD capture)	B'1	Field immediately after activation	B'00
				Top field	B'01
				Bottom field	B'10
				Setting prohibited	B'11

In frame image capture and one-field image capture, a one-frame capture end interrupt occurs when capture for 1 VD finishes. In both-field image capture, a one-field capture end interrupt occurs when capture for 1 VD finishes and a one-frame capture end interrupt occurs when capture for 2 VD finishes. At this time, a one-field capture end interrupt occurs simultaneously with a one-frame capture end interrupt. Figure 34.23 shows the timing of a one-frame capture end interrupt and one-field capture end interrupt in both-field image capture.

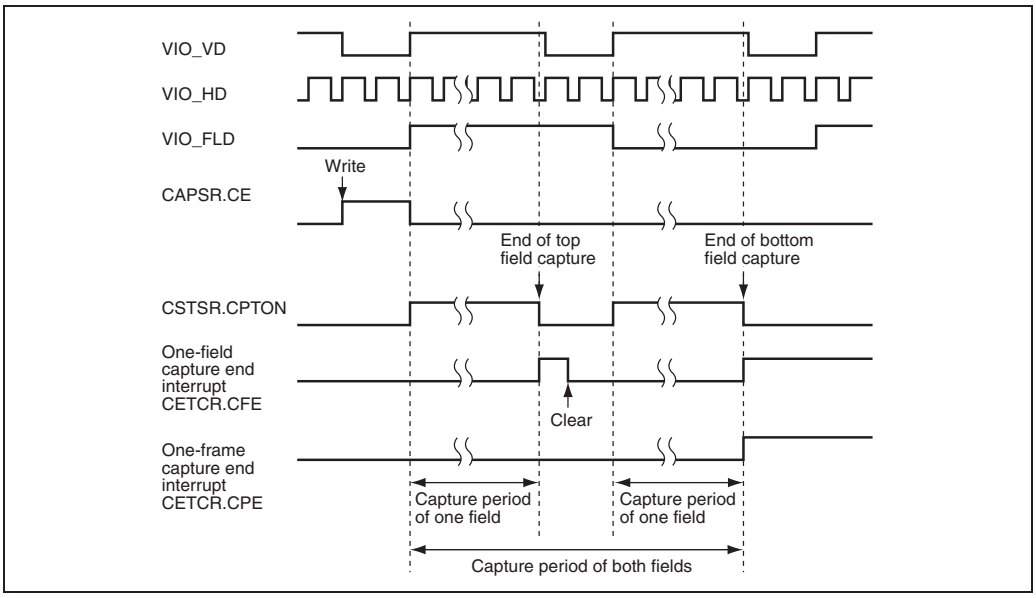

Figure 34.23 One-Frame Capture End Interrupt and One-Field Capture End Interrupt in Both-Field Image Capture

A captured frame image or captured one-field image is stored in the memory from the addresses set in CDAYR and CDACR (figure 34.24). Captured both-field images are stored in different memory areas depending on whether it is a top-field or bottom-field image. A top-field image is stored in the memory from the addresses set in CDAYR and CDACR whereas a bottom-field image is stored in the memory from the addresses set in CDBYR and CDBCR (figure 34.25).

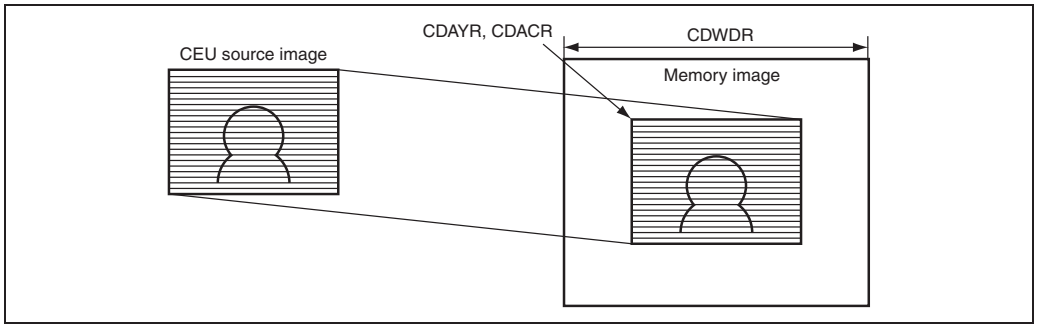

Figure 34.24 Image of Storing Captured Frame Image or Captured One-Field Image in Memory

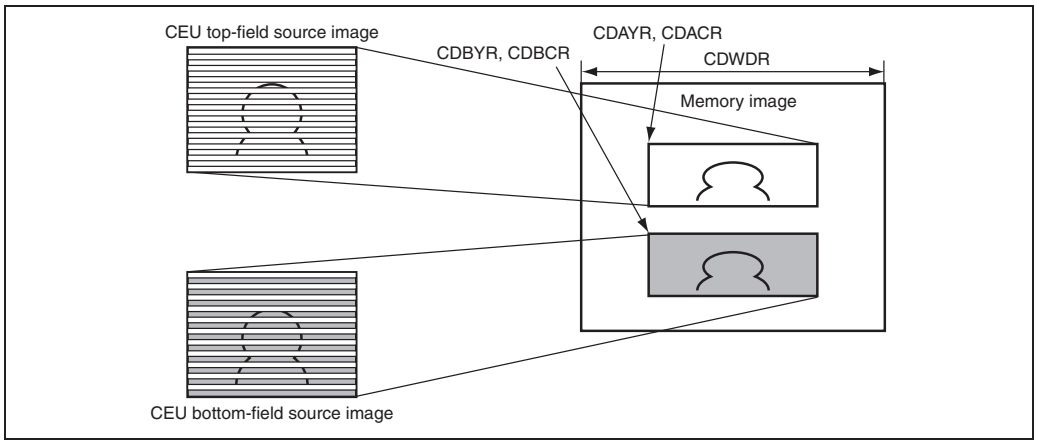

Figure 34.25 Image of Storing Captured Both-Field Images in Memory

If the FCI bits are set to B'00 for continuous capture in interlace input mode, images are continuously captured for 2 VD with the first captured field as the reference in both-field image capture (figure 34.26). In one-field image capture, only the first captured field is continuously captured for 1 VD (figure 34.27).

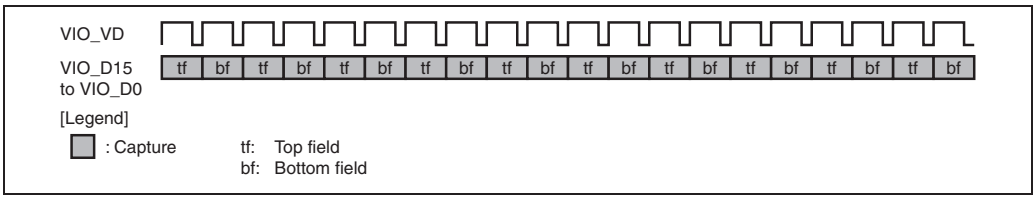

Figure 34.26 Continuous Both-Field Capture in Interlace Mode (Image Immediately after Activation is Top Field (FCI Bits = B'00))

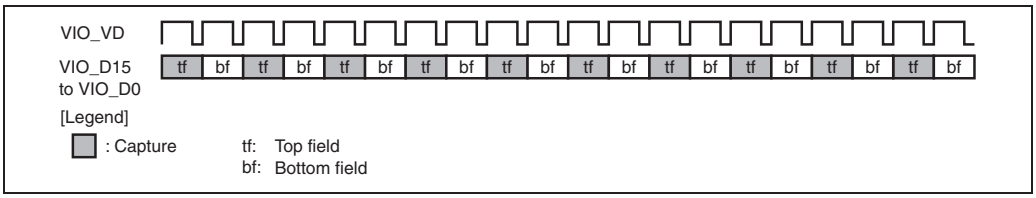

Figure 34.27 Continuous One-Field Capture in Interlace Mode (Image Immediately after Activation is Top Field (FCI Bits = B'00))

(1) Storage of Interlace Input as Frame Image

The CEU can store an interlace source image in the memory as a frame image. To store an interlace source image as a frame image, make the following register settings:

Input mode: Interlace (IFS bit = B'1)

Capture image: Both-field (CIM bit = B'0)

Image to start capture: Any setting other than the prohibited setting (FCI bits = as desired)

Figure 34.28 shows a memory image of capturing both fields of an interlace input and storing it as a frame image in the memory. Set the start addresses of the memory destination for the captured top-field image in CDAYR and CDACR, and the start addresses of the memory destination for the captured bottom-field image in CDBYR and CDBCR. When storing an interlace image as a frame image in the memory, set the horizontal image size of the memory area in CDWDR with the top-field image and bottom-field image placed next to each other as shown in figure 34.28. In addition, set the number of captured lines of the field image in the VWDTH bits in CAPWR.

A memory image of folding the horizontal image size of the memory area in figure 34.28 at CDWDR/2 is shown in figure 34.29. Setting the registers to form the image in figure 34.28 enables an interlace image to be stored as a frame image in the memory as shown in figure 34.29.

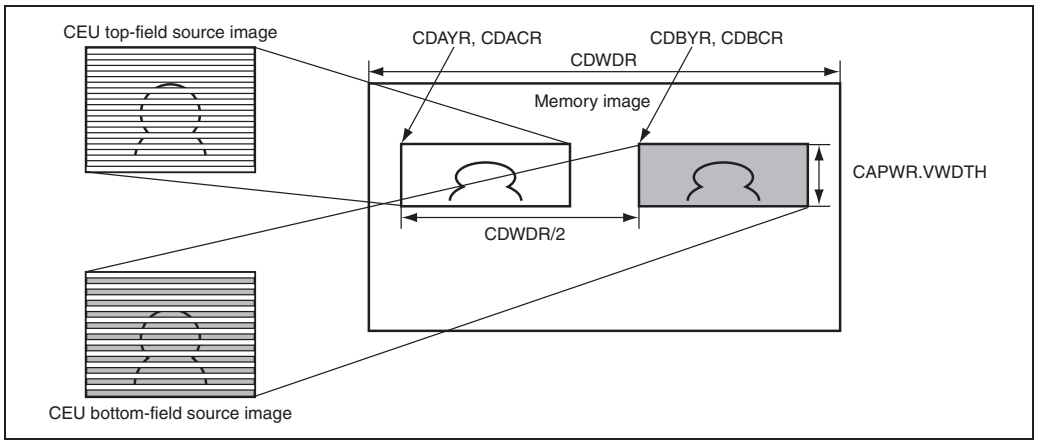

Figure 34.28 Image of Storing Captured Both-Fields of Interlace Input in Memory

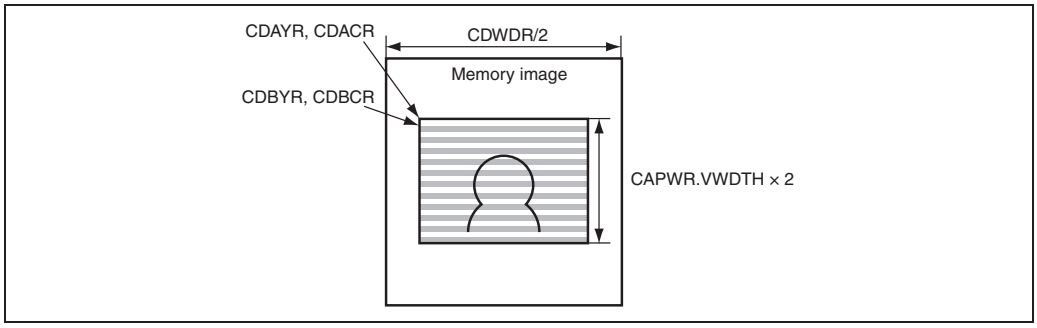

Figure 34.29 Image of Storing Interlace Input as Frame Image in Memory

34.3.8 Camera Strobe Control Register (CSTCR)

Note: CSTCR is not supported in this LSI. Do not attempt to modify this regiser.

CSTCR controls the strobe emission signal. CSTCR is not used in data fetch mode.

Except for the bit used in manual mode, CSTCR should not be modified during strobe emission or in the emission reserved state (STE bit = B'1). If CSTCR is modified during strobe emission or in the emission reserved state, correct operation cannot be guaranteed. Only the SEWR bit is used in manual mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	—	—	—	—	—	SMOD[1:0]		—	—	SXPD	SERD	—	—	—	STE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	SVPOL	0	R/W	Sets the polarity of the strobe sync signal in automatic mode. The polarity of the strobe sync signal can be set independently of the capture interface settings (VDPOL and HDPOL bits in CAMCR). The strobe control unit has an internal counter used to assert an emission signal at the emission timing set in CSECR. This bit sets the edge polarity of VD at which the internal counter is started. 0: Count starts at the rising edge of the vertical sync signal. 1: Count starts at the falling edge of the vertical sync signal.

Bit	Bit Name	Initial Value	R/W	Description
24	SHPOL	0	R/W	Sets the polarity of the strobe sync signal in automatic mode 1 or 2. The polarity of the strobe sync signal can be set independently of the capture interface settings (VDPOL and HDPOL bits in CAMCR). The strobe control unit has an internal counter used to assert or negate an emission signal at the emission timing set in CSECR. This bit sets the edge polarity of HD at which the internal counter is incremented. 0: Count is incremented at the rising edge of the horizontal sync signal. 1: Count is incremented at the falling edge of the horizontal sync signal.
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	SEPOL	0	R/W	Sets the polarity of the strobe sync signal in automatic mode 3. The setting of this bit is valid only in automatic mode 3 (SMOD bits = 11). The polarity of the strobe sync signal can be set independently of the capture interface settings (VDPOL and HDPOL bits in CAMCR) and SVPOL bit setting. The strobe control unit has an internal counter used to negate an emission signal at the emission timing set in CSECR. This bit sets the edge polarity of VD at which the internal counter is incremented. 0: Count is incremented at the rising edge of the vertical sync signal. 1: Count is incremented at the falling edge of the vertical sync signal.
19 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
16	SEWR	0	R/W	Sets the emission pin status in manual mode. The setting of this bit is valid only in manual mode (SMOD bits = 10). The emission pin immediately reflects this bit setting regardless of other bit settings. 0: Forcibly drives the strobe emission signal low. 1: Forcibly drives the strobe emission signal high.
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	SMOD[1:0]	00	R/W	These bits set the strobe operating mode. Automatic mode or manual mode can be selected for the strobe function. These bits must not be modified during strobe operation. If modified, correct operation cannot be guaranteed. 00: Strobe operates in automatic mode 1. 01: Strobe operates in automatic mode 2. 10: Strobe operates in manual mode. 11: Strobe operates in automatic mode 3.
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	SXRD	0	R	Indicates the pin state of the strobe exposed signal which is sampled at the system clock. 0: No strobe exposed signal is input. 1: Strobe exposed signal is input. Note: The strobe exposed signal is high-active.

Bit	Bit Name	Initial Value	R/W	Description
4	SERD	0	R	Indicates the pin state of the strobe emission signal which is sampled at the system clock. 0: No strobe emission signal is output. 1: Strobe emission state Note: The strobe emission signal is high-active.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	STE	0	R/W	Enables or disables strobe emission at the next vertical sync signal in automatic mode. If this bit is set to 1 when the vertical sync signal is input, the emission signal is asserted when the internal counter reaches the value set in the STCT bits in CSECR. This bit is automatically cleared to 0 by a vertical sync signal input. To emit the strobe at the next vertical sync signal input, set this bit to 1 again before the next vertical sync signal input. The polarity of the vertical sync signal is determined by the SVPOL bit setting. 0: Does not emit the strobe. 1: Emits the strobe. Note: When manual mode is selected, this bit must be cleared to 0. Do not write 1 to this bit when the emission signal is being asserted in automatic mode 2.

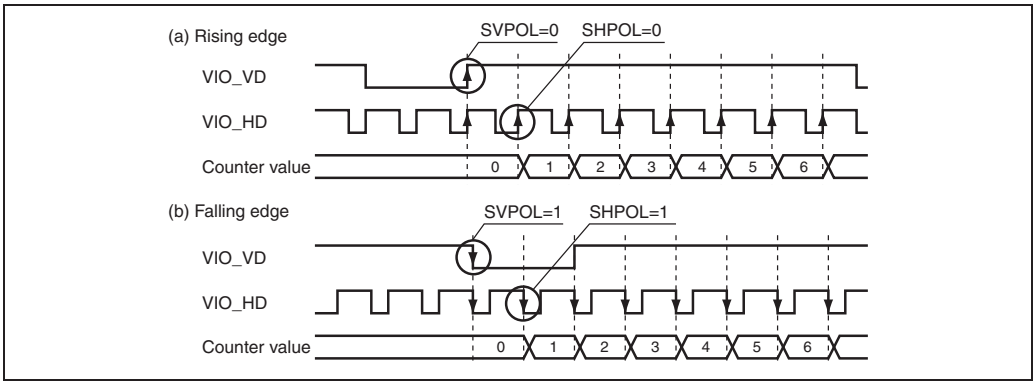

Figure 34.30 Internal Counter Timing Determined by SVPOL and SHPOL Bits

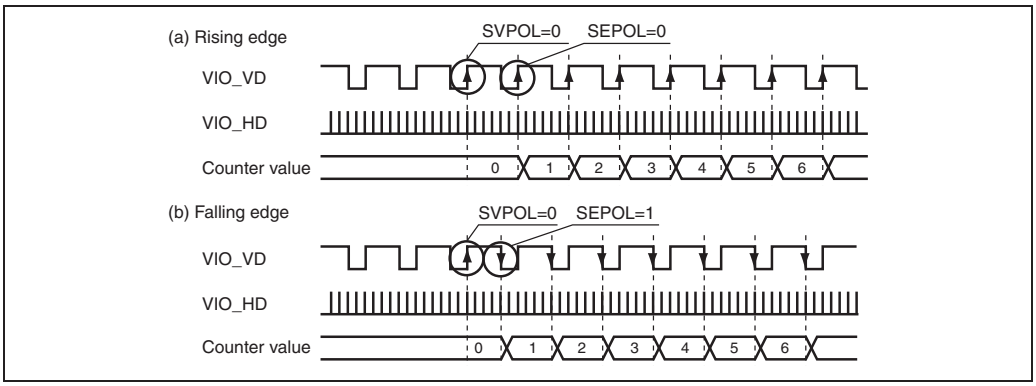

Figure 34.31 Internal Counter Timing Determined by SVPOL and SEPOL Bits

The strobe function has automatic and manual modes. Each mode has the following operations.

(1) Automatic Mode 1 (SMOD Bits = B'00)

- Emission can be enabled or disabled by setting the STE bit.
- The emission signal is asserted at the HD count set by the STCT bits in CSECR.
- The emission signal can be negated only by the exposed signal (writing to the SEWR bit is ignored).

In automatic mode 1, the HD input is counted from the VD edge, and the emission signal is asserted when counting reaches the value set in the STCT bits. The emission signal remains high until the exposed signal is input and is not negated even when the next VD is input. Use manual mode to forcibly negate the emission signal.

Note: For the exposed signal input, drive it high for two or more camera clock cycles.

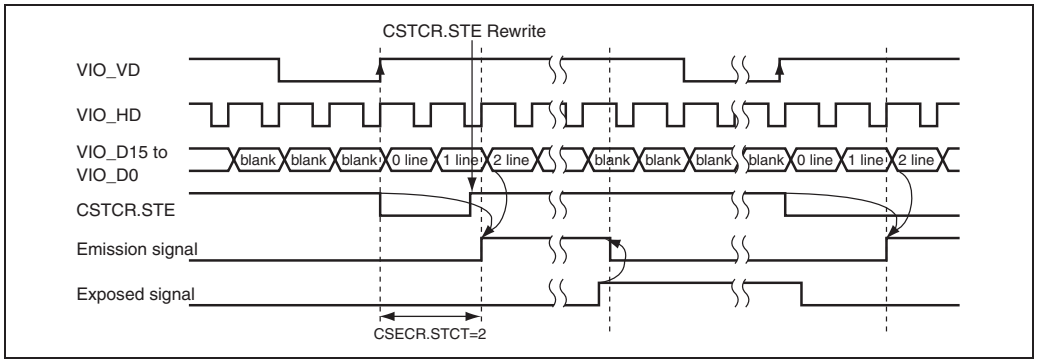

Figure 34.32 Operation Timing of Automatic Mode 1

(2) Automatic Mode 2 (SMOD Bits = B'01)

- Emission can be enabled or disabled by setting the STE bit.
- The emission signal is asserted at the HD count set by the STCT bits in CSECR.
- The emission signal is negated when HD is counted up to the value set by the SEL bits in CSECR.
- The emission signal is not negated even if the exposed signal is asserted.

Operation in automatic mode 2 is similar to that in automatic mode 1 up to the point where the emission signal is asserted. The condition for negating the emission signal is different. The emission signal is negated by input of the exposed signal in automatic mode 1, whereas in automatic mode 2, the emission signal is negated when HD is input for the number of times set in CSECR after the emission signal has been asserted. If the HD count set by the SEL bits is longer than the period until the next VD input, the emission signal is not negated at the next VD input. Strobe control using the exposed signal is not done in automatic mode 2.

In automatic mode 2, the condition for negating the emission signal differs from that in automatic mode 1. The HD inputs are counted, and when the HD count reaches the value set by the SEL bits, the emission signal is negated.

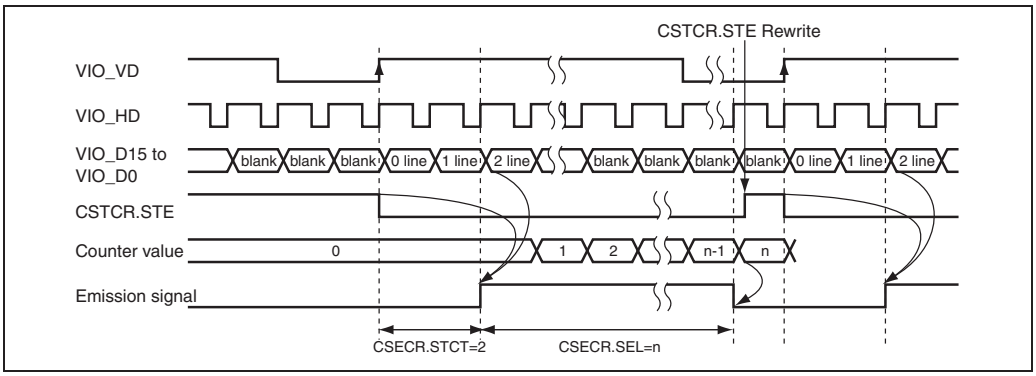

Figure 34.33 Operation Timing of Automatic Mode 2

(3) Manual Mode (SMOD Bits = B'10)

- The emission pin can only be controlled by writing to the SEWR bit.
- The emission timing control counter does not operate. (The STE bit, and the STCT bits in CSECR are ignored.)
- The emission signal is not negated even when the exposed signal is asserted.

In manual mode, the state of the emission pin can be controlled directly by writing to the SEWR bit. In manual mode, the state of the exposed signal can be controlled only by the SEWR bit, and the VD and exposed signals are not referred to.

After the SEWR bit has been written to, it takes several to several tens of system clock cycles for the state of the emission pin to actually change. This delay time depends on the ratio of the camera clock frequency to the system clock frequency. The delay becomes greater as the camera clock becomes slower than the system clock.

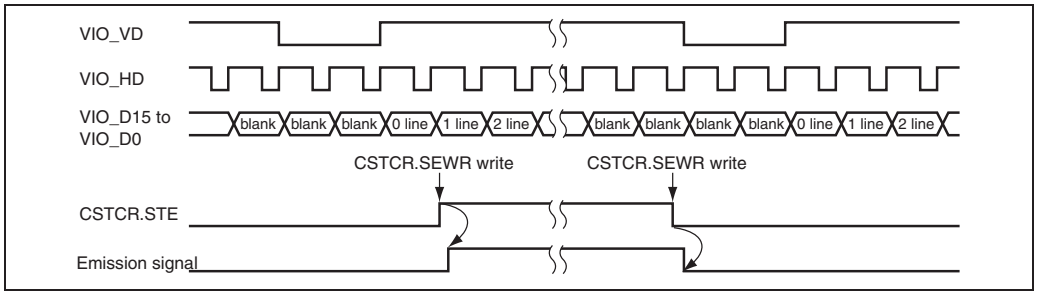

Figure 34.34 Operation Timing of Manual Mode

(4) Automatic Mode 3 (SMOD Bits = B'11)

- Emission can be enabled or disabled by setting the STE bit.
- The emission signal is asserted at the VD input.
- The emission signal is negated when VD is counted up to the value set by the SEL bits in CSECR.
- The emission signal is not negated even if the exposed signal is asserted.

In automatic mode 3, the emission signal is asserted at the VD edge. The emission signal is negated when VD is input for the number of times set in the SEL bits in CSECR after the emission signal has been asserted.

Strobe control using the exposed signal is not done in automatic mode 3.

In automatic mode 3, unlike automatic mode 1 and automatic mode 2 which are synchronized with HD, the emission signal is controlled in synchronization with VD.

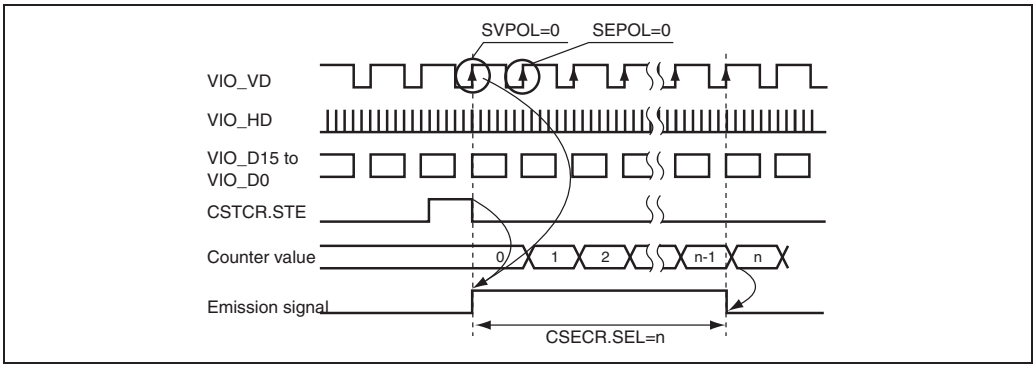

Figure 34.35 Operation Timing of Automatic Mode 3

34.3.9 Camera Strobe Emission Count Register (CSECR)

Note: CSECR is not supported in this LSI. Do not attempt to modify this regiser.

CSECR sets the wait time until the strobe emission signal is asserted, and how long the emission signal is asserted.

The setting of CSECR is not referred to in manual mode. CSECR is also not used in data fetch mode. Do not modify this register during the period that starts when emission is reserved (STE bit in CSTCR is B'1) and ends when the emission signal is negated.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	STCT[13:0]	H'0000	R/W	These bits set the timing until the emission signal is output (counts the number of rising or falling edges of HD). Counting the number of HD inputs starts when capturing begins, and the emission signal is driven high when HD has been input for the number set by these bits.
15, 14	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
13 to 0	SEL[13:0]	H'0000	R/W	Assert Period of Strobe Emission Signal • Automatic mode 2 (HD units) When automatic mode 2 is selected, set the assert period of the strobe emission signal with the number of HD inputs. Do not clear these bits to 0 when automatic mode 2 is selected. • Automatic mode 3 (VD units) When automatic mode 3 is selected, set the assert period of the strobe emission signal with the number of VD inputs. Do not clear these bits to 0 when automatic mode 3 is selected.

34.3.10 CEU Register Control Register (CRCNTR)

CRCNTR controls switching of the planes of registers with a 2-plane configuration.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	RVS	0	R/W	Sets the timing to switch the register plane in both-field capture. The setting of this bit is valid only when the RC bit is 1 in both-field capture. 0: Switches the register plane every two VDs. 1: Switches the register plane every VD.

Bit	Bit Name	Initial Value	R/W	Description
3, 2	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
1	RS	0	R/W	Specifies which register plane is used by the CEU in synchronization with VD. The setting of this bit is valid only when the RC bit is 0. 0: Uses plane A of the register. 1: Uses plane B of the register.
0	RC	0	R/W	Specifies switching of the register plane used by the CEU in synchronization with VD. If the register plane is not switched, the register plane specified by the RS bit is used. 0: Uses the specified register plane in synchronization with VD. 1: Switches the register plane in synchronization with VD.

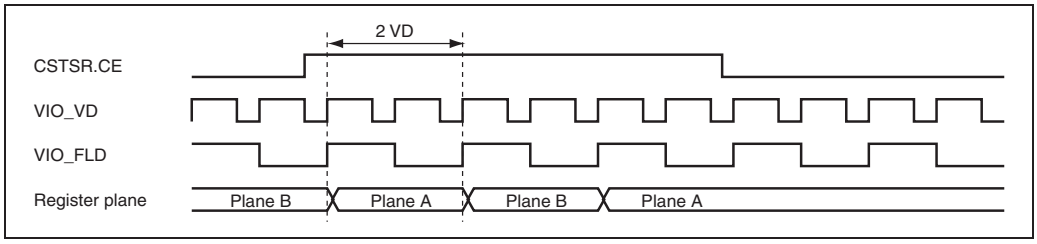

Figure 34.36 Timing for Register Plane Switching when RVS Bit is B'0

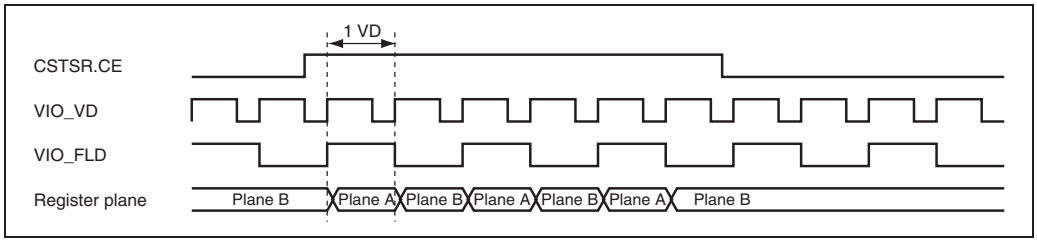

Figure 34.37 Timing for Register Plane Switching when RVS Bit is B'1

34.3.11 CEU Register Forcible Control Register (CRCMPR)

CRCMPR forcibly controls switching of the planes of registers with a 2-plane configuration. Setting this register enables direct control of register plane switching.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to B'1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	RA	0	R/W	Indicates the register plane currently specified. This register value automatically changes in synchronization with VD for starting capture. To start capture with plane A of the register when a setting to switch the register plane in synchronization with VD has been made (RC bit in CRCNTR is 1), specify plane B of the register using this bit. 0: Specifies plane A of the register. 1: Specifies plane B of the register.

34.3.12 Capture Filter Control Register (CFLCR)

CFLCR sets the scale-down factor for the filter to scale images down.

The CEU has an image scale-down filter which can be used to scale down the captured images before storing them in the memory. Set CFLCR to 0 when not performing scale-down (same size output). If a value other than 0 is set in CFLCR, scale-down is performed. In data fetch mode, set CFLCR to 0.

When handling an interlace source image as a frame image, set CFLCR to 0 to not use the filter.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VMANT[3:0]				VFRAC[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HMANT[3:0]				HFRAC[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	VMANT[3:0]	H'0	R/W	Mantissa Part of Vertical Scale-Down Factor The specifiable range is H'0 to H'F. When H'0 is set for the VMANT bits and H'000 is set for the VFRAC bits, the scale-down filter is not used.
27 to 16	VFRAC[1:0]	H'000	R/W	Fraction Part of Vertical Scale-Down Factor The specifiable range is H'000 to H'FFF. The fraction of the scale-down factor that cannot be set with only the VMANT bits must be set with these bits.
15 to 12	HMANT[3:0]	H'0	R/W	Mantissa Part of Horizontal Scale-Down Factor The specifiable range is H'0 to H'F. When H'0 is set for the HMANT bits and H'000 is set for the HFRAC bits, the scale-down filter is not used.
11 to 0	HFRAC[11:0]	H'000	R/W	Fraction Part of Horizontal Scale-Down Factor The specifiable range is H'000 to H'FFF. The fraction of the scale-down factor that cannot be set with only the HMANT bits must be specified with these bits.

An image scale-down filter is installed in the CEU, and the captured images can be scaled down and stored in the memory.

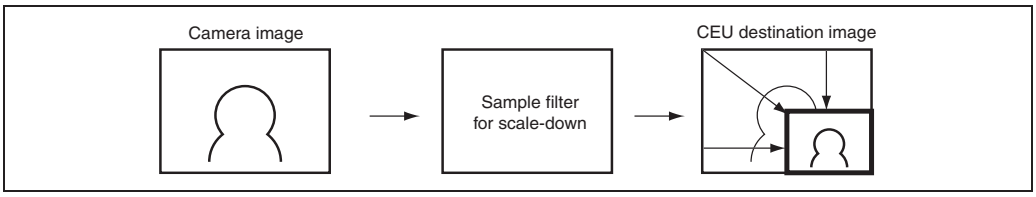

Figure 34.38 Scale-Down of Captured Image

The formulas for obtaining the MANT (VMANT or HMANT) and FRAC (VFRAC or HFRAC) values from the input pixel count and output pixel count of the filter are shown below. Set the MANT and FRAC bits in order to obtain the desired output pixel count from the number of pixels input to the CEU.

First, calculate preliminary MANT and FRAC values. The parameters needed for calculation are defined as follows:

$$\alpha = MANT \times 4096 + FRAC \quad \text{. . . Formula 1}$$

$$SCL \text{ (scaling factor)} = \frac{4096}{\alpha} \quad \text{. . . Formula 2}$$

Assuming an operator $\lfloor x \rfloor$ which discards fractions of an integer x, output size ($SIZE_D$) of the scaled-down filter can be calculated with formula3.

$$SIZE_D = \left\lfloor \frac{SIZE_P}{1 + (SIZE_P \times MANT_{pre} - 1)} \right\rfloor \quad \cdots \text{ Formula 3}$$

$MANT_{pre} = 1 \leftarrow (0 \leqq MANT < 2)$
$MANT_{pre} = 2 \leftarrow (2 \leqq MANT < 4)$
$MANT_{pre} = 4 \leftarrow (4 \leqq MANT < 8)$
$MANT_{pre} = 8 \leftarrow (8 \leqq MANT)$

$SIZE_P$ is calculated by formula 4, 5, and 6. The formula used is different by Horizontal direction, Vertical direction and SCL value. S_{in} is a size of the input image.

case1 : SCL > 1/2

$$SIZE_P = S_{in} \quad \cdots \text{ Formula 4}$$

case2: SCL ≦ 1/2, Horizontal direction

$$SIZE_P = 2 \times \left\lfloor \frac{Sin}{MANT_{pre}} \times \frac{1}{2} \right\rfloor \quad \cdots \text{ Formula 5}$$

case3: SCL ≦ 1/2, Vertical direction

$$SIZE_P = \left\lfloor \frac{Sin}{MANT_{pre}} \right\rfloor \quad \cdots \text{ Formula 6}$$

The number of output pixels can be obtained by substituting the temporarily calculated MANT, FRAC, and input image size into these formulas. If the calculated number of output pixels is smaller than the number of output pixels used to obtain the preliminary MANT and FRAC values, recalculate with a smaller FRAC (α) value, and set the MANT and FRAC values in this register so that a pixel value greater than the desired number of output pixels can be obtained.

Table 34.8 Setting Examples for Each Scale-Down Filter Factor

Scale-Down Factor	FRAC		MANT	Input Pixel Count	Output Pixel Count	Clipping Size (CFSZR)
	Decimal	Hexadecimal				
7/8	576	H'240	1	640	560	560

1/16	4088	H'FF8	15	640	40	40

Note: When an image is scaled down, set the scaled-down image size to at least 48 pixels by 48 lines, and to no more than 2048 pixels wide. When an image is not scaled down (same size output), this restriction does not apply.

Attention: The Scale-Down filter of CEU is two step composition. In pre-filter in the former steps, a right and bottom edge of the image might be lacked. The lacking pixel count can be calculated by the following expression.

$$\text{Lack-pixels} = Sin - SIZE_P \times MANT_{pre}$$

34.3.13 Capture Filter Size Clip Register (CFSZR)

CFSZR sets the clipping size for fine adjustment of the image size output from the filter, and must be set in combination with CFLCR. When clipping the output size of the filter, set the clipping size as a number of pixels, and the setting unit should be four pixels. CFSZR must be set even when scale-down is not performed (same size output).

In data fetch mode, set CFSZR according to the setting of CAPWR.

This register cannot be used in data enable fetch mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 18	VFCLP[11:2]	H'000	R/W	These bits set the vertical clipping value of the filter output size (4-pixel units).
17, 16	VFCLP[1:0]		R	
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 1	HFCLP[11:1]	H'000	R/W	These bits specify the horizontal clipping value of the filter output size (4-pixel units).
0	HFCLP[0]		R	

The scale-down filter in the CEU may output an odd number of pixels or lines depending on the settings. To adjust the output size of the filter, the CEU clips the destination image by using the number of pixels specified in CFSZR, as shown in figure 34.39. The clipping size must be specified vertically and horizontally in 4-pixel units.

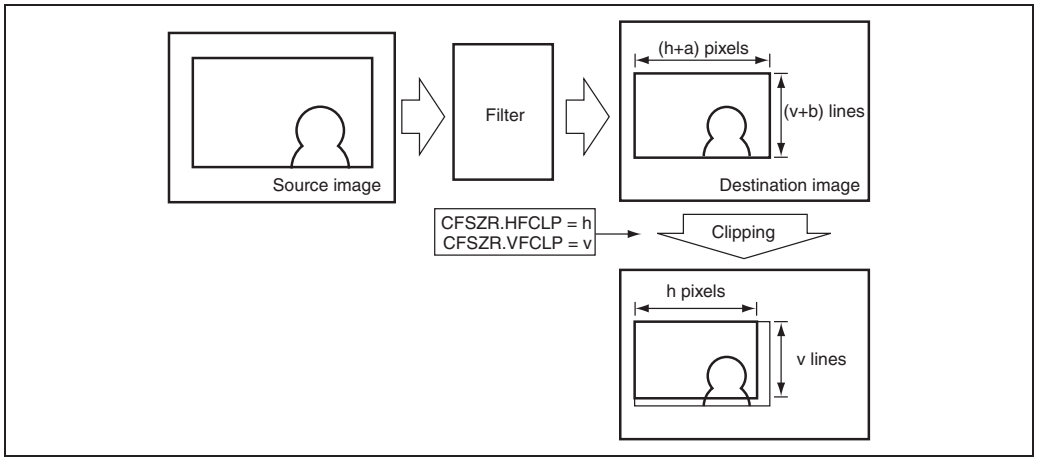

Figure 34.39 Clipping of Image Output from Filter

The pixels to be clipped are counted from the top-left corner of a display. The pixels located to the right of the specified number of pixels or below the specified number of lines are discarded by the clipping function. If the number of pixels specified in CFSZR is larger than that output from the filter, correct operation cannot be guaranteed. To avoid this, the clipping size specified in CFSZR must be equal to or smaller than the number of pixels output from the filter.

Note: In data fetch mode, the following settings are required. Data cannot be fetched correctly unless the following settings are made.
VFCLP = CAPWR.VWDTH
8-bit interface: HFCLP = CAPWR.HWDTH/2
16-bit interface: HFCLP = CAPWR.HWDTH

34.3.14 Capture Destination Width Register (CDWDR)

CDWDR sets the horizontal image size in the memory area where the captured image is to be output in 4-byte units (4-pixel units).

In data fetch mode, set CDWDR according to the setting of CAPWR.

This register cannot be used in data enable fetch mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 2	CHDW[12:2]	H'0000	R/W	These bits specify the horizontal image size in the memory area where the captured image is to be stored (4-byte units). The image data captured by the CEU is stored in the memory. If the right end of the captured image does not match the horizontal image size in the memory area as shown in figure 34.40, some addresses must be skipped at the right end of the image when storing the captured image. Therefore, the horizontal image size in the memory area where the captured image is to be stored must be set in these bits. The maximum value to be set is 8188 bytes (8188 pixels). In data fetch mode, set as follows: 8-bit interface: CHDW = CAPWR.HWDTH 16-bit interface: CHDW = CAPWR.HWDTH × 2
1, 0	CHDW[1:0]		R	

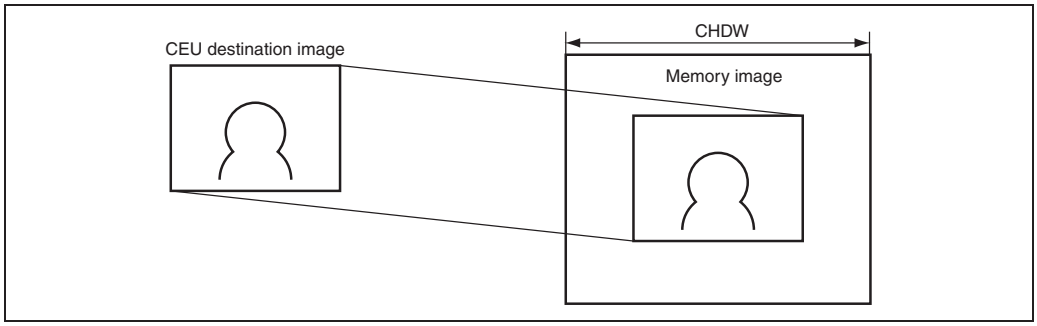

Figure 34.40 Captured Image and Memory Area Image

34.3.15 Capture Data Address Y Register (CDAYR)

CDAYR specifies the address where the luminance (Y) component of the captured data is to be stored in frame image capture or one-field image capture, the address where the luminance (Y) component of the captured top field is to be stored in both-field image capture, and the address where the fetched data is to be stored in data fetch. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the Y (luminance) component of the captured data is to be stored by CDAYR. In both-field image capture, set the start address of the memory area where the Y (luminance) component of the captured top-field image is to be stored by CDAYR. In data fetch, set the start address of the memory area where data is to be stored by CDAYR.

Because the address must be specified in 32 bits, the address set by CDAYR must be in longword units. As the setting is in 4-pixel units for image capture and 4-byte units for data fetch, the lower two bits are always fixed to 0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 2 1, 0	CAYR[31:2] CAYR[1:0]	H'0000 0000	R/W R	• Frame image capture: These bits set the address for storing the Y (luminance) component data of the captured data (4-pixel units). • One-field image capture: These bits set the address for storing the Y (luminance) component data of the captured data (4-pixel units). • Both-field image capture: These bits set the address for storing the Y (luminance) component data of the captured top-field data (4-pixel units). • Data fetch: These bits set the address for storing data (4-byte units). • Data enable fetch in a bundle write: Set the address of the starting point of the starting point of the memory area where the captured data is to be stored in 32-byte units.

Set the address of the starting point of the memory area where the fetched data is to be stored in this register, as shown in figure 34.41.

- Frame image capture: Set the address of the starting point of the memory area where the Y component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the Y component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the Y component of the captured top-field image is to be stored.
- Data fetch: Set the address of the starting point of the memory area where the fetched data is to be stored. In data fetch mode, the data is simply stuffed in order from the start address so the end address becomes as follows:

  End address = CDAYR + number of fetched bytes - 1
- Data enable fetch in a bundle write: Set the address of the starting point of the starting point of the memory area where the captured data is to be stored in 32-byte units.

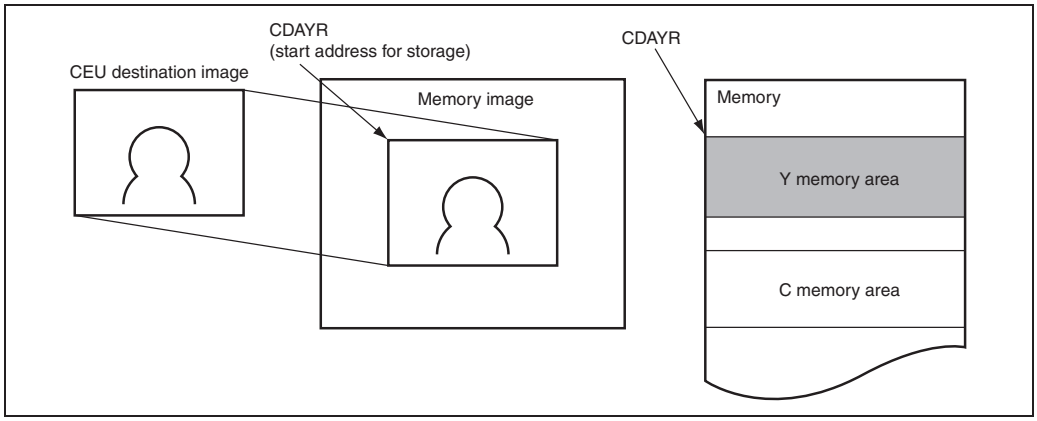

Figure 34.41 Relationship between Captured Image and Y Component Memory Area

34.3.16 Capture Data Address C Register (CDACR)

CDACR specifies the address where the chrominance (C) component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the chrominance (C) component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the C (chrominance) component of the captured data is to be stored by CDACR. In both-field image capture, set the start address of the memory area where the C (chrominance) component of the captured top-field image is to be stored by CDACR. CDACR is not used in data fetch.

Because the address must be specified in 32 bits, the address set by CDACR must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 2 1, 0	CACR[31:2] CACR[1:0]	H'0000 0000	R/W R	• Frame image capture: These bits set the address for storing the C (chrominance) component data of the captured data (4-pixel units). • One-field image capture: These bits set the address for storing the C (chrominance) component data of the captured data (4-pixel units). • Both-field image capture: These bits set the address for storing the C (chrominance) component data of the captured top-field data (4-pixel units).

Set the address of the starting point of the memory area where the C component of the captured image is to be stored in this register, as shown in figure 34.42. The C component has an output data format like that in figure 34.43, and is saved in the memory in this format.

- Frame image capture: Set the address of the starting point of the memory area where the C component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the C component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the C component of the captured top-field image is to be stored.

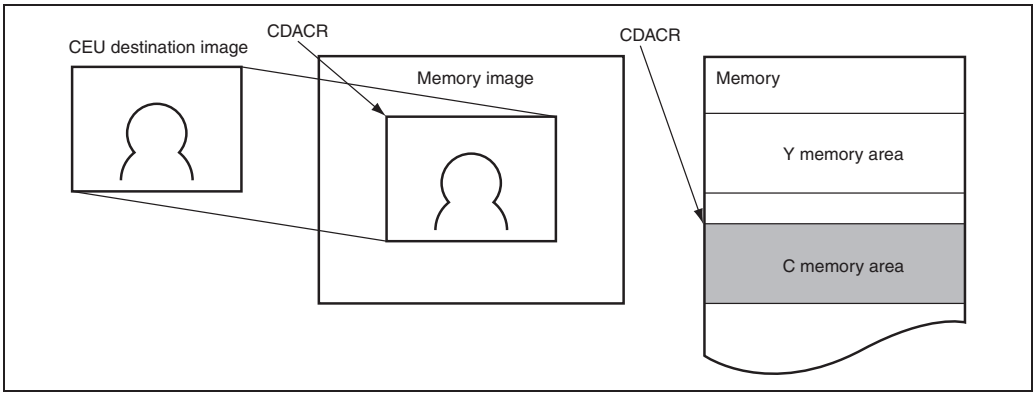

Figure 34.42 Relationship between Captured Image and C Component Memory Area

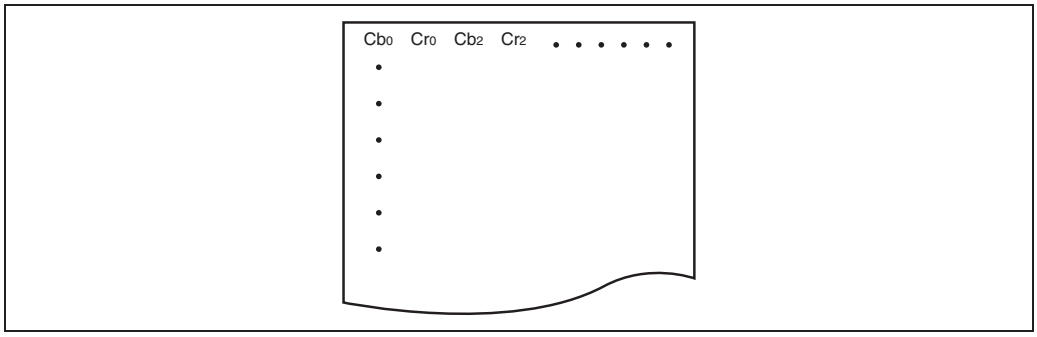

Figure 34.43 Image of Storing C Components in Memory

34.3.17 Capture Data Bottom-Field Address Y Register (CDBYR)

CDBYR specifies the address where the luminance (Y) component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the Y (luminance) component of the captured bottom-field image is to be stored by CDBYR. CDBYR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBYR must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Set the address of the starting point of the memory area where the Y component of the captured bottom-field image is to be stored in this register, as shown in figure 34.44.

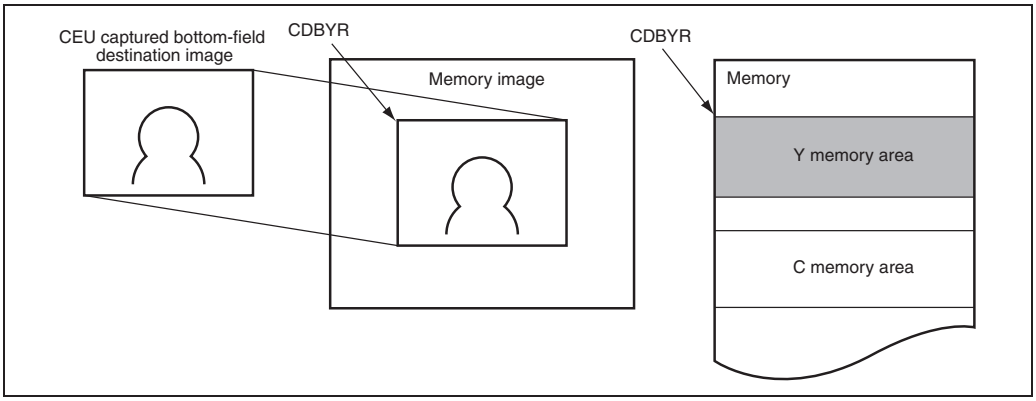

Figure 34.44 Relationship between Captured Bottom-Field Image and Y Component Memory Area

34.3.18 Capture Data Bottom-Field Address C Register (CDBCR)

CDBCR specifies the address where the chrominance (C) component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the C (chrominance) component of the captured bottom-field image is to be stored by CDBCR. CDBCR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBCR must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 3	CBVS[11:3]	H'000	R/W	These bits set the number of lines output to the memory in a bundle write. Set the number of lines of captured data to be written to the memory by a bundle write as a multiple of eight. This register is valid only when the CBE bit in CDOCR is 1. When the CBE bit is 1 and this register cleared to 0, the CEU operates with the number of lines of captured data to be written to the memory as eight.
2 to 0	CBVS[2:0]		R	

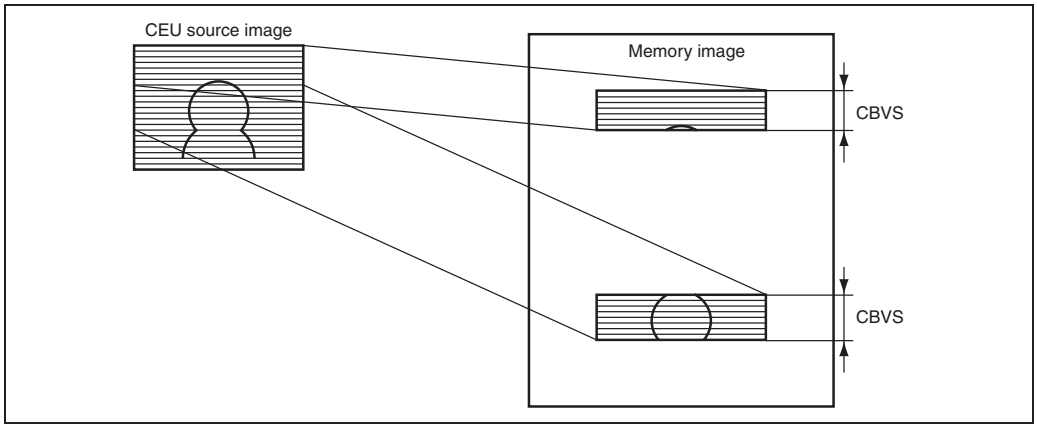

Figure 34.47 Image of Storing Captured Image in Memory by Bundle Write

34.3.20 Capture Low-Pass Filter Control Register (CLFCR)

CLFCR specifies whether or not to operate the low-pass filter. In data fetch mode, clear the LPF bit to B'0.

The characteristic of the low-pass filter installed in the CEU causes the phase location of the image processed by the low-pass filter to be shifted right by one pixel compared to the raw image.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	LPF	0	R/W	Enables or disables operation of the low-pass filter. The low-pass filter removes high-frequency components from the destination image in the horizontal direction. Clear this bit to 0 in data fetch mode. 0: Low-pass filter not used 1: Low-pass filter used (only in the horizontal direction)

34.3.21 Firewall Operation Control Register (CFWCR)

CFWCR specifies the upper limit of the write addresses in data enable fetch. When the VD input from an external module dose not go low and end notification is not given, this register can prevent writing to memory from being out of control.

This register is enabled only in data enable fetch.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	FWV[26:0]	H'0000 000	R/W	These bits specify the upper limit of a write address. For example, when 0x0c008000 is set to the upper limit address, it becomes FWV[26:0]=0x0600400.
4 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	FWE		R/W	With the setting of FWE = 1, when an address exceeds the value set with FWV, the address is retained and an interrupt source FWF is set. After this, the address is not incremented and data is overwritten on the upper limit address. 0: Firewall is not activated. 1: Firewall is activated.

34.3.22 Capture Data Output Control Register (CDOCR)

CDOCR sets the format for outputting captured data to the memory. In data fetch mode, set the CDS bit to B'1 and the CBE bit to B'0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
16	CBE	0	R/W	Controls the number of lines of captured data to be written to the memory. • Image capture This bit controls the number of lines of captured data to be written to the memory. When bundle write is set by this register, captured data is written in line units specified by CBDSR to the addresses specified by CDAYR and CDACR, and CDAYR2 and CDACR2 (CDBYR and CDBCR, and CDBYR2 and CDBCR2 for the bottom field in both-field capture) alternately (figure 34.48). When captured data has been written for the number of lines set by CBDSR, a write end interrupt corresponding to each address setting register occurs. However, after write for one-frame (one-field) capture ends, a bundle write end interrupt does not occur even when bundle write has finished. • Data synchronous fetch This bit controls the number of lines of captured data to be written to the memory. When bundle write is set by this register, captured data is written in line units specified by CBDSR to the addresses specified by CDAYR and CDAYR2 alternately. When captured data has been written for the number of lines set by CBDSR, a write end interrupt corresponding to each address setting register occurs. However, after write for one-frame capture ends, a bundle write end interrupt does not occur even when bundle write has finished.

Bit	Bit Name	Initial Value	R/W	Description
16	CBE	0	R/W	• Data enable fetch This bit controls the number of bytes of captured data to be written to the memory. When bundle write is set by this register, captured data is written in byte units specified by CBDSR to the addresses specified by CDAYR and CDAYR2 alternately. When captured data has been written for the number of bytes set by CBDSR, a write end interrupt corresponding to each address setting register occurs. Also, only in data enable fetch, a bundle write end interrupt occurs when bundle write has finished after write for one-frame capture ends. Table 34.9 shows the correspondence between address setting registers and write end interrupt sources. Figure 34.49 shows the timing of write end interrupts. 0: Normal write 1: Bundle write
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CFXAD	0	R/W	Sets the fixed address mode for outputting images or data processed by the CEU to the memory. If fixed address mode is selected, the addresses to which the CEU outputs images are not incremented and are always the same. In fixed address mode, addresses whose lower five bits are 0 must be set to the output address registers, CDAYR, CDACR, CDBYR, and CDBCR. 0: Output addresses for the output section are incremented (normal operation). 1: Output addresses for the output section are fixed (fixed address mode).
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	CDS	0	R/W	Sets the image format when outputting the image data captured in the YCbCr 4:2:2 format to the memory. When 0 is written to this bit, only the luminance component (Y) is output and no chrominance components (Cb and Cr) are output for the odd-numbered lines. With an interlace source image, similarly only the luminance component (Y) is output and no chrominance components (Cb and Cr) are output for the odd-numbered lines of the field. In data fetch mode, set this bit to 1. 0: Converts the YCbCr 4:2:2 format to the YCbCr 4:2:0 format before outputting data to the memory. 1: Outputs data in the YCbCr 4:2:2 format to the memory without conversion.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	COLS	0	R/W	Controls swapping in longword units for data output from the CEU. 0: Data is not swapped in longword units. 1: Data is swapped in longword units.
1	COWS	0	R/W	Controls swapping in word units for data output from the CEU. 0: Data is not swapped in word units. 1: Data is swapped in word units.
0	COBS	0	R/W	Controls swapping in byte units for data output from the CEU. 0: Data is not swapped in byte units. 1: Data is swapped in byte units.

CDBYR2, CDBCR2	CPBE4 bit in CETCR

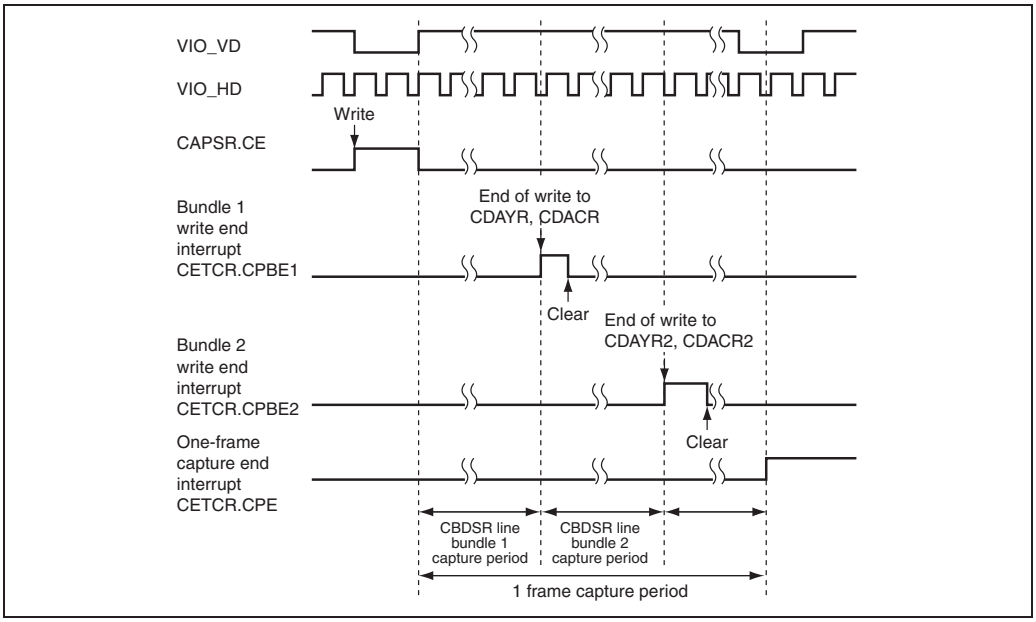

Figure 34.49 Timing of Write End Interrupts

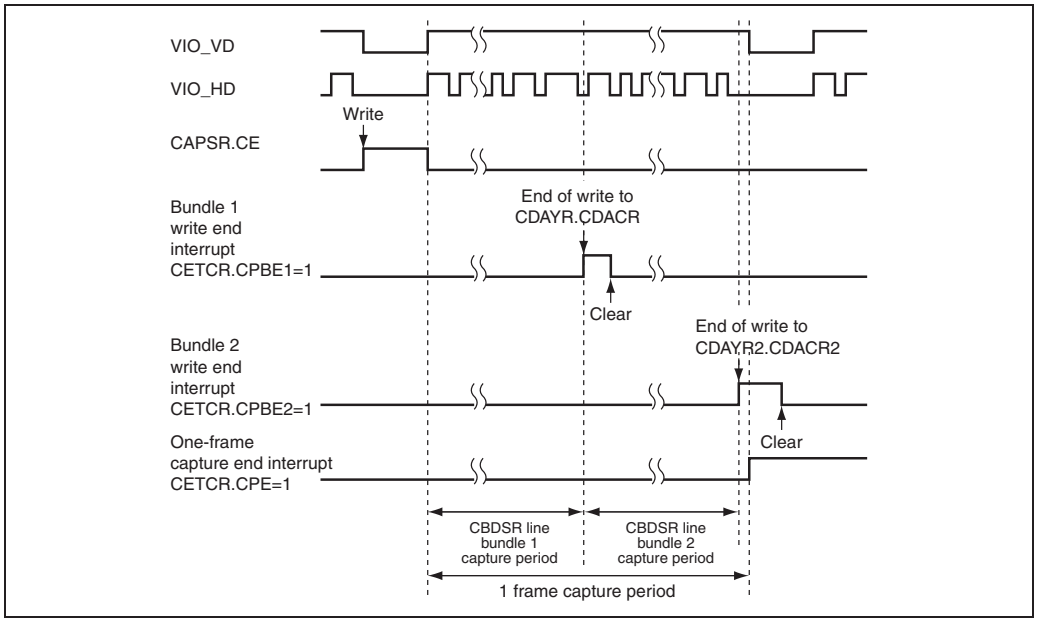

Figure 34.50 Timing of Write End Interrupts (Data Enable Fetch)

For data output from the CEU, the COLS, COWS, and COBS bits control swapping in longword, word, and byte units, respectively. Set these bits when data is misaligned because of a difference in endian. The data swapping bits are shown below. These bits can be set similarly in data fetch mode.

Data can be swapped in byte, word, longword, and byte-word-longword units, as shown in figure 34.51. To enable data swapping, set the corresponding control bit to B'1.

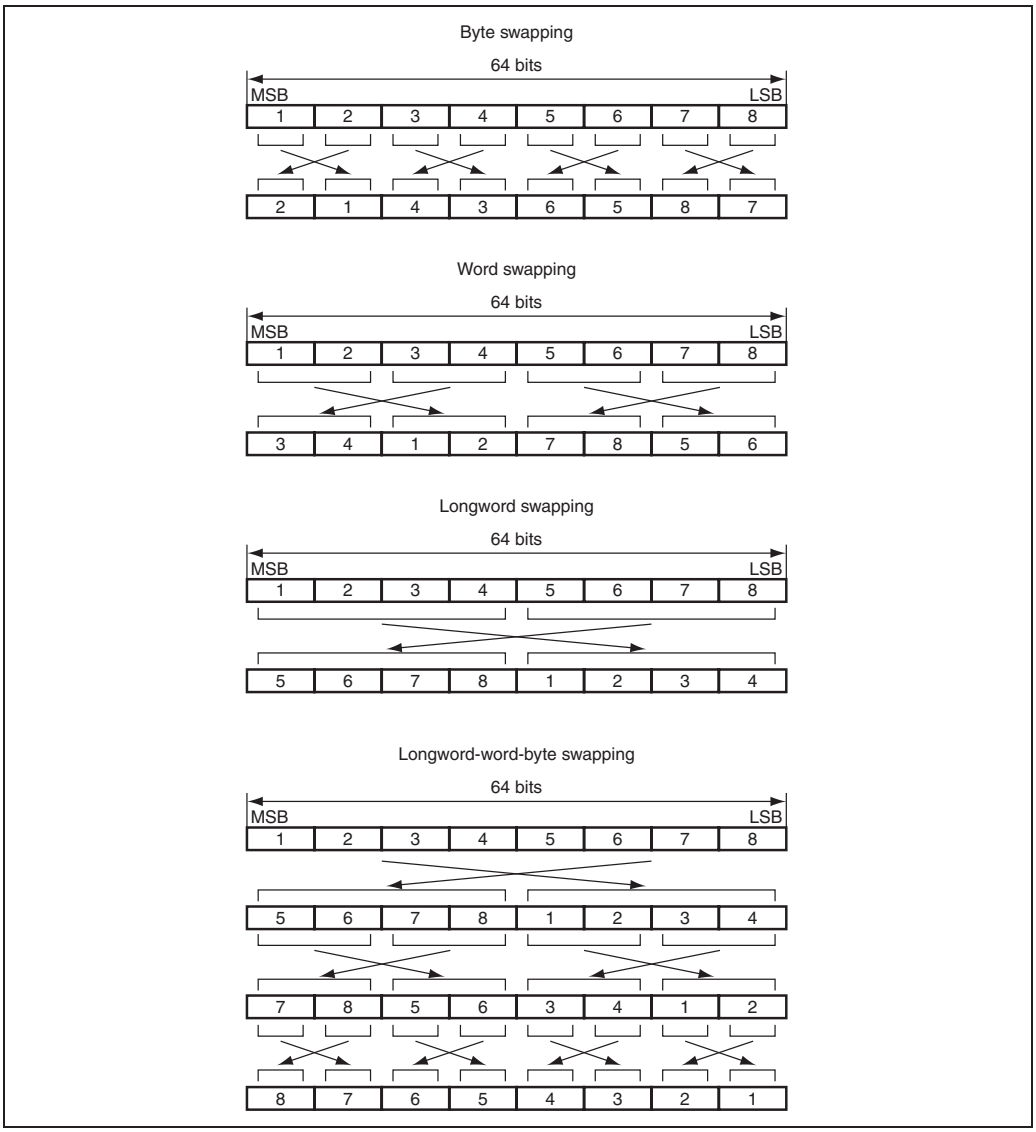

Figure 34.51 Data Swapping by Data Aligner

34.3.23 Capture Data Complexity Level Register (CDDCR)

CDDCR sets how to acquire the complexity level of the captured image. The CEU calculates the complexity level of the image from the luminance component value of the captured image. The result of comparing the complexity levels of continuous images can be useful information in detecting a scene change. CDDCR is not used in data fetch mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	DCOE	0	R/W	Enables or disables output of the complexity level of the captured image to the memory. When writing 1 to this bit, always set a memory address to write the complexity level. If capturing is started with no address set, data in the memory may be overwritten. In data fetch mode, clear this bit to 0. 0: Complexity level of the captured image is not output to the memory. 1: Complexity level of the captured image is output to the memory.
3, 2	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	DCSL[1:0]	00	R/W	These bits select the operation pixel range when calculating the complexity level of an image. 00: Calculates the complexity level of the luminance component for 16 lines of the captured image. 01: Calculates the complexity level of the luminance component for eight lines of the captured image. 10: Calculates the complexity level of the luminance component for one display of the captured image. 11: Setting prohibited

34.3.24 Capture Data Complexity Level Address Register (CDDAR)

CDDAR specifies the address where the complexity level of the captured image is to be stored. The CEU writes the complexity level of the captured image to the memory when the DCOE bit in CDDCR is B'1. Set the start address of the memory area where the complexity level of the captured image is to be stored by CDDAR. CDDAR is not used in data fetch mode.

Note that the destination address should be set for each frame (field) also in continuous capture.

Whether or not to acquire the complexity level of the captured image is set by the DCOE bit in CDDCR, and the acquisition range (16 lines, eight lines, or one display) is set by the DCSL bit in CDDCR.

Because the address must be specified in 32 bits, the address set by CDDAR must be in longword units. As the setting is in longword units, the lower two bits are always fixed to 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
9	VDIE	0	R/W	VD Interrupt Enable 0: Disables a VD interrupt. 1: Enables a VD interrupt.
8	HDIE	0	R/W	HD Interrupt Enable 0: Disables an HD interrupt. 1: Enables an HD interrupt.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	IGRWIE	0	R/W	Register-Access-During-Capture Interrupt Enable 0: Disables a register-access-during-capture interrupt. 1: Enables a register-access-during-capture interrupt.
3, 2	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
1	CFEIE	0	R/W	CFE Interrupt Enable 0: Disables a CFE interrupt. 1: Enables a CFE interrupt.
0	CPEIE	0	R/W	One-Frame Capture End Interrupt Enable 0: Disables a one-frame capture end interrupt. 1: Enables a one-frame capture end interrupt.

34.3.26 Capture Event Flag Clear Register (CETCR)

CETCR notifies the CPU of the source of an interrupt that is generated in the CEU. The flags of CETCR can be used as interrupt signals. When the corresponding interrupt is enabled, an interrupt is generated. To clear the interrupt, clear the bit corresponding to the interrupt source to 0. After several cycles have passed after modifying the bit, the interrupt is cleared.

To clear the bit corresponding to the interrupt source to be cleared to 0 and retain that state, write 1 to that bit. For example, to clear only the CPE bit to 0, write H'FFFF FFFE to CETCR.

In CETCR, only bits to which 0 is written are cleared. Bits to which 1 is written retain their current values. To clear an interrupt source, write 0 only to the bit corresponding to the interrupt source to be cleared, and 1 to the other bits.

Note: Since the CETCR value becomes undefined in the following cases, clear all bits in CETCR to 0.
- VD and HD bits immediately after reset
- All bits after the clock is stopped
- VD and HD bits after the polarities of the capture interface sync signals are changed

R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	NVD	0	R/W	This bit is used for an interrupt indicating that no VD was input. A non-VD interrupt occurs when the 14-bit internal counter becomes full. Accordingly, this bit is set to 1 when no VD has been input for at least 16,384 lines since the last VD was input.

Bit	Bit Name	Initial Value	R/W	Description
24	NHD	0	R/W	This bit is used for an interrupt indicating that no HD was input. The timing for a non-HD interrupt to occur differs depending on the bit width of the digital image input pins. 8-bit digital image input pins: Occurs when the 11-bit internal counter that is incremented every eight cycles becomes full. Accordingly, this bit is set to 1 when no HD has been input for at least 16,376 cycles since the last HD was input. 16-bit digital image input pins: Occurs when the 12-bit internal counter that is incremented every four cycles becomes full. Accordingly, this bit is set to 1 when no HD has been input for at least 16,380 cycles since the last HD was input. When connecting a camera whose HD is fixed low when VD is low, this bit may be set to 1.
23	FWF	0	R/W	The interrupt is generated when data is written to the address that exceeds the value specified with CFWCR.FMV. This bit is set to 1 when data is written to the address that exceeds the value specified with CFWCR.FMV while CFWCR.FWE = 1.
22	DCOF	0	R/W	This bit is used for an interrupt indicating that the data requested to be transferred during acquisition of the complexity level of an image has been overwritten with subsequent data. Since there is no buffer to store data while acquiring the complexity level of an image, if data transfer to the bus is not completed until the next complexity level is calculated, data waiting to be transferred to the bus will be overwritten by the next data. This bit is set to 1 when the complexity level of the next image overwrites the complexity level of the image waiting to be transferred to the bus.
21	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
20	VBP	0	R/W	This bit is used for an interrupt indicating that VD has been input while the CEU holds data (insufficient V.B.P.). The conditions for a VBP interrupt to occur are as follows: • Condition 1 VD is input when there is captured data within the CEU. • Condition 2 The last transfer data cannot be internally detected due to a write buffer overflow or an illegal HD so that the end timing is unclear until the next VD (By generating a VBP interrupt at the VD input timing, capture fail can be announced.) When a VBP interrupt occurs, a capture end interrupt (CPE bit in CETCR) does not occur and the image of that frame is not captured correctly. Though a capture end interrupt (CPE bit) will occur on rare occasions, it should be ignored in this case. Capturing cannot be performed until the next VD (even if the CE bit (capture reservation signal) in CAPSR is 1, capturing does not start). In the case of condition 2, instead of waiting for a VBP interrupt to occur, execute a software reset (CPKIL bit in CAPSR) to stop capturing and then restart capturing. In this case, since capture operation is terminated without waiting for the next VD, a VBP interrupt does not occur and capturing can be performed from the next VD.
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18	IGVS	0	R/W	This bit is used for an interrupt generated when the number of VD cycles set in CMCYR differ from the number of VD cycles input from an external module. This bit is set to 1 when there is an illegal VD input from an external module. This bit is set to 1 when the number of HD cycles for the VD input to the CEU differs from the value set in the VCYL bits in CMCYR. Note however that when the VCYL bits are cleared to 0, this interrupt does not occur.

Bit	Bit Name	Initial Value	R/W	Description
17	IGHS	0	R/W	This bit is used for an interrupt generated when the number of HD cycles set in CMCYR differ from the number of HD cycles input from an external module. This bit is set to 1 when there is an illegal HD input from an external module. This bit is set to 1 when the number of clock cycles for the HD input to the CEU differs from the value set in the HCYL bits in CMCYR. Note however that when the HCYL bits are cleared to 0, this interrupt does not occur.
16	CDTOF	0	R/W	This bit is used for an interrupt indicating that data overflowed in the CRAM of the write buffer. Since data is input at realtime from an external module in capture operations, the frame image is overwritten unless the captured data is transferred from the CEU internal buffer to the memory at a certain or higher transfer rate. This bit is set to 1 when writing the data in the CRAM of the CEU internal write buffer to the bus is not performed within time and data has overflowed.
15	CPBE4	0	R/W	This bit is used for an interrupt indicating that writing to CDBYR2 and CDBCR2 in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines set in CBDSR has been captured and the last data transfer to the bus has completed. However, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).
14	CPBE3	0	R/W	This bit is used for an interrupt indicating that writing to CDBYR and CDBCR in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines set in CBDSR has been captured and the last data transfer to the bus has completed. However, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).

Bit	Bit Name	Initial Value	R/W	Description
13	CPBE2	0	R/W	This bit is used for an interrupt indicating that writing to CDAYR2 and CDACR2 in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines set in CBDSR has been captured and the last data transfer to the bus has completed. However, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).
12	CPBE1	0	R/W	This bit is used for an interrupt indicating that writing to CDAYR and CDACR in a bundle write has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next HD input. This bit is set to 1 when data for the number of lines set in CBDSR has been captured and the last data transfer to the bus has completed. However, this interrupt does not occur when the last captured data in a bundle write is the last captured data of a frame (field).
11, 10	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
9	VD	Undefined	R/W	This bit is used for an interrupt indicating that VD (vertical sync signal) was input from an external module. This bit is set to 1 when a VD input from an external module is detected. Immediately after the VDPOL bit in CAMCR is modified, a pseudo VD is input and this bit is set to 1. The VD interrupt after the VDPOL bit is modified should be ignored.

Bit	Bit Name	Initial Value	R/W	Description
8	HD	Undefined	R/W	This bit is used for an interrupt indicating that HD (horizontal sync signal) was input from an external module. This bit is set to 1 when an HD input from an external module is detected. Immediately after the HDPOL bit in CAMCR is modified, a pseudo HD is input and this bit is set to 1. The HD interrupt after the HDPOL bit is modified should be ignored.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	IGRW	0	R/W	This bit is used for an interrupt indicating that during capturing, access was attempted to a register to which writing during operation is prohibited. Among the CEU registers, writing during capturing is prohibited for some registers. Table 34.10 shows which registers can/cannot be written to during capturing. This bit is set to 1 when a register to which writing during capturing is prohibited has been written to.
3, 2	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
1	CFE	0	R/W	This bit is used for an interrupt indicating that capturing of one field from an external module has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next VD input (see figure 34.54). This interrupt occurs only in both-field capture mode.
0	CPE	0	R/W	This bit is used for an interrupt indicating that capturing of one frame from an external module has finished. This interrupt is output when the last captured data has been transferred and the end notification received, regardless of the next VD input. This interrupt indicates that capturing of one frame has finished. This bit is set to 1 when the image of the size set in CAPWR is captured and the last data transfer to the bus finished (see figure 34.55).

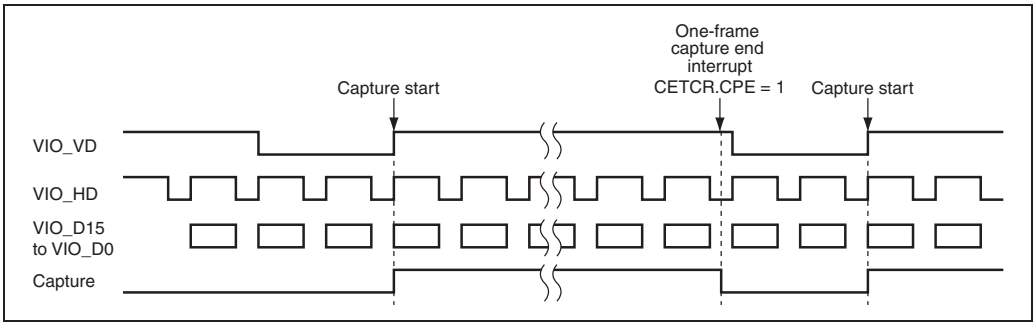

Figure 34.55 CPE Generation Timing

34.3.27 Capture Status Register (CSTSR)

CSTSR indicates the internal status of the CEU. CSTSR differs from CETCR in that no interrupt is generated for the events indicated in CSTSR.

The CEU operating/halt state can be confirmed using CSTSR. To confirm the halt state of the CEU, make sure that all status bits (bits 9, 8, and 0) indicating that the CEU is operating are cleared to 0 for sure.

9	CPREQ	0	R	Indicates the request output port level of the bridge interface.
8	CPACK	0	R	Indicates the acknowledge input port level of the bridge interface.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CPTON	0	R	Indicates that the CEU is operating. This bit retains 1 during the period that starts from the internal VD at capture start and ends when a one-frame capture end interrupt occurs. Figure 34.56 shows the CEU operating period.

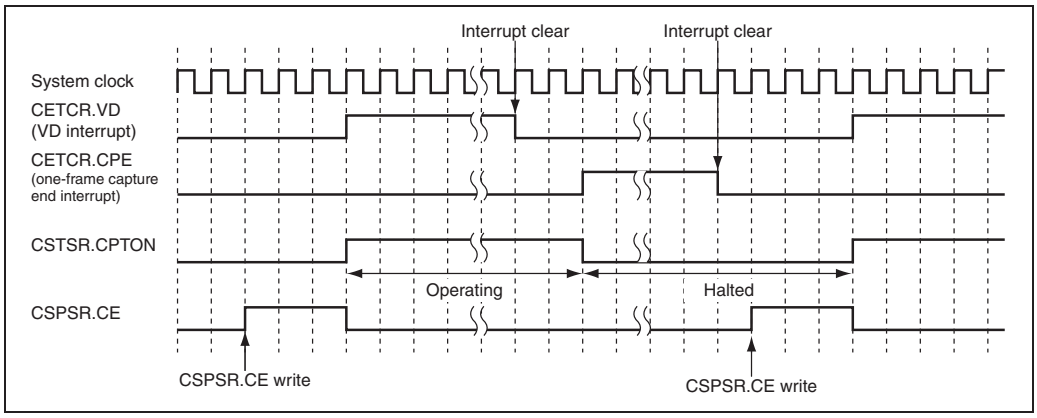

Figure 34.56 Operating Status during Capturing

34.3.28 Capture Software Reset Register (CSRTR)

CSRTR executes a module reset of the CEU internal circuit. This reset processing that does not take the bus state in account should not be used in the normal state.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	$\overline{\text{ALLRST}}$
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ALLRST	0	R/W	Resets the entire CEU and request signals to the bus. 0: Normal state 1: Performs a module reset of the entire sync circuit of the CEU.

Do not modify the ALLRST bit except for in special cases, such as when the entire system hangs. If the ALLRST bit is written to while the CEU is operating, a fatal error may occur; the system may get out of control, or memory areas other than the specified area may be overwritten.

34.3.29 Capture Data Size Register (CDSSR)

CDSSR indicates the size of data written to the memory in data enable fetch. As this register indicates a correct value at the end of capture, confirm this register when capture is completed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CDSS[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CDSS[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CDSS[31:0]	H'0000 0000	R	Indicate the size of data written to the memory in data enable fetch. In a bundle write, size of data written to the selected address at the end of one-frame capture is indicated. In a bundle write, as soon as the number of bytes specified by CBDSR is transferred to the bus, address to which data is written is switched. Therefore, if one-frame capture is completed at the same time as a bundle write is completed, this register indicates H'0000 0000. Figures 34.57 and 34.58 show the overall timing of the CDSSR operation in a bundle write.

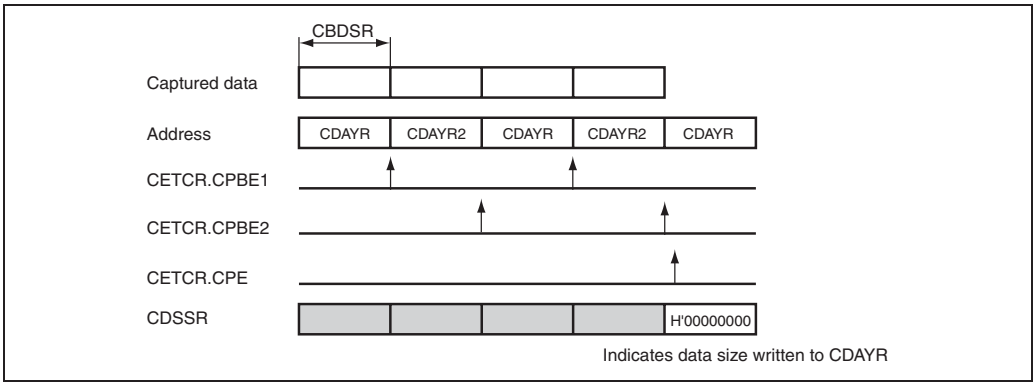

Figure 34.57 Overall Timing of CDSSR Operation in Bundle Write (When Bundle Write End and Capture End Coincide)

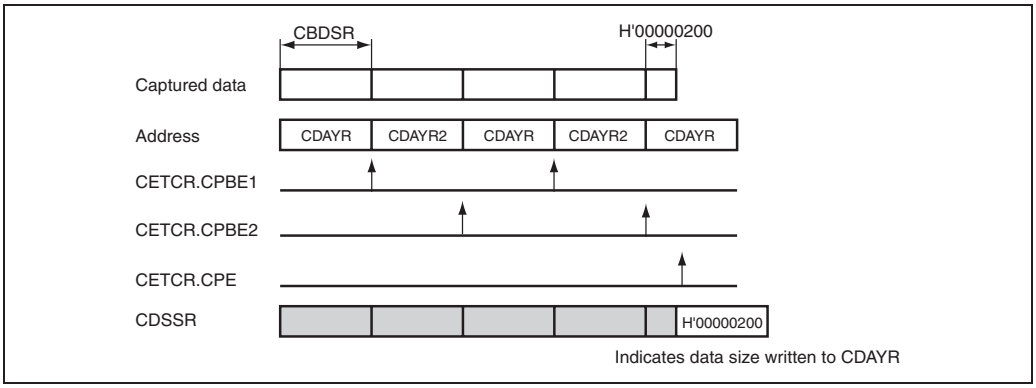

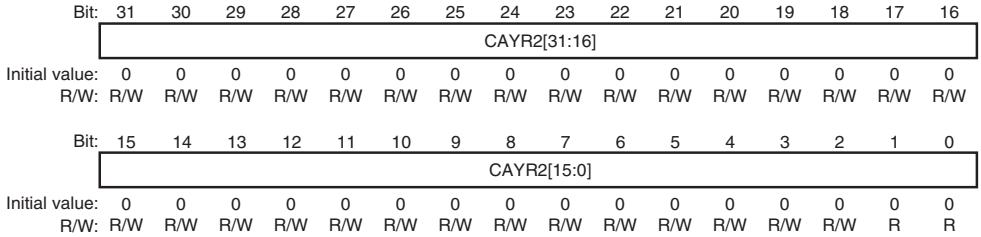

Figure 34.58 Overall Timing of CDSSR Operation in Bundle Write (When Bundle Write End and Capture End Does Not Coincide)

34.3.30 Capture Data Address Y Register 2 (CDAYR2)

CDAYR2 specifies the address for the luminance (Y) component used in a bundle write. CDAYR2 is used only in a bundle write.

CDAYR2 specifies the address where the Y component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the Y component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the Y component of the captured data is to be stored by CDAYR2. In both-field image capture, set the start address of the memory area where the Y component of the captured top-field image is to be stored by CDAYR2. CDAYR2 is not used in data fetch.

Because the address must be specified in 32 bits, the address set by CDAYR2 must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	CAYR2[31:2]	H'0000 0000	R/W	• Frame image capture: These bits set the address for storing the Y component data of the captured data (4-pixel units).
1, 0	CAYR2[1:0]		R	• One-field image capture: These bits set the address for storing the Y component data of the captured data (4-pixel units).
				• Both-field image capture: These bits set the address for storing the Y component data of the captured top-field data (4-pixel units).

Set the address of the starting point of the memory area where the Y component of the captured image is to be stored in this register, as shown in figure 34.59.

- Frame image capture: Set the address of the starting point of the memory area where the Y component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the Y component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the Y component of the captured top-field image is to be stored.
- Data enable fetch: Set the address of the starting point of the memory area where the fetched data is to be stored in 32-byte units.

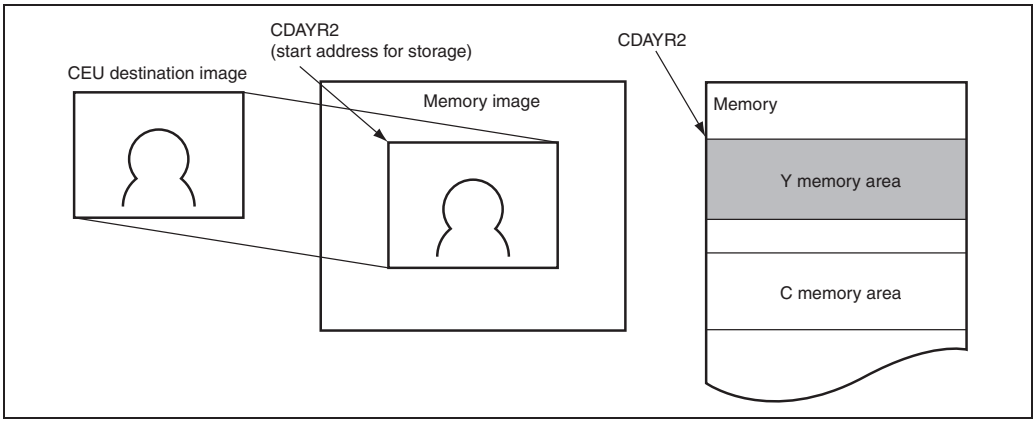

Figure 34.59 Relationship between Captured Image and Y Component Memory Area

34.3.31 Capture Data Address C Register 2 (CDACR2)

CDACR2 specifies the address for the chrominance (C) component used in a bundle write. CDACR2 is used only in a bundle write.

CDACR2 specifies the address where the C component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the C component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the C component of the captured data is to be stored by CDACR2. In both-field image capture, set the start address of the memory area where the C component of the captured top-field image is to be stored by CDACR2. CDACR2 is not used in data fetch.

Because the address must be specified in 32 bits, the address set by CDACR2 must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CACR2[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CACR2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	CACR2[31:2]	H'0000 0000	R/W	• Frame image capture: These bits set the address for storing the C component data of the captured data (4-pixel units). • One-field image capture: These bits set the address for storing the C component data of the captured data (4-pixel units). • Both-field image capture: These bits set the address for storing the C component data of the captured top-field data (4-pixel units). • Data enable fetch: These bits set the address for storing data (32-byte units).
1, 0	CACR2[1:0]		R	

Set the address of the starting point of the memory area where the C component of the captured image is to be stored in this register, as shown in figure 34.60. The C component has an output data format like that in figure 34.61, and is saved in the memory in this format.

- Frame image capture: Set the address of the starting point of the memory area where the C component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the C component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the C component of the captured top-field image is to be stored.

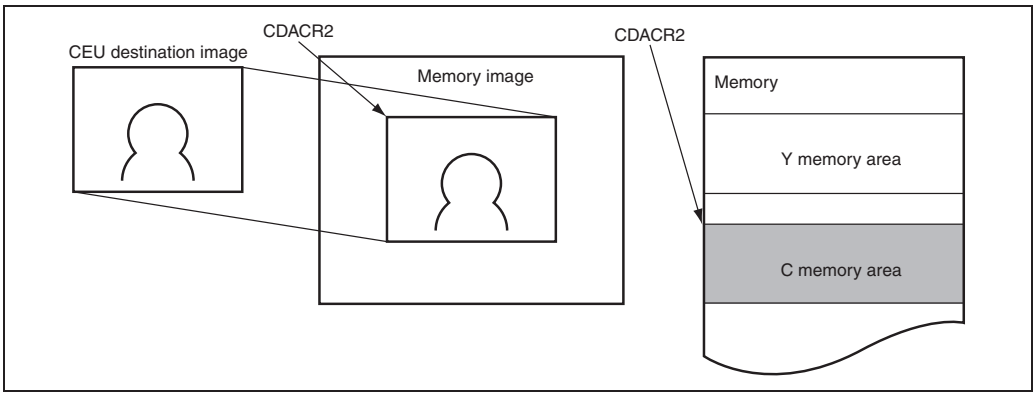

Figure 34.60 Relationship between Captured Image and C Component Memory Area

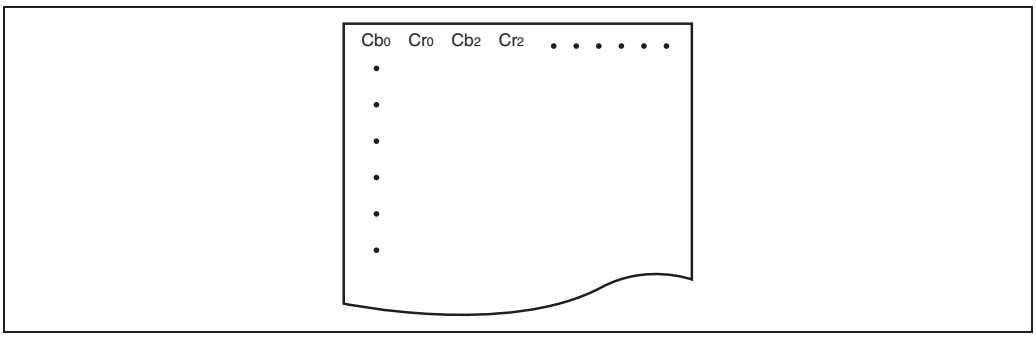

Figure 34.61 Image of Storing C Components in Memory

34.3.32 Capture Data Bottom-Field Address Y Register 2 (CDBYR2)

CDBYR2 specifies the address for the luminance (Y) component of the bottom field used in a bundle write. CDBYR2 is used only in a bundle write.

CDBYR2 specifies the address where the Y component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the Y component of the bottom-field image captured in both-field image capture is to be stored by CDBYR2. CDBYR2 is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBYR2 must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	CBYR2[31:2]	H'0000 0000	R/W	These bits set the address for storing the Y component data of the captured bottom-field data (4-pixel units).
1, 0	CBYR2[1:0]		R	

Set the address of the starting point of the memory area where the Y component of the captured bottom-field image is to be stored in this register, as shown in figure 34.62.

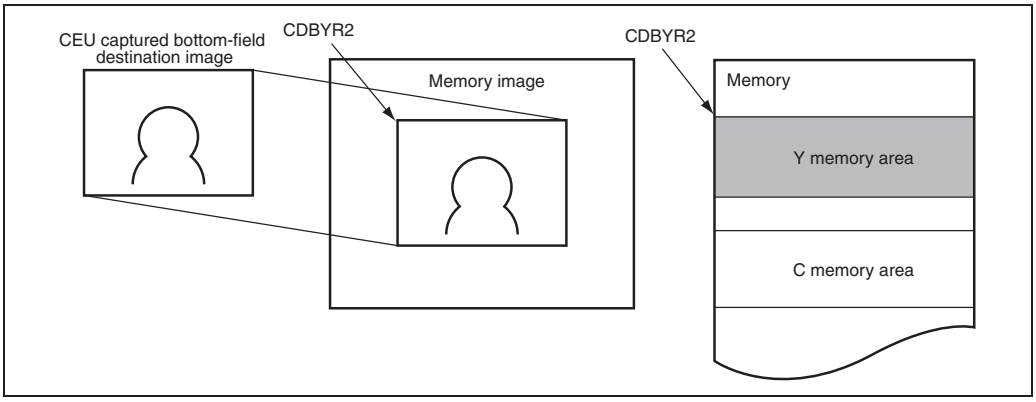

Figure 34.62 Relationship between Captured Bottom-Field Image and Y Component Memory Area

34.3.33 Capture Data Bottom-Field Address C Register 2 (CDBCR2)

CDBCR2 specifies the address for the chrominance (C) component of the bottom field used in a bundle write. CDBCR2 is used only in a bundle write.

CDBCR2 specifies the address where the C component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the C component of the bottom-field image captured in both-field image capture is to be stored by CDBCR2. CDBCR2 is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBCR2 must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CBCR2[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	CBCR2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	CBCR2[31:2]	H'0000 0000	R/W	These bits set the address for storing the C component data of the captured bottom-field data (4-pixel units).
1, 0	CBCR2[1:0]		R	

Set the address of the starting point of the memory area where the C component of the captured bottom-field image is to be stored in this register, as shown in figure 34.63. The C component has an output data format like that in figure 34.64, and is saved in the memory in this format.

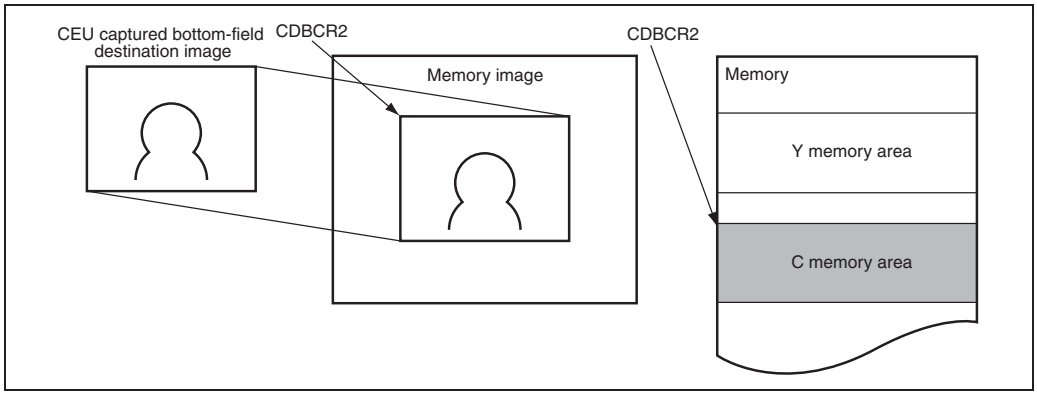

Figure 34.63 Relationship between Captured Bottom-Field Image and C Component Memory Area

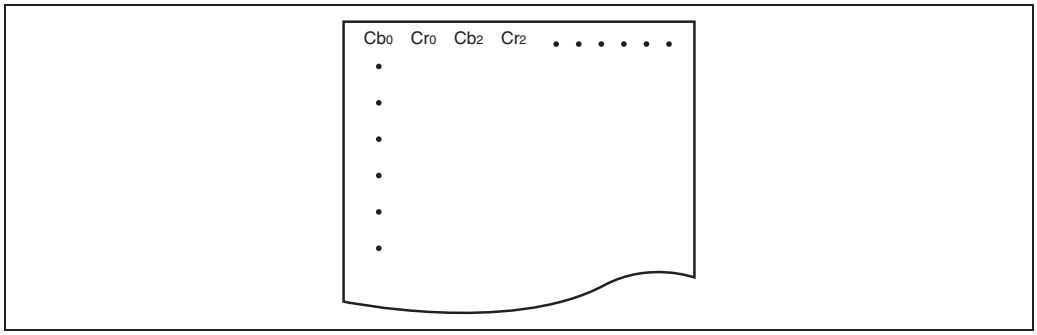

Figure 34.64 Image of Storing C Components in Memory

34.4 Usage Notes for CEU

34.4.1 Conditions for Connection to an External Module

(1) Clock Frequency

The external input clock should have a frequency at least the same as the CEU operating clock frequency, with jitter on both sides included.

CEU operating clock frequency ≥ External input clock frequency

(2) Blanking Period

The blanking (back-porch) period of the horizontal sync signal HD must be at least 20 cycles.

(3) Fixed Period of Field Identification Signal

The field identification signal FLD should be fixed for at least 1-HD period since a VD input

34.4.2 End Interrupt Output at Time of Scale-Down Processing

Depending on the scale-down factor in relation to the number of input pixels, the number of pixels output by the scale-down filter might be less than the required number of pixels. As a result, the interrupt for the end of the capture might not be output. This is indicated by an "—" in the Interrupt column of table 34.11. Do not set the size of values indicated by an "—" in table 34.12.

Table 34.11 Conditions for Generating an End Interrupt for Scale-Down Processing

Horizontal MANT Register Settings CFLCR[15:12]	Number of Input Horizontal Pixels CAPWR[12:0]	Number of PRE Filter Output Pixels	Image	Interrupt
0 or more, less than 2	Normal operation			
2 or more, less than 4	16n	Even	Clipped capture	Clipped capture
	16n + 4	Even	Clipped capture	Clipped capture
	16n + 8	Even	Clipped capture	Clipped capture
	16n + 12	Even	Clipped capture	Clipped capture
4 or more, less than 8	16n	Even	Clipped capture	Clipped capture
	16n + 4	Odd	*	Clipped capture
	16n + 8	Even	Clipped capture	Clipped capture
	16n + 12	Odd	*	Clipped capture
8 or more	16n	Even	Clipped capture	Clipped capture
	16n + 4	Even	Clipped capture	Clipped capture
	16n + 8	Odd	—	—
	16n + 12	Odd	*	Clipped capture

[Legend]

*: 4 pixels other than the specified range for capture affect the output pixel of horizontal end filter. There is no trouble with picture quality for the extraction capture.

—: Trouble with operations might be generated. Set the size of the value other than this.

34.4.3 Restrictions on Input/Output Functions

Table 34.12 lists the restrictions regarding the CEU input/output functions.

Table 34.12 Restrictions on CEU Input/Output Functions

Item	Restrictions
External module interface	The operating clock of the external module should always have a frequency at most the same as that of the CEU operating clock, with jitter on both sides included.
	Selecting the interface, or modifying the frequency of the external module operating clock or HD/VD polarity must be done when capture operations are halted for sure.
	The capture horizontal size in image capture must be specified as follows: 8-bit interface: 8-cycle units 16-bit interface: 4-cycle units
	The capture horizontal size in data fetch must be specified as follows: 8-bit interface: 4-cycle units 16-bit interface: 2-cycle units
	The capture vertical size must be specified in 4-line units.
	The maximum number of cycles in the horizontal sync signal period should be 16,383 external input clock cycles.
	The maximum number of lines (HD count) in the vertical sync signal should be 16,383 lines.
	The minimum number of captured pixels should be 48 × 48.
	The maximum number of captured pixels should be 64M (8188 × 8188) pixels. Note that it always depends on the camera clock frequency.
	Captured size in data enable fetch Maximum: 6 Mbytes (2048 × 1536 × 2) Minimum: 16 bytes (must be specified in 4-byte units)

Item	Restrictions
Memory output	The output address must be specified in longword units.
	The horizontal size of the destination image (memory) must be specified in 4-pixel units.
	The number of horizontal output pixels (= horizontal clipping size) must be specified in 4-pixel units.
	The number of vertical output lines (HD) (= vertical clipping size) must be specified in 4-line (HD) units.
	In fixed address mode, the lower five bits in an output address must be 0, and the output size must be specified in 8-pixel (8-byte) units.
	In data enable fetch bundle write, the output address must be specified in 32-byte units.
Internal processing	The filter clipping size must be specified as a value equal to or lower than the actual output size of the filter.

34.4.4 CSI2 connection special setting

When CSI2 is connected and used (CAMCR.DTIF[1:0] = b'11), A special following setting is necessary.

- CAMOR.HOFST[12:0]

  Horizontal offset is every two pixels. And, a set value is twice the pixel count.

  For example, When 60 pixels are done in offset, CAMOR.HOFST[12:0] is 0x0078

- CAPWR.HWDTH[13:0]

  The pixel count that does capture is defined as "N". A set value is ((N – 2) * 2) or more.

Section 35 Video Engine Unit (VEU)

The VEU is a module used connected to the buses via bus bridge modules. The VEU reads an image from a specified memory area, and writes it back to a specified address.

35.1 Features

- Four modules are installed (VEU0, VEU1, VEU2, and VEU3)
- Format conversion using the RGB ⇔ YCbCr conversion function
- Scaling of an image using the filter function
- Tone reduction (quantization) to pack RGB data in 32-bit units
- Dithering for tone reduction of RGB data
- Removal of high-frequency components using the low-pass filter function
- Low-pass filter is applied to only the boundary of the blocks using the deblocking filter function
- Median filter function
- Edge enhancement of an image (enhancer function)
- Edge emphasis processing with FIR filter (VEU2 and 3)
- Plain α can be scaled (with RGB resize: VEU2 and 3)

35.2 Functional Overview of VEU

The functional overview of the VEU is shown in table 35.1. Some functions of the VEU cannot be used at the same time unless the VEU is re-activated. Table 35.2 shows which functions can/cannot be used simultaneously during one VEU activation.

Note that when the instructions at other places in this manual differ from instructions in the following table, the instructions in section 35.4, Usage Notes for VEU, are given priority.

Table 35.1 Functional Overview of VEU

Item	Function	Description	Note
Input format	YCbCr (4:4:4/4:2:2/4:2:0)		
	RGB pack		
Output format	YCbCr (4:4:4/4:2:2/4:2:0)		
	RGB pack		
Read mode	Normal read	8 to 960 lines can be set as the number of lines in bundle read	
	Bundle read		
Low-pass filter	Removal of high-frequency components		
FIR filter	Removal of high-frequency components / Edge enhancement		Only VEU2 and VEU3
Deblocking filter	Removal of high-frequency components only at the boundary of blocks		
Enhancer	Enhancement of image		
Median filter	Removal of shot noise		
Rotation/ inversion of image	Vertical or horizontal inversion	Can be specified independently	A combination of both functions can realize rotation by 180 degrees
	Rotation by 90 or 270 degrees	Rotated clockwise	
Scale-up, scale-down, or no scaling	Scale-up or scale-down of memory display	Any scaling factor from × 1/16 to × 16	
Format conversion	YCbCr ⇔ RGB conversion	Bidirectional conversion between YCbCr format and RGB format	

Item	Function	Description	Note
Dithering (tone reduction)	24 bpp	Full colors (16,700,000 colors)	Dithering not possible
	18 bpp	260,000 colors	Dithering not possible
	16 bpp	High colors (65,536 colors)	
	12 bpp	4,096 colors	
	8 bpp	256 colors	
Maximum image size	16M pixels	4092 pixels × 4092 lines*1,*2	
Minimum image size	4 x 4 pixels	4 pixels x 4 lines*3	

Note: The scaling factor of the filter can be set between 1/16 and 16. For details, see section 35.3.11, VEU Resize Filter Control Register (VRFCR), and section 35.3.12, VEU Resize Filter Size Clip Register (VRFSR).

*1 When the tap count is set to 11, the maximum number of horizontal pixel is to be 2048.

*2 The maximum input size in the resize processing becomes in 8188x8188 and the maximum output size becomes 4092x8188. (VEU2,VEU3)

*3 When the tap count is set to 11, the minimum image size becames 8x8.

Table 35.2 Simultaneous Usage of Functions in One VEU Activation

	Bundle Mode	Color Conversion	Low-Pass Filter (Deblocking Filter)	FIR Filter	Median Filter	Enhancer	Vertical/ Horizontal Inversion	90°/270° Rotation	Scale-Up/ Scale-Down
Bundle Mode	—	O	×	×	×	O	O	×	O
Color Conversion	O	—	O	O	O	O	O	O	O
Low-Pass Filter (Deblocking Filter)	×	O	—	×	O*1,*2	×	O	O*3	×
FIR Filter	×	O	×	—	×	×	O	×	×
Median Filter	×	O	O*1,*2	×	—	×	O	O*3	×
Enhancer	O	O	×	×	×	—	O	×	O
Vertical/ Horizontal Inversion	O	O	O	O	O	O	—	O	O
90°/270° Rotation	×	O	O*3	×	O*3	×	O	—	×
Scale-Up/ Scale-Down	O	O	×	×	×	O	O	×	—

[Legend]

O: Possible

×: Not possible

Notes: The register values corresponding to the items in this table are shown below.

Bundle mode: VESTR.VBE

Color conversion: VTRCR.TE

Low-pass filter: VFMCR.LPHV

Deblocking filter: VFMCR.LPHV && VFMCR.DBLK

Median filter: VFMCR.MED

Enhancer: VENHR.ENHH || VENHR.ENHV

Vertical/horizontal inversion: VFMCR.VMRR/VFMCR.HMRR

90°/270° rotation: VFMCR.POTR/VFMCR.POTL

Scale-up/scale-down: VRFCR != 0

1 order of deblocking filter → median filter is allowed. However, a reversed order is not allowed. (When a high-speed filter is processed, reverse order is possible.)

2 When the tap count is set to 11, the concurrent usage is not possible.

3 It is not possible to operate simultaneously when a high-speed filter is processed.

Figure 35.1 shows a block diagram of the VEU.

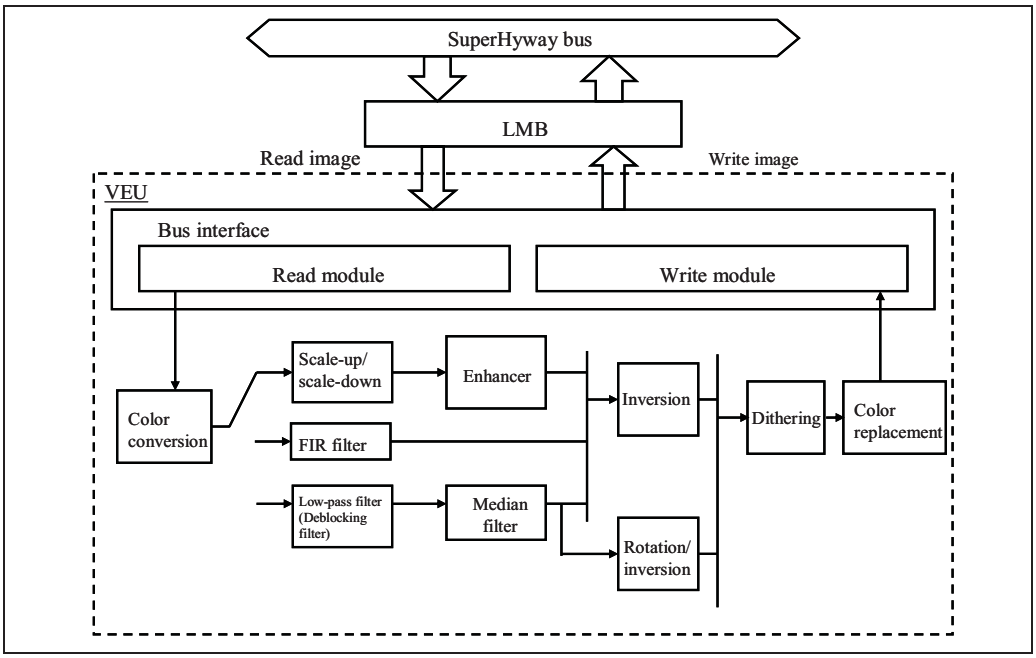

Figure 35.1 Block Diagram of VEU

Note: In figure 35.1, inversion indicates horizontal or vertical inversion, and rotation indicates 90° or 270° rotation.
In the inversion circuit after scale-up/scale-down, horizontal inversion, vertical inversion, or 180° rotation, which is a combination of the two types of inversion, can be performed.
In the rotation/inversion circuit after the median filter, in addition to the possible operations in the inversion circuit after scale-up/scale-down, 90° rotation, 270° rotation, a combination of 90° rotation and horizontal inversion, or a combination of 90° rotation and vertical inversion can be performed. When a high-speed filter is processed, the rotation operation cannot be used. (VMFCR.FLTPI=1)

- Operation

  Figure 35.2 shows the sequence of the VEU operation processing. Though the VEU has various functions, some functions cannot be used simultaneously during one VEU activation, as shown in table 35.2. Either flow 1a/1b or flow 2 shown in figure 35.2 is possible. Accordingly, processing in different flows cannot be performed together.

  1. Flow 1 is selected when the following condition is satisfied.
     VESTR.VBE || (VENHR.ENHH || VENHR.ENHV) || (VRFCR != 0) or VFMCE.FLTPI = 1
  2. Flow 2 is selected in cases other than above.

  Flow 1 separates into Flow 1a/1b further according to the condition.

  1a. It becomes scale-up/scale-down/edge emphasis processing of Flow 1a for VFMCR.FLTPI=0.

  1b. It becomes line filter processing of Flow 1b for VFMCR.FLTPI=1.

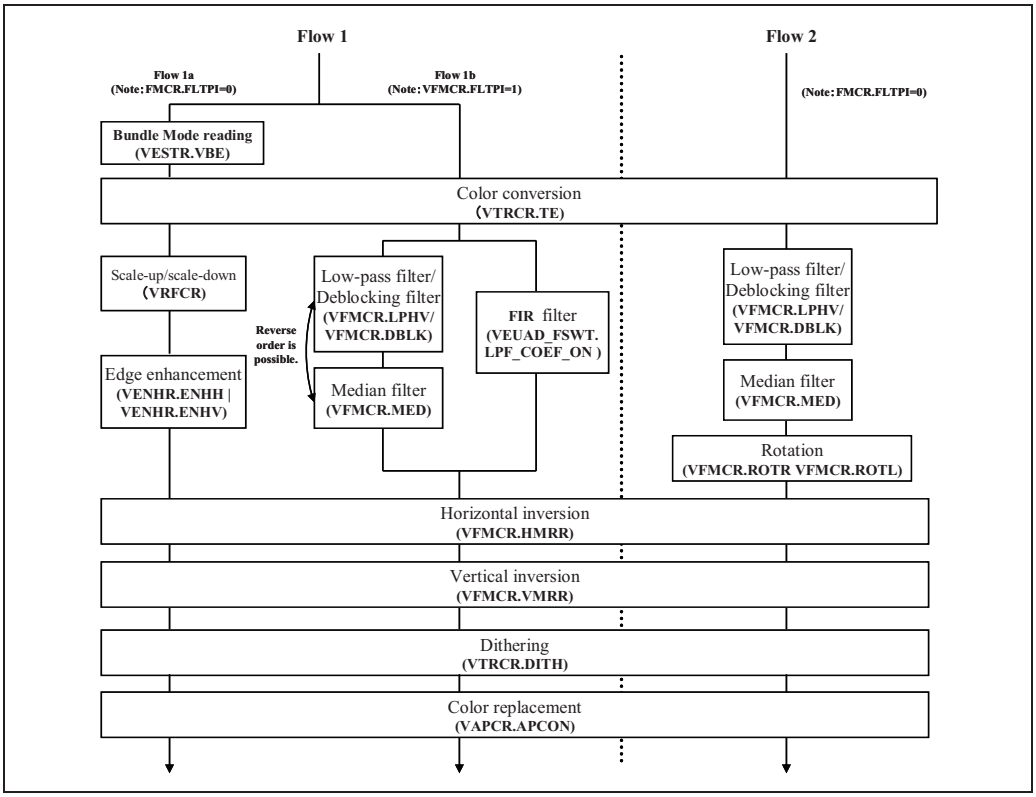

Figure 35.2 Register Settings, Processing Flows, and Simultaneously Executable Functions of VEU

35.3 Register Descriptions of VEU

(1) R/W Restrictions on VEU Registers

The read/write restrictions on the VEU registers are listed below. If the following register handling is not guaranteed, a malfunction may occur.

1. For the read-only bits in all VEU registers and the reserved areas, writing 1 is prohibited. Do not specify an unspecified value.
2. Though a value other than 0 may be read from a read-only bit, do not modify this bit.
3. For registers (bits) to which writing during operation is prohibited, do not modify them during operation (reading is possible). The VEU operating state can be confirmed by reading the VE bit in the VEU start register (VESTR). Modify the above registers when this bit is 0.
4. Allocate all VEU registers in a non-cacheable area.

(2) Terms and Abbreviations Used in This Section

The terms used in this section are described below.

1. "software reset" indicates that the VEU processing was halted and the current processing is stopped. The image processing result of the frame in which a software reset occurs is not guaranteed.
2. "module reset" indicates the VEU internal circuit was forcibly reset. In a module reset, reset processing is performed with no consideration to the hardware state. Therefore, if a module reset is generated when the VEU is operating normally, the VEU peripheral hardware may become unable to operate.
3. "during operation" in this section indicates a state in which the VE bit in the VEU start register (VESTR) is set to 1.
4. When a bit name in a register is referred to in this section, it is indicated in the format of (register name).(bit name).

   Example: VESTR.VE

(3) List of Registers

The register configuration of the VEU is shown in table 35.3. The register states in each processing mode are shown in table 35.4.

Table 35.3 Register Configuration of VEU

Register Name	Abbr.	R/W	Address	Access Size
VEU0 start register	VE0STR	R/W	H'FE92 0000	32
VEU0 source memory width register	VE0SWR	R/W	H'FE92 0010	32
VEU0 source size register	VE0SSR	R/W	H'FE92 0014	32

* For details, refer to section 1-D Overview of reset

35.3.1 VEU Start Register (VESTR)

VESTR controls activation of the VEU and software reset of VEU processing. Before starting VEU processing by VESTR, all registers related to the VEU must be set.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	VBE	—	—	—	—	—	—	—	VE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	VBE	0	R/W	Sets the bundle read mode (N-line read mode). In bundle read mode (N-line read mode), the VEU divides a one-frame image at the number of lines set by VBSSR and reads data for that number of lines. When the VEU is activated in bundle read mode (N-line read mode), rotation processing, deblocking filter processing, low-pass filter processing, and median filter processing cannot be executed (horizontal inversion, vertical inversion, and horizontal-vertical inversion are possible). 0: Normal operation 1: Bundle read (N-line read) mode
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	VE	0	R/W	Controls the VEU processing start and software reset of processing (processing halt). If this bit is set to 1 when the VEU is halted, the VEU starts processing images in the memory according to the register settings, and this bit is read as 1. In addition, if 0 is written to this bit when it is 1, the current VEU processing is immediately terminated. The end of software reset processing can be confirmed when this bit becomes 0 after a software reset has been issued to the VEU. Confirm that this bit is 0 before restarting the VEU after a software reset. 0: NOP (software reset processing when 0 is written to this bit when it is 1) 1: VEU processing starts

If B'1 is written to the VE bit when the VBE bit is B'1 at VEU activation, bundle read mode (N-line read mode) is selected. In bundle read mode, data is read from two memory areas alternately for the number of lines set by the VBSS bits in VBSSR. If reading for the entire frame is not finished when the VEU has completed reading for the number of lines set by VBSSR, a bundle end interrupt (VEVTR.VBEND) occurs and the VEU waits for reading to be restarted. To restart reading, first clear the bundle end interrupt source, and then write B'1 to the VE bit again (write with the VBE bit still set to B'1). After repeating this until reading for the entire frame finishes, a one-frame end interrupt (VEVTR.VEEND) occurs. The image of processing in bundle read mode is shown in figure 35.5. The status of normal image processing, read processing in bundle read mode, and waiting of read to be restarted in bundle read mode can be confirmed by reading VSTAR.

Notes on software reset:

1. Though the VEU end interrupt flag (VEVTR.VEEND) may become B'1 depending on the timing to issue a VEU software reset, the processed image of the frame in which a software reset was issued is not guaranteed.
2. Even when the VEEND flag does not become B'1 after a VEU software reset, the VEEND flag must always be cleared to B'0.
3. When issuing a software reset in bundle read mode, issue it before reading is restarted subsequent to a bundle end interrupt.

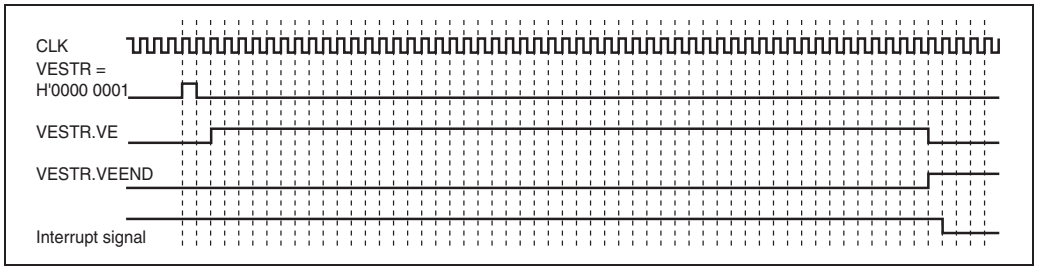

Figure 35.3 Operation Timing of VE Bit and Each Status

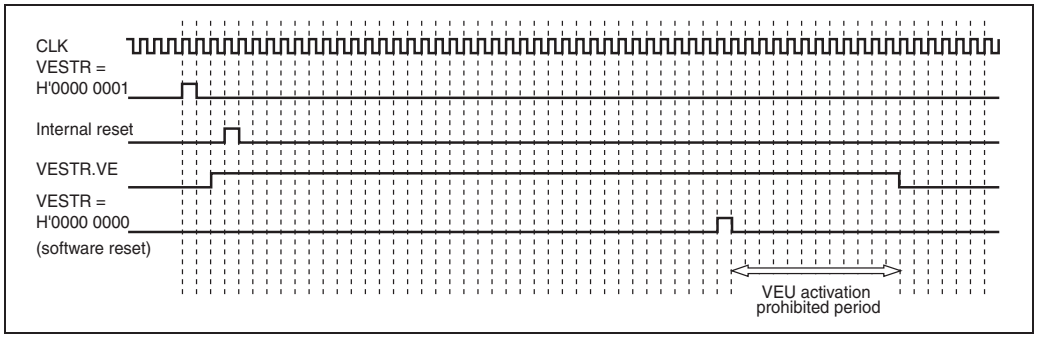

Figure 35.4 Operation Timing of Software Reset and Each Status

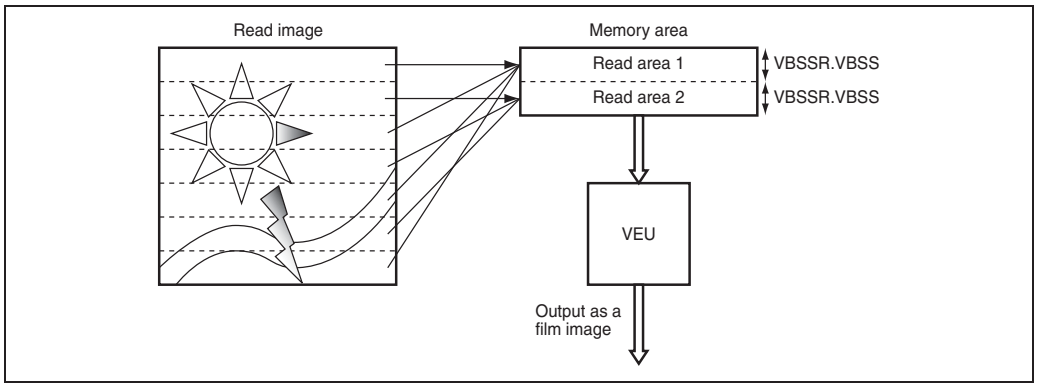

Figure 35.5 Image of Bundle Read Mode Processing

35.3.2 VEU Source Memory Width Register (VESWR)

VESWR sets the memory width of the source memory area of the VEU.

Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 2 1, 0	VSW[15:2] VSW[1:0]	H'0000	R/W R	These bits set the width of the source memory area of the VEU (4-pixel units). This setting should be made in 2-pixel units when the RPKF bits in VTRCR are set to 0,1,3,7, or 13.

In the VSW bits, set the horizontal width of the source memory area where the source image is located in the VEU processing as a number of bytes. This setting must be made in byte units that correspond to four pixels of the source image. If the read image is in the YCbCr format, make a setting matching the Y component. For reading data in the YCbCr 4:2:0, YCbCr 4:2:2, and YCbCr 4:4:4 formats, the VSW setting, VSW setting, and (VSW setting × 2) are applied respectively to the horizontal width of the source memory area for the C component. When the RPKF bits in VTRCR are set to 0,1,3,7, or 13 (RGB 2 bytes/pixel or RGB 4 bytes/pixel), a setting in byte units that corresponds to two pixels of the source image is possible. As shown in (A) in figure 35.6, when an image is clipped from the memory area, the right-end address of a line's image is discontinuous from the left-end address of the next line's image. Compared to this, (B) in figure 35.6 shows an example where the horizontal size of an image input to the VEU matches the horizontal length of the memory. In this case, the right-end address of a line's image and the left-end address of the next line's image have continuous values.

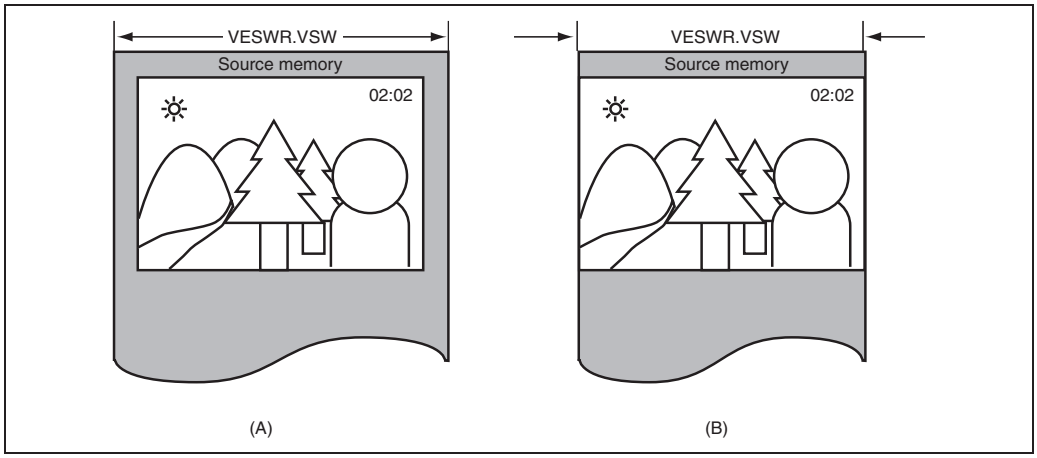

Figure 35.6 Relationship between Image Clipping Size and VESWR

35.3.3 VEU Source Size Register (VESSR)

VESSR sets the vertical and horizontal sizes (number of pixels) of the image read by the VEU.

Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 16 (28 to 16)	VVSS[11:0]	H'000	R/W	These bits set the number of vertical pixels read by the VEU. Set the number of vertical read pixels of the source image read by the VEU in these bits (see figure 35.7). • Scale-up/down, enhancer, or bundle read is not performed (see figure 35.7): A setting in 2-pixel units is possible for the following cases: Reading and writing are both in RGB format. RPKF bit in VTRCR is either 3 (RGB 2 bytes/pixel), 0, 1, 7, 13 (RGB 4 bytes/pixel) and WPKF bit in VTRCR is either 1, 2, 6 (RGB 2 bytes/pixel), 14, 19, 20, 22, 23 (RGB 4 bytes/pixel). Other than those settings, specify a setting in 4-pixel units. • Scale-up/down, enhancer, or bundle read is performed, a setting in 1-pixel unit is possible (see figure 35.7). However, the data should be allocated in the memory to specify 2-pixel units when the input format is YCbCr4:2:0. The maximum value to be set is 4092 pixels.

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 0 (12~0)	VHSS[11:0]	H'000	R/W	These bits set the number of horizontal pixels read by the VEU. Set the number of horizontal read pixels of the source image read by the VEU in these bits (see figure 35.7). • Scale-up/down, enhancer, or bundle read is not performed (see figure 35.7): A setting in 2-pixel units is possible for the following cases: Reading and writing are both in RGB format. RPKF bit in VTRCR is either 3 (RGB 2 bytes/pixel), 0, 1, 7, 13 (RGB 4 bytes/pixel) and WPKF bit in VTRCR is either 1, 2, 6 (RGB 2 bytes/pixel), 14, 19, 20, 22, 23 (RGB 4 bytes/pixel). Other than those settings, specify a setting in 4-pixel units. • Scale-up/down, enhancer, or bundle read is performed, a setting in 1-pixel unit is possible (see figure 35.7). However, set in the VESWR.VSW[15:0] a value (a value that VHSS[11:0] specify in 4-pixel units) × 4 / (P_density_y in use format) or more. Further, the data should be allocated in the memory to specify in 2-pixel units when the input format is YCbCr4:2:0 and YCbCr4:2:2. The maximum value to be set is 4092 pixels.

Note: When resizing it, it can be assumed the horizontal 8188 or less and it is vertical 8188 or less (Only VEU2 and VEU3). However, it is necessary to do the ratio and the output setting for the output size not to exceed the horizontal 4092 and vertical 8188 in that case. (example, VESSR.VHSS=8188→VRFCR.VHMNT=2, VRFCR.VHFRC=4, VRSOR.VHCLOFS=0, and VRFSR.VHCLP=4092)

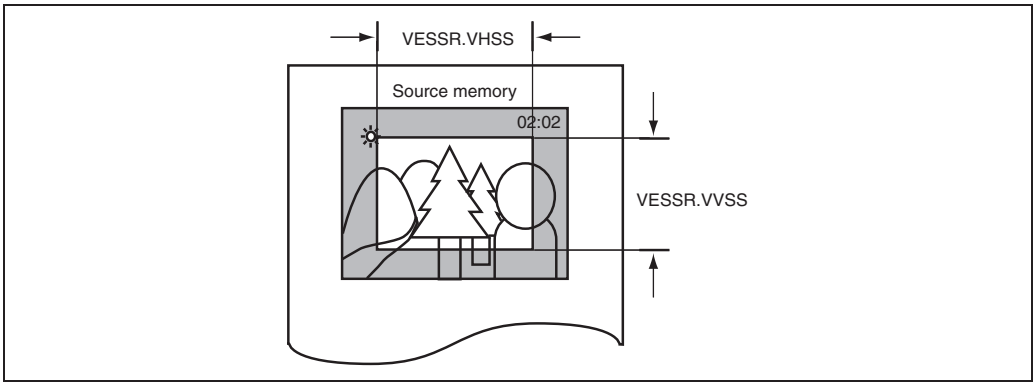

Figure 35.7 Relationship between Read Size and VESSR

35.3.4 VEU Source Address Y Register (VSAYR)

VSAYR sets the start address for the Y/RGB plane of the image read by the VEU.

Modifying this register during operation is prohibited. However, this register can be modified in the restart wait state (when VSTAR = H'0000 1001) in N-line read mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	VSAY[31:2]	H'0000 0000	R/W	These bits set the start address for reading the Y/RGB plane by the VEU (longword units).
1, 0	VSAY[1:0]		R	

Set the start address for the Y/RGB plane of the source image of the VEU in the VSAY bits, as shown in figure 35.8. When reading a YCbCr image, specify the start address of the Y plane. When reading an RGB image, specify the start address (top-left address in the read image area) of the RGB plane. Figure 35.8 shows the input format for the Y plane of the YCbCr format. For the input format of the RGB format, refer to table 35.8.

Note: In bundle read mode, set two addresses alternately for each VEVTR.VBEND interrupt.

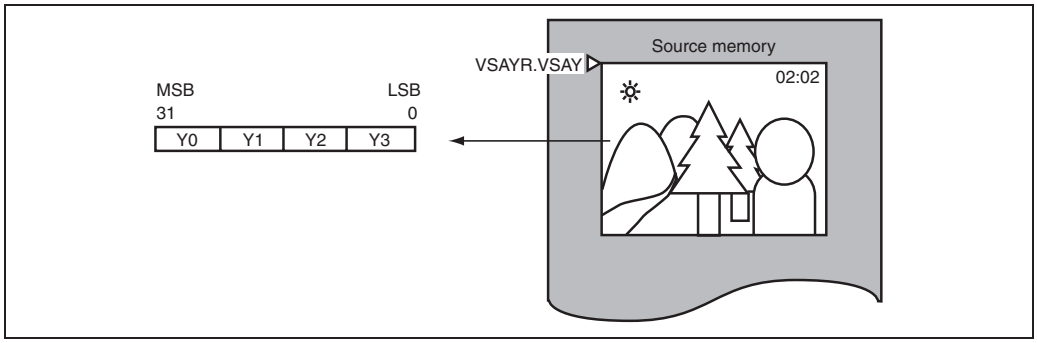

Figure 35.8 Address Set in VSAYR and Y-Plane Format

35.3.5 VEU Source Address C Register (VSACR)

VSACR sets the start address for the C plane of the image read by the VEU.

Modifying this register during operation is prohibited. However, this register can be modified in the restart wait state (when VSTAR = H'0000 1001) in N-line read mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 2 1, 0	VSAC[31:2] VSAC[1:0]	H'0000 0000	R/W R	These bits set the start address for reading the C plane by the VEU. (1-longword units. 2-longword units for the YCbCr 4:4:4 format.)

Set the start address for the C plane of the source image of the VEU in the VSAC bits, as shown in figure 35.9. When reading a YCbCr image, specify the start address (top-left address in the read image area) of the C plane. Figure 35.9 shows the input format for the C plane. When reading an RGB image, VSACR is not used. VSACR should be set in 1-longword units for the YCbCr 4:2:0 or YCbCr 4:2:2 format, and in 2-longword units for the YCbCr 4:4:4 format.

Note: In bundle read mode, set two addresses alternately for each VEVTR.VBEND interrupt.

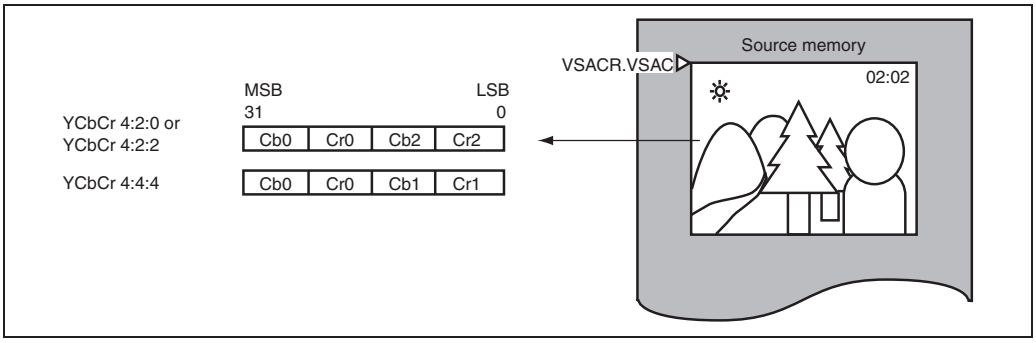

Figure 35.9 Address Set in VSACR and C-Plane Format

35.3.6 VEU Bundle Source Size Register (VBSSR)

VBSSR sets the number of lines (number of pixels) to be read when the VEU is activated once in bundle read mode (N-line read mode). VBSSR needs to be set only in bundle read mode.

Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 3 2, 0	VBSS[11:3] VBSS[2:0]	H'000	R/W R	These bits set the number of lines to be read when the VEU is activated once in bundle read mode (N-line read mode) (8-line units).

Set the number of lines of the source image to be read by the VEU in one processing in bundle read mode in the VBSS bits. The VBSS bits should be set in 8-line units, and the maximum value to be set is 960 lines.

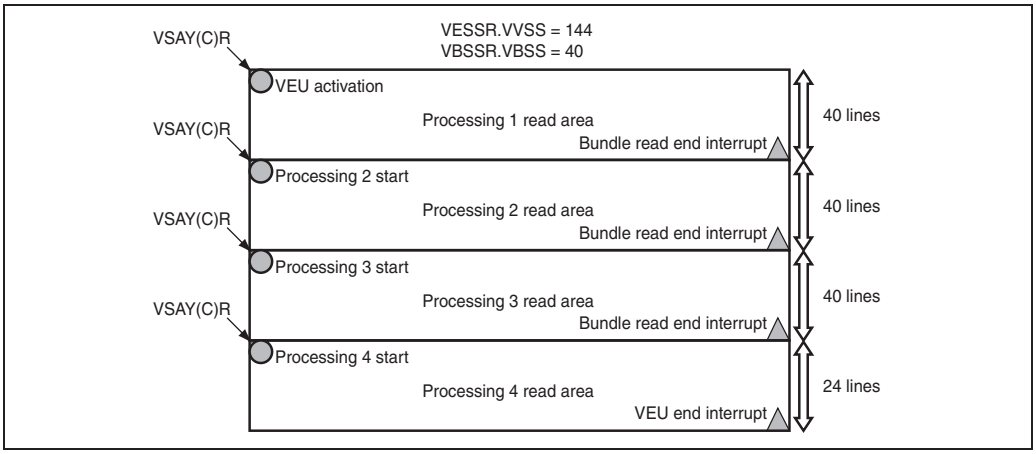

Figure 35.10 Relationship between Read Image in Bundle Read Mode and Read Image in Each Processing

35.3.7 VEU Destination Memory Width Register (VEDWR)

VEDWR sets the memory width of the destination memory area of the VEU.

Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VDW[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 2	VDW[15:2]	H'0000	R/W	These bits set the width of the destination memory area of the VEU (longword units).
1, 0	VDW[1:0]		R	

Set the horizontal width of the destination memory area where the destination image is located as a number of bytes in the VDW bits. This setting must be made in byte units that correspond to four pixels of the destination image. If the drawing image is in the YCbCr format, make a setting matching the Y component. For writing data in the YCbCr 4:2:0, YCbCr 4:2:2, and YCbCr 4:4:4 formats, the VDW setting, VDW setting, and (VDW setting × 2) are applied respectively to the horizontal width of the destination memory area for the C component. When the WPKF bits in VTRCR are set to 1, 2, 6 (RGB 2 bytes/pixel), 8 to 14, 19, 20, 22, 23 (RGB 4 bytes/pixel), a setting in byte units that corresponds to two pixels of the destination image is possible. As shown in (A) in figure 35.11, when an image is pasted to the back display or the like in the memory area, the right-end address of a line's image is discontinuous from the left-end address of the next line's image. Compared to this, (B) in figure 35.11 shows an example where the horizontal size of an image output from the VEU matches the horizontal length of the memory. In this case, the right-end address of a line's image and the left-end address of the next line's image have continuous values.

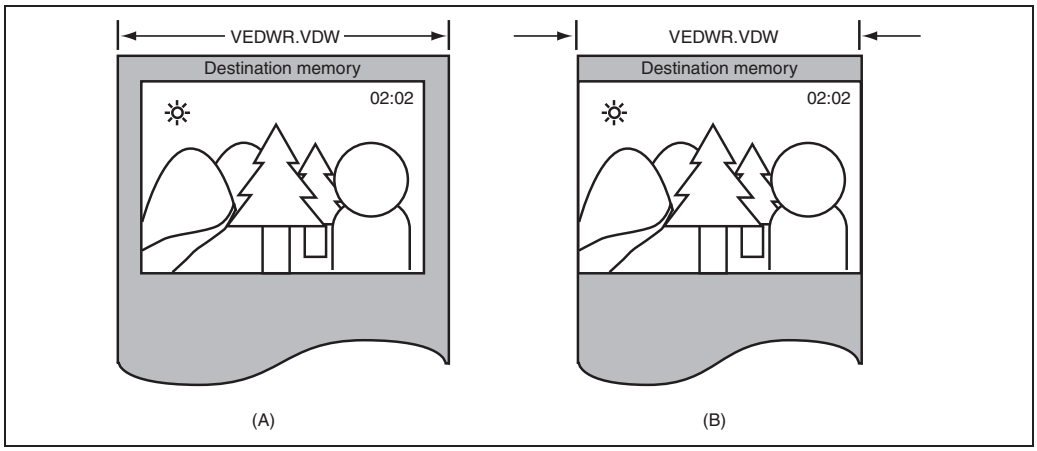

Figure 35.11 Relationship between Image Pasting Size and VEDWR

35.3.8 VEU Destination Address Y Register (VDAYR)

VDAYR sets the start address for the Y/RGB plane of the image drawn by the VEU.

Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VDAY[31:16]

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VDAY[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	VDAY[31:2]	H'0000 0000	R/W	These bits set the start address for drawing the Y/RGB plane by the VEU (longword units).
1, 0	VDAY[1:0]		R	

Set the start address of the destination image (top-left address in the destination image area) of the VEU in the VDAY bits, as shown in figure 35.12. When drawing a YCbCr image, specify the start address of the Y plane. When drawing an RGB image, specify the start address of the RGB plane.

When VTRCR.WPKF = 6 (RGB 16-bpp), a setting in word units is possible.

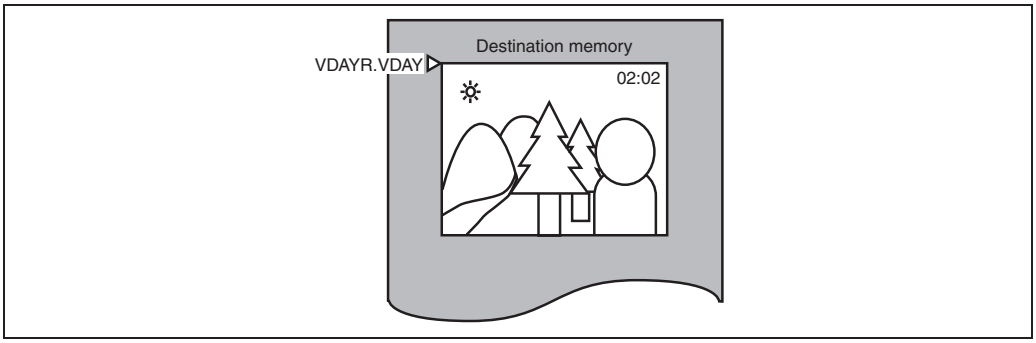

Figure 35.12 Address Set in VDAYR

The point specified as the address to be set in VDAYR changes when the image is rotated or inverted. This specification point of the address for each processing is shown in table 35.5. Figure 35.13 illustrates the address specification point in block processing, and figure 35.14 illustrates that in line processing. The gray quadrangle is assumed as the destination image and the ☆ marks as the address specification points.

The address specification point if neither scale-up/down, enhancer, bundle read, nor VFMCR.FLTPI = 0 is performed is the top-left address for the block located in one of the four corners with the destination image divided into blocks of 16 × 16 pixels. In a case that scale-up/down, enhance, and bundle read are not used and even FLTPI = 0, or either scale-up/down, enhance, or bundle read is used, each address specification point becomes one of the four corners in the destination image.

Table 35.5 Address Specification Point for Setting VDAYR

	No Rotation/ Inversion	90° Rotation	270° Rotation	90° Rotation + Horizontal Inversion	90° Rotation + Vertical Inversion	Horizontal Inversion	Vertical Inversion	Horizontal Inversion + Vertical Inversion
Block processing: No scale-up/down, enhancer, or bundle read and even FLTPI = 0.	—	D	E	F	G	A	B	C
Line processing: Scale-up/down, enhancer, or bundle read performed and even VFMCR.FLTPI = 1.	—	×	×	×	×	H	J	K

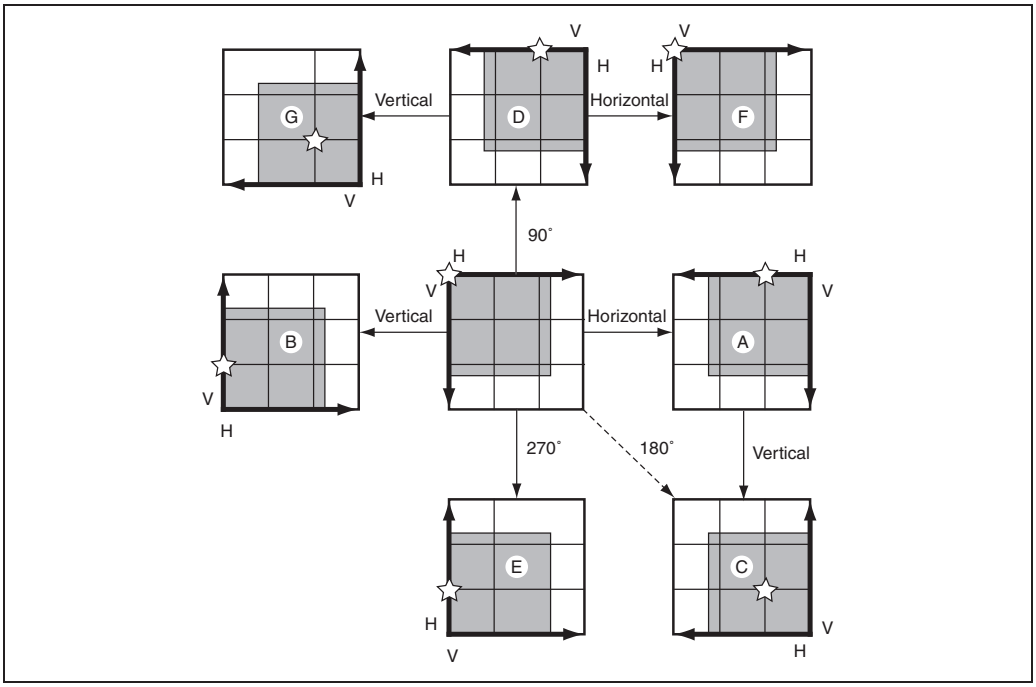

Figure 35.13 Location of Address Specification Point for VDAYR (Block Processing)

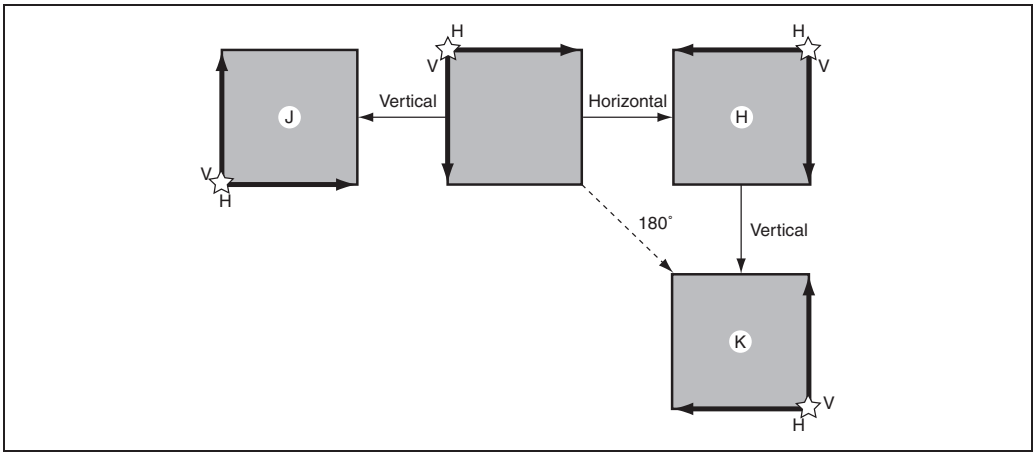

Figure 35.14 Location of Address Specification Point for VDAYR (Line Processing)

When drawing a YCbCr image, specify an address of the Y plane. When drawing an RGB image, specify an address of the RGB plane.

The formulas for setting the addresses are shown below.

Offset_ad	Becomes the address location of the top-left corner in the destination image	
yuv420out	Drawing format is YCbCr 4:2:0	1: VTRCR. CHDS = 0 0: VTRCR. CHDS = 1 or 2
clip_hsize	Horizontal size of line processing output	VRFSR.VHCLP
clip_vsize	Vertical size of line processing output	VRFSR.VVCLP
clip_vsize_c	Vertical size (C) of line processing output	(clip_vsize + 1)/2: VTRCR. CHDS = 0 (round-down) clip_vsize: VTRCR. CHDS = 1 or 2
dest_width	Destination memory width	VEDWR.VEW
dest_width_c	Destination memory width (C)	dest_width: VTRCR.CHDS = 2 dest_width × 2: VTRCR.CHDS = 2
src_hblk	Horizontal block count	VESSR.VHSS/16 (round-up)
src_vblk	Vertical block count	VESSR.VVSS/16 (round-up)
src_sideh	Horizontal size of right-end block	(VESSR.VHSS + 15)%16 + 1
src_sidev	Vertical size of bottom-end block	(VESSR.VHSS + 15)%16 + 1
< >	Operator changing a negative value to 0	0 when the value in < > is 0 or lower, otherwise the value in < >

For P_density_y of an RGB output, see table 27.6. For P_density_y and P_density_c of a YCbCr output, see table 35.7.

35.3.9 VEU Destination Address C Register (VDACR)

VDACR specifies the start address for the C plane of the image drawn by the VEU.

Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VDAC[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VDAC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	VDAC[31:2]	H'0000 0000	R/W	These bits set the start address for drawing the C plane by the VEU. (1-longword units. 2-longword units for the YCbCr 4:4:4 format.)
1, 0	VDAC[1:0]		R	

Set the start address of the destination image (top-left address in the destination image area) of the VEU in the VDAC bits, as shown in figure 35.15. When drawing a YCbCr image, specify the start address of the C plane. When reading an RGB image, VDACR is not used.

The point specified as the address to be set in VDACR changes when the image is rotated or inverted. As this specification point is similar to that for VDAYR, see figure 35.13 and table 35.5 for details. However, when an image is drawn in the YCbCr 4:2:0 format, the number of lines output in the vertical direction for the C component is half of the number of lines for the Y component or an RGB output. When calculating the address in the vertical direction (memory width × number of vertical lines), take notice that the number of lines will become half. (See the description in section 35.3.8, VEU Destination Address Y Register (VDAYR).)

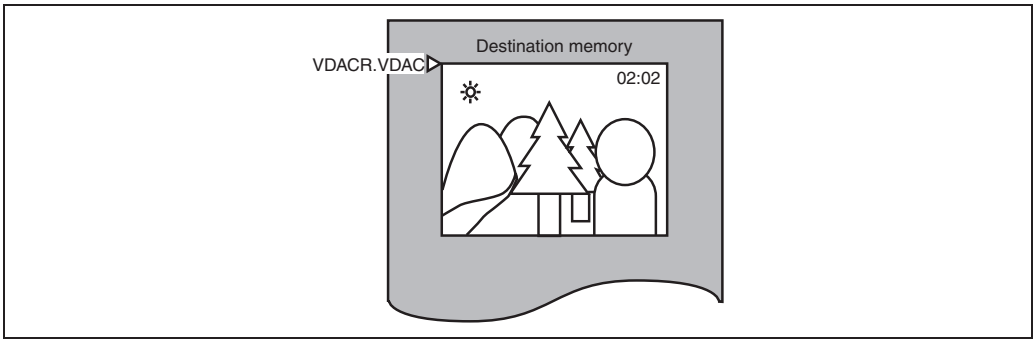

Figure 35.15 Address Set in VDACR

35.3.10 VEU Transform Control Register (VTRCR)

VTRCR mainly sets the processing contents related to color conversion by the VEU and the input/output data format.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

R/W:	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	PAD[7:0]	H'00	R/W	These bits set the PAD value to be stuffed into the output data when the VEU output data is in the RGB format. Some forms of RGB output data packs (see table 35.6) include a PAD field as shown in figure 35.16. In the PAD field, any 8-bit data can be added. Specify the value to be added to the PAD field to these bits.*
23, 22	CHDS[1:0]	00	R/W	These bits select the output format when the VEU output data is in the YCbCr format. For the YCbCr format, data is output in one of the pack patterns shown in table 35.7. Conversion from YCbCr 4:4:4 to YCbCr 4:2:2 or YCbCr 4:2:0 is performed by taking the average of two pixels for the horizontal direction, and simply skipping pixels for the vertical direction. The planes for outputting the Y and C data to memory are separate. Therefore, the ratio of the Y:C memory areas is 2:1 for YCbCr 4:2:0, 2:2 for YCbCr 4:2:2, and 2:4 for YCbCr 4:4:4. 00: YCbCr 4:2:0 output for YCbCr-format output 01: YCbCr 4:2:2 output for YCbCr-format output 10: YCbCr 4:4:4 output for YCbCr-format output 11: Setting prohibited
21	WPKF	0	R/W	These bits set the output data pack form when the VEU output data is in the BGR format. When the BGR888(3byte/pix) format output is used, it changes to the setting of VTRCR.WPKFR=1 and the VTRCR.WPKF=H '15.

20 to 16	WPKF[4:0]	00000	R/W	These bits set the output data pack form when the VEU output data is in the RGB format. The VEU packs output data into a 32-bit pack. When data is output in the RGB format and YCbCr format, the data is packed into one of the patterns shown in tables 35.6 and 35.7, respectively. For RGB-format output, set a value in the WPKF column in table 35.18 in these bits. When the RGB stuffing output pack is used (WPKF = H'10, H'11, H'12, or H'15), the start line must have the pack form of phase 0 shown in table 35.6.

Note: * When the alpha resize is used, the alpha value is output to the change of the PAD value. (Only VEU2 and 3: ALP_ON=1).

Bit	Bit Name	Initial Value	R/W	Description
15, 14	CHRR[1:0]	00	R/W	These bits set the source image form for the VEU. When a YCbCr image is input, output is done in one of the pack patterns shown in table 35.7. 00: Source image is read in the YCbCr 4:2:0 format 01: Source image is read in the YCbCr 4:2:2 format 10: Source image is read in the YCbCr 4:4:4 format 11: Setting prohibited
13, 12	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	RPKF[3:0]	000	R/W	These bits set the RGB input data pack form when the VEU input data is in the RGB format. Table 35.8 shows the relationship between the RGB format selected by these bits and the input form. When the VEU input data is in the RGB format, set a value in the RPKF column in table 35.8 in these bits.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	DITH	0	R/W	Selects whether dithering is applied or not when performing tone reduction of an RGB image. The VEU has a tone reduction function for RGB images. The number of tones after this processing is determined by the WPKF bit setting. Tone reduction processing for RGB images uses quantization which causes the resultant image to contain false contours. This problem becomes more serious as the number of tones is reduced, and it generally degrades the image quality. The VEU can perform dithering to lessen this degradation caused by tone reduction. 0: Does not apply dithering at tone reduction for the VEU destination image in the RGB format 1: Applies dithering at tone reduction for the VEU destination image in the RGB format

Bit	Bit Name	Initial Value	R/W	Description
3 2	TM2 TM1	0 0	R/W R/W	Selects the color converting equation of color conversion circuit. 00: Use color conversion of full-range RGB[0,255] ⇔ Y[16,235], CbCr[16,240] conforms to ITU-R BT.601. 01: Use color conversion of full range RGB[0,255] ⇔ YCbCr[0,255] conforms to ITU-R BT.601. 10: Use color conversion of full-range RGB[0,255] ⇔ Y[16,235], CbCr[16,240] conforms to ITU-R BT.709. 11: Use color conversion of full-range RGB[16,235] ⇔ Y[16,235], CbCr[16,240] conforms to ITU-R BT.709.
1 0	TE RY	0 0	R/W R/W	The TE bit turns on or off the circuit for RGB ⇔ YCbCr conversion. The RY bit specifies whether the image input is in the YCbCr format or RGB format. Table 35.9 shows the relationship between the TE and RY bit settings and the input/output data format. 00: Reads a YCbCr source image and does not perform YCbCr → RGB conversion 01: Reads an RGB source image and does not perform RGB → YCbCr conversion 10: Reads a YCbCr source image and performs YCbCr → RGB conversion 11: Reads an RGB source image and performs RGB → YCbCr conversion

35.3.11 VEU Resize Filter Control Register (VRFCR)

VRFCR sets the scale-up/down factor for the image scaling filter. When performing scale-up/down processing, some other processings cannot be performed simultaneously (see table 35.14).

Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VVMNT[3:0]				VVFRC[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VHMNT[3:0]				VHFRC[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	VVMNT[3:0]	H'0	R/W	Mantissa Part of Vertical Scaling Factor These bits set the vertical scaling factor. A value from H'0 to H'F can be set. When the VVMNT bits are set to H'0 and the VVFRC bits to H'000, the output is the same size.
27 to 16	VVFRC[11:0]	H'000	R/W	Fraction Part of Vertical Scaling Factor These bits set the vertical scaling factor. A value from H'000 to H'FFF can be set.
15 to 12	VHMNT[3:0]	H'0	R/W	Mantissa Part of Horizontal Scaling Factor These bits set the horizontal scaling factor. A value from H'0 to H'F can be set. When the VHMNT bits are set to H'0 and the VHFRC bits to H'000, the output is the same size.
11 to 0	VHFRC[11:0]	H'000	R/W	Fraction Part of Horizontal Scaling Factor These bits set the horizontal scaling factor. A value from H'000 to H'FFF can be set.

The VEU has an image scaling filter that can scale the image up and down, as shown in figure 35.17. The scaling filter cannot be operated simultaneously with the median filter, deblocking filter, or low-pass filter, and rotation is also prohibited. Accordingly, set B'0 to the bits in VFMCR, except the HMRR (horizontal inversion) and VMRR (vertical inversion) bits, when setting VRFCR.

The scaling factor for scale-up/down can be set between 1/16 to 16.

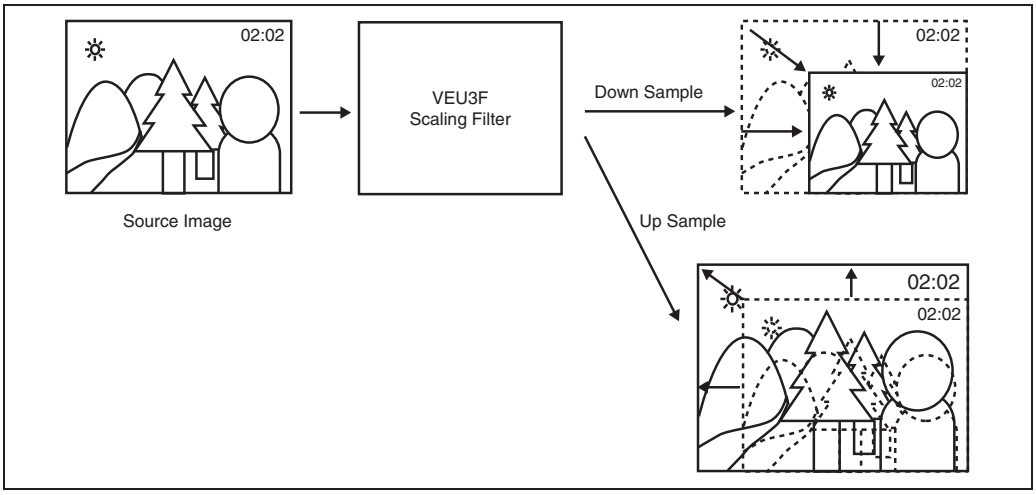

Figure 35.17 Scaling of Image by VEU

The formulas for obtaining the output pixel count of the scale-up/-down from the scaling ratio and the input pixel count are defined as follows:

$$\alpha = MANT \times 4096 + FRAC \quad \text{. . . Formula 1}$$

$$SCL \text{ (scaling factor)} = \frac{4096}{\alpha} \quad \text{. . . Formula 2}$$

In a formula listed below, decimal place of a calculation result of <A> is rounded off. Here, a input image size is indicated as Sin, and a output image size as SIZE.

Note: Horizontal: Sin = VESSR.VHSS
Vertical: Sin = VESSR.VVSS

[Scale-down]

$$SIZE =< 1 + (< 1 + (Sin - 1) / MANTpre > - 1) \times MANTpre \times SCL > \quad [1/16 < SCL \leq 1\ ]$$

…Formula 3

$$MANTpre = 1 \quad [1 \leq MANT > 4]$$
$$= 2 \quad [4 \leq MANT > 8]$$
$$= 4 \quad [8 \leq MANT > 16] \quad \text{…Formula 4}$$

[Scale-up]

SIZE = < 1 + (Sin – 1) × SCL > [1 < SCL ≤ 16, VRSCR.AMD = 0] …Formula 5
SIZE - < Sin × SCL > [1 < SCL ≤ 16, VRSCR.AMD = 1] …Formula 6

Note: See section 35.3.14, VEU Resize Filter Control Register (VRSCR) details on the AMD bit

Example : Scale up 88 pixels to 352 pixels (VRSCR.AME = 0)

SCL = 352/88 = 4, suppose SCL = 4, and the preliminary settings of MANT = 0 and FRAC = 1024 are made based on formulas 1 and 2. Substituting these in formula 5 results in an output pixel count of 349. Since this calculated value is smaller than the desired output pixel count of 352, set FRAC to a value that is smaller than this value but at the same time the maximum value (MANT = 0, FRAC = H'3FF). At this point, the output pixel count is 349, which is not the desired output pixel count so that the calculation to be repeated. Setting to a value FRAC = H'3F7, the output pixel count becomes 352 which is the desired output pixel count. So set MANT = 0, FRAC = H'3F7 for the scaling up 88 pixels to 352.

Table 35.10 Settings for Each Horizontal Scaling Factor of Scaling Filter

		FRAC		
Scaling Factor	**AMD**	**Decimal**	**Hexadecimal**	**MANT**
8	0	508	H'1FC	0
4	0	1017	H'3F9	0
2	0	2039	H'7F7	0
1.5	0	2723	H'AA3	0
8	1	512	H'200	0
4	1	1024	H'400	0
2	1	2048	H'800	0
1.5	1	2730	H'AAA	0
7/8	0	585	H'249	1
3/4	0	1365	H'555	1
5/8	0	2457	H'999	1
1/2	0	0	H'0	2
1/4	0	0	H'0	4
1/8	0	0	H'0	8

35.3.12 VEU Resize Filter Size Clip Register (VRFSR)

VRFSR sets the clipping (discarded) size of fractions in pixels output from the filter, and must be set in combination with VRFCR.

Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	VVCLP[11:0]

R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	VHCLP[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 16 (28 to 16)	VVCLP[11:0]	H'000	R/W	These bits set the vertical clipping size after scale-up/down in pixel units (1-pixel units). This setting should be made in 2-pixel units when the YCbCr format is 4:2:0.*
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 0	VHCLP[11:0]	H'000	R/W	These bits set the horizontal clipping size after scale-up/down in pixel units (4-pixel units). This setting should be made in 2-pixel units when the WPKF bits (write pack) in VTRCR are set to 1, 2, 6, 8 to 14, 19, 20, 22, or 23.

Note: When resizing it, it can be assumed it is vertical 8188 or less (Only VEU2 and VEU3).

The VVCLP and VHCLP bits in the VRFSR register set the output size when line processing (scale-up/down, enhancer, or bundle read) is performed. The size can be specified in 4-pixel units horizontally and in 1-pixel (2-pixel for YCbCr4:2:0 format) units vertically in VRFSR. However, a setting in 2-pixel units horizontally is possible for RGB 2 bytes/pixel (VTRCR.WPKF=1, 2, 6) and RGB 4 bytes/pixel (VTRCR.WPKF=8 to 14, 19, 20, 22, 23).

The maximum value to be set in the VVCLP and VHCLP bits in the VRFSR register is 4092 pixels. The minimum value for them is 4 pixels*[1]. Note that the values should be such that VRFSR.VHCLP + VRSOR.VHCLOFS ≤ 4092*[2].

Note: 1 When the FIR11tap filter is used, The minimum value for them is 8 pixels

2 When the FIR11tap filter is used, it becomes 2048 or less (VEU2,3).

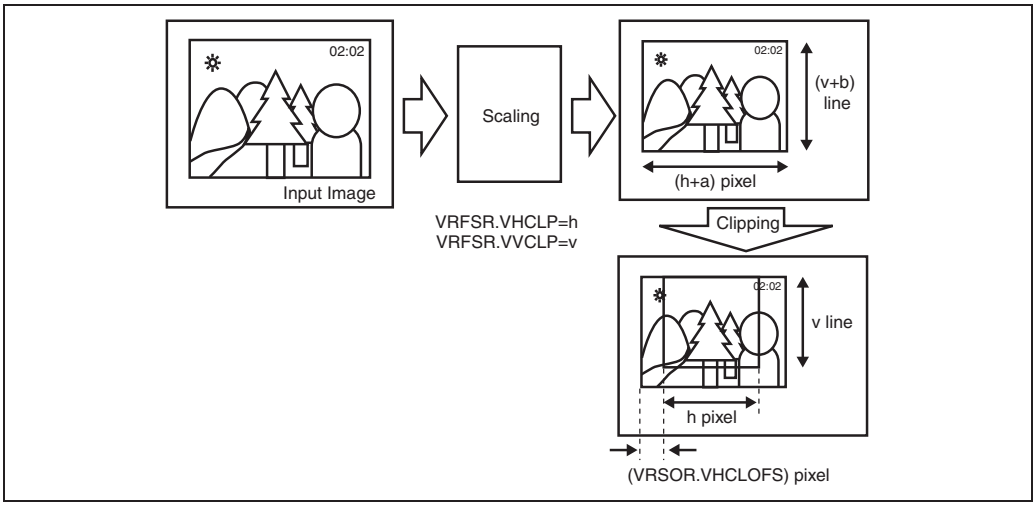

Figure 35.18 Clipping of Image Output from VEU Scaling Filter

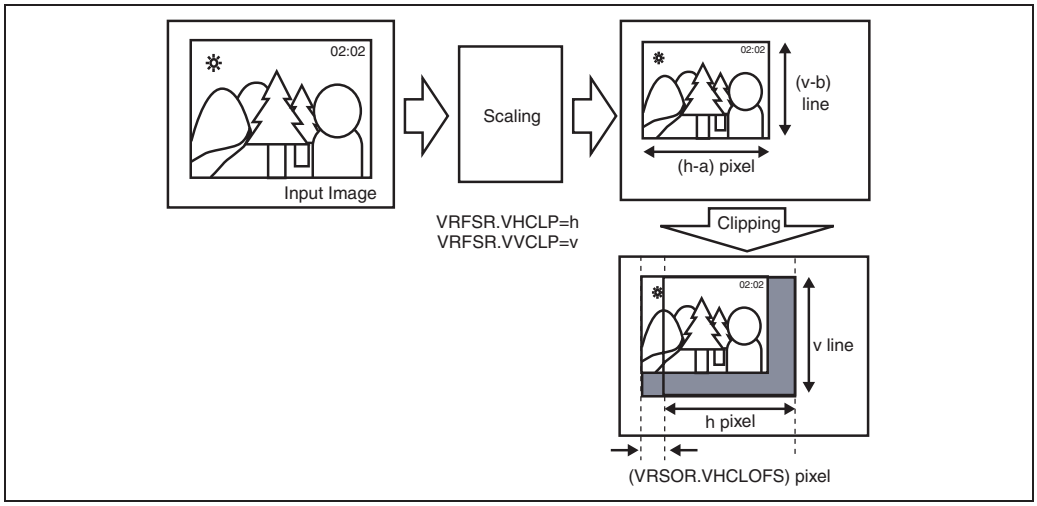

Figure 35.19 Shifting of Image Output from VEU Scaling Filter

If the values are smaller than the filter output pixel count, output images are clipped as shown in figure 35.18. The number of output pixels is counted from the position shifted to the right by the offset specified in the VHCLOFS bit in the VRSOR register. The pixels that are located at the right of the specified pixel count or below the specified line count are discarded by the clipping function.

If the values are larger than the filter output pixel count, images are output by complementing pixels up to the specified pixel count according to the FMD bit in the VRSCR register, where the pixels are counted from the position shifted to the right by the offset specified in the VHCLOFS bit in the VRSOR register (see figure 35.19).

However, if the horizontal number of pixels specified in VRFSR is larger than the number of the scaling filter output pixels rounded up to the nearest multiple of 4, the complementary function does not work. In this case, the VEU may be hung up, so the VRFSR value should be a value that is obtained by calculating by the formulas 1 to 6 and rounding up to a multiple of 4.

If the filter output pixel count obtained by the formulas 1 to 6 is equal to 4M +N (M is an integer. N = 1 to 4), VRFSR.VV(H)CLP ≤ 4M+4.

When scale-up/down is not performed, set VRFSR.VHCLP = VESSR.VHSS, VRFSR.VVCLP = VESSR.VVSS.

35.3.13 VEU Enhance Register (VENHR)

VENHR sets up the filter (enhancer) for enhancing the edges of images. Some other processings cannot be performed simultaneously with the edge enhancement processing (see table 35.2). Modifying this register during operation is prohibited.

The enhancer cannot be operated simultaneously with the median filter, deblocking filter, or low-pass filter, and rotation is also prohibited. Accordingly, set B'0 to the bits in VFMCR, except the HMRR (horizontal inversion) and VMRR (vertical inversion) bits, when setting VENHR.

Moreover, when the alpha resize is used, enhancement processing cannot be used(VEU2,3).

0	ENHH	0	R/W	Enables or disables edge enhancement in the horizontal direction. 0: Horizontal edge enhancement is not performed 1: Horizontal edge enhancement is performed

35.3.14 VEU Resize Filter Control Register (VRSCR)

VRSCR performs scaling filter adjustments for line processing (with scaling, enhance, and bundle read). For block processing, set all of the initial values of VRSCR to 0 (without scaling, enhance, or bundle read).

Writing 1 to the read-only bits is prohibited. If 1 is written to any of these bits a malfunction may occur. Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	AMD	FMD	LC[1:0]		—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	AMD	0	R/W	This bit specifies the pixel count generated when the scaling filter performs a scale-up. When AMD = 1 is specified, int (n * scale-up factor) pixels are created by complementing horizontal and vertical pixels in the destination image for AMD = 0. 0: The pixel count obtained at a scale-up is 1+int ((n1)*scale-up factor). 1: The pixel count obtained at a scale-up is int (n*scale-up factor).
30	FMD	0	R/W	This bit specifies the pixel complementing method for the scaling filter. When the scaling filter outputs an image that does not fill the clip size, the pixels are complemented up to the clip size. 0: Copy right (lower) pixels and provide complementary pixels. 1: Provide complementary right(lower) pixels of a color specified by VFLCR.
29, 28	LC[1:0]	00	R/W	These bits specify the number of pixels for source image horizontal-left clipping. From 0 to 3 can be specified. Because the source address registers VSAYR and VSCAR are both in longword units, if the input format is YCbCr, the starting position for horizontal clipping from the background image is in four-pixel units. Therefore, if you perform background image clipping from pixel position at the left end 4M+LC (M; integer, LC: 0-3), 4M is adjusted by the VSAYR read start address, and the lower two bits are adjusted by this bit (LC). When the value of this bit has been set, input to the scaling filter is specified by the VHSS bits in VESSR and the LC bits in VRSCR for the horizontal direction and by the VVSS bits in VESSR for the vertical direction.
27 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

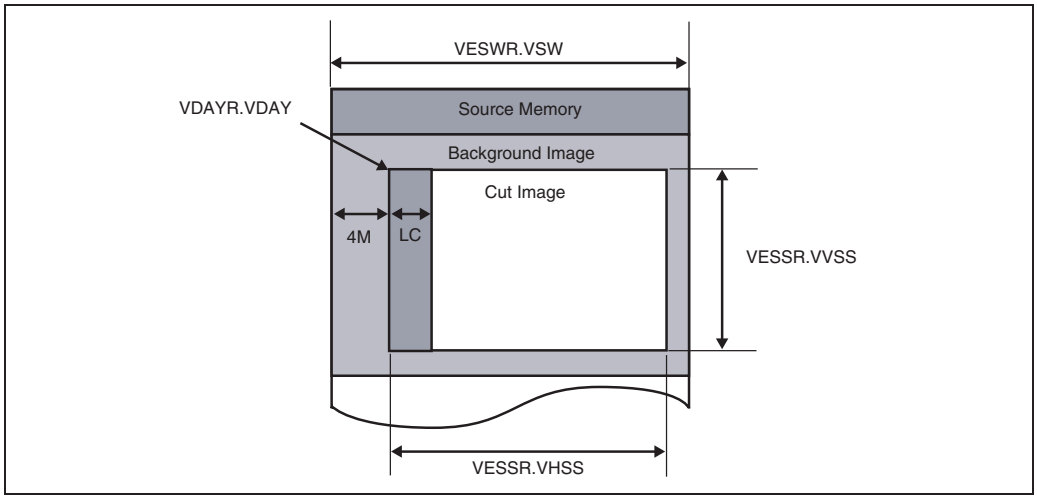

Figure 35.20 Relations between the Background Image and Clipping Pixel Location

35.3.15 VEU Resize Filter Size Clip Offset Register (VRSOR)

VRSOR sets the left clip offset when images are clipped bases on the filter output pixel count. For details on the offset positions, see figures 35.18 and 35.19. When following Flow 2 in figure 35.2, set an offset that is smaller than the horizontal number of pixels of the output image after scaling down.

Also, make sure such that VRFSR.VHCLP + VRSOR.VHCLOF ≤ 4092*.

Note: When the FIR11tap filter is used, it becomes 2048 or less (VEU2,3).

When this register is set, the VRFCR and VRFSR registers should also be set. Since the register setting is used as the output size when Flow 2 describe in section 35.2, Functional Overview of VEU (Scale-up/down, enhancer, or bundle read is performed), this register should be set even if scale-up/down is not performed.

Writing to this register during operation is prohibited.

31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	VVCLOFS [7:0]	H'00	R/W	Specifies the vertical clip offset by the number of pixel (one-pixel unit) after scale-up/down(Only VEU2 and 3).
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	VHCLOFS [7:0]	H'00	R/W	Specifies the lateral clip offset by the number of pixel (one-pixel unit) after scale-up/down.

35.3.16 VEU Filter Mode Control Register (VFMCR)

VFMCR sets the operating mode for filter processing.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	MEDFST	0	R/W	Changes the order of applying the median filter and deblocking filter when the FLTPI bit is set to 1. 0: Applies the LPF/deblocking filer and median filter in this order. 1: Applies the median filer and LPF/deblocking filter in this order. Note: Only when a high-speed filter is processed(FLTPI=1), it is possible to use it.
24	FLTPI	0	R/W	Controls fast processing of LPF, deblocking filer, and median filter. 0: Disables fast processing of LPF, deblocking filer, and median filter. 1: Enables fast processing of LPF, deblocking filer, and median filter. Note: When the FIR filter is used, it is necessary to

Bit	Bit Name	Initial Value	R/W	Description
				set it to 1(VEU2,3). When the FLTPI is set to 1, the possible settings are restricted to the followings: (1) VFMCR.ROTR = 0 (2) VFMCR.ROTL = 0 (3) VESTR.VBE = 0 (4) VRSOR.VHCLOFS = 0 (VEU0,1) (5) VRFSR.VVCLP = VSSR.VVSS (VEU0,1) (6) VRFSR.VHCLP = VSSR.VHSS (VEU0,1) (5)' VRSOR.VVCLOFS＋VRFSR.VVCLP=VSSR.VVSS(VEU2,3) (6)' VRSOR.VHCLOFS＋VRFSR.VHCLP<=VSSR.VHSS(VEU2,3)
23 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	MED	0	R/W	Enables or disables usage of the median filter. When the median filter is applied to an image, scale-up/down processing and edge enhance processing cannot be performed at the same time. In bundle read mode, the median filter cannot be used. Therefore, when this bit is set to 1, set VRFCR, VENHR, and the VBE bit in VESTR to 0. (Interoperating with the scale-up/down processing, edge enhance processing, and bundle read mode is prohibited.) The relationship between this bit and the filter operation is shown in table 35.11. 0: Median filter is not used 1: Median filter is applied to the source image

Bit	Bit Name	Initial Value	R/W	Description
15, 13	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
12 (13 to 12)	TPN[1:0]	00	R/W	Sets the FIR filter (high-speed process: FLTPI = 1) and the number of taps of the low-pass filter (LPF). 00: Count for FIR filter or LPF tap is set to 3 taps (initial value) 01: Count for FIR filter or LPF tap is set to 5 taps 10: FIR filter count is set to 11 taps*
11, 10	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
9	DBLK	0	R/W	Enables or disables usage of the deblocking filter. When the deblocking filter is applied to an image in bundle read mode, scale-up/down processing and edge enhance processing cannot be performed at the same time. When this bit is set to 1, set VRFCR, VENHR, and the VBE bit in VESTR to 0. Specifies the lateral clip offset by the number of pixel (one-pixel unit) after scale-up/down. The relationship between this bit and the filter operation is shown in table 35.11. 0: LPF is applied to the entire source image (normal mode) 1: LPF is applied to only the boundary of the 8 × 8 pixel blocks of the source image (deblocking mode)
8	LPHV	0	R/W	Enables or disables usage of the low-pass filter. In bundle read mode, the low-pass filter cannot be used. When the low-pass filter is applied to an image, scale-up/down processing and edge enhance processing cannot be performed at the same time. When this bit is set to 1, set VRFCR, VENHR, and the VBE bit in VESTR to 0. (Interoperating with the scale-up/down processing, edge enhance processing, and bundle read mode is prohibited.) The relationship between this bit and the filter operation is shown in table 35.11. 0: NOP 1: LPF is applied to the source image

Bit	Bit Name	Initial Value	R/W	Description
				Note: When the FIR filter is used, it is necessary to set it to 1(VEU2,3).
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	VMRR	0	R/W	Enables or disables usage of the vertical inversion (symmetric with regard to horizontal axis) filter. The relationship between this bit and the rotate/invert operation is shown in table 35.12. 0: NOP 1: Vertical inversion (symmetric with regard to horizontal axis) filter is applied to the source image
4	HMRR	0	R/W	Enables or disables usage of the horizontal inversion (symmetric with regard to vertical axis) filter. The relationship between this bit and the rotate/invert operation is shown in table 35.12. 0: NOP 1: Horizontal inversion (symmetric with regard to vertical axis) filter is applied to the source image
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	ROTL	0	R/W	Enables or disables usage of the 270-degree rotation (clockwise) filter. In bundle read mode, rotation cannot be performed. When rotation processing is performed for an image, scale-up/down processing and edge enhance processing cannot be performed at the same time. When this bit is set to 1, set VRFCR, VENHR, and the VBE bit in VESTR to 0. (Interoperating with the scale-up/down processing, edge enhance processing, and bundle read mode is prohibited.) The relationship between this bit and the rotate/invert operation is shown in table 35.12. 0: NOP 1: 270-degree rotation (clockwise) filter is applied to the source image

Bit	Bit Name	Initial Value	R/W	Description
0	ROTR	0	R/W	Enables or disables usage of the 90-degree rotation (clockwise) filter. In bundle read mode, rotation cannot be performed. When rotation processing is performed for an image, scale-up/down processing and edge enhance processing cannot be performed at the same time. When this bit is set to 1, set VRFCR, VENHR, and the VBE bit in VESTR to 0. (Interoperating with the scale-up/down processing, edge enhance processing, and bundle read mode is prohibited.) The relationship between this bit and the rotate/invert operation is shown in table 35.12. 0: NOP 1: 90-degree rotation (clockwise) filter is applied to the source image

Note: * When the tap count is set to 11, the maximum number of horizontal pixel is to be 2048. The setting enables only for the VEU2 and VEU3.
The setting disables other than when FLTPI = 1. Further more, in scale-up/-down or enhancing, set to 0 or 1.

Table 35.11 Relationship between MED, DBLK, and LPHV Bits and Filter Operation

MED Bit	DBLK Bit	LPHV Bit	Filter Operation
0	0	0	Passed through
0	0	1	Low-pass filter/FIR filter
0	1	1	Deblocking filter
1	1	1	Deblocking filter + median filter*
1	0	0	Median filter
1	0	1	Low-pass filter + Median filter**
Other than above			Setting prohibited

Note: * The order of deblocking filter → median filter cannot be changed.
** It is effective only to process a high-speed filter (FLTPI=1).

Table 35.12 Relationship between VMRR, HMRR, ROTL, and ROTR Bits and Rotate/Invert Operation

VMRR Bit	HMRR Bit	ROTL Bit	ROTR Bit	Rotate/Invert Operation
0	0	0	0	No rotation/inversion
0	0	0	1	Rotated by 90 degrees clockwise
0	0	1	0	Rotated by 270 degrees clockwise
0	1	0	1	Rotated by 90 degrees clockwise and then inverted in the horizontal direction
1	0	0	1	Rotated by 90 degrees clockwise and then inverted in the vertical direction
0	1	0	0	Inverted in the horizontal direction
1	0	0	0	Inverted in the vertical direction
1	1	0	0	Rotated by 180 degrees
Other than above				Setting prohibited

To rotate the image 270 degrees and then invert it in the horizontal direction, rotate the image 90 degrees and then invert it in the vertical direction. Likewise, to rotate the image 270 degrees and then invert it in the vertical direction, rotate the image 90 degrees and then invert it in the horizontal direction.

Figures 35.21 and 35.22 show the relationship between the rotated/inverted images and raw image.

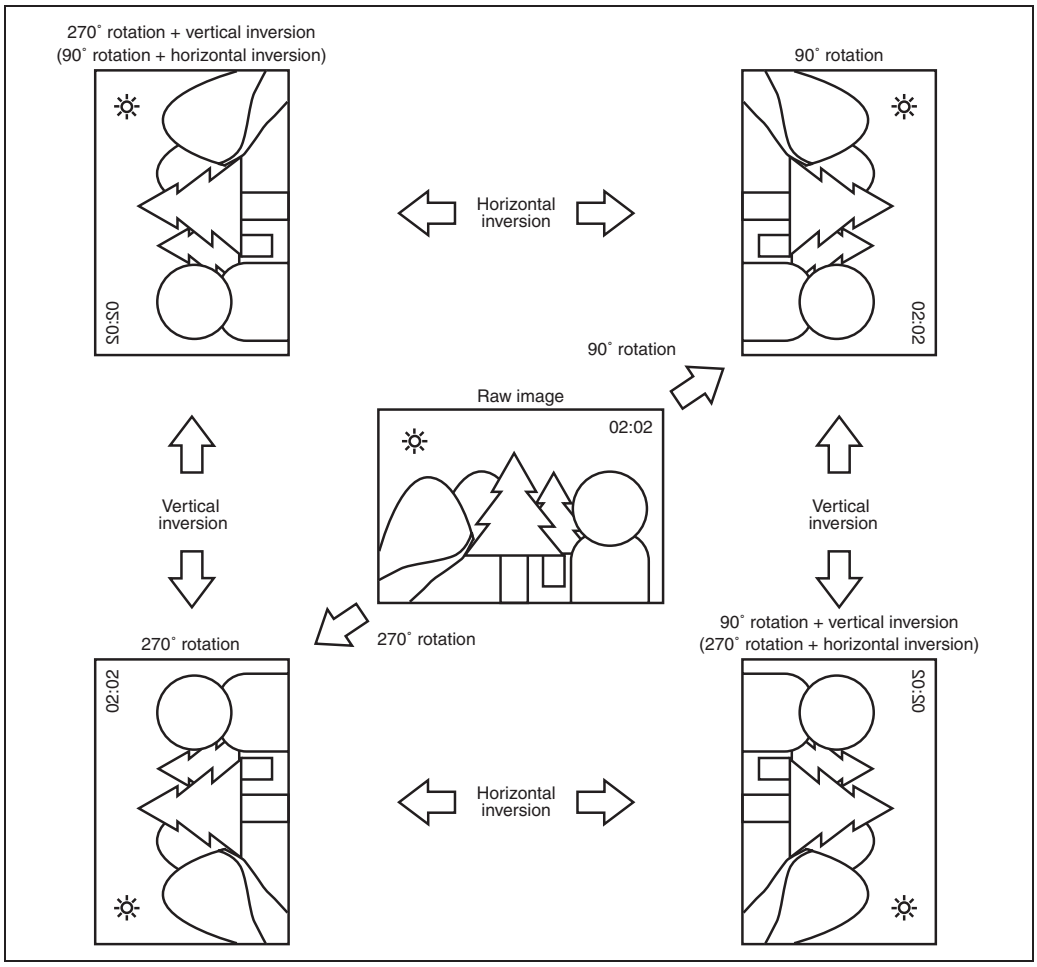

Figure 35.21 Relationship between Rotated/Inverted Images and Raw Image

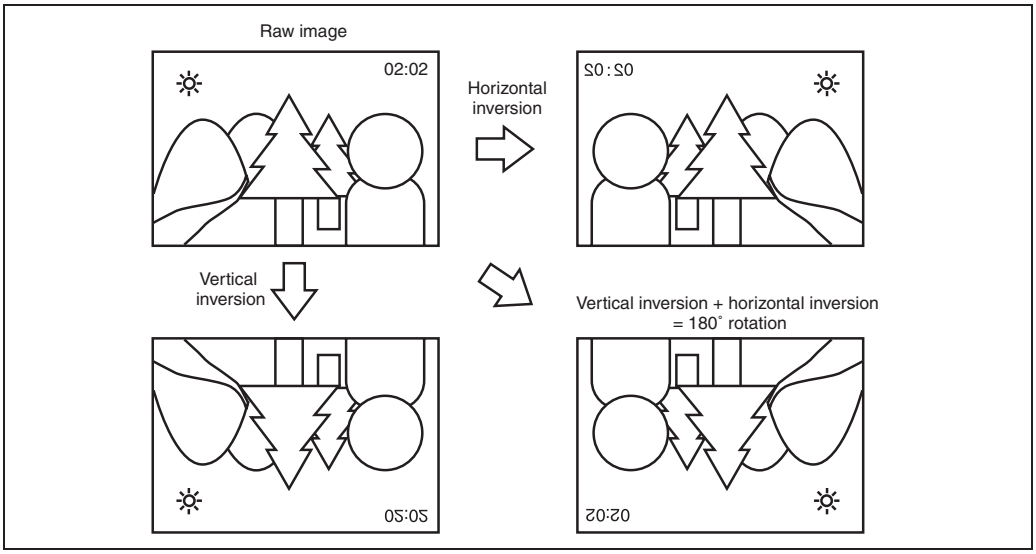

Figure 35.22 Relations between Inverted Images and Raw Image

35.3.17 VEU Vertical Tap Coefficient Register (VVTCR)

VVTCR sets the vertical tap coefficients when applying the low-pass filter.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 20	VSHFT[2:0]	000	R/W	These bits specify the shift capacity after vertical tap calculation. Set how many pixels the location is to be shifted right after adding each vertical tap coefficient. This setting must correspond to the sum of the VTPC0 to VTPC4 bits. See table 35.13 for details on the values corresponding to the total value of VVTCR.VTPC.
19 to 16	VTPC4[3:0]	H'0	R/W	These bits set vertical tap coefficient 4 (clear these bits to 0 for a 3-tap filter). Set the component of the pixel two pixels right of that location to be given when applying a 5-tap low-pass filter. Clear these bits to 0 when applying a 3-tap low-pass filter.
15 to 12	VTPC3[3:0]	H'0	R/W	These bits set vertical tap coefficient 3. Set the component of the pixel on the right of that location to be given when applying a low-pass filter.

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	VTPC2[3:0]	H'0	R/W	These bits set vertical tap coefficient 2. Set the component of that location to be given when applying a low-pass filter.
7 to 4	VTPC1[3:0]	H'0	R/W	These bits set vertical tap coefficient 1. Set the component of the pixel on the left of that location to be given when applying a low-pass filter
3 to 0	VTPC0[3:0]	H'0	R/W	These bits set vertical tap coefficient 0 (clear these bits to 0 for a 3-tap filter). Set the component of the pixel two pixels left of that location to be given when applying a 5-tap low-pass filter. Clear these bits to 0 when applying a 3-tap low-pass filter.

	6	12	13	14	13	12

Note: Horizontal and vertical taps should be set in the same size.

35.3.19 VEU Designated Color Register (VAPCR)

VAPCR specifies the designated color.

When any pixel in an image to be processed by the VEU is the same as the designated color set by this register, that pixel is replaced with the conversion color set by VECCR. For an RGB output, clear the lower bits except the valid bits to 0. For a YCbCr output, only the YCbCr 4:4:4 format is supported.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

24	APCON	0	R/W	Enables or disables replacement of the designated color. 0: VEU processed image is output as it is 1: VEU processed image is output after pixels corresponding to the designated color have been replaced with the conversion color
23 to 16	RAPC[7:0]	H'00	R/W	These bits specify the R (Cb) component of the designated color.
15 to 8	GAPC[7:0]	H'00	R/W	These bits specify the G (Y) component of the designated color.
7 to 0	BAPC[7:0]	H'00	R/W	These bits specify the B (Cr) component of the designated color.

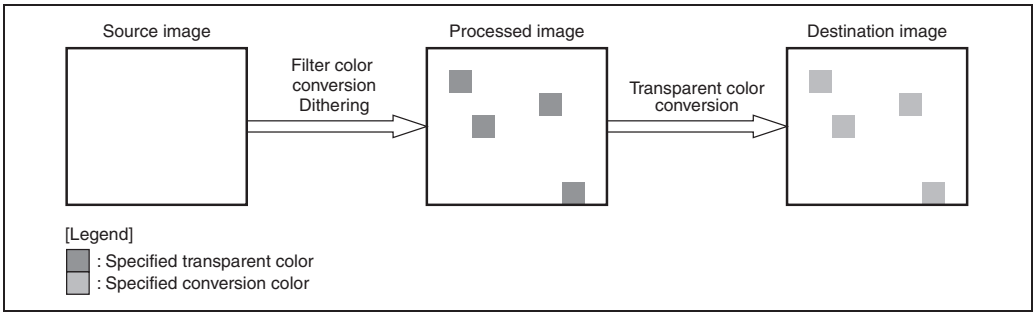

Figure 35.23 Replacement of Designated-Color Pixels in VEU Processed Image with Conversion –Color Pixels

35.3.20 VEU Conversion Color Register (VECCR)

VECCR specifies the conversion color.

When any pixel in an image to be processed by the VEU is the same as the designated color set by VAPCR, that pixel is replaced with the conversion color set by this register. For an RGB output, clear the lower bits except for the valid bits to 0. For a YCbCr output, only the YCbCr 4:4:4 format is supported.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
23 to 16	RCHGC[7:0]	H'00	R/W	These bits specify the R (Cb) component of the conversion color.
15 to 8	GCHGC[7:0]	H'00	R/W	These bits specify the G (Y) component of the conversion color.
7 to 0	BCHGC[7:0]	H'00	R/W	These bits specify the B (Cr) component of the conversion color.

35.3.21 VEU Fill Color Specification Register (VFLCR)

VFLCR is a fill color specification register.

When the FMD bit in VRSCR is set to 1, VFLCR specifies the fill color used to complement pixels when the pixel area created by the VEU scaling filter is smaller than the clip area specified by the clip size register. For RGB output, specify 0 for the lower bits other than the valid bits. RGB

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	RFILC[7:0]	H'00	R/W	These bits specify the R (Cb) component of the fill color.
15 to 8	GFILC[7:0]	H'00	R/W	These bits specify the G (Y) component of the fill color.
7 to 0	BFILC[7:0]	H'00	R/W	These bits specify the B (Cr) component of the fill color.

35.3.22 VEU Address Fixed Register (VAFXR)

VAFXR specifies fixed mode for the addresses of the data output from the VEU.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VAFIX
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	VAFIX	0	R/W	Sets fixed mode for output addresses. When this bit is 1, the addresses to draw the image output from the VEU is fixed to the values set in VDAYR. When this bit is 0, the output address is incremented according to the data and VEDWR. Fixed address mode is enabled only when the VEU destination image is in the RGB format. For YCbCr destination images, set the following bits or register to 0; the bits MED, LPHV, ROTL, and ROTR in VFMCR (which prohibit median filter, low-pass filter, and rotation), VRFCR (same-size output), and the lower three bits in VDAYR and VRFSR (which disable other than burst transfer). 0: Output addresses are not in fixed address mode 1: Output addresses are in fixed address mode

35.3.23 VEU Swapping Register (VSWPR)

VSWPR sets swapping within the 64-bit data at the data input/output section of the VEU.

When dividing addresses into 64 bits, make the following setting for each case.

- When swapping data in longword units for all inputs/outputs: H'0000 0044
- When swapping data in word units for all inputs/outputs: H'0000 0022
- When swapping data in byte units for all inputs/outputs: H'0000 0011
- When swapping data in byte units from the MSB to the LSB: H'0000 0077

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	VEOLS	0	R/W	Sets swapping in longword units for output data. In longword swapping for output data, data is swapped in longword units within the 32 bits on the MSB side and within the 32 bits on the LSB side for 64-bit data in the VEU output section (figure 35.24). 0: Output data is not swapped in longword units 1: Output data is swapped in longword units
5	VEOWS	0	R/W	Sets swapping data in word units for output data. In word swapping for output data, data is swapped in word units within the 32 bits on the MSB side and within the 32 bits on the LSB side for 64-bit data in the VEU output section (figure 35.25). 0: Output data is not swapped in word units 1: Output data is swapped in word units
4	VEOBS	0	R/W	Sets swapping data in byte units for output data. In byte swapping for output data, data is swapped in byte units within each 16 bits for 64-bit data in the VEU output section (figure 35.26). 0: Output data is not swapped in byte units 1: Output data is swapped in byte units
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	VEILS	0	R/W	Sets swapping data in longword units for input data. In longword swapping for input data, data is swapped in longword units within the 32 bits on the MSB side and within the 32 bits on the LSB side for 64-bit data in the VEU input section (figure 35.24). 0: Input data is not swapped in longword units 1: Input data is swapped in longword units
1	VEIWS	0	R/W	Sets swapping data in word units for input data. In word swapping for input data, data is swapped in word units within the 32 bits on the MSB side and within the 32 bits on the LSB side for 64-bit data in the VEU input section (figure 35.25). 0: Input data is not swapped in word units 1: Input data is swapped in word units

Bit	Bit Name	Initial Value	R/W	Description
0	VEIBS	0	R/W	Sets swapping data in byte units for input data. In byte swapping for input data, data is swapped in byte units within each 16 bits for 64-bit data in the VEU input section (figure 35.26). 0: Input data is not swapped in byte units 1: Input data is swapped in byte units

35.3.24 VEU Event Interrupt Enable Register (VEIER)

VEIER enables or disables output of the interrupt signal of a VEVTR flag.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	VBENDE	0	R/W	Enables or disables the interrupt signal of VEVTR.VBEND to be output. 0: Disables output of the VEVTR.VBEND interrupt signal 1: Enables output of the VEVTR.VBEND interrupt signal
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	VEENDE	0	R/W	Enables or disables the interrupt signal of VEVTR.VEEND to be output. 0: Disables output of the VEVTR.VEEND interrupt signal 1: Enables output of the VEVTR.VEEND interrupt signal

35.3.25 VEU Event Register (VEVTR)

VEVTR indicates the interrupt source when an internal interrupt occurs in the VEU. Whether output of the interrupt signal of each source in VEVTR is enabled or disabled is set by VEIER.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	VB END	—	—	—	—	—	—	—	VE END
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	VBEND	0	R/W	This flag is set to 1 when VEU processing has finished for a single read (reading of the number of lines set in VBSSR) in bundle read mode (N-line read mode). The VEU enters the read restart wait state when this flag is set. Therefore, after clearing the interrupt source, switch the address registers, and start reading again (VESTR = H'0000 0011). [Reading] 0: Indicates in progress of reading in bundle read processing, or this flag has already been cleared 1: Indicates that restart is being waited in bundle read processing [Writing] 0: Clears this flag by writing 0 to it 1: Holds the current value

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	VEEND	0	R/W	This flag is set to 1 when VEU processing has totally finished. This flag is not cleared unless 0 is written to clear the bit after VEU processing ends. Therefore, 0 must be written to this bit to clear it before the VEU is activated again. [Reading] 0: Indicates that VEU processing has not finished, or this flag has already been cleared 1: Indicates that VEU processing has finished [Writing] 0: Clears this flag by writing 0 to it 1: Holds the current value

35.3.26 VEU Status Register (VSTAR)

VSTAR indicates the internal status of the VEU and the internal signal states.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	INTL	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	VB PRC	—	—	—	VB READ	—	—	—	—	—	—	—	VE PRC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
24	INTL	0	R	Indicates the assert state of the VEU interrupt signal to the CPU. 0: Indicates that no interrupt signal is asserted at the VEU interrupt signal port 1: Indicates that an interrupt signal is asserted at the VEU interrupt signal port
23 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	VBPRC	0	R	Indicates the VEU status in bundle read mode. For details, see table 35.27. 0: Indicates that the VEU is not operating in bundle read (N-line read) mode 1: Indicates that the VEU is operating in bundle read (N-line read) mode
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	VBREAD	0	R	For details, see table 35.18. 0: Indicates that the VEU is waiting to be restarted in bundle read (N-line read) mode 1: Indicates that the VEU is reading in bundle read (N-line read) mode
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	VEPRC	0	R	Indicates the same value as the VE bit in VESTR. For details, see table 35.18. 0: VEU is ready (halted) 1: VEU is busy (operating state)

The VEU operates in either normal operating mode or bundle read mode. In normal operating mode, the registers are not to be modified between activation and processing end. In bundle read mode, there are two operating states: read processing state and the state waiting for the VEU to be restarted by software. The values when reading VSTAR in each state are shown in table 35.17. Figure 35.27 shows the VSTAR state transitions in normal operating mode, and figure 35.27 shows the VSTAR state transitions in bundle read mode.

Table 35.17 VSTAR Value Read in Each State

Operating Mode		VBPRC Bit	VBREAD Bit	VEPRC Bit
Normal operation	Halted	0	0	0
	Operating	0	0	1
N-line read mode	Halted	0	0	0
	During read processing	1	1	1
	Waiting for restart	1	0	1

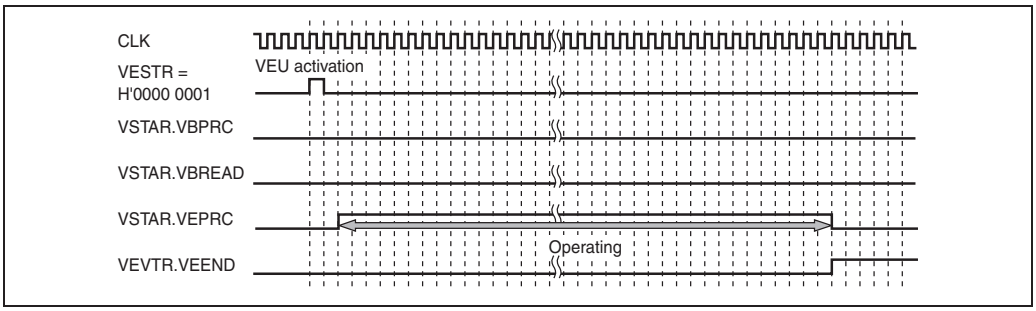

Figure 35.27 VSTAR State Transitions in Normal Operating Mode

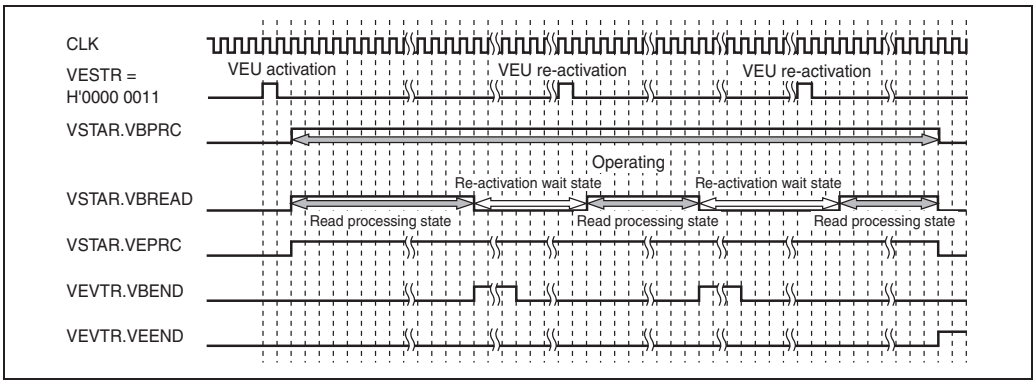

Figure 35.28 VSTAR State Transitions in Bundle Read Mode

35.3.27 VEU Module Reset Register (VBSRR)

VBSRR executes the module reset of the VEU.

Writing 1 to read-only bits is prohibited. If 1 is written to any of these bits, a malfunction may occur. Modifying this register during operation is prohibited.

If a module reset is performed during operation, the logic circuits handshaking with the CPU bus are forcibly reset, and malfunction may also affect modules other than the VEU. To correctly break the handshake with the CPU bus before VEU termination, see section 35.3.1, VEU Start Register (VESTR).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	ALLRST	0	W	Module Reset When 1 is written to this bit, all internal control signals of the VEU are reset. 0: Setting prohibited 1: Internal reset of the VEU
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

35.3.28 VEU Resize Passband Register (VRPBR)

VRPBR sets the signal passbands when scale-up/-down is performed. When this register is set, the VRFCR and VRFSR registers should be also set. Writing this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	VBW[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	HBW[6:0]						
Initial vlaue:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	VBW[6:0]	H'00	R/W	Sets the vertical signal passband when scaling-up/down.
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	HBW[6:0]	H'00	R/W	Sets the horizontal signal passband when scaling-up/down.

When scaling up vertically (the VMNT bit in the VRFCR register is 0), set 64 in the VBW bit in the VRPBR register.

When scaling down vertically (the VMNT bit in the VRFCR register is other than 0), set a value obtained by the following formula in the VBW bit in the VRPBR register:

$$VSPBR.VBW = \left(64 \times \frac{4096 \times VMANTpre}{4096 \times VRFCR.VMNT + VRFCR.VFRC} \right)$$

Where VMANTpre is

4(8 ≤ VRFCR.VMNT<16)
2(4 ≤ VRFCR.VMNT<8)
1(1 ≤ VRFCR.VMNT<4)

Note that <A> is an operation that rounds value A down to the nearest integer.

When scaling up horizontally (the HMNT bit in the VRFCR register is 0), set 64 in the HBW bit in the VRPBR register.

When scaling down horizontally (the HMNT bit in the VRFCR register is other than 0), set a value obtained by the following formula in the HBW bit in the VRPBR register:

$$VSPBR.HBW = \left(64 \times \frac{4096 \times HMANTpre}{4096 \times VRFCR.HMNT + VRFCR.HFRC} \right)$$

Where HMANTpre is

4(8 ≤ VRFCR.HMNT<16)
2(4 ≤ VRFCR.HMNT<8)
1(1 ≤ VRFCR.HMNT<4)

Note that <A> is an operation that rounds value A down to the nearest integer.

35.3.29 VEU Resize interpolation setting register(VEUAD_RSZ_ITP)

VEUAD_RSZ_ITP sets the interpolation method when resizing images. However, it is possible to use it only with VEU2 and 3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	BLADV	0	R/W	The interpolation accuracy in the bilinear / nearest neighbor interpolation is changed. The aliasing characteristic of 1/2~1/4 reduction processing is improved by this function. This set value is not effective following the expansion or 1/8 reductions(VVMNT[VHMNT]<=1 or VVMNT[VHMNT]>=8). 0: The bilinear /nearest neighbor interpolation enhancing is not done (initial value). 1: The bilinear /nearest neighbor interpolation enhancing is done
27 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	ALP_TH_ON	0		Enables or disables usage of threshold clipping for the alpha pixels. 0: The clipping is not done (initial value). 1: The clipping is done.
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	ALP_ON	0	R/W	Enables or disables usage of scaling-up/down for the alpha pixels. 0: The scaling is not done (initial value). 1: The scaling is done. Note: it is not possible to use it in a bicubic mode. Please use it as BC_ON=0.
19 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	BC_ON	0	R/W	Sets the bicubic interpolation when the scaling-up/down. 0: bilinear / nearest neighbor interpolation 1: bicubic interpolation(initial value)

15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	NE_ON_A	0	R/W	Sets the method of interpolating for alhpa when non-bicubic interpolation. 0: bilinear(initial value) 1: nearest neighbor*
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	NE_ON_R	0	R/W	Sets the method of interpolating for R/Cr when non-bicubic interpolation. 0: bilinear(initial value) 1: nearest neighbor*
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	NE_ON_G	0	R/W	Sets the method of interpolating for G/Y when non-bicubic interpolation. 0: bilinear(initial value) 1: nearest neighbor*
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	NE_ON_B	0	R/W	Sets the method of interpolating for B/Cb when non-bicubic interpolation. 0: bilinear(initial value) 1: nearest neighbor*

Note: * It is possible to use it at the expansion or 1/1~1/4 reductions.

35.3.30 VEU FIR Filter Horizontal Coefficient Register Y0 (VEUAD_FCOE_HY0)

VEUAD_FCOE_HY0 to VEUAD_FCOE_HY2 set the horizontal tap coefficients for the luminance (Y) component and G-pixel component of the FIR filter. The each coefficient is signed 8-bit data and the VHY5 is the center tap. Set the sum of tap coefficients to a 2's power and the shift value to a $\log_2$ (the sum of coefficients).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	VHU8[7:0]	H'00	R/W	Horizontal FIR filter tap coefficient 8 for chrominance (Cb) component or B-pixel in RGB.
23 to 16	VHU9[7:0]	H'01	R/W	Horizontal FIR filter tap coefficient 9 for chrominance (Cb) component or B-pixel in RGB.
15 to 8	VHU10[7:0]	H'00	R/W	Horizontal FIR filter tap coefficient 10 for chrominance (Cb) component or B-pixel in RGB.
3 to 0	HUSFT[3:0]	H'0	R/W	Horizontal FIR filter bit shift value for chrominance (Cb) component or B-pixel in RGB.

35.3.36 VEU FIR Filter Horizontal Coefficient Register CR0 (VEUAD_FCOE_HCR0)

VEUAD_FCOE_CR0 to VEUAD_FCOE_CR2 set the horizontal tap coefficients for the luminance (Cr) component and R-pixel component of the FIR filter. The each coefficient is signed 8-bit data and the VHV5 is the center tap. Set the sum of tap coefficients to a 2's power and the shift value to a $\log_2$ (the sum of coefficients).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VHV0[7:0]								VHV1[7:0]

3 to 0	VUSFT[3:0]	H'0	R/W	Vertical FIR filter bit shift value for chrominance (Cb) component or B-pixel in RGB.

35.3.45 VEU FIR Filter Vertical Coefficient Register CR0 (VEUAD_FCOE_VCR0)

VEUAD_FCOE_CR0 to VEUAD_FCOE_CR2 set the vertical tap coefficients for the luminance (Cr) component and R-pixel component of the FIR filter. The each coefficient is signed 8-bit data and the VVV5 is the center tap. Set the sum of tap coefficients to a 2's power and the shift value to a $\log_2$ (the sum of coefficients).

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	VVV8[7:0]	H'00	R/W	Vertical FIR filter tap coefficient 8 for chrominance (Cr) component or R-pixel in RGB.
23 to 16	VVV9[7:0]	H'01	R/W	Vertical FIR filter tap coefficient 9 for chrominance (Cr) component or R-pixel in RGB.
15 to 8	VVV10[7:0]	H'00	R/W	Vertical FIR filter tap coefficient 120 for chrominance (Cr) component or R-pixel in RGB.
3 to 0	HVSFT[3:0]	H'0	R/W	Vertical FIR filter bit shift value for chrominance (Cr) component or R-pixel in RGB.

35.3.48 VEU FIR Filter Calculation Optional Setting Register (VEUAD_FSWT)

VEUAD_FSWT performs the optional settings for the FIR filter calculation. This register specifies a rounding selection and a sign-extended for the chrominance data in shifting bits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
												LPF_COEF_ON				CSGNOF

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved
20	LPF_COEF_ON	1	R/W	FIR filter input coefficient specification register The coefficient input to the FIR filter is selected. 0: FIR registers（VEUADx_FCOE_HY0~HCR2、VEUADx_FCOE_VY0~VCR2） 1: LPF registers (VVTCR,VHTCR：initial value)
19 to 17	—	All 0	R	Reserved
16	CSGNOF	1	R/W	Chrominance Signed Bit Extension Option 0: Bit is sign-extended 1: Bit is not sign-extended* (initial value)
15 to 9	—	All 0	R	Reserved
8	RCV	0	R/W	Rounding Specifications for Chrominance (Cr) Component or R-pixel in RGB 0: Round down (initial value) 1: Round up
7 to 5	—	All 0	R	Reserved
4	RCU	0	R/W	Rounding Specifications for Chrominance (Cb) Component or B-pixel in RGB 0: Round down (initial value) 1: Round up
3 to 1	—	All 0	R	Reserved
0	RCY	0	R/W	Rounding Specifications for luminance or G-pixel in RGB 0: Round down (initial value) 1: Round up

Note: * Not to be specified when the coefficient specified for the FIR filter is a negative value. This can be used only when all the coefficients are positive.

35.3.49 VEU Alpha Resize Clip Threshold Setting Register (VEUAD_ALPTH)

VEUAD_ALPTH sets the threshold to pixel value after the alpha is resized and replaces pixel value according to the VEUAD_ALPVAL register value. However, it is possible to use it only with VEU2 and 3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ALP_TH1								ALP_TH0							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	ALP_TH1	H'00	R/W	Alpha threshold setting register 1 When pixel value is ALP_TH1 or more, the pixel is replaced with VEUAD_ALPVAL.ALP_VAL2.
7 to 0	ALP_TH0	H'00	R/W	Alpha threshold setting register 0 When pixel value is ALP_TH0 or less, the pixel is replaced with VEUAD_ALPVAL.ALP_VAL0.

35.3.50 VEU Alpha Resize Clip Value Setting Register (VEUAD_ALPVAL)

VEUAD_ALPVAL specifies pixel value replaced when pixel value after α is resized exceeds (falls below) the threshold. It becomes effective only at VEUAD_RSZ_ITP.ALP_TH_ON=1. However, it is possible to use it only with VEU2 and 3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
									ALP_VAL2							
Initial valude:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	ALP_VAL1								ALP_VAL0							
Initial valude:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R /W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	ALP_VAL2	H'00	R/W	Alpha clip value setting register 2 Sets the pixel replaced value, when pixel value is VEUAD_ALPTH.ALP_TH1 or more.
15 to 8	ALP_VAL1	H'00	R/W	Alpha clip value setting register 1
7 to 0	ALP_VAL0	H'00	R/W	Alpha clip value setting register 0 Sets the pixel replaced value, when pixel value is VEUAD_ALPTH.ALP_TH0 or less.

35.4 Usage Notes for VEU

(1) Restrictions during Operation

Do not halt the clock or module during VEU operation.

(2) Restrictions on Input/Output Functions

Note that when restrictions at other places in this manual differ from restrictions in the following table, restrictions in the following table are given priority.

Table 35.18 Restrictions on VEU Input/Output Functions

Item	Pack Type	Restrictions
Input	RGB565, 4 bytes/pixel	• The start address for input must be specified in longword units. • The horizontal size of the raw image (memory) must be specified in byte units that correspond to two pixels of the source image.
	Others	• The start address for input must be specified in longword units. However, when the RGB stuffing pack is input, the address must be specified so that reading starts from the pack of phase 0. • The horizontal size of the raw image (memory) must be specified in byte units that correspond to four pixels of the destination image.
Output	RGB565 4 bytes/pixel	• The output address must be specified in longword units. • The horizontal size of the destination image (memory) must be specified in byte units that correspond to two pixels of the destination image.
	Others	• The output address must be specified in longword units. • The horizontal size of the destination image (memory) must be specified in byte units that correspond to four pixels of the destination image.

(3) Data alignment restriction

In the line processing of VEU, data is accessed by 8 byte alignment. Therefore, the byte in the image terminal might be exceeded and it access it. However, when data is output, extra four bytes are not written because masking is word enable it done. There is a similar 8 byte alignment restriction in the block processing of the rotation operation etc.

Reading of the data of the line processing rounds up in four pixels and is read. Please note that the address in the horizontal terminal is different according to the format.

(4) Input access area in block processing

There is a possibility of accessing it exceeding the horizontal input data area when the block processing is done. This extra bytes differs according to the format, and is shown in the following table. In the block processing, please reserve this extra bytes in addition to the input image area.

Format	Number of excess access bytes from inputting the horizontal edge (maximum)
YUV：Y image	12 bytes
YUV：C image(422/420)	12 bytes
YUV：C image(444)	20 bytes
RGB565	50 bytes
RGB0888(8880)	96 bytes
RGB24/BGR24	73 bytes

Section 36 Blend Engine Unit (BEU)

36.1 Features

The BEU is a module used connected to the buses via bus bridge modules. The BEU blends three displays, supports some function as follow

- Supports video display.
- Supports OSD (On-Screen Display).
- Supports graphic display.
- The three displays can be blended at desired positions.
- Any one of the three inputs can be used as the parent display.
- The location of a child display can overflow from the parent display, but the overflowed area is not output.

36.1.1 Functional Overview

The functional overview of the BEU is shown in the table 36.1

Table 36.1 Functional Overview of BEU

Classification	Item	Function	Description	Note
Input format	YCbCr format	YCbCr 4:4:4/4:2:2/4:2:0 αYCbCr 4:4:4/4:2:2/4:2:0	α, Y, and C are input from separate planes. For YCbCr 4:2:0, the vertical line is read twice.	With input system 1, conversion is possible for RGB/YCbCr
	RGB format	RGB pack alpha RGB pack alpha plane + RGB pack		
Output format	YCbCr format	YCbCr 4:4:4/4:2:2/4:2:0	Y and C are output to separate planes	With output, conversion is possible for RGB/YCbCr
	RGB format	RGB pack alpha RGB pack		
Source/ destination image size	Maximum	4092 × 4092	YCbCr420: 2-pixel units both horizontally and vertically YCbCr422: 2-pixel units horizontally In other formats 1-pixel units can be specified.	
	Minimum	4 × 4 pixels : parent display 1 × 1 pixels : child display		
Dithering (tone reduction)	RGB decrease color	18, 24bpp: dithering not possible		
		8, 12, 16bpp : dithering possible		
Blending	Blend source	three displays from image memory		• Any of the three inputs can be used as the parent display. • The three displays can be blended at desired locations. • Overflow from the parent display area is allowed, but the overflowed area is not output. • The tile pattern can be blended.
	Select the alpha of input	pixel alpha, fixed alpha, alpha plane		
	alpha blend	8, 1bpp(RGB only)		
OSD	Data format	8 bpp	It is possible to select 256 color of full color	Input 3 possible only
	CLUT size	32-bit αRGB 32-bit αYCbCr		
Color key	Color replace	Compare data: RGB, Y Replace date: α RGB, α Y	α and RGB/Y data replacement	The three input are possible
	transparency color	Compare data: α RGB, α Y Replace data: α	Replace α data only	
Color space conversion	compliant color space	ITU-R BT.601 ITU-R BT.709	The conversion is possible as follows RGB<->BT.601 RGB<->BT.709	With input system 1 and output systerm, conversion is possible
Display data output	Destination setting	Output system + write back to memory		

36.1.2 Module Block

Figure 36.1 is block diagram of BEU respectively. BEU is composed of bus interface (Bus I/F) to LMB (Local Media Bridge) and input pixel format converter (RPF) in three input systems, blend processing part (Blend Core), outputpixel format converter (WPF).

Input pixel format converter (RPF) in three systems is read the image data from each plane imager through the bus interface, converts those different formats of three systems into the same format so that it may be possible to process internal.

Blend core inputs three image data that converted into the same format by RPF, and blends those images. The resultion of blend processing is input to output pixel format converter (WPF). It is converted the format to be stored in output plane image. The image data that the format conversion is done is stored in output plane through the bus interface.

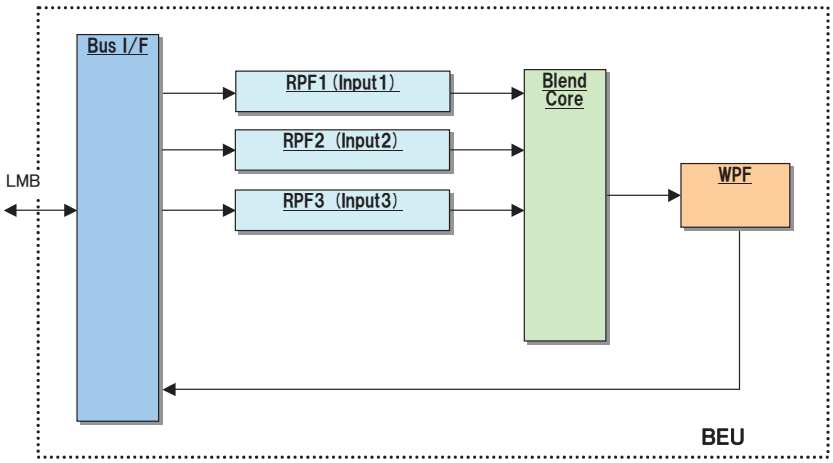

Figure 36.1 Block Diagram of BEU

Function explanation
Bus I/F : bus interface
RPF1~3: input pixel format converter
Blend Core : blend process
WPF : output pixel format converter
LMB : local media bridge

Figure 36.2 is shown the block diagram of input pixel format converter (RPF). RPF is composed of the input format development (de-packing unit), index color development (OSD-CLUT unit) Color key unit, color space converter and dither unit.

The de-packing unit and OSD-CLUT unit progress the image data input from the bus interface to the image format of internal processing.

Color key unit specifies the color substitution and the penetration color for the image data input from the output selecter of De-packing unit and OSD-CLUT.

Color space converter does the color space conversion of RGB-YCbCr to the image data input from Color Key if necessary, and processes the dither to the output image in Dither unit according to the output image format.

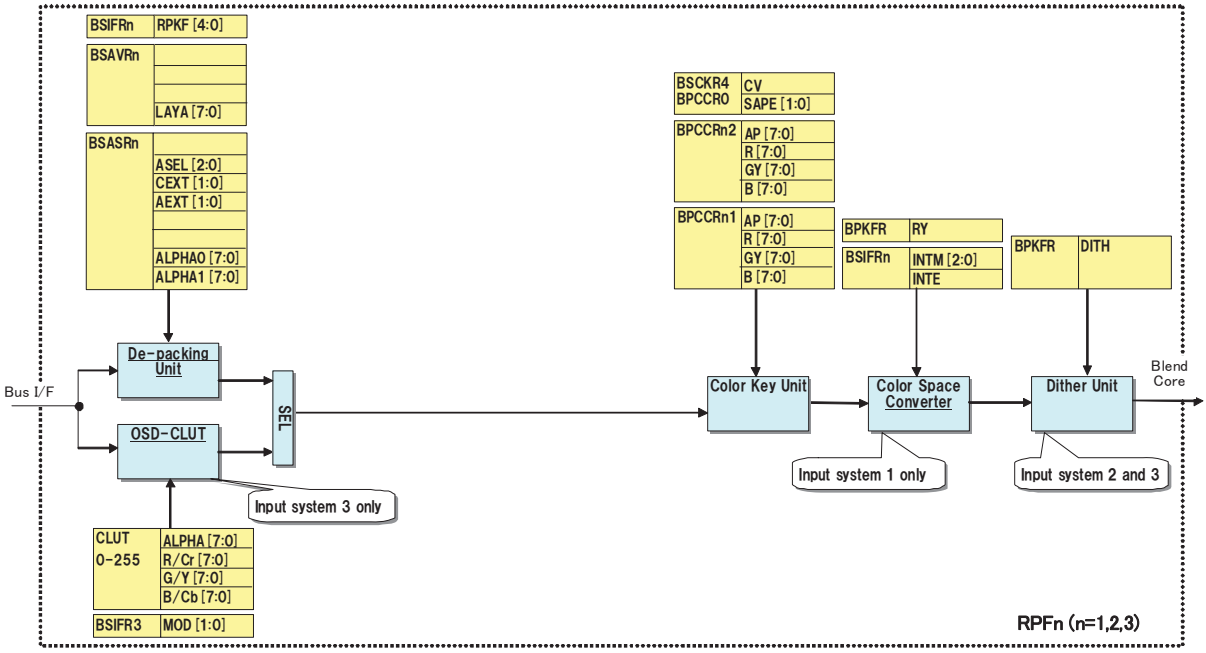

Figure 36.2 BEU-RPF block diagram

Function explanation
De-packing Unit : input format development
OSD-CLUT : index color developent
Color Key Unit : color key processing (color substitution, penetration color)
Color Space Converter : color space converter processing
Dither Unit : dither processing
SEL : the selecter of De-packing Unit and OSD-CLUT
The image data is composed of alpha data and color data (RGB/YCbCr).

Figure 36.3 is shown the block diagram of Blend Core. Blend Core is composed of two blend units (Blend Unit-m, m=A, C) and input switch container (SEL) of those blend unit.

Two blend units operate the image blending that connects each input with SEL and the out of Blend Unit-m.

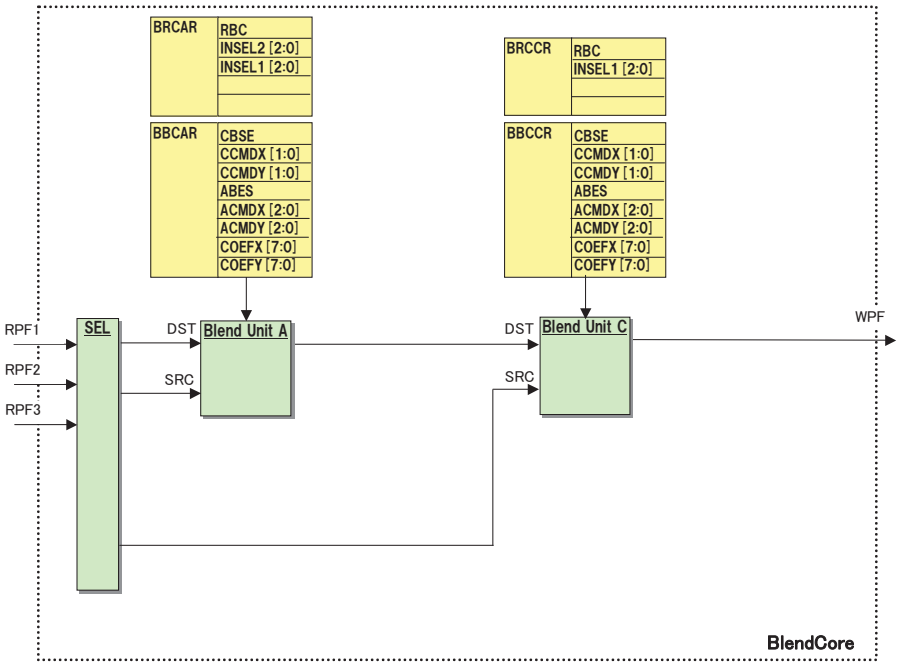

figure 36.3 Block diagram of Blend Core

Function explanation
Blend Unit-m : blend operater
SEL : the selecter of blend operater

Figure 36.4 is shown the block diagram of output pixel format converter (WPF). WPF is composed of color space converter and output format converter (Packing Unit).

Color space converter operates the conversion for RGB-YCbCr. Packing Unit operates the format conversion according to the format that stored in image plane.

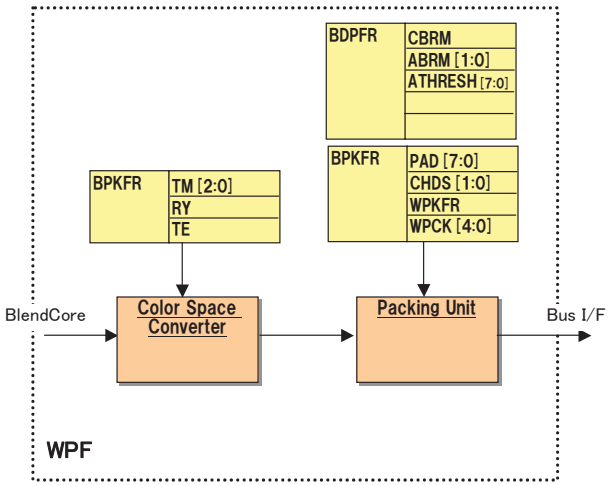

figure 36.4 Block diagram of WPF

Function explanation
Color space converter : color space converter unit
Packing unit : output format converter unit

36.2 Description of BEU Registers

36.2.1 Description of BEU Registers

Table 36.2 is shown the description of BEU registers. Most of BEU registers have a 2-side configuration (side A, side B). The register incorporated in the BEU consists of two sides registers. An incorporated register with tow sides of registers has a mirror address to access the register set not currently being used.

This LSI has three BEU. The address of BEU1, BEU2 and BEU3 register is allocated as follows.

- BEU1 : H'FE93_0000 ~ H'FE93_3FFF
- BEU2 : H'FE93_4000 ~ H'FE93_7FFF
- BEU3 : H'FE93_8000 ~ H'FE93_BFFF

Table 36.2 is shown the BEU1 register.

Table 36.2 BEU Register Configurations

			Addresses			
Register Name	Symbol	R/W	Address (A side)	Address (B side)	Mirror Address	Access size
Start/stop register	BESTR	R/W	H'FE93_0000	—	—	32
Input 1:source image memory width	BSMWR1	R/W	H'FE93_0010	H'FE93_1010	H'FE93_2010	32
Input 1:source image size	BSSZR1	R/W	H'FE93_0014	H'FE93_1014	H'FE93_2014	32
Input 1:source image Y/RGB start address	BSAYR1	R/W	H'FE93_0018	H'FE93_1018	H'FE93_2018	32
Input 1:source image Cb/Cr start address	BSACR1	R/W	H'FE93_001C	H'FE93_101C	H'FE93_201C	32

36.2.2 Register explanation

In the following, it explains the register of BEU.

- For the read-only bits in all BEU registers and the reserved areas, writing 1 is prohibited. Do not specify an unallowable value.
- Most BEU registers have a 2-side configuration (side A, side B). For registers (bit) to which writing during operation is prohibited, do not modify them during operation (reading is possible). The BEU operating state can be confirmed by reading the BEPRC bit in the BEU status register (BSTAR). Modify the above registers when this bit is B'0. When a mirror address is written to for a 2-side register, the register on the unused side is always accessed. To directly write to side A or side B, prohibit writing to the plane currently used.

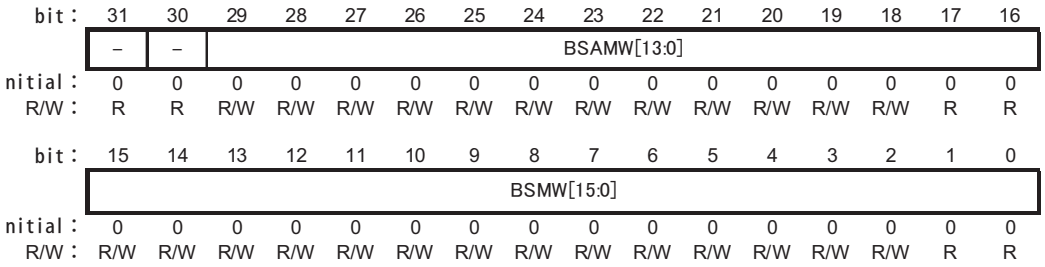
There is a possibility of the operation failure when the above-mentioned register operation is not guaranteed.

The terms used in this section are described below.

- "forcible termination" or "software reset" indicates that the BEU2 processing was forcibly terminated. In this case, the current processing is stopped but hardware terminates normally. The image processing result of the frame in which a software reset occurs is not guaranteed.
- "module reset" indicates the BEU internal circuit was forcibly reset. In a module reset, reset processing is performed with no consideration to the hardware state. Therefore, if a module reset is generated when the BEU is operating normally, the BEU peripheral hardware may become unable to operate.
- "during operation" in this section indicates a state in which the BEPRC bit in the BEU status register (BSTAR) is set to B'1.
- When a bit name in a register is referred to in this section, it is indicated in the format of (register name).(bit name). Example: BESTR.BEIVK

36.2.3 BEU Start Register (BESTR)

BESTR activates and halts the BEU, and enables or disables input displays. Before activating the BEU, all registers that specify the operating parameters, except for this register, must be set.



bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	CHON3	CHON2	CHON1	–	–	–	–	–	–	–	BEIVK
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	CHON3	0	R/W	Each bit specifies whether the corresponding input system is used or not. 1 must be written to the bit corresponding to the input system selected as the parent display by the PWD bits in BBLCR1. If the parent display is set not to be used, the BEVIO bit in BEVTR is set to 1 immediately after the BEU is activated, and processing is halted. CHONn (n = 1 to 3) 0: Input system n is not used. 1: Input system n is used.
9	CHON2	0	R/W	
8	CHON1	0	R/W	
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	BEIVK	0	R/W	Controls the start and stop of BEU processing. If 1 is written to this bit when the BEU is halted, the BEPRC bit in BSTAR is set to 1 and blending starts. In addition, if 0 is written to this bit when the BEU is in the operating state (BEPRC bit = 1), BEU processing is halted after the software reset processing is carried out. Note that if 0 is written to this bit when the BEU is halted (BEPRC bit = 0), no operation takes place. 0: NOP (software reset processing if 0 is written to this bit when BEPRC bit = 1). 1: BEU processing starts.

36.2.4 BEU Source Memory Width Registers 1 to 3 (BSMWR1 to BSMWR3)

BSMWR are registers that set the memory width of the source memory areas of BEU input systems 1 to 3.

Bit	Bit Name	Initial Value	R/W	Description
31 to 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 18	BSAMW[13:2]	H'0000	R/W	These bits set the α plane source memory area width of input systems 1 to 3 (set by the number of bytes. Long word or word units).
17, 16	BSAMW[1:0]		R	
15 to 2	BSMW[15:2]	H'0000	R/W	These bits set the source memory area width of input systems 1 to 3 (set by the number of bytes. Long word or word units). These bits set the horizontal width of the source memory area where the source image is located. These bits are set in 2-longword units for input data in the YCbCr or RGB24bpp (stuffing) format, and in longword units for input data in other formats. For a YCbCr 4:4:4 image, the setting is doubled in the BEU because the data size of the C plane is twice as large as that of the Y plane.
1,0	BSMW[1:0]		R	

36.2.5 BEU Source Size Registers 1 to 3 (BSSZR1 to BSSZR3)

BSSZR are registers that set the vertical and horizontal sizes of the images read by BEU input systems 1 to 3.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	BVSS[11:0]											
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	BHSS[11:0]											
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 16	BVSS[11:0]	H'000	R/W	These bits set the number of vertical pixels read by input systems 1 to 3. These bits set the number of vertical read pixels of the source image read by input systems 1 to 3. When input system n is YCbCr 4:2:0, these bits can be set in 2-pixel units. For other formats, these bits can be set in 1-pixel units. The setting should be in 4-pixel units in VOU or LCDC output mode The settings are in 8-pixel units in VOU output mode when VSKIP is enabled. When input system n is the parent display, the size set in these bits becomes the destination image size. Therefore, when the BEU operates together with the VOU or LCDC, make this setting match the destination image size of the interacting block. Specify 4-pixel units for BVSS when input system 3 is in OSD mode.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 0	BHSS[11:0]	H'000	R/W	These bits set the number of horizontal pixels read by input systems 1 to 3. These bits set the number of horizontal read pixels of the source image read by input systems 1 to 3. When input system n is YCbCr4:2:2 or YCbCr4:2:0, these bits can be set in 2-pixel units, for other formats these bits can be set in 1-pixel units. The setting should be in 4-pixel units in VOU output mode, and in 8-pixel units in LCDC mode (only for the parent display size). When input system n is the parent display, the size set in these bits becomes the destination image size. Therefore, when the BEU operates together with the VOU or LCDC, make this setting match the destination image size of the interacting block. Specify 4-pixel units for BHSS when input system 3 is in OSD mode.

36.2.6 BEU Source Address Y Registers 1 to 3 (BSAYR1 to BSAYR3)

BSAYR are registers that set the start address for the Y/RGB plane of the images read by BEU input systems 1 to 3.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BSAY[31:16]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSAY[15:0]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	BSAY[31:2]	H'0000 0000	R/W	These bits set the start address for reading the Y/RGB plane of input systems 1 to 3 (2-longword or longword units). When reading a YCbCr image, set the start address of the Y plane. When reading an RGB image, set the start address of the RGB plane. These bits are set in 2-longword units for input data in the YCbCr or RGB24bpp (stuffing) format, and in longword units for input data in other formats.
1, 0	BSAY[1:0]		R	

36.2.7 BEU Source Address C Registers 1 to 3 (BSACR1 to BSACR3)

BSACR are registers that set the start address for the C plane of the images read by BEU input systems 1 to 3.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BSAC[31:16]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSAC[15:0]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	BSAC[31:2]	H'0000 0000	R/W	These bits set the start address for reading C plane of input systems 1 to 3 (longword units). When reading YCbCr image, set the start address of C plane. Note that when reading RGB image, this register is not used.
1, 0	BSAC[1:0]		R	

36.2.8 BEU Source Address α Registers 1 to 3 (BSAAR1 to BSAAR3)

BSAAR are registers that set the start address for the α plane of the images read by BEU input systems 1 to 3.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BSAA[31:16]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSAA[15:0]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	BSAA[31:2]	H'0000 0000	R/W	These bits set the start address for reading the α plane of input systems 1 to 3 (longword units).
1, 0	BSAA[1:0]		R	

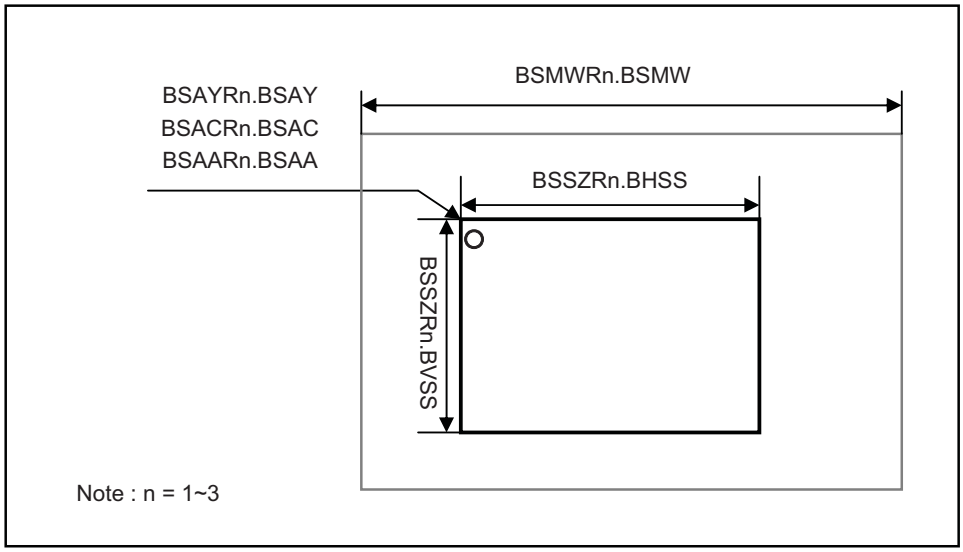


Figure 36.5 Number of Read Pixels of Input System n and Start Addresses

36.2.9 BEU Source Image Format Registers 1 to 2 (BSIFR1 to BSIFR2)

BSIFR are registers that specify the format of the images read by BEU input systems 1 to 2.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	INTM[2:0]			INTE	–	CHRR[2:0]						RPKF[4:0]				
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 13	INTM[2:0]	3'b000	R/W	These bits set the color space converter in the input pixel format converter n-unit (RPFn). These bits are only used input system 1. 000: ITU-R BT.601 standard for YCbCr with 8-bit full scale RGB color conversion are used. (initial) BT.601[16,235/240] <-> RGB[0,255] 001: ITU-R BT.601 standard for YCbCr with 8-bit full scale RGB color conversion are used. BT.601[0,255] <-> RGB[0,255] 010: ITU-R BT.709 standard for YCbCr with 8-bit full scale RGB color conversion are used. BT.709[16,235/240] <-> RGB[0,255] 011: ITU-R BT.709 standard for YCbCr with ARIB STD-B24 standard for RGB color conversion are used. BT.709[16,235/240] <-> RGB[16,235] 100-111: Setting prohibited
12	INTE	0	R/W	Turns on or off the RGB ⇔ YCbCr conversion circuit. The direction of conversion is selected with BPKFR.RY 0: No RGB ⇔ YCbCr conversion 1: RGB ⇔ YCbCr conversion performed Note: When performing RGB ⇔ YCbCr conversion, read the source image so that the conversion result has the same format as the other input systems. For details, see table 36.3.

Bit	Bit Name	Initial Value	R/W	Description
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10 to 8	CHRR[2:0]	000	R/W	The format of the image input to input system n is determined by the settings of the RY bit in BPKFR and the INTE bit. When YCbCr image is input to input system n, the data pack form can be selected by the setting of these bits. The data pack forms are shown in table 36.4. 000: Image read in the YCbCr 4:4:4 format 001: Image read in the YCbCr 4:2:2 format 010: Image read in the YCbCr 4:2:0 format 011-111: Setting prohibited
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	RPKF[4:0]	00000	R/W	These bits set the RGB input data pack form when the image input to input system n is in the RGB format. The format of the image input to input system n is determined by the settings of the RY bit in BPKFR and the INTE bit. When an RGB image is input to input system 1, the data pack form can be selected from the data pack forms in table 32.5 by the setting of these bits.

Table 36.3 The relation between BSIFRn.INTE, BPKFR.RY and input data pack

21	5b'10101		–	B0	B0	B0	B0	B0	G0	G0	G0	G0	G0	R0	R0	R0	R0	R0	A0	B1	B1	B1	B1	B1	G1	G1	G1	G1	G1	R1	R1	R1	R1	R1	A1

Note : when the No2 (RGB 24-bit) is selected, the reading initial address must specify the address that becomes the first of the pixel.

A0, A1 in the table show α value.

36.2.10 BEU Source Image Format Register 3 (BSIFR3)

BSIFR3 is register that specify the format of the images read by BEU input systems 3.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	MOD 1	MOD 0	–	CHRR[2:0]						RPKF[4:0]				
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	MOD1	0	R/W	Sets the method for fetching source image data when input system 3 is in OSD mode. This bit should be set to 1 (CLUT) only when input system 3 is in OSD mode. Access to read from or write to the CLUT during operation is prohibited. When input system 3 is an OSD and this bit is 1, the color information and alpha values are obtained by referencing the CLUT. The CLUT contents can be modified by longword access from H'FE93 3000 to H'FE93 33FF. The color information and alpha values of the CLUT are stored in the order shown in figure 36.6. Note that the initial values of the CLUT are undefined. 0: Same graphic image or video input as input systems 1 and 2 1: Color information and alpha values are referenced from the CLUT.

Bit	Bit Name	Initial Value	R/W	Description
12	MOD0	0	R/W	Sets whether input system 3 is operated in normal mode or OSD mode. When this bit is 0, input system 3 handles graphic images and video inputs, and the operation is the same as that of input system 1 or 2. In this case, the number of read pixels of the source image is set by BSSZR3. When this bit is 1, input system 3 handles OSD images, and supports repeated pattern output. Repeated pattern output indicates output of tiles with the same picture in rows. The size of one tile is determined by the BHSS and BVSS bits in BSSZR3, and the size in which to paste it to the destination display is determined by the TPHS and TPVS bits in BTPSR. The output appears different according to the magnitude relation of the BSSZR3 and BTPSR settings, as shown in figure 36.7. 0: Input system 3 is used as the same Graphic or Video as input systems 1 and 2 1: Input system 3 is used as OSD.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10 to 8	CHRR[2:0]	000	R/W	When the RY bit in BPKFR is 0, the image input to input system 3 is in the YCbCr format, and the data pack form can be selected by the setting of these bits. The data pack forms for a YCbCr image input in input system 3 are shown in table 36.4. 000: Image read in the YCbCr 4:4:4 format 001: Image read in the YCbCr 4:2:2 format 010: Image read in the YCbCr 4:2:0 format 011~111: Setting prohibited
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	RPKF[4:0]	00000	R/W	These bits set the RGB input data pack form when the image input to input system 3 is in the RGB format. When the RY bit in BPKFR is 1, the image input to input system 3 is in the RGB format, and the data pack form can be selected from the data pack forms in table 36.5 by the setting of these bits.

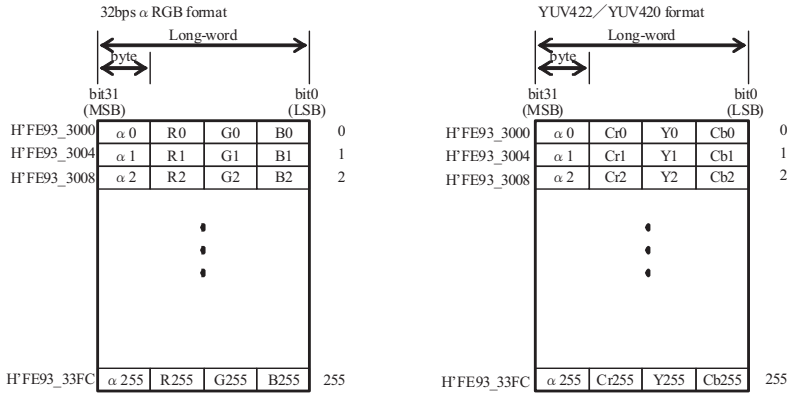

Figure 36.6 Order of Storing CLUT color information

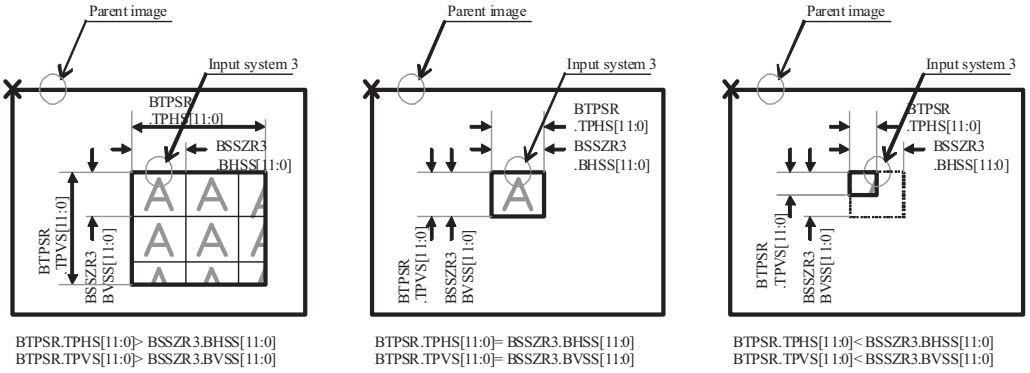

Figure 36.7 Repeated Pattern Output

36.2.11 BEU Tile Pattern Size Register (BTPSR)

BTPSR specifies the size for pasting image to the destination display when input system 3 is in OSD mode.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	TPVS[11:0]											
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	TPHS[11:0]											
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 16	TPVS[11:0]	H'000	R/W	These bits set the vertical output size of a tile pattern. Set the vertical size for pasting to the destination display when OSD mode is selected for input system 3 in these bits. For YCbCr 4:2:0, these bits can be set in 2-pixel units. For other formats, these bits can be set in 1-pixel units and the maximum value is 4092. This setting is ignored when input system 3 is not in OSD mode.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 0	TPHS[11:0]	H'000	R/W	These bits set the horizontal output size of a tile pattern. Set the horizontal size for pasting to the destination display when OSD mode is selected for input system 3 in these bits. When input system 3 is not OSD mode, this setting is disregarded. Moreover, input system 3 becomes and this set size becomes an output image size for the parents screen in the OSD mode. For YCbCr 4:2:2 and YCbCr 4:2:0, these bits can be set in 2-pixel units. For other formats, these bits can be set in 1-pixel units. For YCbCr 4:2:0 or YCbCr 4:2:2, the minimum setting value is two pixels, the other formats are one pixel, and the maximum setting value is 4092 pixels. The bits BLOCR3 [1:0] of the blend offset position are added to the BTPSR.TPHS setting value when input system 3 is child screen, and reading data is generated even in the pixel within the range of the value rounded up four-pixel units (There is no problem because pixel data within the range rounded up is not used if it is possible to read). The price rounded up must not rise 4092 though the maximum setting value is 4092. If the input system 3 is set as the parent display (in the

	case, please set BLOCR3 [1:0] to 0), these bits can be set in four-pixel units, and set the ouput image size to the value rounded up.

36.2.12 BEU Blend Control Register 1 (BBLCR1)

BBLCR1 sets blending of the BEU input systems.

Modifying this register during operation is prohibited.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	PWD[2:0]								MT[2:0]

R/W :	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–			–								PXA
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 24	PWD[2:0]	00	R/W	These bits specify the parent display at BEU processing. The source image read size (BSSZR1 to BSSZR3) of the input system selected by these bits as the parent display is used as the destination display size. 000: Input system 1 is set as the parent display. 001: Input system 2 is set as the parent display. 010: Input system 3 is set as the parent display. 011~111: Setting prohibited
23 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18 to 16	MT[2:0]	001	R/W	These bits specify the output mode for BEU processing*. 001: Memory output mode Other than above: Setting prohibited
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PXA	0	R/W	Selects the pixel-unit alpha value of the input system or the alpha value specified in BPKFR.PAD[7:0] as the value to be added to the PAD field when the RGB output pack includes the PAD field. The α data finally output is decided depending on BBCmR and BRCmR register (n=A, C) set. 0: Alpha value set in the PAD bits in BPKFR is used for the PAD field in the destination image. 1: Pixel-unit alpha value of the input system is used for the PAD field in the destination image.

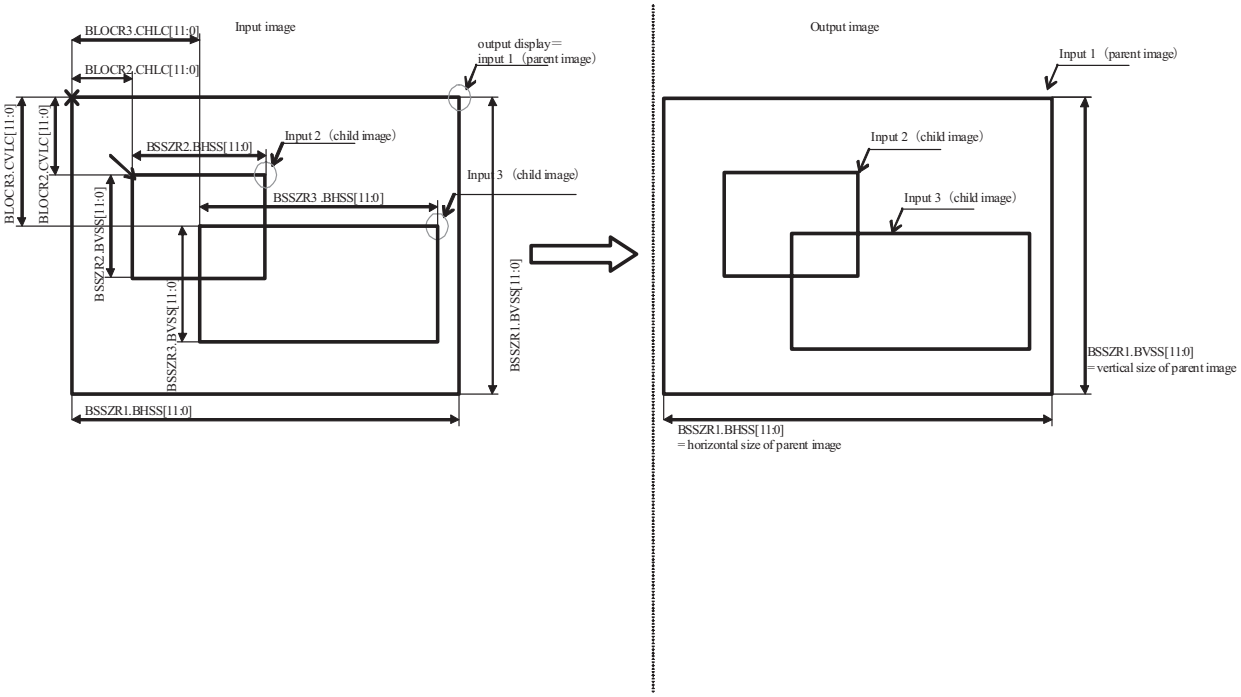

Figure 36.8 The Output Image

36.2.13 Blend Location Registers 1 to 3 (BLOCR1 to BLOCR3)

BLOCR are registers that specify the locations for input systems 1 to 3 at BEU blending.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	CVLC[11:0]											
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	CHLC[11:0]											
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 16	CVLC[11:0]	H'000	R/W R	These bits specify the number of pixels for the vertical offset from the base point as the blending start location of input systems 1 to 3. it is possible to be set by 1 pixel unit. Set 0 to BLOCRn.CVLC[11:0] when the input n is parent image.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 0	CHLC[11:0]	H'000	R/W R	These bits specify the number of pixels for the horizontal offset from the base point as the blending start location of input systems 1 to 3. It is possible to be set by 1 pixel unit. Set 0 to BLOCRn.CHLC[11:0] when the input n is parent image.

Figures 36.10 to 36.11 show destination displays of the BEU. The destination display size matches that of the parent display size. The parent display can be selected as input system 1, 2, or 3 by the PWD bits in BBLCR1. The order in which to overlay these input systems can be specified as desired, independent of the parent display setting. Blending operation is not performed for areas where the source displays do not overlap. Areas in a child display which overflow from the parent display are not written to the destination display (see figure 36.9).

The top-left corner of the parent display (= destination display) becomes the base point. The locations of the child displays are expressed by offsets from the base point. For example, if input display 1 is set as the parent display, the top-left corner of input display 1 becomes the base point, the location of input display 2 is determined by the CHLC and CVLC bits in BLOCR2, and the location of input display 3 is determined by the CHLC and CVLC bits in BLOCR3.

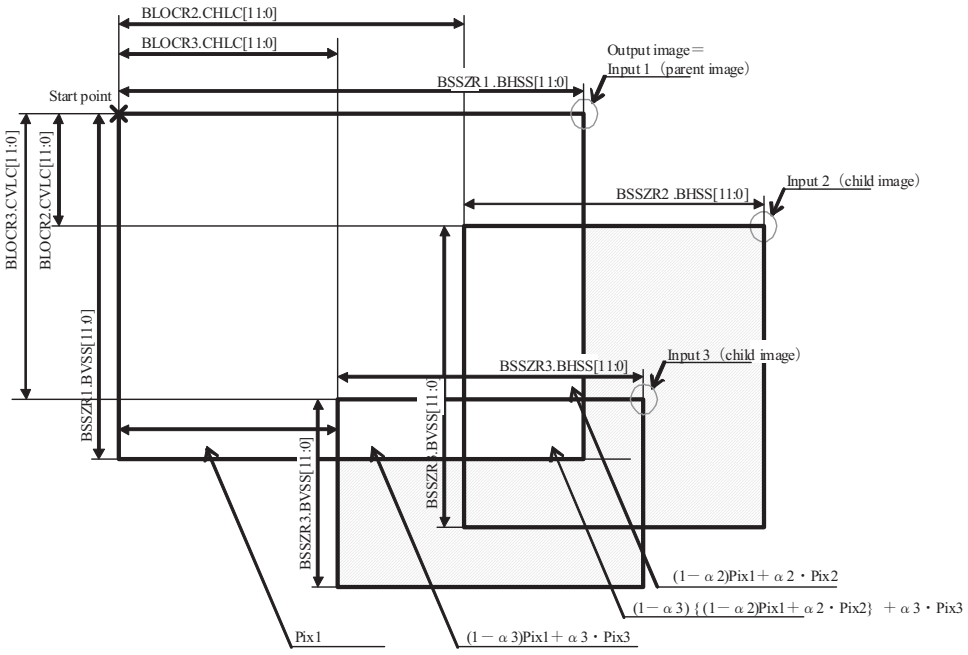

Figure 36.9 BEU Destination Display

R/W :	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	PAD[7:0]	H'00	R/W	These bits specify the PAD value in the output data pack. When data is output in a pack shown in table 36.8, set the value to be stored in the PAD field in these bits. When the BBLCR1.PXA bit is 0, the setting becomes effective.
23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 20	TM[2:0]	0	R/W	These bits specify the color conversion in the output pixel format converter (WPF). 000: Use ITU-R BT.601 YCbCr and 8-bit full scale RGB color conversion. BT.601[16,235/240] <-> RGB[0,255] 001: 8-bit full scale BT.601 YCbCr and 8-bit full scale RGB color vonversion BT.601[0,255] <-> RGB[0,255] 010: Use ITU-R BT.709 YCbCr and 8-bit full scale RGB color conversion. BT.709[16,235/240] <-> RGB[0,255] 011: Use ITU-R BT.709 YCbCr and ARIB STD-B24 RGB color conversion BT.709[16,235/240] <-> RGB[16,235] 100~111: Setting prohibited
19 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	NRM	0	R/W	This bit is set whether to divide the output color value from Blend Core to WPF in the α value. It is possible to use it when converting it from the format of color data (Premultiplied Color) multiplied by the α value into the format of color data (Non Premultiplied Color) not multiplied by the α value. 0: The output color value is not divided in the α value. 1: The output color value is divided in the α value.

Bit	Bit Name	Initial Value	R/W	Description
16	DITH2	0	R/W	Selects quantization or dithering for tone reduction in input system 2. 0: Performs quantization at tone reduction in input system 2. 1: Performs dithering at tone reduction in input system 2. Note: Dithering is performed only when the format for reading images is set to the RGB format (BPKFR.RY = 1).
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	DITH1	0	R/W	Selects quantization or dithering for tone reduction in input system 1. 0: Performs quantization at tone reduction in input system 1. 1: Performs dithering at tone reduction in input system 1. Note: Dithering is performed only when the format for reading images is set to the RGB format (BPKFR.RY = 1).
11	RY	0	R/W	The RY bit selects the direction of RGB ⇔ YCbCr conversion. Table 36.6 shows the relationship between the TE and RY bit settings and the input/output data format. 0: Blend Core is operated by the YCbCr format 1: Blend Core is operated by the RGB format
10	TE	0	R/W	
10	TE	0	R/W	The TE bit sets enable or disable of the RGB ⇔ YCbCr color space conversion circuit in output pixel format conversion unit (WPF). 0: disable RGB ⇔ YCbCr conversion in WPF 1: enable RGB ⇔ YCbCr conversion in WPF
9, 8	CHDS[1:0]	00	R/W	These bits set the YCbCr output format of the BEU. The YCbCr data output pack forms are shown in table 36.7. 00: Output as YCbCr 4:4:4 when the image output from input system 2 is in the YCbCr format 01: Output as YCbCr 4:2:2 when the image output from input system 2 is in the YCbCr format 10: Output as YCbCr 4:2:0 when the image output from input system 2 is in the YCbCr format 11: Setting prohibited
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	WPKFR	0	R/W	Sets the output data pack form when BEU output data is in RGB format. The RGB data pack forms are shown in table 36.8.
4 to 0	WPCK[4:0]	00000	R/W	These bits specify the BEU output pack form. The BEU packs output data into a 32-bit pack. When data is output in the RGB format, the data is packed into one of the patterns shown in table 36.8. Set a value in the WPCK column in table 36.8 in these bits.

Table 36.6 Relationship between TE and RY Bits in BPKFR and Input/Output Data Format

TE Bit	RY Bit	Blend Core Input	WPF Output
0	0	YCbCr format	YCbCr format
0	1	RGB format	RGB format
1	0	YCbCr format	RGB format
1	1	RGB format	YCbCr format

The P in table is shown PAD. The value output to the PAD is set by BBLCR1.PXA and BPKFRPAD.PAC

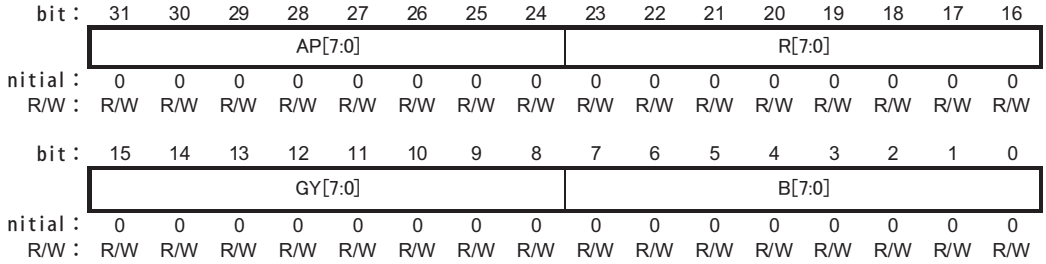
36.2.15 BEU Transparent Color Control Register 0 (BPCCR0)

BPCCR0 enables or disables transparent color comparison or color replacement.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CV2	CV1	CV0	–	–	–	–	–	–	SAPE 32	SAPE 31	SAPE 22	SAPE 21	SAPE 12	SAPE 11
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 12	CV2 CV1 CV0	000	R/W	CV2: Input system 3 display color replacement function CV1: Input system 2 display color replacement function CV0: Input system 1 display color replacement function When input pixel values of input system 1 to input system 3 match BPCCRx1.R, BPCCRx1.GY, and BPCCRx1.B, those pixel values and α are replaced with BPCCRx2. (They correspond to each input system at x: 1, 2, and 3.) Color replacement function is enabled when the input format for that input system is RGB 565, 666, 888, or YCbCr. Color replacement function can be set independently for each input system. When CV2 = 1, set BPCCR0.SAPE32-31 = 0. When CV1 = 1, set BPCCR0.SAPE22-21 = 0. When CV0 = 1, set BPCCR0.SAPE12-11 = 0. Note 1: Color replacement function cannot be specified when performing center enlargement (BBLCR1.SELRDD = 1) on input data. Note 2: System 1 transparent color function cannot be used when using system 1 color replacement. 0: Input system x display color replacement function off 1: Input system x display color replacement function on
11 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

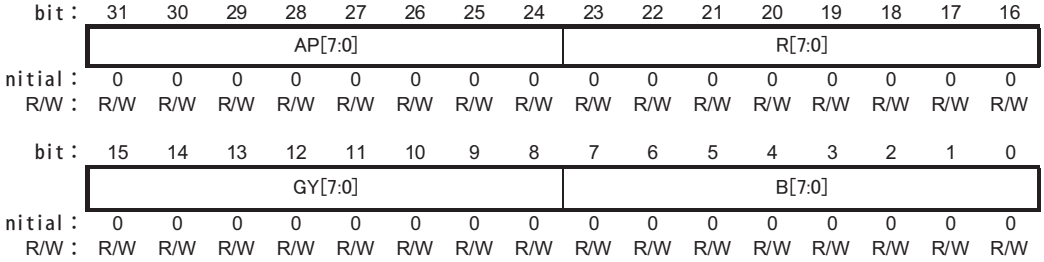


Bit	Bit Name	Initial Value	R/W	Description
5	SAPE32	0	R/W	Two types of color comparison are possible for each input system as transparent color comparison. When the SAPE32 bit is set to 1, input data of input system 3 is compared with the data set in BPCCR32. When the SAPE31 bit is set to 1, input data of input system 3 is compared with the data set in BPCCR31. When both the SAPE32 and SAPE31 bits are cleared to 0, data comparison is disabled. 00: Disables data comparison 1 and 2 for input system 3. 01: Enables data comparison 1 for input system 3. 10: Enables data comparison 2 for input system 3. 11: Enables data comparison 1 and 2 for input system 3.
4	SAPE31	0	R/W	
3	SAPE22	0	R/W	Two types of color comparison are possible for each input system as transparent color comparison. When the SAPE22 bit is set to 1, input data of input system 2 is compared with the data set in BPCCR22. When the SAPE21 bit is set to 1, input data of input system 2 is compared with the data set in BPCCR21. When both the SAPE22 and SAPE21 bits are cleared to 0, data comparison is disabled. 00: Disables data comparison 1 and 2 for input system 2. 01: Enables data comparison 1 for input system 2. 10: Enables data comparison 2 for input system 2. 11: Enables data comparison 1 and 2 for input system 2.
2	SAPE21	0	R/W	
1	SAPE12	0	R/W	Two types of color comparison are possible for each input system as transparent color comparison. When the SAPE12 bit is set to 1, input data of input system 1 is compared with the data set in BPCCR12. When the SAPE11 bit is set to 1, input data of input system 1 is compared with the data set in BPCCR11. When both the SAPE12 and SAPE11 bits are cleared to 0, data comparison is disabled. 00: Disables data comparison 1 and 2 for input system 1. 01: Enables data comparison 1 for input system 1. 10: Enables data comparison 2 for input system 1. 11: Enables data comparison 1 and 2 for input system 1.
0	SAPE11	0	R/W	

36.2.16 BEU Transparent Color Control Registers 1(BPCCRn1 (n=1 to 3))

BPCCRn1 are registers that set the compare data used in transparent color comparison and the alpha value.

If the pack form of BEU input systems 1 to 3 is RGB565, RGB666, RGB888, or YCbCr, the input data is compared with the R, GY, and B data set in these bits. The bit size to be compared differs for each input pack form, and bits become valid from the upper side. Clear bits other than the valid bits to 0.



Note that only the Y component is to be compared in case of the YCbCr format. In case of the RGB565 pack form, for example, the R data is compared with the value in the R[7:3] bits, the G data with the value in the GY[7:2] bits, and the B data with the value in the B[7:3] bits.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	AP[7:0]	H'00	R/W	Color replace function: set 0 Transparent color function: α data for substitution of set # 1 These bits set the alpha value used at a data comparison match. Performs data comparison with the BPCCRxx value corresponding to each bit when the input pack form of BEU input system 1 is RGB565, RGB666, RGB888, or YCbCr with the SAPExx bit in BPCCR0 set to 1. When data comparison results in a match, the pixel-unit alpha value is replaced with the alpha value set in these bits (xx = 11, 12, 21, 22, 31, or 32).
23 to 16	R[7:0]	H'00	R/W	Color replace function: compare data R (RGB) Transparent color function: compare data R of set #1 Set 0 to the LSB side of R element to be compared, except when the comparison data of RGB format is not 24bpp. Set BPCCRn1.GY and the BPCCRn.B bit similarly.
15 to 8	GY[7:0]	H'00	R/W	Color replace function: compare data G (RGB) or Y (YCbCr) Transparent color function: compare data G (RGB) or Y (YCbCr of set #1
7 to 0	B[7:0]	H'00	R/W	Color replace function: compare data B (RGB) Transparent color function: compare data B of set #1

36.2.17 BEU Transparent Color Control Registers 2(BPCCRn2 (n=1 to 3))

BPCCRn2 are registers that set the compare data used in transparent color comparison and the alpha value.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	AP[7:0]	H'00	R/W	Color replace function: set 0 Transparent color function: α data for substitution of set # 1 These bits set the alpha value used at a data comparison match. Performs data comparison with the BPCCRxx value corresponding to each bit when the input pack form of BEU input system 1 is RGB565, RGB666, RGB888, or YCbCr with the SAPExx bit in BPCCR0 set to 1. When data comparison results in a match, the pixel-unit alpha value is replaced with the alpha value set in these bits (xx = 11, 12, 21, 22, 31, or 32).
23 to 16	R[7:0]	H'00	R/W	Color replace function: compare data R (RGB) Transparent color function: compare data R of set #1 Set 0 to the LSB side of R element to be compared, except when the comparison data of RGB format is not 24bpp. Set BPCCRn1.GY and the BPCCRn.B bit similarly.
15 to 8	GY[7:0]	H'00	R/W	Color replace function: compare data G (RGB) or Y (YCbCr) Transparent color function: compare data G (RGB) or Y (YCbCr of set #1
7 to 0	B[7:0]	H'00	R/W	Color replace function: compare data B (RGB) Transparent color function: compare data B of set #1

36.2.18 BEU Destination Memory Width Register (BDMWR)

BDMWR sets the memory width of the destination memory area of the BEU.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	BDAC[31:2]	H'0000 0000	R/W	These bits set the start address for drawing the C plane by the BEU (longword units). When drawing a YCbCr image, set the start address of the C plane. Note: When drawing an RGB image, this register is not used.
1, 0	BDAC[1:0]		R	

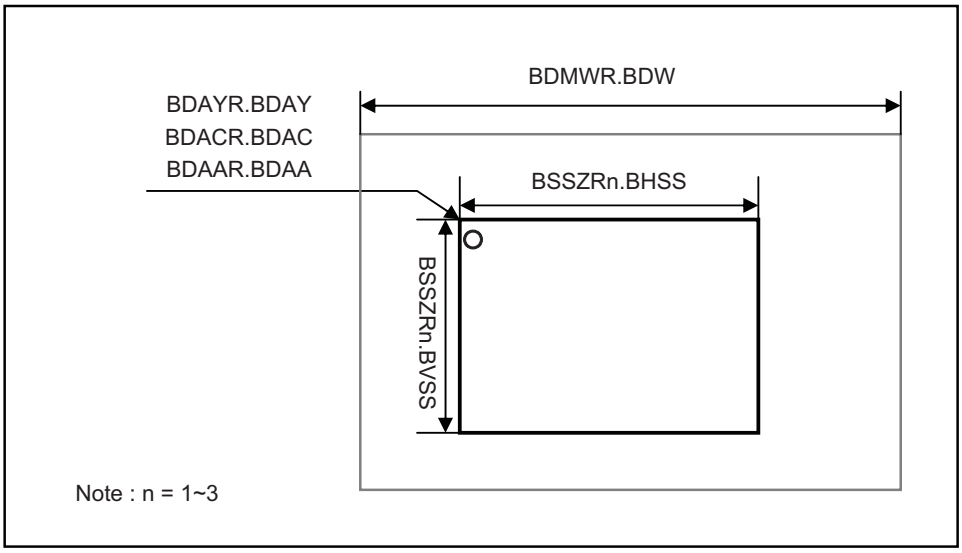

Figure 36.13 Destination Display Size and Start Address

36.2.21 BEU Destination Pixel Format Register (BDPFR)

BDPFR sets the destination pixel format that output to memory.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	ABRM[1:0]		ATRESH[7:0]							
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25, 24	ABRM[1:0]	00	R/W	ABRM select the operation method at decreasing bit of the α data. When the case of 1bit and the BDPFR.ABRM=b '10 are set, the output α decides according to the threshold set by the BDPFR.ATHRESH bit. 00: the number of α bit conversion : LSB is cut 01: the number of α bit conversion : round operation 10: the number of α bit conversion : threshold judgment (when it is 1bpp) 11: Setting prohibited
23 to 16	ATRESH [7:0]	H'00	R/W	The threshold when converting it into 1bit -α data BDPFR.ATHRES set the threshold to convert 8bit-α data into 1bit-α data when BDPFR.ABRM is set b'10. 1bit-α data is set 0 that the value of 8bit-α data is less than ATHRES. Except the 1bit-α data is set 1.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

36.2.22 BEU Address Fixed Register (BAFXR)

BAFXR sets fixed address mode for the data output from the BEU.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	BAFIX
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	BAFIX	0	R/W	When this bit is 1, the addresses to write the image output from the BEU is fixed to the values set in BDAYR and BDACR. When this bit is 0, the address is incremented according to BDMWR. 0: Output addresses of the BEU are not in fixed address mode. 1: Output addresses of the BEU are in fixed address mode. Note: Fixed address mode can be used only for RGB images. Correct operation cannot be guaranteed for YCbCr images.

36.2.23 BEU Swapping Register (BSWPR)

BSWPR sets swapping within 64-bit data at the data input/output section of the BEU.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MODSEL	–	–	–	–	–	–	–	–	–	–	–	AIS3	BEILS3	BEIWS3	BEIBS3
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	AIS2	BEILS2	BEIWS2	BEIBS2	–	BEOLS	BEOWS	BEOBS	AIS1	BEILS1	BEIWS1	BEIBS1
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	MODSEL	0	R/W	When MODSEL = 1 in BSWPR, swap setting is possible for each input system. When MODSEL = 0 in BSWPR, the swap settings made by BEILS, BEIWS, and BEIBS bits in BSWPR are available for all input systems. 0: Disables swap setting mode for each input system. 1: Enables swap setting mode for each input system.
30 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19	AIS3	0	R/W	0: byte ordr of α plane of input system 3 is swapped according to swap control {BEILS3, BEIW3, BEIBS3} of the data system. 1: The control of the swap of byte order of α plane of input system 3 is done as follows. BSILS3 | BEIWS3 | BEIBS3 = 0 : not swapped BSILS3 | BEIWS3 | BEIBS3 = 0 : swapped in long word, word, byte word units.
18	BEILS3	0	R/W	0: Input system 3 (multidisplay) input data is not swapped in longword units. 1: Input system 3 (multidisplay) input data is swapped in longword units.
17	BEIWS3	0	R/W	0: Input system 3 (multidisplay) input data is not swapped in word units. 1: Input system 3 (multidisplay) input data is swapped in word units.
16	BEIBS3	0	R/W	0: Input system 3 (multidisplay) input data is not swapped in byte units. 1: Input system 3 (multidisplay) input data is swapped in byte units.

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	AIS2	0	R/W	0: byte ordr of α plane of input system 2 is swapped according to swap control {BEILS2, BEIWS2, BEIBS2} of the data system. 1: The control of the swap of byte order of α plane of input system 2 is done as follows. BSILS2 | BEIWS2 | BEIBS2 = 0 : not swapped BSILS2 | BEIWS2 | BEIBS2 = 0 : swapped in long word, word, byte word units.
10	BEILS2	0	R/W	0: Input system 2 (multidisplay) input data is not swapped in longword units. 1: Input system 2 (multidisplay) input data is swapped in longword units.
9	BEIWS2	0	R/W	0: Input system 2 (multidisplay) input data is not swapped in word units. 1: Input system 2 (multidisplay) input data is swapped in word units.
8	BEIBS2	0	R/W	0: Input system 2 (multidisplay) input data is not swapped in byte units. 1: Input system 2 (multidisplay) input data is swapped in byte units.
7	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	BEOLS	0	R/W	Sets swapping in longword units for output data. In longword swapping for output data, data is swapped in longword units within the 32 bits on the MSB side and within the 32 bits on the LSB side for 64-bit data in the BEU output section. 0: BEU output data is not swapped in longword units. 1: BEU output data is swapped in longword units.
5	BEOWS	0	R/W	Sets swapping data in word units for output data. In word swapping for output data, 16 bits are swapped in word units from the MSB side or LSB side for 64-bit data in the BEU output section. 0: BEU output data is not swapped in word units. 1: BEU output data is swapped in word units.

Bit	Bit Name	Initial Value	R/W	Description
4	BEOBS	0	R/W	Sets swapping data in byte units for output data. In byte swapping for output data, 16 bits are swapped in byte units from the MSB side or LSB side for 64-bit data in the BEU output section. 0: BEU output data is not swapped in byte units. 1: BEU output data is swapped in byte units.
3	AIS1	0	R/W	0: byte ordr of α plane of input system 1 or all input systems is swapped according to swap control {BEILS1, BEIWS1, BEIBS1} of the data system. 1: The control of the swap of byte order of α plane of input system 1 or all input systems is done as follows. BSILS1 | BEIWS1 | BEIBS1 = 0 : not swapped BSILS1 | BEIWS1 | BEIBS1 = 0 : swapped in long word, word, byte word units. (1) BSWPR.MODSEL=0 Same byte swap of alpha plane is set to all the input system reading parts in the BEU by setting the BSWPR.AIS1 bit. (2) BSWPR.MODSEL=1 The byte swap of input plain α is set to system n(n=1 to3) each input respectively by setting the BSWPR.AISn bit.
2	BEILS1	0	R/W	Sets swapping data in longword units for input data. In longword swapping for input data, data is swapped in longword units within the 32 bits on the MSB side and within the 32 bits on the LSB side for 64-bit data in the BEU input section (for all input systems). (1) BSWPR.MODSEL=0 BEILS1 = 1 in BSWPR, data is swapped in longword units within the 32 bits on the MSB side and within the 32 bits on the LSB side for 64-bit data in the BEU input read section (for all input systems). BEILS1 = 0 in BSWPR, data is not swapped in longword units. (2) BSWPR.MODSEL=1 BEILSn = 1 in BSWPR, data is swapped in longword units within the 32 bits on the MSB side and within the 32 bits on the LSB side for 64-bit data in the BEU input system 1 to 3 read section. BEILSn = 0 in BSWPR, data is not swapped in longword units. 0: the alpha plane of the input system 1 or all input systems is not swapped in longword units. 1: the alpha plane of the input system 1 or all input systems is swapped in longword units.

Bit	Bit Name	Initial Value	R/W	Description
1	BEIWS1	0	R/W	Sets swapping data in word units for input data. In word swapping for input data, 16 bits are swapped in word units from the MSB side or LSB side for 64-bit data in the BEU input section (for all input systems). (1) BSWPR.MODSEL = 0 BEIWS1 = 1 in BSWPR, data is swapped in word units within the 16 bits on the MSB or LSB side for 64-bit data in the BEU2 input read section (for all input systems). BEIWS1 = 0 in BSWPR, data is not swapped in word units. (2) BSWPR.MODSEL = 1 BEIWSn = 1 in BSWPR, data is swapped in word units within the 16 bits on the MSB or LSB side for 64-bit data in the BEU2 input system 1 read section. BEIWSn = 0 in BSWPR, data is not swapped in word units. 0: the input data of system 1 or all systems is not swapped in word units. 1: the input data of system 1 or all systems is swapped in word units.
0	BEIBS1	0	R/W	Sets swapping data in byte units for input data. In byte swapping for input data, 16 bits are swapped in byte units from the MSB side or LSB side for 64-bit data in the BEU input section (for all input systems). (1) BSWPR.MODSEL = 0 BEIBS1 = 1 in BSWPR, data is swapped in byte units within the 16 bits on the MSB or LSB side for 64-bit data in the BEU2 input read section (for all input systems). BEIBS1 = 0 in BSWPR, data is not swapped. (2) BSWPR.MODSEL = 1 BEIBS = 1 in BSWPR, data is swapped in byte units within the 16 bits on the MSB or LSB side for 64-bit data in the BEU2 input system 1 read section. BEIBS = 0 in BSWPR, data is not swapped. 0: the input system 1 or all input systems is not swapped in byte units. 1: the input system 1 or all input systems is swapped in byte units.

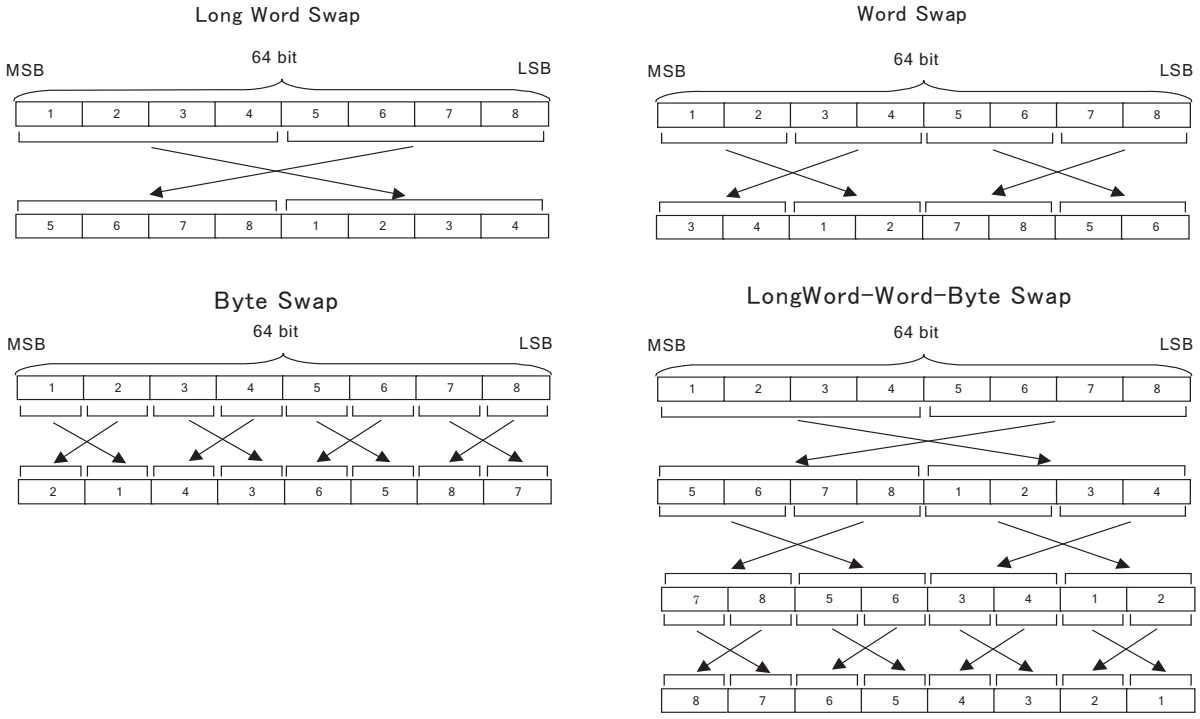

Figure 36.14 Data Swapping by Data Aligner

36.2.24 BEU Event Interrupt Enable Register (BEIER)

BEIER enables or disables output of the interrupt signal of a BEVTR flag.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	FINTE	–	–	–	–	–	–	BEVIOE	BEEND E
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	FINTE	0	R/W	BEIER.FINTE sets whether to generate the BEEND interrupt of each field or frame in the mode that output to the memory and BEU-VOU2 operation.
1	BEVIOE	0	R/W	Enables or disables the interrupt signal of the BEVIO bit in BEVTR to be output. 0: Disables output of the interrupt signal of the BEVIO bit in BEVTR. 1: Enables output of the interrupt signal of the BEVIO bit in BEVTR.
0	BEENDE	0	R/W	Enables or disables the interrupt signal of the BEEND bit in BEVTR to be output. 0: Disables output of the interrupt signal of the BEEND bit in BEVTR. 1: Enables output of the interrupt signal of the BEEND bit in BEVTR.

36.2.25 BEU Event Register (BEVTR)

BEVTR indicates the interrupt source when an internal interrupt occurs in the BEU. Whether output of the interrupt signal of each source in BEVTR is enabled or disabled is set by BEIER.

Modifying this register during operation is prohibited.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	INTREQ
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	BEVIOE	BEENDE
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	INTREQ	0	R	This bit is set to 1 when an interrupt source occurs in the BEU while output of the corresponding interrupt signal is enabled in BEIER. This bit remains cleared to 0 in the case where even though an interrupt source occurs in the BEU, output of the corresponding interrupt signal is disabled in BEIER, or in the case where even though output of the corresponding interrupt signal is enabled in BEIER, no interrupt source occurs in the BEU. 0: Indicates no interrupt is output externally. 1: Indicates an interrupt source has occurred in the BEU, and an interrupt is being output externally.
15 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	BEVIO	0	R/W	BEVIO Flag (violation status) [Reading] 0: Indicates that no violation setting has been detected, or the BEVIO flag has already been cleared. 1: Indicates that a violation setting has been detected. [Writing] 0: Clears the BEVIO flag by writing 0 to it. 1: NOP

Bit	Bit Name	Initial Value	R/W	Description
0	BEEND	0	R/W	BEEND Flag (end status) [Reading] 0: Indicates that BEU processing has not finished, or the BEEND flag has already been cleared. 1: Indicates that BEU processing has finished. [Writing] 0: Clears the BEEND flag by writing 0 to it. 1: NOP

The BEEND flag (end status) is set when BEU operation has finished. At this time, if the BEENDE bit (enables or disables an end interrupt) in BEIER is 1, be2o_intreq_n (interrupt signal) becomes active. The BEEND flag can be reset by writing 0 to the BEEND bit. The BEEND flag is not cleared unless 0 is written to the BEEND bit after BEU processing ends. Therefore, 0 must always be written to the BEEND bit to clear it before the BEU is activated again.

When operation ends normally, the BEIVK bit (operation start) in BESTR is reset when both be2o_beuw_endreq_w (bus acquisition signal request) and be2i_beuw_ack_w (write acknowledge) of the Media bus bridge are active. The BEEND flag is reset when be2i_beuw_end (bus acquisition signal) of the Media bus bridge becomes active.

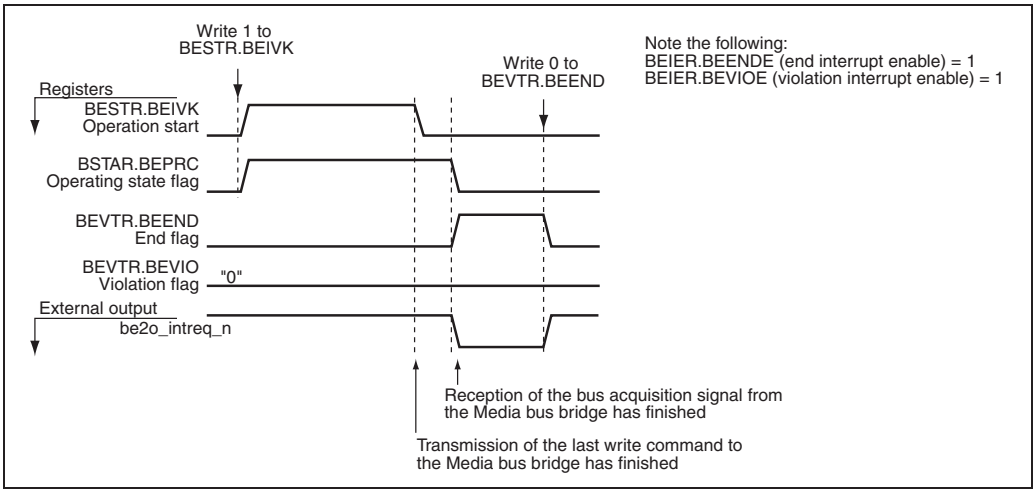

Figure 36.15 Operation Sequence without Violation Setting and Forcible Setting of End Flag

When a violation setting is made as shown in figure 36.16, and the BEIVK bit (operation start) in BESTR is set to 1, the BEU does not start operation and the BEVIO flag (violation status) is set. At this time, if the BEVIOE bit (enables or disables a violation interrupt) in BEIER is 1, be2o_intreq_n (interrupt signal) becomes active. The BEVIO flag can be reset by writing 0 to the BEVIO bit. When the BEVIO flag is set, the BEEND bit (end status) in BEVTR is not set, and the scheduling section, data transfer section, and data processing section are not activated.

The BEVIO flag is not cleared unless 0 is written to the BEVIO bit after BEU processing ends. Therefore, 0 must always be written to the BEVIO bit to clear it before the BEU is activated again.

The BEIVK bit is reset simultaneously to the BEVIO flag being set.

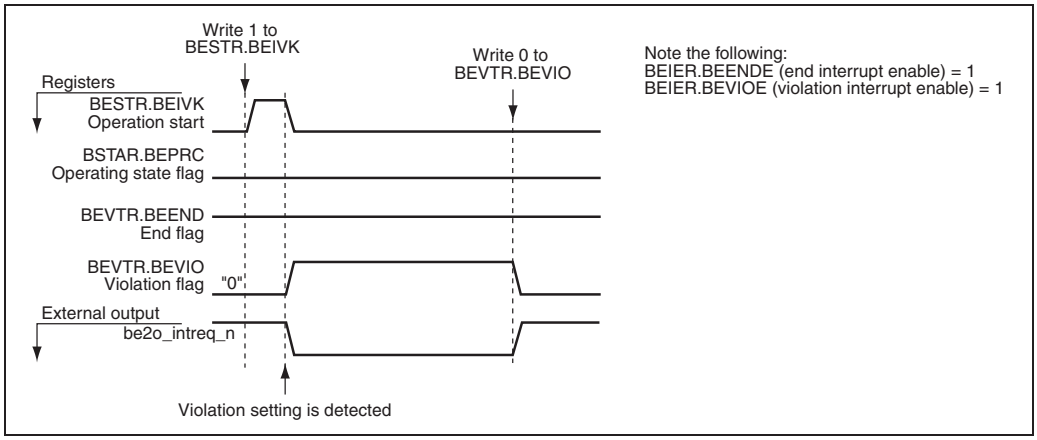

Figure 36.16 Operation Sequence with Violation Setting and Forcible Setting of Violation Flag

36.2.26 BEU Register Control Register (BRCNTR)

BRCNTR controls switching of the planes of BEU registers with a 2-plane configuration. Modifying these registers during operation is prohibited.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	RS	RC
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	RS	0	R/W	Specifies the register plane. Specifies which register plane is used by the BEU in synchronization with VSYNC. The setting of this bit is valid only when the RC bit is 0. 0: BEU uses plane A of the register. 1: BEU uses plane B of the register.
0	RC	0	R/W	Enables register plane switching. Specifies whether or not to switch the register plane used by the BEU in synchronization with VSYNC. If the register plane is not switched, the register plane specified by the RS bit is used. If the BEU is operating alone at register plane switching, the register plane is switched when the BEU is activated. If the BEU is operating together with the VOU or LCDC, the register plane is switched by the switching signal from the VOU or LCDC. 0: Uses the specified register plane. 1: Switches the register plane.

36.2.27 BEU Status Register (BSTAR)

BSTAR indicates the internal status of the BEU and the internal signal states.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	REGST	–	–	–	–	–	–	–	BEPRC
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	REGST	0	R	Indicates which register plane is currently used. 0: BEU is using plane A of the register. 1: BEU is using plane B of the register.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	BEPRC	0	R	This bit is set to 1 when the BEU is activated by the BEIVK bit in BESTR. This bit being set to 1 indicates that the BEU is operating. During this period, do not modify registers that are prohibited to be modified during operation. This bit is automatically cleared to 0 simultaneously with clearing of the BEEND flag in BEVTR. 0: BEU is halted. 1: BEU is operating.

36.2.28 BEU Module Reset Register (BBRSTR)

BBRSTR executes the module reset of the BEU.

Modifying this register during operation is prohibited. If B'1 is written to the ALLRST bit during operation, the logic circuits handshaking with the CPU bus are forcibly reset, and malfunction may also affect modules other than the BEU.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	RCH	0	R/W	Specifies the register plane forcibly. This bit forcibly switches the register plane currently used. Switching of the register plane can be done by this register only when the RC bit in BRCNTR is 1. To forcibly switch the register plane, set the RC bit to 1 in advance. 0: Specifies plane A of the register. 1: Specifies plane B of the register.

36.2.30 BEU Source Alpha Select Register n (n = 1 to 3) (BSASRn)

BSASRn (n = 1 to 3) control the alpha data of input system n and color data.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31	CBES	0	R/W	Set the blend operational expression of color data in Blend Unit-m. The blend coefficient x is set by BBCmR.CCMDX, and the blend coefficient y is set by BBCmR.CCMDY. 0: (blend coefficient x) *(input color data of DST) + (blend coefficient y)*(input color data of SRC) 1: (blend coefficient x)*(input color data of DST) - (blend coefficient y)*(input color data of SRC)
30 to 28	CCMDX	00	R/W	Set the blend coefficient x in the blend operational expression set by BBCmR.CBES. 000: the input alpha data of DST 001: 255 – (the input alpha data of DST) 010: the input alpha data of SRC 011: 255 – (the input alpha data of SRC) 100: the fixed alpha value 1 (COEFX) 101~111: setting prohibited
27	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 24	CCMDY	00	R/W	Set the blend coefficient y in the blend operational expression set by BBCmR.CBES. 000: the input alpha data of DST 001: 255 – (the input alpha data of DST) 010: the input alpha data of SRC 011: 255 – (the input alpha data of SRC) 100: the fixed alpha value 2 (COEFY) 101~111: setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
23	ABES	0	R/W	Set the blend operational expression of alpha in Blend Unit-m. The blend coefficient x is set by BBCmR.ACMDX, and the blend coefficient y is set by BBCmR.ACMDY. 0: (blend coefficient x) *(input alpha data of DST) + (blend coefficient y)*(input alpha data of SRC) 1: (blend coefficient x)*(input alpha data of DST) - (blend coefficient y)*(input alpha data of SRC)
22 to 20	ACMDX [2:0]	000	R/W	Set the blend coefficient x in the blend operational expression set by BBCmR.ABES. 000: the input alpha data of DST 001: 255 – (the input alpha data of DST) 010: the input alpha dat of SRC 011: 255 – (input alpha data of SRC) 100: the fixed alpha value 1 (COEFX)
18 to 16	ACMDY [2:0]	000	R/W	Set the blend coefficient y in the blend operation expression set by BBCmR.ABES. 000: the input alpha data of DST 001: 255 – (the input alpha data of DST) 010: the input alpha data of SRC 011: 255 – (the input alpha data of SRC) 100: the fixed alpha value 2 (COEFY)
15 to 8	COEFX	H'00	R/W	Set the fixed alpha value 1 when BBCmR.CCMDX is set b'100 or BBCmR.ACMDX is set b'100
7 to 0	COEFY	H'00	R/W	Set the fixed alpha value 2 when BBCmR.CCMDY is set b'100 or BBCmR.ACMDY is set b'100

Section 37 Video Processing Unit (VPU5HG)

The VPU5HG is a multi-codec module which provides encoding and decoding capabilities on the basis of multiple video coding schemes, e.g., H.264/AVC, MPEG-4, MPEG-2 and VC-1. Equipped with SHwy interface and combined with a CPU core, e.g., SH2A, the VPU5HG permits implementation of a video processing system on a chip (SOC) for mobile designs such as cellular phones, DSCs and DVCs as well as set-top designs such as DVD recorders.

37.1 Features

The VPU5HG has the following excellent features:

- Flexible architecture (microcode)
  H.264/MPEG-4 AVC High Profile (HP) encoding and decoding
  H.262/MPEG-2 AVC Main Profile (MP) encoding and decoding
  MPEG-4 ASP Advanced Simple Profile (ASP) encoding and decoding
  VC-1 SP/MP/AP (Simple, Main, Advanced Profile) decoding
  H.263 Baseline encoding and decoding
- Support for full HDTV resolutions
  1920 pixels × 1080 lines × 30 frames/second
  High throughput achieved by parallel operation on two codec elements (2 CEs) (capability to process 1280 clock cycles/2 MB)
  Bus master operation via 64-bit SHwy interface
- Data handled on a picture-by-picture basis
  Encodes and decodes data one picture (frame or field) at a time.
- High picture quality
  Supports the H.264 high-efficiency coding tools (CABAC, interlace, 8 × 8 frequency conversion, and quantization matrix).
  High-efficiency motion vector detection by a combination of discrete search and trace search
  Highly efficient real-time intra-prediction by Prediction from Original Image (POI)
  Optimal-mode selection by Rate-Distortion (RD) cost evaluation
  Picture quality control based on activity analysis results which match visual models
- Block-noise elimination filter incorporated
  This filter reduces block noise to support the standards (MPEG-4, MPEG-2, H.263 and DivX) to which in-loop filters are not applied. Post-filtering is incorporated to reduce block noise for signals in formats (MPEG-4, MPEG-2, H.263, and DivX) where a filter is not applied within the loop.

- Low power dissipation
  Dynamically disables the clocks for the entire VPU5HG.
  Dynamically disables the clocks for individual submodules.

See table 27.1 for details of the specification of the VPU5HG.

Table 27.1 Main Functions of the VPU5HG

Item	Description
Encoding standard supported	H.264 High Profile@Level 4.1
	Main Profile@Level 4.1
	Baseline Profile@Level 3
	MPEG-2 Main Profile@High Level
	MPEG-4 advanced Simple Profile@Level 5, Simple Profile@Level 6
	H.263 Baseline@Level 40
Decoding standard supported	H.264 High Profile@Level 4.1
	Main Profile@Level 4.1
	Baseline Profile[1]@Level 3
	MPEG-2 Main Profile@High Level
	MPEG-4 Advanced Simple Profile[2]@Level 5, Simple Profile@Level 6
	VC-1 Simple Profile@Medium Level, Main Profile@High LevelVC-1 Advanced Profile@Level 3
	H.263 Baseline@Level 40
Image post-processing	Block noise elimination filter (for decoding MPEG-2, MPEG-4 and H.263 images only)
Maximum throughput	1920 pixels × 1080 lines × 30 frames/second (at operation frequencies: 162 MHz or more)
Maximum bit rate	40 Mbps (at operation frequencies: 162 MHz or more)
	Except for MPEG-4 Data Partition (30 Mbps) and VC-1 AP (38 Mbps)
Picture size supported	Minimum size: Horizontally 80 pixels × Vertically 80 lines
	Maximum size: Horizontally 1920 pixels × Vertically 1080 lines
	Horizontally: 8-pixel units
	Vertically: 8-line units
	320 × 180 and 854 × 480 (WVGA+) are supported
Color format	YCbCr 4:2:0 format

Item	Description
Bit stream format	Video elementary stream
	(See table 27.2, detail on the processing range in encoding and decoding)
	Function to add/remove the emulation prevention byte in the H.264 VCL-NAL unit[3].
	Function to remove the emulation prevention byte in the VC-1 AP bit stream data unit.
Picture structure	Frame structure
	Field structure
Motion detection	Motion search accuracy: 1/4 pixels (1/2 pixels for MPEG-2, MPEG-4, and H.263) Motion search range: Horizontal (H) ±64 pixels, Vertical (V) ±32 lines, and search range enhanced feature.

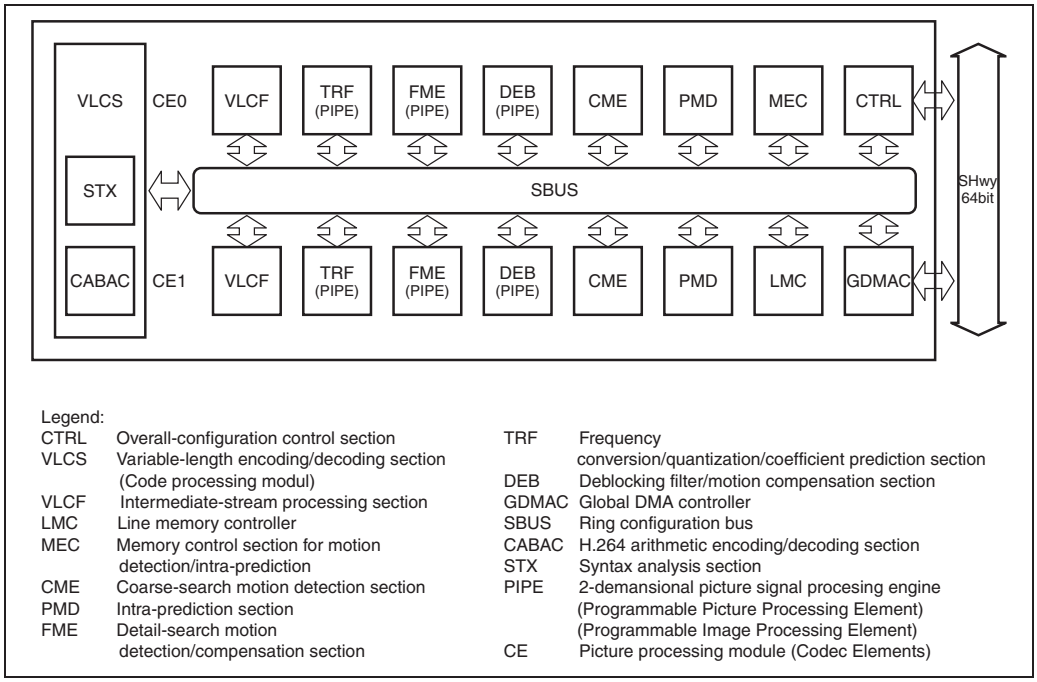
Notes: 1. It is non-corresponed toASO/FMO/RS
2. It is non-corresponed toGMC(Global Motion Compensation), Qpel MC
3. VCL(Video Coding Layer), NAL(Network Abstraction Layer)

Table 27.2 Data Handled by the VPU5HG

Standard	Encoding	Decoding
MPEG-4	VOP header and subsequent	Video packet header or Motion shape texture and subsequent data
H.264	Slice header and subsequent data	Slice data and subsequent data
H.263	Picture header and subsequent data	Picture header and subsequent data
MPEG-2	Picture header and subsequent data	Picture header and subsequent data
MPEG-1	Not supported	Picture header and subsequent data
VC-1	Not supported	Slice data and subsequent data

Table 27.3 lists some of the parameters included in the headers which are added by software for encoding. Set these listed parameters to the fixed values shown in table 27.3.

Table 27.3 Setup of the Intra-header Parameters for Encoding



Standard	Intra-header Parameter	Setting	Remarks
MPEG-4	quarter_sample	0	Does not support QpelMC.
H.264	mb_adaptive_frame_field_flag	0	Does not support MB-AFF.
	direct_8x8_inference_flag	1	Supports block sizes greater than or equal to 8 × 8 only.
	weighted_pred_flag	0	Does not support weighted prediction video encoding.
	weighted_bipred_idc	0	
	constrained_intra_pred_flag	0	Not supported.
	direct_spatial_mv_pred_flag	1	Supports spatial direct mode only.
MPEG-2	concealment_motion_vectors	0	Not supported.

Figure 27.1 shows a block diagram of the VPU5HG.

Table 27.1 explains its submodules. |
The VPU5HG offers interface for each of the two systems for the target and initiator connected to the 64-bit SHwy bus.

The VPU5HG consist of: a code processing module (VLCS) which performs variable-length encoding and decoding; picture processing modules (CEs) which process 2-dimensional picture signals; an MEC and LMC which control the internal memory shared by the submodules; a GDMAC which provides master transfer to external RAM as the SHwy initiator and a CTRL which achieves overall control. The submodules are connected together via a ring configuration bus (SBUS). The CEs are two systems which interact with each other to perform parallel processing of two macroblocks per period of 1280 clock cycles. The VPU5HG is only available for MPEG-4/H.263 encoding if one of its CEs is used. In this case, the CE used is CE0.

The STX in the VLCS uses microcode to flexibly encode and decode pictures. The TRF, FME and DEB in each CE also use microcode to do the same.

Legend:

CTRL	Overall-configuration control section	TRF	Frequency conversion/quantization/coefficient prediction section
VLCS	Variable-length encoding/decoding section (Code processing modul)	DEB	Deblocking filter/motion compensation section
VLCF	Intermediate-stream processing section	GDMAC	Global DMA controller
LMC	Line memory controller	SBUS	Ring configuration bus
MEC	Memory control section for motion detection/intra-prediction	CABAC	H.264 arithmetic encoding/decoding section
CME	Coarse-search motion detection section	STX	Syntax analysis section
PMD	Intra-prediction section	PIPE	2-demansional picture signal procesing engine (Programmable Picture Processing Element) (Programmable Image Processing Element)
FME	Detail-search motion detection/compensation section	CE	Picture processing module (Codec Elements)

Figure 27.1 VPU5HG Block Diagram

(1) Microcode Configurations

Table 27.4 and 27.5 show the microcode configurations for VPU5HG. Settings are required for the encoding standard, the VLCS (encode processing module), and the CE (picture processing module) which performs 2DG picture signal processing.

Table 27.4 VPU5HG Encoding Microcode Configurations

	VLCS Microcode		CE Microcode	
Standard	**Name**	**Size**	**Name**	**Size**
H.264	s264e.bin	16 Kbytes	p264e_h.bin	41 Kbytes
MPEG-4/H.263	smp4e.bin	44 Kbytes	pmp4e_h.bin	48 Kbytes
			pmp4e_s.bin (*)	44 Kbytes
MPEG-2	smp2e.bin	35 Kbytes	pmp2e_h.bin	44 Kbytes

Note: Firmware for encoding which involves one CE.

Tabler27.5 VPU5HG Decoding Microcode Configurations

	VLCS Microcode		CE Microcode	
Standard	**Name**	**Size**	**Name**	**Size**
H.264	s264d.bin	40 Kbytes	p264d_h.bin	48 Kbytes
MPEG-4/H.263	smp4d.bin	42 Kbytes	pmp4d_h.bin	40 Kbytes
MPEG-1/-2	smp2d.bin	32 Kbytes	pmp2d_h.bin	36 Kbytes
VC-1 SP/MP	svc1d.bin	24 Kbytes	pvc1d_h.bin	52 Kbytes
VC-1 AP	svc1apd.bin	36 Kbytes		

37.2 Register Description

The VPU5HG contains the registers (table 27.6) which can directly be read/write-accessed by the host CPU. It also contains the internal registers (table 27.8 and 27.9) which can be configured by the initialization routine.

The host can access any long word (32 bits) in the registers.

The internal registers can be configured using the initialization routine the VPU5HG GDMAC, which serves as a master, transfers operation control parameter settings from the external RAM to an internal register or memory. Before the VPU5HG is activated, the operation control parameters are stored in a predetermined format in the external memory. Data in the internal registers can be accessed in units of 64 bits.

The registers with names which are prefixed with "VP5_CE_" should be configured when the picture processing module (CE) is activated. The registers with names which are prefixed with "VP5_VLC_" should be configured when the code processing module (VLCS) is activated. The registers with names which are prefixed with "VP5_" should be configured when the CE or VLCS is activated. Suffixes 0 and 1 for registers indicate that these registers are for CE0 and CE1.

The grayed portions represent reserved areas for debugging or future functional expansion. Do not access the reserved areas. Never access the registers when the VPU5HG is in the module standby mode (with the operation clock placed in hold status).

Table 27.6 VPU5HG Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
VPU5HG version control register H	VP5_VCRH	R	H'FE90 0000	32
VPU5HG version control register L	VP5_VCRL	R	H'FE90 0004	32

37.2.1 VPU5HG Version Control Register H (VP5_VCRH)

VP5_VCRH is a version control register (VCR) for SHwy. It reads a fixed value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TOPMB								BOTMB							
Initial value:	1	1	1	0	1	0	0	0	1	1	1	0	1	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VCID															
Initial value:	0	1	0	1	0	1	0	1	1	1	1	1	0	1	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TOPMB	H'E8	R	High-order eight bits for the upper address allocated to the VPU5HG.
23 to 16	BOTMB	H'E8	R	High-order eight bits for the lower address allocated to the VPU5HG.
15 to 0	VCID	H'55F4	R	VPU5HG identification number (VPU) Bit [15]: Reserved Bits [14:10]: 10101: Indicate "V." Bits [9:5]: 01111: Indicate "P." Bits [4:0]: 10100: Indicate "U."

37.2.2 VPU5HG Version Control Register L (VP5_VCRL)

VP5_VCRL is a version control register (VCR) for the SHwy. It reads a fixed value.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VPU				ARC		VER					REV				
Initial value	0	1	0	1	0	1	0	0	0	1	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MERR								PERR							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	VPU	0101	R	VPU Series Information 101: Indicates the VPU5
27, 26	ARC	01	R	VPU Configuration Information 01: Indicates the VPU5H configuration.
25 to 21	VER	010	R	Version Information 00: Indicates the VPU5HC 01: Indicates the VPU5HM 10: Indicates the VPU5HG/VPU5HG2 Others: Reserved
20 to 16	REV	00001	R	Revision Information H'01: Indicates a revision H'02 to H'1F: Reserved
15 to 8	MERR	All 0	R	merr_flags Indicates a VPU5HG-specific error defined in SHwy VCR.Fixedly set to 0 for the VPU5HG implementation.
7 to 0	PERR[7:6]	All 0	R	perr_flags
	PERR[5]		R/W	Indicates an error generated in an interface between VPU5 and a packet rooter.
	PERR[4]		R	
	PERR[3:0]		R/W	Set the bit listed in table 27.10 for the VPU5 implementation.

Table 27.10 PERR

37.2.3 VPU5HG Command Register (VP5_CMD)

The VP5_CMD register controls the VPU5HG operation.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	MRST	RST	—	—	—	—	—	—	—	—	VE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	MRST	0	R/W	Software Module Reset Regardless of the VPU5HG operation state, software module reset causes the internal registers to return to their initial states. To operate the VPU5HG after software module reset, reconfigure all the registers. Do not set both this bit and the VE bit to 1 (for performing software module reset and activation at the same time). Do not set both this bit and the RST bit to 1 (for performing software module reset and software reset at the same time). After this bit is set to 1, it is switched back to 0 automatically. 0: — 1: Forcibly terminates the VPU5HG operation. (Module reset)

Bit	Bit Name	Initial Value	R/W	Description
9	RST	0	R/W	Software Reset After bus master operation by the VPU5HG, software reset stops the VPU5HG and causes its internal registers to return to their initial states. To operate the VPU5HG after software module reset, reconfigure all the registers. Do not set both this bit and the VE bit to 1 (for performing software reset and activation at the same time). Do not set both this bit and the MRST bit to 1 (for performing software reset and software module reset at the same time). After this bit is set to 1, it is switched back to 0 automatically. 0: — 1: Terminates the VPU5HG operation after bus master operation.
8 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	VE	0	R/W	Operation Enable This bit specifies the start of the VPU5HG processing. After this bit is set to 1, it is switched back to 0 automatically. 0: — 1: Starts the VPU5HG operation. The VPU5HG evaluates the VP5_CTRL settings to perform processing. Table 27.11 and 27.12 show the combinations of the operation control parameters specified in VP5_CTRL. When VP5_STATUS.VC = 1 (at setting up the VLCS), do not start the VLCS. When VP5_STATUS.CC = 1 (at setting up the CE), do not start the CE.

37.2.4 VPU5HG Overall Control Register (VP5_CTRL)

The VP5_CTRL register specifies the overall operation of the VPU5HG.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	VL_PED[2:0]			—	VL_MED[2:0]			CEMD	CE_PED[2:0]			—	CE_MED[2:0]

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30 to 28	VL_PED[2:0]	000	R/W	VLCS Parameter Endian Settings These bits make endian settings for the operation control parameters for the code processing module (VLCS). The operation control parameters are set in the internal registers by the initialization routine. Bit 30 specifies interchanging data in byte units, bit 29 interchaning data in word (16-bit) units, and bit 28 interchanging data in long-word (32-bit) units. B W LW Byte order 0 0 0 : 12345678 (Big endian) 0 0 1 : 56781234 0 1 0 : 34127856 0 1 1 : 78563412 1 0 0 : 21436587 1 0 1 : 65872143 1 1 0 : 43218765 1 1 1 : 87654321 (little endian)
27	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
26 to 24	VL_MED[2:0]	000	R/W	VLCS Microcode Endian Settings These bits make endian settings for the microcode e for the code processing module (VLCS). Bit 26 specifies interchanging data in byte units, bit 25 interchanging data in word (16-bit) units, and bit 24 interchanging data in long-word (32-bit) units. B W LW Byte order 0 0 0 : 12345678 (Big endian) 0 0 1 : 56781234 0 1 0 : 34127856 0 1 1 : 78563412 1 0 0 : 21436587 1 0 1 : 65872143 1 1 0 : 43218765 1 1 1 : 87654321 (little endian)
23	CEMD	0	R/W	CE Operation Mode 0: Starts encoding the picture processing module (CE) 1: Starts decoding the picture processing module (CE)
22 to 20	CE_PED[2:0]	000	R/W	CE Parameter Endian Settings These bits make endian settings for the operation control parameters for the picture processing module (CE). The operation control parameters are set in the internal registers by the initialization routine. Bit 22 specifies interchanging data in byte units, bit 21 interchanging data in word (16-bit) units, and bit 20 interchanging data in long-word (32-bit) units. B W LW Byte order 0 0 0 : 12345678 (Big endian) 0 0 1 : 56781234 0 1 0 : 34127856 0 1 1 : 78563412 1 0 0 : 21436587 1 0 1 : 65872143 1 1 0 : 43218765 1 1 1 : 87654321 (little endian)

Bit	Bit Name	Initial Value	R/W	Description
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	CE_MED[2:0]	000	R/W	CE Microcode Endian Settings These bits make endian settings for the microcode for the picture processing module (CE). Bit 18 specifies interchanging data in byte units, bit 17 interchanging data in word (16-bit) units, and bit 16 interchanging data in long-word (32-bit) units. B W LW Byte order 0 0 0 : 12345678 (Big endian) 0 0 1 : 56781234 0 1 0 : 34127856 0 0 1 : 78563412 1 0 0 : 21436587 1 0 1 : 65872143 1 1 0 : 43218765 1 1 1 : 87654321 (little endian)
15 to 12	VL_SO[3:0]	H'0	R/W	Source Offset Specification for the Code Processing Module (VLCS) Microcode /Operation Parameters H'0: — H'C (12): Specifies 12 for the VPU5HG.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10	VME	0	R/W	Code Processing Module (VLCS) Microcode Downloading 0: Does not download the code processing module microcode 1: Downloads the code processing module microcode.

Bit	Bit Name	Initial Value	R/W	Description
9	VCN	0	R/W	Code Processing Module (VLCS) Restart The VLCS suspends its operation after it has processed data ending at the last position in the stream or intermediate-stream buffer. At this time, this bit is set to 1 and a 1 is written to the VE bit in the VP5_CMD register, thereby causing the VPU5 to continue the operation. To terminate rather than continue the VPU5 operation after it is suspended, disable the buffer end interrupt with the VP5_IRQ_ENB register. To continue the operation, set this bit to 1 and write a 1 to the VE bit in the VP5_CMD register. At this time, the other settings should be the same as those used for the immediately preceding activation. 0: Normally starts the code processing module. 1: Restarts the code processing module.
8	VE	0	R/W	Code Processing Module (VLCS) Enable 0: Does not start the code processing module. 1: Starts the code processing module.
7 to 4	CE_SO[3:0]	H'0	R/W	Source Offset Specification for the Picture Processing Module (CE) Microcode /Operation Control Parameters 0: — 1: Specifies 11 for the VPU5HG.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	CME	0	R/W	CE Microcode Downloading 0: Does not download the picture processing module microcode. 1: Downloads the picture processing module microcode.

Bit	Bit Name	Initial Value	R/W	Description
1	CCN	0	R/W	Operation Restart The CE suspends its operation after it has processed data ending at the last position in the intermediate-stream buffer. At this time, this bit is set to 1 and a 1 is written to the VE bit in the VP5_CMD register, thereby causing the VPU5 to continue the operation. To terminate rather than continue the VPU5 operation after it is suspended, disable the buffer end interrupt with the VP5_IRQ_ENB register. To continue the operation, set this bit to 1 and write a 1 to the VE bit in the VP5_CMD register. At this time, the other settings should be the same as those used for the immediately preceding activation. 0: Normally starts the picture processing module. 1: Restarts the picture processing module.
0	CE	0	R/W	Picture Processing Module (CE) Enable 0: Does not start the picture processing module. 1: Starts the picture processing module.

The VLCS and CE can be operated independently of each other. Table 27.11 and 12.10 show the combinations of the operation control parameter settings for the VLCS and CE. The downloading of the microcode is required when switching between the operation modes (encode and decode). It is not required when changing the type of picture.

Table 27.11 VLCS Operation Control Parameter Settings

VME	VE	Operation
0	1	Starts VLCS normal operation.
1	0	Downloads only the VLCS microcode.
1	1	After download the VLCS microcode, starts VLCS normal operation.

Table 27.12 CE Operation control Parameter Settings

CME	CE	Operation
0	1	Starts CE normal operation.
1	0	Downloads only the CE microcode.
1	1	After download the CE microcode, starts CE normal operation.

37.2.5 VPU5HG Interrupt Control Register (VP5_IRQ_ENB)

VP5_IRQ_ENB is an interrupt control register for the VPU5HG.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	VISE1	—	VISE0	—	—	VBBE	VBAE	—	CISE1	—	CISE0	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R/W	R	R	R/W	R/W	R	R/W	R	R/W	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	VLE	—	—	—	—	—	—	—	CEE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	VISE1	0	R/W	VLCS Intermediate-Stream 1 Buffer End Interrupt Enable 0: Disables the VLCS intermediate-stream 1 buffer end interrupt. Be sure to use this value for the VPU5HG 1: Enables the VLCS intermediate-stream 1 buffer end interrupt. Do not use this value for the VPU5HG.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28	VISE0	0	R/W	VLCS Intermediate-Stream 0 Buffer End Interrupt Enable 0: Disables the VLCS intermediate-stream 0 buffer end interrupt. Be sure to use this value for the VPU5HG. 1: Enables the VLCS intermediate-stream 0 buffer end interrupt. Do not use this value for the VPU5HG.
27, 26	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
25	VBBE	0	R/W	VLCS Stream B Buffer End Interrupt Enable 0: Disables the VLCS stream B buffer end interrupt. Be sure to use this value for the VPU5HG. 1: Enables the VLCS stream B buffer end interrupt. Do not use this value for the VPU5HG.
24	VBAE	0	R/W	VLCS Stream A Buffer End Interrupt Enable 0: Disables the VLCS stream A buffer end interrupt. Be sure to use this value for the VPU5HG. 1: Enables the VLCS stream A buffer end interrupt. Do not use this value for the VPU5HG.
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
22	CISE1	0	R/W	CE Intermediate Stream 1 Buffer End Interrupt Enable 0: Disables the CE intermediate stream 1 buffer end interrupt. 1: Enables the CE intermediate stream 1 buffer end interrupt.
21	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
20	CISE0	0	R/W	CE Intermediate Stream 0 Buffer End Interrupt Enable 0: Disables the CE intermediate stream 0 buffer end interrupt. 1: Enables the CE intermediate stream 0 buffer end interrupt.
19 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	VLE	0	R/W	VLCS Termination Interrupt Enable 0: Disables the VLCS termination interrupt. 1: Enables the VLCS termination interrupt.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CEE	0	R/W	Enables the VLCS termination interrupt. 0: Disables the CE termination interrupt. 1: Enables the CE termination interrupt

37.2.6 VPU5HG Interrupt Status Register (VP5_IRQ_STA)

VP5_IRQ_STA is a register which indicates the cause of a VPU5HG interrupt. The flag which indicates the occurrence of an interrupt can only be cleared to 0. To clear a bit, write a 0 to the bit and write 1s to the other bits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	VIS1	—	VIS0	—	—	VBB	VBA	—	CIS1	—	CIS0	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R/W	R	R	R/W	R/W	R	R/W	R	R/W	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	VLE	—	—	—	—	—	—	—	CE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	VIS1	0	R/W	VLCS Intermediate Stream 1 Buffer End Interrupt Status 0: — 1: Indicates the VLCS has processed data up to the end of the intermediate stream 1 buffer.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28	VIS0	0	R/W	VLCS Intermediate Stream 0 Buffer End Interrupt Status 0: — 1: Indicates the VLCS has processed data up to the end of the intermediate stream 0 buffer.
27, 26	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
25	VBB	0	R/W	VLCS Stream B Buffer End Interrupt Status 0: — 1: Indicates the VLCS has processed data up to the end of the stream B buffer.
24	VBA	0	R/W	VLCS Stream A Buffer End Interrupt Status 0: — 1: Indicates the VLCS has processed data up to the end of the stream A buffer.
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22	CIS1	0	R/W	CE Intermediate Stream 1 Buffer End Interrupt Status 0: — 1: Indicates the CE has processed data up to the end of the intermediate stream 1 buffer.
21	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
20	CIS0	0	R/W	CE Intermediate Stream 0 Buffer End Interrupt Status 0: — 1: Indicates the CE has processed data up to the end of the intermediate stream 0 buffer.
19 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	VLE	0	R/W	VLCS Termination Interrupt Status 0: — 1: Indicates the VLCS has terminated its operation.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CE	0	R/W	Termination Interrupt Status 0: — 1: Indicates the CE has terminated its operation.

37.2.7 VPU5HG Clock Supply Control Register (VP5_CLK_STOP)

The VP5_CLK_STOP register controls the clock for each VPU5HG module.

Do not access this register during operation (i.e., while CS =1 or VS = 1 in the VP5_STATUS register).

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CSMD	CSTP
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	CSMD	0	R/W	Inactive-block Selection This bit selects whether to disable clock supply to each internal module or to the whole system when clock supply to the VPU5HG stops dynamically. Do not access this bit during operation (i.e., while CS = 1 or VS = 1 in VP5_STATUS). 0: Disables the operation clock supply to each module. Clock supply starts when each module becomes active and stops when it becomes inactive. 1: Disables the operation clock supply to the whole system. Clock supply starts when the system becomes active and stops when it becomes inactive.

Bit	Bit Name	Initial Value	R/W	Description
0	CSTP	0	R/W	Module Clock Supply Settings This bit stops the operation clock supply to individual modules in the VPU5HG dynamically. Do not access this bit during operation (i.e., while CS =1 or VS = 1 in VP5_STATUS). 0: Dynamically stops the operation clock supply. 1: Always supplies the operation clocks.

37.2.8 VP5_STATUS: VPU5HG Status Register (VP5_STATUS)

The VP5_STATUS register indicates the VPU5HG status.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	VC	CC	—	—	—	—	—	—	VS	CS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	VC	0	R	Code Processing Module (VLCS) Setup Status Bit 0: Indicates the VLCS is not active. 1: Indicates the VLCS is active. VLCS should not be started during VLCS setup.
8	CC	0	R	Picture Processing Module (CE) Status Bit 0: Indicates the CE is not active. 1: Indicates the CE is active. CE should not be started during CE setup.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	VS	0	R	Code Processing Module (VLCS) Status Bit 0: Indicates the VLCS is not active. 1: Indicates the VLCS is active.
0	CS	0	R	Picture Processing Module (CE) Status Bit 0: Indicates the CE is not active. 1: Indicates the CE is active.

37.2.9 Motion Vector Count Register (VP5_CE_MV_NUM)

The VP5_CE_MV_NUM register indicates the number of motion vectors (MVs) for encoding. This register becomes valid after the completion of CE encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MV0															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MV1															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	MV0[15:0]	All 0	R	Number of MVs referenced by ref0 (0 to 32640)
15 to 0	MV1[15:0]	All 0	R	Number of MVs referenced by ref1 (0 to 32640)

37.2.10 Forward Reference Horizontal Motion Vector Sum Register (VP5_CE_MVH_REF0)

The VP5_CE_MVH_REF0 register indicates the sum of forward reference horizontal MVs for encoding. This register becomes valid after the completion of CE encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MVH															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MVH															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MVH0[31:0]	All 0	R	Sum of horizontal motion vectors (-2, 147, 483, 648 to 2, 147, 483, 647)

37.2.11 Forward Reference Vertical Motion Vector Sum Register (VP5_CE_MVV_REF0)

The VP5_CE_MVV_REF0 register indicates the sum of forward reference vertical MVs for encoding. This register becomes valid after the completion of CE encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MVV															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MVV															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MVV0[31:0]	All 0	R	Sum of vertical motion vectors (-1, 040, 400 to 1, 040, 399)

37.2.12 Backward Reference Horizontal Motion Vector Sum Register (VP5_CE_MVH_REF1)

The VP5_CE_MVH_REF1 register indicates the sum of backward reference horizontal MVs for encoding. This register becomes valid after the completion of CE encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MVH															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MVH															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MVH1[31:0]	All 0	R	Sum of horizontal motion vectors (-2, 147, 483, 648 to 2, 147, 483, 647)

37.2.13 Backward Reference Vertical Motion Vector Sum Register (VP5_CE_MVV_REF1)

VP5_CE_MVV_REF1 register indicates the sum of backward reference vertical MVs for encoding. This register becomes valid after the completion of CE encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MVV															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MVV															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MVV1[31:0]	All 0	R	Sum of vertical motion vectors (-1, 040, 400 to 1, 040, 399)

37.2.14 CE Microcode Base Address Register (VP5_CE_MBA)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CMBA[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMBA[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMBA[31:0]	All 0	R/W	CE Microcode Base Address Specification These bits specify in units of 32 bytes the start address for storing the CE microcode. Before starting the CE for the VPU5HG, place the microcode in the address specified in this register.

37.2.15 CE Parameter Base Address Register 0 (VP5_CE_PBA0)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CPBA[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CPBA[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CPBA0[31:0]	All 0	R/W	CE Parameter Base Address Specification These bits specify in units of 32 bytes the start address for storing the CE0 operation control parameter. Before starting the CE for the VPU5HG, place the operation configuration parameter (initialization routine format) in the address specified in this register.

37.2.16 CE Parameter Base Address Register 1 (VP5_CE_PBA1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CPBA[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CPBA[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CPBA1[31:0]	All 0	R/W	CE1 Parameter Base Address Specification These bits specify in units of 32 bytes the start address for storing the CE1 operation control parameter. Before starting the CE for the VPU5HG, place the operation configuration parameter (initialization routine format) in the address specified in this register.

37.2.17 CE Error Code Register (VP5_CE_ERR)

VP5_CE_ERR indicates the warning status which is present after CE operation. This register's values are determined at the end of operation. Warning takes place when the specified upper or lower limit is reached. Typically, it does not take place concerning a stream encoded with the VPU5HG.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ERC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EPY[7:0]								EPX[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	ERC[15:0]	All 0	R	Warning Code 0: Indicates normal termination. 1: Indicate warning status. Lists the warnings at decoding time in table 27.13 and at encoding time in table 27.14.
15 to 8	EPY[7:0]	All 0	R	Indicates the internal status This bit is for debagging. Not for the end user.
7 to 0	EPX[7:0]	All 0	R	Indicates the internal status This bit is for debugging. Not for the end user.

Table 27.13 Decode Warnings

Bit position	Symbol	Error description
20	CRO	Indicates the internal status This bit is for debugging. Not for the end user.
19	INTRA_MODE_CLIP	INTRA_MODE is used although it should not be used.
18	MV_RANGE_OVER	The MV range exceeds the specified maximum.

Table 27.14 Encode warnings

Bit position	Symbol	Error description
20	CRO	Indicates the internal status This bit is for debugging. Not for the end user.

37.2.18 Intermediate-Stream Bit Count Register 0 (VP5_CE_INT_TB0)

VP5_CE_INT_TB0 indicates the number of bits in a CE0 intermediate stream. This register becomes valid after the completion of encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	VB[26:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:						R	R	R	R	R	R	R	R	R	R	R

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	—	Reserved These bits are always read as 0. The write value should always be 0.
26 to 0	VB0[26:0]	All 0	R	Intermediate-Stream 0 Bit Count Indicate the number of bits in intermediate stream 0. (H'000 0000 to H'7FF FFFF)

37.2.19 Intermediate-Stream Bit Count Register 1 (VP5_CE_INT_TB1)

VP5_CE_INT_TB1 indicates the number of bits in a CE1 intermediate stream. This register becomes valid after the completion of encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	VB[26:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VB[26:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 0	VB1[26:0]	All 0	R	Intermediate-Stream 1 Bit Count Indicate the number of bits in intermediate stream 1. (H'000 0000 to H'7FF FFFF)

37.2.20 Macroblock Attribute Register (VP5_CE_MB_ATTR)

The VP5_CE_MB_ATTR register indicates the macroblock attributes at encoding time. This register becomes valid after the completion of CE encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	INTRA[12:0]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	INTER[12:0]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 16	INTRA[12:0]	All 0	R	Intra Macroblock Count Indicate the number of intra macroblocks in a picture. (0 to 8160)
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	INTER[12:0]	All 0	R	Inter Macroblock Count Indicate the number of inter macroblocks in a picture. (0 to 8160)

37.2.21 Macroblock Intra SAD Register (VP5_CE_MB_SADA)

The VP5_CE_MB_SADA register indicates the intra sum of absolute differences (SAD) of macroblocks at H.264 encoding time. This register becomes valid after the completion of CE encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SADA[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SADA[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SADA[31:0]	All 0	R	Intra Macroblock SAD Indicate total value of the intra SAD of macroblocks in a picture at H.264 encoding time (0 to 534,765,600). Indicates 0 other than H.264.

37.2.22 Macroblock Inter SAD Register (VP5_CE_MB_SADR)

The VP5_CE_MB_SADR register indicates the inter sum of absolute differences (SAD) of macroblocks at encoding time. This register becomes valid after the completion of CE encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SADR[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SADR[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SADR[31:0]	All 0	R	Inter Macroblock SAD Indicate total value of the inter SAD of macroblocks in a picture (0 to 534,765,600).

37.2.23 Macroblock Used SAD Register (VP5_CE_MB_USAD)

The VP5_CE_MB_USAD register indicates the sum of absolute differences (SAD) of encoded macroblocks at encoding time in H.264 encoding. This register becomes valid after the completion of CE encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	USAD[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	USAD[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	USAD[31:0]	All 0	R	Used SAD Indicate total value of the SAD of macroblocks in a picture for the mode determined by intra/inter mode decision at H.264 encoding time (0 to 534,765,600). Indicates 0 other than H.264.

37.2.24 Activity Sum Register (VP5_CE_ASUM)

The VP5_CE_ASUM register indicates the sum of total activities of macroblocks. This register becomes valid after the completion of CE encoding

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	ASUM[23:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ASUM[23:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	ASUM[23:0]	All 0	R	Activity Sum Indicate the sum of total activities of macroblocks in a picture. To obtain this sum, follow these steps: [Step1] Determine the activity evaluation value act_8 × 8 for the 8 × 8 pixel block as follows. $act_8x8 = \sum_{i=0}^{63} \mid p_i - average_p \mid / 8$ where p_i is a pixel value (0 - 255) and average_p is an average of pixel values in the 8 × 8 block. [Step2] Select the minimum from the activity evaluation values of the four 8 × 8 pixel blocks in the macroblock. [Step3] Determine the sum of the total activities for the macroblocks in one picture.

37.2.25 Activity Register (VP5_CE_ACT)

The VP5_CE_ACT register indicates the maximum and minimum values for activities of macroblocks for encoding. This register becomes valid after the completion of encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	AMAX[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	AMIN[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 16	AMAX[10:0]	All 0	R	Activity Maximum Value Indicate the maximum value for activities of macroblocks in a picture. (0 to 2,040) For information about the activity evaluation formula for macroblocks, refer to the VP5_CE_ASUM register description.
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	AMIN[10:0]	All 0	R	Activity Minimum Value Indicate the minimum value for activities of macroblocks in a picture. (0 to 2,040) For information about the activity evaluation formula for macroblocks, refer to the VP5_CE_ASUM register description.

37.2.26 Quantization Coefficient Sum Register (VP5_CE_QSUM)

The VP5_CE_QSUM register indicates the sum of quantization coefficients for pictures at encoding time. This register becomes valid after the completion of encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	QSUM[18:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:														R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	QSUM[18:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18 to 0	QSUM[18:0]	All 0	R	Quantization Coefficient Sum Sum of picture quantization coefficients (0 to 416, 160)

37.2.27 Virtual Buffer Register (VP5_CE_DJS)

The VP5_CE_DJS register indicates the virtual buffer value which is available after encoding. This register becomes valid after the completion of encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DJ[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DJ[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DJ[31:0]	All 0	R	Virtual Buffer Indicate the virtual buffer amount (signed) which is reached after encoding. (-2,147,483,658 to 2,147,483,657) These bits are valid when macroblock-level quantization parameter control based on TM5 step 2 is provided (i.e., when dq_disable in the VP5_CE_ENC_CTRL register is 0). The virtual buffer is updated for each macroblock by using the formula below. The virtual buffer's updated value after picture processing is reflected in this register. Virtual buffer (j) = Virtual buffer (j-1) + Intermediate code amount - Target code amount where j indicates a macroblock number.

37.2.28 MB Average Luminance Sum Register (VP5_CE_YSUM)

The VP5_CE_YSUM register indicates the total value of macroblock average for luminance at encoding time. This register becomes valid after the completion of encoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	YSUM[24:16]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	YSUM[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	—	Reserved These bits are always read as 0. The write value should always be 0.
24 to 0	YSUM[24:0]	All 0	R	Macroblock Luminance Average Sum Sum of the macroblock luminance average (0 to 2,080,800)

37.2.29 VLCS Firmware-Based Address Register (VP5_VLC_MBA)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VMBA[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VMBA[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	VMBA[31:0]	All 0	R/W	VLCS Microcode-Based Address Specification These bits specify the start address in 32-byte units for storing the VLCS microcode. Before starting the VLCS in the VPU5HG, place the microcode (initialization routine format) in the address specified in this register.

37.2.30 VLCS Parameter-Based Address Register 0 (VP5_VLC_PBA0)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VPBA[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VPBA[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	VPBA0[31:0]	All 0	R/W	VLCS Parameter-Based Address Specification These bits specify the start address in 32-byte units for storing the VLCS operation control parameter. Before starting the VLCS in the VPU5HG, place the operation control parameter (initialization routine format) in the address specified in this register.

37.2.31 VLCS Parameter-Based Address Register 1 (VP5_VLC_PBA1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VPBA[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VPBA[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	VPBA1[31:0]	All 0	R/W	VLCS Parameter-Based Address Specification These bits specify the start address in 32-byte units for storing the VLCS operation control parameter. Before starting the VLCS in the VPU5HG, place the operation control parameter (initialization routine format) in the address specified in this register.

37.2.32 Picture Byte Count Register (VP5_VLC_TB)

The VP5_VLC_TB register indicates the number of bytes which exist after picture processing. This register becomes valid after the completion of VLCS encoding, decoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TB[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TB[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TB[31:0]	All 0	R	Total Bytes Indicate the number of processing bytes which exist after picture processing (0 to 4294967295). At encoding time, these bits indicate the number of bytes output by processing data (in units of pictures) via the overall VLCS operation. They include bytes output before the stream for alignment. They also include inserted emulation prevention bytes. That number does not include the size of a slice if the processing of the slice was aborted due to a fatal error during the encoding by the VLCS. At decoding time, these bits indicate the number of bytes which the VLCS referenced for processing the last slice. They include padding bytes preceding the slice. They also include deleted emulation prevention bytes. They do not include cabac_zero_word. If processing of the slice was aborted due to a fatal error, these bits indicate the number of bytes for the portion which was subject to getbit processing before the abortion (any fractions are rounded off).

37.2.33 VLCS Status Register H (VP5_VLC_ERRH)

The VP5_VLC_ERRH register indicates the error and warning status after the completion of the VLCS operation. The status bits vary depending on the operation mode. If two or more errors or warnings are detected, this register provides information about the error or warning at the highest level of seriousness (ELVL). If they are at the same level of seriousness, this register provides information about the first error or warning detected. The values in this register are determined after the completion of operation.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	ESRC[1:0]		ELVL[1:0]		SN[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R		R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30, 29	ESRC[1:0]	00	R	VLCS Block Where Error/Warning Was Detected 00: No error/warning detected 01: Error/warning detected in the VLCS CTL 10: Error/warning detected in the STX 11: Error/warning detected in the CABAC
28, 27	ELVL[1:0]	00	R	Error/Warning Level 00: No error/warning detected 01: Warning. (A problem was detected, but it was ignored and processing continued.) 10: Error. (Concealment was applied and processing coninued.) 11: Fatal error. (Execution stopped.)

Bit	Bit Name	Initial Value	R/W	Description
26 to 16	SN[10:0]	All 0	R	Error Processing Termination Slice Number Indicate the number (0 to 2,047) of a slice which caused an error/warning for H.264 processing. 0 corresponds to the first slice. These bits are invalid and are always read as 0 for processing non-H.264 content.
15 to 8	MBH[7:0]	All 0	R	MB H Position Horizontal position of an MB which caused an error/warning. (0 to 119)
7 to 0	MBV[7:0]	All 0	R	MB V Position Vertical position of an MB which caused an error/warning. (0 to 67)

37.2.34 VLCS Status Register (VP5_VLC_ERRL)

The VP5_VLC_ERRL register indicates the error and warning status after the completion of the VLCS operation. The status bits vary depending on the operation mode. If two or more errors or warnings are detected, this register provides information about the error or warning at the highest level of seriousness (ELVL). If the errors or warnings are at the same level of seriousness, this register provides information about the first error or warning detected. The values in this register are determined after the completion of operation.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	ERC[5:0]	H'00	R	Error Code Indicate error code. The code varies depending on the ESRC bits in the VP5_VLC_ERRH register. If the ESRC bit indicates STX or CABAC, the code is the number of the syntax element which is the major cause of the problem. For details, refer to table 27.15 to 27.19.
25 to 0	SBCV[25:0]	H'000 0000	R	Indicate the error occurrence position by using the number of reference bits starting at the beginning of the picture. At encoding time, these bits indicate the number of bytes which exist before inserting the emulation prevention byte. At decoding time, they indicate the number of bytes which exist after deleting the emulation prevention byte. Thus, they do not indicate the address of stream data in memory when using the function to insert/delete the emulation prevention byte.

Table 27.15 Error Codes (Not Depending on Codec)

ESRC	ELVL	ERC	Error description
00	00	H'00	Normal termination
01	10	H'01	Unconsecutive macroblock start addresses were detected. (Slices were ignored because their overlapping was detected.) This error is not detected if the I bit for the command stream is 1 at decoding time. (This is because the internal macroblock address counter is forcibly set to the specified value in the command stream.) This error is not detected at encoding time.
01	10	H'02	Unconsecutive macroblock start addresses were detected. (Unconsecutive macroblocks were detected, and the required macroblock was output as an error macroblock.) This error is not detected if the I bit for the command stream is 1 at decoding time. (This is because the internal counter is forcibly set to the specified value in the command stream.) This error is not detected at encoding time.
01	10	H'03	When a command stream was used for decoding, the VOP last macroblock (lower right) was not detected in the last slice.
01	10	H'04	At decoding time, an attempt was made to process a macroblock larger than a range of screen sizes, and the slice was ignored.
01	10	H'05	When a command stream was used for decoding, the processing was completed without the command for the last slice.
01	11	H'3D	When operation for a channel could not continue, LDMAC write buffer full status was detected in that channel. (Write buffer overflow)
01	11	H'3E	Abnormal command was detected in a command stream.
01	11	H'3F	Abnormal word count was detected in a command stream. (Up to 1023 command words/slice)

Table 27.16 Error Codes (H.264 Processing)

ESRC	ELVL	ERC	Error description
10	10	H'01	The mb_skip_run value exceeded the number of remaining MBs.
10	10	H'02	The mb_type value exceeded the specifiable range.
10	10	H'03	The sub_mb_type value exceeded the specifiable range.
10	10	H'04	The intra_chroma_pred_mode value exceeded the specifiable range.
10	10	H'05	The ref_idx value exceeded the specifiable range.
10	10	H'06	The mvd value exceeded the specifiable range.
10	10	H'08	The coded_block_pattern value exceeded the specifiable range.
10	10	H'09	The mb_qp_delta value exceeded the specifiable range.
10	10	H'0A	A bit row not found in the table was specified for coeff_token.
10	10	H'0B	A value out of the correct range was specified for total_coeff.
10	10	H'0C	The level value exceeded the specifiable range.
10	10	H'0D	A bit row not found in the table was specified for total_zeros.
10	10	H'0E	A value out of the correct range was specified for total_zeros.
10	10	H'0F	A bit row not found in the table was specified for run_before.
10	10	H'10	A value out of the correct range was specified for run_before.
10	01	H'11	An illegal value was specified for pcm_alignment_zero_bit.
10	01	H'12	An illegal value was specified for rbsp_stop_one_bit or rbsp_alignment_zen_bit.
11	01	H'01	An illegal value was specified for cabac_alignment_one_bit.
11	10	H'02	The ref_idx value exceeded the specifiable range.
11	10	H'03	The mvd value exceeded the specifiable range.
11	10	H'05	The mb_qp_delta value exceeded the specifiable range.
11	10	H'06	The level value exceeded the specifiable range.
10	10	H'07	An illegal value was specified for end_of_slice_flag.
11	01	H'08	An illegal value was specified for pcm_alignment_zero_bit.
11	01	H'09	An illegal value was specified for rbsp_stop_one_bit or rbsp_alignment_zero_bit.
10	11	N/A	The intermediate stream was illegal at encoding time. Not enough buffer space might be available to read necessary data. The ERC value is for debugging. Not for the end user.

ESRC	ELVL	ERC	Error description
10	01	H'02	The code amount per MB exceeded the specified value at encoding time.
11	11	H'01	The intermediate stream was illegal at encoding time (i.e., during CABAC processing). Not enough buffer space might be available to read necessary data.
11	01	H'02	The code amount per MB exceeded the specified value at encoding time (i.e., during CABAC processing).

Table 27.17 Error Codes (MPEG-2/MPEG-1 Processing)

ESRC	ELVL	ERC	Error description
10	10	H'01	An illegal value was specified for slice_start_code.
10	10	H'02	An illegal value was specified for quantiser_scale_code.
10	10	H'03	The macroblock address exceeded the number of macroblock in a picture.
10	10	H'04	A bit row not found in the table was specified for macroblock_address_increment.
10	10	H'05	A bit row not found in the table was specified for macroblock_type.
10	10	H'06	frame_motion_type/field_motion_type value exceeded the specifiable range.
10	10	H'07	A bit row not found in the table was specified for motion_code.
10	10	H'08	A bit row not found in the table was specified for coded_block_pattern.
10	10	H'09	A bit row not found in the table was specified for the DC coefficient of a non-intra MB. .
10	10	H'0A	The AC coefficient value exceeded the specifiable range.
10	10	H'0B	A bit row not found in the table was specified for the AC coefficient.
10	10	H'0C	The LEVEL value of ESCAPE code was specified 0 (setting 0 is prohibited).
10	10	H'0D	slice_vertical_position is incorrect.
10	01	H'10	marker_bit was not a correct value.
10	01	H'11	The size had been GetBit was exceeded the slice size which was specified by the slice parameter.
10	01	H'12	A non-zero value exists in byte alignment.

ESRC	ELVL	ERC	Error description
10	11	N/A	The intermediate stream was illegal at encoding time. Not enough buffer space might be available to read necessary data. The ERC value is for debugging. Not for the end user.

Table 27.18 Error Codes (MPEG-4/H.263 Processing)

ESRC	ELVL	ERC	Error description
10	10	H'01	mcbpc exceeded the specifiable range.
10	10	H'02	mb_type(B) exceeded the specifiable range.
10	10	H'03	cbpy(intraMB) exceeded the specifiable range.
10	10	H'04	cbpy(interMB) exceeded the specifiable range.
10	10	H'05	cbpb exceeded the specifiable range.
10	10	H'06	horizontal_mv_data or vertical_mv_data was not found in the table.
10	10	H'07	dct_dc_size_luminance, dct_dc_size_chrominance were not found in the table.
10	10	H'08	AC coefficient of the intraMB was not found in the table.
10	10	H'09	AC coefficient of the interMB was not found in the table.
10	10	H'0a	escape type1 and type2 indicated the error, which was not found in the table.
10	10	H'0b	Indicated 64 coefficients were in per block.
10	10	H'0c	Indicated the VP header quantization parameter was 0.
10	10	H'0d	macroblock_number in VP didn't match with the location of MB at currently decoding.
10	10	H'0e	modulo_time_base was an illegal value. (0 was read 256 times or more, or contents didn't match with the one in VOP headder.)
10	10	H'0f	The vop_coding_type value in the VP did not match the vop_coding_type value in the VOP.
10	10	H'10	intra_dc_vlc_thr value in VP didn't match with the value of intra_dc_vlc_thr value in VOP.
10	01	H'11	vop_fcode_forward value in VP didn't match with the value of vop_fcode_forward in VOP.
10	01	H'12	vop_fcode_backward value in VP, modulo = time = basesaan didn't match with the value of vop_fcode_backward in VOP.
11	01	H'13	gob_number in gob_layer didn't match with GOB number at currently decoding.

ESRC	ELVL	ERC	Error description
11	10	H'14	The quantization parameter in gob_layer was 0.
11	10	H'15	At Data Partition (DP) decoding time, mcbpc exceeded the specifiable range.
11	10	H'16	At DP decoding time, cbpy(intraMB) exceeded the specifiable range.
11	10	H'17	At DP decoding time, cbpy(interMB) exceeded the specifiable range.
11	10	H'18	At DP decoding time, horizontal_mv_data or verticatl_mv_data were not found in the table.
11	01	H'19	At DP decoding time, dct_dc_size, dct_dc_size_chrominance were not found in the table.
11	01	H'1a	At RVLC decoding time, the second ESCAPE code was an illegal value.
10	11	H'1b	At DP decoding time, the number of MBs of DP3 were more than the number of MBs of video packet.
10	01	H'1c	DC marker was not detected at DP decoding time.
10	10	H'1d	At DP decoding time, MOTION marker was not detected.
10	10	H'1e	At DP decoding time, The number of MBs of DP3 were more than the number of MBs of video packet.
10	01	H'30	Marker bit was 0.
10	01	H'31	The coefficient was out of range in coefficient escape code processing.
10	01	H'32	DC coefficient was out of range in H.263 processing.
10	01	H'33	The size had been GetBit was exceeded the slice size specified by the slice parameter.
10	11	N/A	The intermediate stream was illegal at encoding time. Not enough buffer space might be available to read necessary data. The ERC value is for debugging. Not for the end user.
10	01	H'02	The video packet size exceeded the size specified by VP5_VLC_SH: word 16 at DP encoding time.
10	11	H'03	The DP buffer of VLC_S was overflow at DP encoding time. The stream might be got damages.

Table 27.19 Error Codes (VC-1 Processing)

ESRC	ELVL	ERC	Error description
10	10	H'01	cbpcy (I) was outside of the table range.
10	10	H'02	cbpcy (P, 1-MV) was outside of the table range.
10	10	H'03	cbpcy (P, 4-MV) was outside of the table range.
10	10	H'04	cbpcy (B) was outside of the table range.
10	10	H'05	bmvtype was illegal.
10	10	H'06	TTMB was outside of the table range.
10	10	H'08	TTBLK was outside of the table range.
10	10	H'0a	SUBBLKPAT was outside of the table range.
10	10	H'0a	MVDATA was outside of the table range.
10	10	H'10	There were 64 or more coefficients in a single block.
10	10	H'11	The DC coefficient was outside of the table range.
10	10	H'12	When the AC coefficient was Escape code, an Escape code was furthermore included.
10	10	H'13	The mode of coefficient Escape was outside of the table range.
10	10	H'14	The AC coefficient for Escape was outside of the table range.
10	10	H'15	Run or Level for Escape was outside of the table range.
10	01	H'16	The AC coefficient of the inter MB was outside of the table range.
10	10	H'17	The coefficient value of Escape Type 3 was 0.
10	10	H'18	The MQUANT range exceeded the range between 1 and 31.
10	10	H'19	The ABSMQ value was 0.
10	10	H'30	SLICE_ADDR was illegal (Advanced Profile) or Syncmarker was illegal (Simple/Main Profile).
10	01	H'33	The GetBit size exceeded the slice size specified by the slice parameter.

37.2.35 Intermediate Stream Bit Count Register 0 (VP5_VLC_INT_TB0)

The VP5_VLC_INT_TB0 register indicates the number of bits in an intermediate stream for CE0. This register becomes valid after the completion of decoding or .

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	VB[26:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VB[26:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 0	VB1[26:0]	All 0	R	Intermediate Stream Number of 1-bit Indicates the number of 1-bit in intermediate stream. (H'000 0000 to H'7FF FFFF)

37.3 VPU5HG Internal Register Descriptions

The VPU5HG internal registers are 64-bit access registers configured by the initialization routine. Before starting the VPU5HG, values should be stored in the predetermined format shown in section 6.2.2 in the external memory. For operation involving the two CEs, the initialization routine uses two channels: GDMAC channel 0 and channel 1. For operation involving one of these CEs, the initialization routine uses only GDMAC channel 0. Specify the values in the format for each channel in the order shown in this manual. A failure to follow this order might cause a malfunction. If any registers need not be set, it is not problematic to skip the registers while specifying the values. Note that the VPU5HG internal registers might be updated by the VPU5HG during operation. Even if the settings for these registers are the same as before, be sure to reset these registers.

VP5_BAAR0 and VP5_BAAR1 should be set when starting the picture processing module (CE) or code processing module (VLCS) according to the setting category shown in table 27.20 and 27.28. Registers with names which are prefixed with "VP5_CE" should be set when starting the CE. Registers with names which are prefixed with "VP5_VLC" should be set when starting the VLCS.

37.3.1 Base Address Array Register 0 (VP5_BAAR0)

This register specifies the base address of external memory which the VPU5HG should access. The parameters in this register are required when starting the VLCS or CE. Table 27.20 lists the specifiable base addresses.

Common bit fields are available for the base addresses shown in table 27.20.

Table 27.20 Description of Base Address Array 0

No.	Address Offset	Setting Category	Associated DMA Channel	Description	Remarks
8	H'040	CE	DECY0	Decode picture luminance base address	
9	H'048	CE	DECC0	Decode picture chrominance base address	
10	H'050	CE	DECBY0	Decode picture luminance base address (bottom field)	For frame structure and field picgure arrangement only
11	H'058	CE	DECBC0	Decode picture chrominance base address (bottom field)	For frame structure and field picgure arrangement only
12	H'060	CE	TMPY0	Encode picture luminance base address	For encoding which involves one CE only

Table 27.21 VP5_BAAR0 Bit Fields

Bit	Name	Setting value	Description
63 to 32	BAA	Base address	32-bit base address. The smallest unit of external memory accessed at once by the VPU5HG is eight bytes. Be sure to set the low-order three bits for the address specified in BAAR to 0. The unit of alignment might be 32 bytes or more depending on the base address. Specify the base address according to the alignment.
31 to 0	reserved	Reserved	Reserved

In encoding and decoding, the intermediate stream and the intermediate stream control base address should be specified according to the case listed as follows.

At the time of 2-CE encoding, CE output address is specified in the base address of the intermediate stream and the intermediate stream control to be set in VLCS as follows.

VP5_BAAR0.CEIS0 → VP5_BAAR1.VLIS1

VP5_VAAR0.CEIC0 → VP5_BAAR1.VLIC1

VP5_BAAR1.CEIS1 → VP5_BAAR0.VLIS0

VP5_BAAR1.CEIC1 → VP5_BAAR0.VLIC0

At the time of 1-CE encoding (in MPEG-4/H.263 format only), CE output address is specified in the base address of the intermediate stream and the intermediate stream control to be set in VLCS as follows.

VP5_BAAR0.CEIS0 → VP5_BAAR0.VLIS0

VP5_BAAR0.CEIC0 → VP5_BAAR0.VLIC0

At decoding time, VLCS output address is specified in the base address of the intermediate stream and the intermediate stream control to be set CE as follows.

VP5_BAAR0.VLIS0 → VP5_BAAR0.CEIS0

VP5_BAAR0.VLIC0 → VP5_BAAR0.CEIC0

VP5_BAAR1.VLIS1 → VP5_BAAR1.CEIS1

VP5_BAAR1.VLIC1 → VP5_BAAR1.CEIC1

In encoding and decoding, the MV information base address should be specified according to the case listed as follows.

At the time of 2-CE encoding time, MV information base address is specified as follows.

Anchor flame: VP5_BAAR0.MVINFO0 → VP5_BAAR1.MVR1

Anchor flame: VP5_BAAR0.MVINFOB0 → VP5_BAAR1.MVRB1

Anchor flame: VP5_BAAR1.MVINFO1 → VP5_BAAR0.MVR0

Anchor flame: VP5_BAAR1.MVINFOB1 → VP5_BAAR0.MVRB0

At the time of 1-CE encoding (in MPEG-4/H.263 format only), MV information base address is specified as follows.

Anchor flame: VP5_BAAR0.MVINFO0 → VP5_BAAR0.MVR0

At decoding time, MV information base address is specified as follows.

Anchor flame: VP5_BAAR0.MVINFO0 → VP5_BAAR0.MVR0

Anchor flame: VP5_BAAR0.MVINFOB0 → VP5_BAAR0.MVRB0

Anchor flame: VP5_BAAR1.MVINFO1 → VP5_BAAR1.MVR1

Anchor flame: VP5_BAAR1.MVINFOB1 → VP5_BAAR1.MVRB1

Figure 27.2 shows how to set reference picture addresses for MPEG-2/MPEG-4/H.263 decoding.

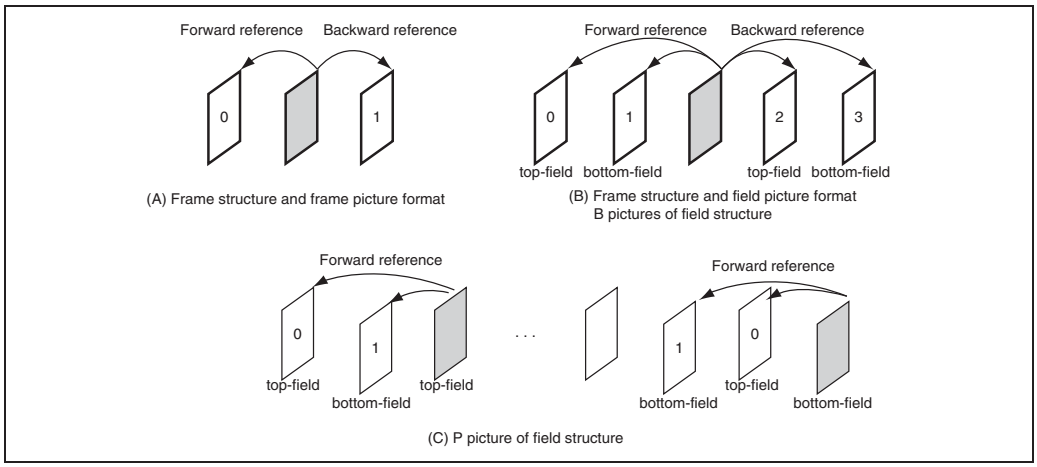

Figure 27.2 Setting Reference Picture Addresses for MPEG2/MPEG4/H.263 Decoding

For MPEG-4/H.263 processing, set the addresses by associating the numbers shown in figure 27.2 with reference picture address n (n = 0, 1) for items 64 through 67 in table 27.20.

In the case of MPEG-2, the method for reference picture address setting varies depending on the structure (frame/field) of streams to be decoded and on the format (frame/field) of pictures in external RAM. For the frame structure and frame picture format, this method is the same as that for MPEG-4 processing. For the frame structure and field picture format or for B pictures of field structure, there are up to four reference pictures as shown in figure 27.2 and thus set the addresses by associating the numbers shown in figure 27.2 with reference picture address n (N = 0, 1, 2, 3) for items 64 through 71 in table 27.20. For P pictures of field structure, be sure to set the last decoded top and bottom fields as shown in figure 27.2.

Figure 27.3 shows how to set reference picture addresses for VC-1 decoding.

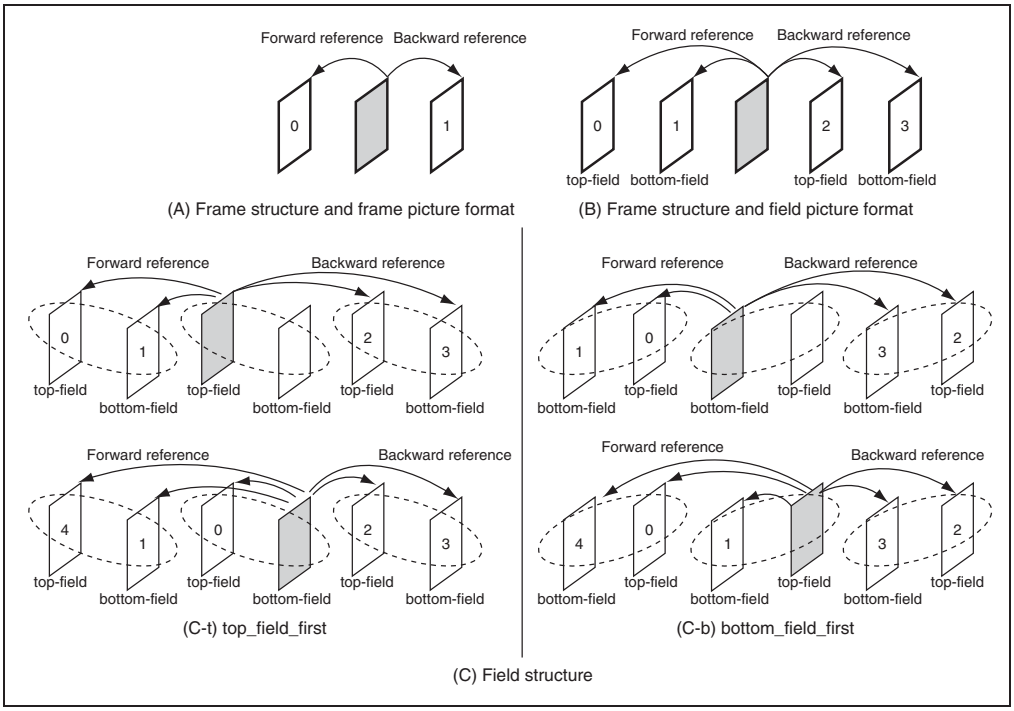

Figure 27.3 Setting Reference Picture Addresses for VC-1 Decoding

In the case of VC-1, the method for reference picture address setting varies depending on the structure (frame/field) of streams to be decoded and on the format (frame/field) of pictures in external RAM. For the frame structure (figure 27.3), this method is the same as that for MPEG-2 processing. For the field structure, there is a need for five reference pictures (three for P pictures) as shown in figure 27.3 and thus set the addresses by associating the numbers shown in figure 27.3 with reference picture address n (n = 0, 1, 2, 3, 4) for items 64 through 73 in table 27.20.

For B picture field encoding, set the references so that the same parity is used for reference.

37.3.2 Decode Luminance Picture DMA Channel Register 0 (VP5_CE_DCHR_DECY0)

This register specifies the operation of the DMA channel (DECY0) to output decode luminance pictures or local decode luminance pictures. The parameters in this register are required when starting the CE.

Bit	Name	Setting value	Description
63 to 48	(reserved)	H'D000	Always set to this value.
47 to 43	(reserved)	0	Always set to this value.
42 to 32	hsize		Horizontal size of the picture area. (The bits are set to a value rounded up to a multiple 16 and divided by 8.) Set the bits to twice the horizontal size of the picture area size when storing frame pictures in external memory for field encoding/decoding.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	4	Set to 4 for the VPU5HG.
8 to 0	(reserved)	8	Always set to this value.

Bits 15:13 make endian settings. Bit 15 specifies interchanging data in byte units, bit 14 interchanging data in word (16-bit) units, and bit 13 interchanging data in long-word (32-bit) units. Similar bit specifications are given for the other DMA channels.

Table 27.22 DMA Channel Register Endian Settings

Bits 15 to 13			
B	**W**	**LW**	**Byte Order**
0	0	0	12345678 (Big endian)
0	0	1	56781234
0	1	0	34127856
0	1	1	78563412
1	0	0	21436587
1	0	1	65872143
1	1	0	43218765
1	1	1	87654321 (Little endian)

37.3.3 Decode Chrominance Picture DMA Channel Register 0 (VP5_CE_DCHR_DECC0)

This register specifies the operation of the DMA channel (DECC0) to output decode chrominance pictures or local decode chrominance pictures. The parameters in this register are required when starting the CE.

Bit	Name	Setting value	Description
63 to 48	(reserved)	H'D000	Always set to this value.
47 to 43	(reserved)	H'0	Always set to this value.
42 to 32	hsize		Horizontal size of the picture area. (The bits are set to a value rounded up to a multiple 16 and divided by 8.) Set the bits to twice the horizontal size of the picture area size when storing frame pictures in external memory for field encoding/decoding.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	4	Set to 4 for the VPU5HG.
8 to 0	(reserved)	9	Always set to this value.

37.3.4 Filter Luminance Picture DMA Channel Register 0 (VP5_CE_DCHR_DISPY0

This register specifies the operation of the DMA channel (DISPY0) to output filter luminance pictures. The parameters in this register are required when starting the CE using at MPEG-1/-2/-4 or H.263. They are also required when starting the CE for VC-1 RangeReduction or RangeMapping stream decoding.

Bit	Name	Setting value	Description
(reserved)	63 to 48	H'D000	Always set to this value.
(reserved)	47 to 43	All 0	Always set to this value.
hsize	42 to 32		Horizontal size of the picture area. (The bits are set to a value rounded up to a multiple 16 and divided by 8.) Set the bits to twice the horizontal size of the picture area size when storing frame pictures in external memory for field encoding/decoding.
(reserved)	31 to 16	All 0	Always set to this value.
endian	15 to 13	0 to 7	Endian. (Refer to table 27.22)
src_offset	12 to 9	5	Set to 5 for the VPU5HG.
(reserved)	8 to 0	32	Always set to this value.

37.3.5 Filter Chrominance Picture DMA Channel Register 0 (VP5_CE_DCHR_DISPC0)

This register specifies the operation of the DMA channel (DISPY0) to output filter chrominance pictures. The parameters in this register are required when starting the CE using at MPEG-1/-2/-4 or H.263. They are also required when starting the CE for VC-1 RangeReduction or RangeMapping stream decoding.

Bit	Name	Setting value	Description
(reserved)	63 to 48	H'D000	Always set to this value.
(reserved)	47 to 43	All 0	Always set to this value.
hsize	42 to 32		Horizontal size of the picture area. (The bits are set to a value rounded up to a multiple 16 and divided by 8.) Set the bits to twice the horizontal size of the picture area size when storing frame pictures in external memory for field encoding/decoding.
(reserved)	31 to 16	All 0	Always set to this value.
endian	15 to 13	0 to 7	Endian. (Refer to table 27.22)
src_offset	12 to 9	5	Set to 5 for the VPU5HG.
(reserved)	8 to 0	33	Always set to this value.

37.3.6 Reference Picture DMA Channel Register (VP5_CE_DCHR_REF)

This register specifies the operation of the DMA channel (REF) to read reference pictures (references). The parameters in this register are required when starting the CE. There is not always a need to set this register for I pictures. Setting it for I pictures is only necessary if decoding involves inter-error concealment (i.e., VP5_CE_VLCF.ec_mode = 1).

Bit	Name	Setting value	Description
63 to 48	(reserved)	H'B000	Always set to this value.
47 to 43	(reserved)	H'0	Always set to this value.
42 to 32	hsize		Horizontal size of the picture area. (The bits are set to a value rounded up to a multiple 16 and divided by 8.) Set the bits to twice the horizontal size of the picture area size when the reference pictures are stored as frame pictures in external memory for field encoding/decoding.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	1	Set to 1 for decoding and 15 for encoding.
8 to 0	(reserved)	0	Always set to this value.

37.3.7 Encode Picture DMA Channel Register 0 (VP5_CE_DCHR_TMP0)

This register specifies the operation of the DMA channel (TMP0) to read encode pictures (templates) when encoding involves one CE. The parameters in this register are required when starting the CE. Setting these parameters is unnecessary for decoding.

For encoding which involves the two CEs, use VP5_CE_DCHR_TMP1 only.

Bit	Name	Setting value	Description
63 to 48	(reserved)	H'B000	Always set to this value.
47 to 43	(reserved)	0	Always set to this value.
42 to 32	hsize	64, 128, 256	Horizontal size of the picture area. (The bits are set to a value rounded up to a multiple 16 and divided by 8.) Set the bits to twice the horizontal size of the picture area size when the encode pictures are stored as frame pictures in external memory for field encoding/decoding.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian (refer to table 27.22.)
12 to 9	src_offset	0	Set to 0.
8 to 0	(reserved)	0	Always set to this value.

37.3.8 MV Information Output DMA Channel Register 0 (VP5_CE_DCHR_MVINFO0)

This register specifies the operation of the DMA channel (MVINFO0) to output MV information. The parameters in this register are required when starting the CE. Do not set this register when outputting no MV information.

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'C000 0000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	6	Set to 6 for the VPU5HG.
8 to 0	(reserved)	18	Always set to this value.

37.3.9 MB Odd Line MV Information DMA Channel Register 0 (VP5_CE_DCHR_MVINFOB0)

In H.264 PIC-AFF, this register specifies the operation of the DMA channel (MVINFO0) to output MB odd line MV information. The parameters in this register are required when starting the CE. Setting is not necessary when MV information is not to be output.

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'C000 0000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	6	Set to 6 for the VPU5HG.
8 to 0	(reserved)	19	Always set to this value.

37.3.10 Anchor Picture MV Information DMA Channel Register 0 (VP5_CE_DCHR_MVR0)

This register specifies the operation of the DMA channel (MVR0) to read anchor picture MV information. At encoding mode time, the register setting is executed at the same time with accessing to the external memory. So that the setting is prohibited when the anchor picture MV information is not used.

- Setting for decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'0890 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	7	Set to 7 for the VPU5HG.
8 to 0	(reserved)	20	Always set to this value.

- Setting for encoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'8890 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	7	Set to 7 for the VPU5HG.
8 to 0	(reserved)	20	Always set to this value.

37.3.11 Anchor Picture MB Odd Line MV Information DMA Channel Register 0 (VP5_CE_DCHR_MVRB0)

In H.264 PIC-AFF or MB-AFF, this register specifies the operation of the DMA channel (MVRB0) to read anchor picture MV information of MB odd line. At encoding time, the register setting is executed at the same time with accessing to the external memory. So that the setting is prohibited when the anchor picture MV information is not used.

- Setting for decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'0898 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	7	Set to 7 for the VPU5HG.
8 to 0	(reserved)	21	Always set to this value.

- Setting for encoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'8898 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	7	Set to 7 for the VPU5HG.
8 to 0	(reserved)	21	Always set to this value.

37.3.12 CE Intermediate Stream DMA Channel Register 0 (VP5_CE_DCHR_CEIS0)

This register specifies the operation of the DMA channel (CEIS0) which allows the CE to input/output intermediate streams. The parameters in this register are required when starting the CE.

- Setting for decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'8880 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	8	Set to 8 for the VPU5HG.
8 to 0	(reserved)	22	Always set to this value.

- Setting for encoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'C000 0000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	8	Set to 8 for the VPU5HG.
8 to 0	(reserved)	22	Always set to this value.

37.3.13 CE Intermediate Control Stream DMA Channel Register 0 (VP5_CE_DCHR_CEIC0)

This register specifies the operation of the DMA channel (CEIC0) which allows the CE to input/output intermediate control streams. The parameters in this register are required when starting the CE.

- Setting for decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'8888 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	8	Set to 8 for the VPU5HG.
8 to 0	(reserved)	23	Always set to this value.

- Setting for encoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'C000 0000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	8	Set to 8 for the VPU5HG.
8 to 0	(reserved)	23	Always set to this value.

37.3.14 Stream A DMA Channel Register (VP5_VLC_DCHR_STRA)

This register specifies the operation of the DMA channel (STRA) which allows the VLCS to input/output streams. The parameters in this register are required when starting the VLCS.

- Setting for decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'08A0 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	10	Set to 10 for the VPU5HG.
8 to 0	(reserved)	24	Always set to this value.

- Setting for encoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'C000 0000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	10	Set to 10 for the VPU5HG.
8 to 0	(reserved)	24	Always set to this value.

37.3.15 Stream B DMA Channel Register (VP5_VLC_DCHR_STRB)

At decoding time, this register specifies the operation of the DMA channel (STRB), which allows VLCS to read the stream. The parameters in this register are required when starting the VLCS.

- Setting for decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'08A8 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	10	Set to 10 for the VPU5HG.
8 to 0	(reserved)	25	Always set to this value.

37.3.16 Command Stream DMA Channel Register (VP5_VLC_DCHR_CMDS)

For decoding, this register specifies the operation of the DMA channel (CMDS) to read command streams for decoding.The parameters in this register are required when starting the VLCS.

- Setting for decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'88B0 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	10	Set to 10 for the VPU5HG.
8 to 0	(reserved)	26	Always set to this value.

37.3.17 VLCS Data Partition DMA Channel Register (VP5_VLC_DCHR_BPDP)

This register specifies the operation of the DMA channel (BPDP), which allows the VLCS to read the data partition information, bit plane information and MapColtolist information. The parameters in this register are required when starting the VLCS.

Set this register for MPEG-4 data partition decoding/VC-1 decoding/H.264MapColtoList setting.

- Setting for decoding (H.264)

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'08B8 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	10	Set to 10 for the VPU5HG.
8 to 0	(reserved)	27	Always set to this value.

- Setting for decoding (MPEG-4)

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'08A8 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	15	Set to 15 for the VPU5HG.
8 to 0	(reserved)	27	Always set to this value.

- Setting for decoding (VC-1)

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'08A8 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	10	Set to 10 for the VPU5HG.
8 to 0	(reserved)	27	Always set to this value.

37.3.18 VLCS Intermediate Stream DMA Channel Register 0 (VP5_VLC_DCHR_VLIS0)

This register specifies the operation of the DMA channel (VLIS0) which allows the VLCS to input/output intermediate streams. The parameters in this register are required when starting the VLCS.

- Setting for decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'C000 0000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	9	Set to 9 for the VPU5HG.
8 to 0	(reserved)	28	Always set to this value.

- Setting for encoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'88A0 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	9	Set to 9 for the VPU5HG.
8 to 0	(reserved)	28	Always set to this value.

37.3.19 VLCS Intermediate Control Stream DMA Channel Register 0 (VP5_VLC_DCHR_VLIC0)

This register specifies the operation of the DMA channel (VLIC0) which allows the VLCS to input/output intermediate control streams. The parameters in this register are required when starting the VLCS.

- Setting for decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'C000 0000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	9	Set to 9 for the VPU5HG.
8 to 0	(reserved)	29	Always set to this value.

- Setting for encoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'88A8 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	9	Set to 9 for the VPU5HG.
8 to 0	(reserved)	29	Always set to this value.

37.3.20 VLCS Co-location Not Coded DMA Channel Register (VP5_VLC_DCHR_CLNC)

This register specifies the operation of the DMA channel (CLNC), which allows the VLCS to input/output the co-location not coded information. The parameters in this register are required when starting the VLCS.

- Setting for B-VOP (MPEG-4)

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'8898 7000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	13	Set to 13 for the VPU5HG.
8 to 0	(reserved)	30	Always set to this value.

- Setting for I-VOP, P-VOP(MPEG4)

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'C000 0000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	13	Set to 13 for the VPU5HG.
8 to 0	(reserved)	30	Always set to this value.

37.3.21 VLCS Data Partition Write DMA Channel Register (VP5_VLC_DCHR_DPW)

This register specifies the operation of the DMA channel (DPW), which allows the VLCS to write the data partition information. The parameters in this register are required when starting the VLCS.

- Setting for decoding (MPEG-4)

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'C000 0000	Always set to this value.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	14	Set to 14 for the VPU5HG.
8 to 0	(reserved)	31	Always set to this value.

37.3.22 GDMAC Operation Control Register (VP5_GDMAC_ARDPRI)

This register controls the internal operation of the GDMAC. The parameters in this register are required when starting the CE and VLCS. Do not change the settings when the CE or VLCS is active. Set the same value for the CE and VLCS.

The bits which are omitted here are reserved. They are set to 0.

- Bits Set for Decoding

Bit	Name	Setting value	Description
37 to 32	(reserved)	16	Always set to this value.

- Bits Set for Encoding

Bit	Name	Setting value	Description
37 to 32	(reserved)	0	Always set to this value.

37.3.23 GDMAC SHwy Arbitration Control Register (VP5_GDMAC_SHWARBT)

This register contains the arbitration settings when the GDMAC accesses the external memory via the SHwy. The parameters in this register are required when starting the CE and VLCS.The bits which are omitted here are reserved. They are set to 0.

Table 27.22 VP5_GDMAC_SHWARBT Bit Fields

Bit	Name	Setting value	Description
39 to 36	ratio	8	Always set to this value. Select 0 for encoding which involves one CE.

37.3.24 CE Sequence Level Control Register (VP5_CE_SPAR)

This register contains the CE control parameters. They are required when starting the CE. They are specified using the CE initialization routine. The bits in the grayed areas and bits which are omitted here are reserved. All these bits are set to 0.

Table 27.23 VP5_CE_SPAR Bit Fields

		Setting		
Name	**Bit**	DEC	ENC	**Description**
62	interlace	0, 1	0, 1	Specifies whether to perform field prediction. 0: Frame prediction 1: Frame/field prediction Table 27.20 shows the combinations of settings for interlacing. To encode B pictures, specify the same structure as that for anchor pictures.
61	field_pic_if	0, 1	0, 1	Field picture input/output flag. Specifies the format of pictures in external RAM. 0: Frame picture 1: Field picture Select 1 when frame pictures are encoded as field pictures or when field structure streams are decoded to output frame pictures. Table 27.20 shows the combinations of settings for interlacing.
60	mb_aff	0, 1	0, 1	For encoding: Specifies the use of adaptive frame/field prediction or frame/field DCT for each MB in frame pictures. Select 0 for H.264 processing. For decoding: Select 0 for processing non-H.264 content. Specify the picture structure for H.264 processing. 0: FLD/FRM 1: AFRM

Name	Bit	Setting		Description
		DEC	ENC	
59	entropy_coding_mode_flag	0, 1	0, 1	Information source encoding specification 0: CAVLC 1: CABAC
58	force_deblock	0, 1	0, 1	Post filter enable 0: Normal Operation 1: Deblock filtering applied (MPEG-1,-2,-4,H.263) Select 0 for encoding.
57	q_scale_type	0, 1	0, 1	Q scale type (MPEG2)
56	q_type	0, 1	0, 1	Quantization type 0: Quantization matrix is not used 1: Quantization matrix is used
54	frame_mbs_only_flag_inv	0, 1	0, 1	H.264: 0: Progressive sequence 1: Interlace sequence MPEG-2: (set same value with field_pic_if) 0: Frame picture 1: Field picture MGEG4/H.263: set to 0. When using VC-1; 0:Progressive 1:Interlace Frame and Interlace Field
53	monochrome	0, 1	0, 1	0: 420, 1: 400 (monochrome)
52	mb_aff_sequence	0, 1	0, 1	mb_adaptive_frame_field 0: Normal sequence 1: MB-AFF sequence
47	avc_profile	0, 1	0, 1	Specifies a profile 0: Baseline, Main 1: High

Name	Bit	Setting		Description
		DEC	ENC	
46	vc1_profile	0,1	0,1	Specifiles a profile 0:Simple,Main 1:Advance
44 to 40	num_ref_frames	0 to 16	0 to 16	Specifies num_ref_frames (for H.264). Select a non-zero value for B pictures.
44	Range_mapy	0, 1	—	Specify MSB for RANGE_MAPY for VC-1 processing.
39, 38	ce	0, 1	0, 1	Number of CEs 0: 1 1: 2 2/3: Reserved Usually, select 1. Select 0 only for encoding which involves one CE.
36	dec_out_disable	0, 1	0, 1	Local-decode picture output suppression 0: Output allowed 1: Output not allowed Select 0 for decoding.
34 to 32	stream_type			Stream type 0: MPEG-4 1: H.263 2: H.264 6: MPEG-2 7: MPEG-1)
31 to 24	mb_width			Horizontal macroblock count in MB units). (Includes the number of MBs distributed across the screen boundary if the horizontal pixel count is not a multiple of 16. Refer to table 27.24.

Name	Bit	Setting		Description
		DEC	ENC	
19 to 16	hsize_odd	0 to 15	0 to 15	For encoding: Set the horizontal picture size remainder (in pixel units). For decoding: Set to 0 for H.264, MPEG-2, VC-1 SP/MP.Set the horizontal picture size remainder (in pixel units) for MPEG-4, H.263,VC-1 AP.
15 to 8	mb_height			Vertical macroblock count (in MB units; Includes the number of MBs distributed across the screen boundary if the vertical pixel count is not a multiple of 16.) At encoding time: The associable minimum picture size is to be changed according to serch_range setting value of VP5_CE_CTRL. Refer to table 27.24.
3 to 0	vsize_odd	0 to 15	0 to 15	For encoding: Set the vertical picture size remainder (in pixel units). For decoding: Set to 0 for H.264, MPEG-2, VC-1 SP/MP.Set the vertical picture size remainder (in pixel units) for MPEG-4, H.263,VC-1 AP.

Table 27.23 Combinations of Interlace Parameter Settings

Mode	Standard	Encoding Method	Input/Output picture format	interlace	field_pic_if
Decoding	H.264	Progressive*4/ Frame	Frame	0	0
			Field	0	1
		Field	Frame	1	0
			Field	1	1
	MPEG4	Progressive*1	Frame	0	0
			Field	0	1
		Frame (Interlace)	Frame	0 (VP5_CE_SPAR) 1 (VP5_VLC_SPAR)	0
			Field	0 (VP5_CE_SPAR) 1 (VP5_VLC_SPAR)	1
	Others	Progressive*1/ Frame	Frame	0	0
			Field	0	1
		Field	Frame	1	0
			Field	1	1
Encoding	H.264	Progressive*1	Frame	0	0
		Field	Frame	1	1*2
			Field	1	1
	MPEG4	Progressive*1	Frame	0	0
		Frame (Interlace)	Frame	0 (VP5_CE_SPAR) 1 (VP5_VLC_SPAR)	0
	Others	Progressive*1	Frame	0	0
		Field	Frame	1	1*2
			Field	1	1
		Frame	Frame	0	0

Notes: When combined with ICB, progressive encoding stores only frame pictures and field encoding stores only field pictures.

1. Progressive encoding above means frame encoding which does not involve adaptive frame/field prediction for each MB.
2. Set twice hsize in VP5_CE_DCHR_DECY0/1, VP5_CE_DCHR_DECC0/1, VP5_CE_DCHR_REF and VP5_CE_DCHR_TMP1. In VP5_BAAP0/1, specify the picture base address as the start address of the field. That is, specify the position of the bottom field which is displaced one line from the top field.

37.3.25 CE Picture-Level Control Register (VP5_CE_PPAR)

This register contains the CE control parameters. They are required when starting the CE. They are specified using the CE initialization routine. Bits which are omitted here are reserved. The bits are set to 0.

Setting this register is unnecessary for decoding.

- H.264 Bit fields

Bit	Name	Setting value	Description
63 to 61	pic_type		Type of picture encoding 0: I 1: P 2: B
60 to 56	refidx_last0		Number of valid L0 reference planes. For P pictures, set to 0 (single reference) or 1 (multi-reference). For B pictures, set to 0 (single reference).
52 to 48	refidx_last1	0 to 31	Number of valid L1 reference planes. At encoding time, set to 0 (single reference)
47	bottom_field	0 to 1	Bottom field flag 0: Top field 1: Bottom field
46	col_field_pic	0, 1	Anchor picture field flag 0: Frame 1: Field
32	const_intra_pred	0, 1	constrained_intra_pred_flag. Fixedly set to 0 for encoding.
28 to 24	qp_c_offset0	(-12) to (+12)	qp_chroma_index_offset value (Cb for HighProfile)
23 to 19	qp_c_offset1	(-12) to (+12)	qp_chroma_index_offset value (Cr for HighProfile)
17, 16	deblock_filter_idc	0 to 2	disable_deblocking_filter_idc
15 to 12	alpha_offset	(-6) to (+6)	slice_alpha_c0_offset_div2
11 to 8	beta_offset	(-6) to (+6)	slice_beta_offset_div2

Bit	Name	Setting value	Description
7 to 4	motion_mb_h	(-3) – (+3)	Horizontal motion quantity (in MB units) Specifies in MB units the quantity of horizontal motion of the entire screen. If this is done for encoding PAN pictures, then a search is performed mostly along the motion direction, thereby improving the picture quality. If the quantity of motion of the entire screen is unknown, select 0. If the screen size is less than CIF (352 × 288), select 0. The specifiable values and associated fcode settings vary depending on the motion detection search range. Refer to table 27.24.
3 to 0	motion_mb_v	(-1) – (+1)	Vertical motion quantity (in MB units) Specifies in MB units the quantity of vertical motion of the entire screen. If this is done for encoding PAN pictures, then a search is performed mostly along the motion direction, thereby improving the picture quality. If the quantity of motion of the entire screen is unknown, select 0. If the screen size is less than CIF (352 × 288), select 0. The specifiable values and associated fcode settings vary depending on the motion detection search range. Refer to table 27.24.

- MPEG-2 /MPEG-1Bit Fields

Bit	Name	Setting value	Description
63 to 61	pic_type	0 to 2	Picture type 0: I 1: P 2: B
60 to 56	refidx_last0	0, 1	Subtract 1 from the number of valid L0 reference planes (Valid for encoding only). For P pictures, set to 0 (single reference) or 1 (multi-reference).

Bit	Name	Setting value	Description
52 to 48	refidx_last1	0 to 31	Subtract 1 from the number of valid L1 reference planes (Valid for encoding only). Set to 0 (single reference).
47	bottom_field	0, 1	Bottom field flag 0: Top field 1: Bottom field
33	alt_vscan	0, 1	alternate_vertical_scan
25	top_field_first	0, 1	0: Bottom field comes first 1: Top field comes first
24	concealment_motion_vector	0, 1	concealment_motion_vector
23	frame_pred_frame_dct	0, 1	frame_pred_frame_dct
22	intra_vlc_format	0, 1	MPEG-2 intra VLC table switching
21, 20	intra_dc_precision	0 to 2	MPEG-2 internal DC accuracy
7 to 4	motion_mb_h	(-3) – (+3)	Horizontal motion quantity (in MB units) Specifies in MB units the quantity of horizontal motion of the entire screen. If this is done for encoding PAN pictures, then a search is performed mostly along the motion direction, thereby improving the picture quality. If the quantity of motion of the entire screen is unknown, select 0. If the screen size is less than CIF (352 288), select 0. The specifiable values and associated fcode settings vary depending on the motion detection search range. Refer to table 27.24.

Bit	Name	Setting value	Description
3 to 0	motion_mb_v	(-1) – (+1)	Vertical motion quantity (in MB units) Specifies in MB units the quantity of vertical motion of the entire screen. If this is done for encoding PAN pictures, then a search is performed mostly along the motion direction, thereby improving the picture quality. If the quantity of motion of the entire screen is unknown, select 0. If the screen size is less than CIF (352 × 288), select 0. The specifiable values and associated fcode settings vary depending on the motion detection search range. Refer to table 27.24.

- MPEG-4/H.263 Bit Fields

Bit	Name	Setting value	Description
63 to 61	pic_fype	0 to 2	Picture type 0: I 1: P 2: B
60 to 56	refidx_last0	0	Subtract 1 from the number of valid L0 reference planes (Valid for encoding only). Set to 0 (single reference).
52 to 48	refidx_last1	0	Subtract 1 from the number of valid L1 reference planes (Valid for encoding only). Set to 0 (single reference).
45	runding_type	0, 1	vop_rounding_type
42	resync_marker	0, 1	Resync_marker_disable inversion value
41	data_partitioned	0, 1	DP ON/OFF
40	reversible_vlc	0, 1	RVLC ON/OFF
38 to 36	intra_dc_vlc_thr	0 to 7	Intra_dc_vlc_thr (specifies QP threshold value to switch VLCtable)

Bit	Name	Setting value	Description
33	alt_vscan	0, 1	Alternate_vertical_scan 0: zigzag scan 1: alternate scan
25	top_field_first	0, 1	0: bottom field is the initial field 1: top field is the initial field
7 to 4	motion_mb_h	(-3) – (+3)	Horizontal motion quantity (in MB units) Specifies in MB units the quantity of horizontal motion of the entire screen. If this is done for encoding PAN pictures, then a search is performed mostly along the motion direction, thereby improving the picture quality. If the quantity of motion of the entire screen is unknown, select 0. If the screen size is less than CIF (352 x 288), select 0. The specifiable values and associated fcode settings vary depending on the motion detection search range. Refer to table 27.24.
3 to 0	motion_mb_v	(-1) – (+1)	Vertical motion quantity (in MB units) Specifies in MB units the quantity of vertical motion of the entire screen. If this is done for encoding PAN pictures, then a search is performed mostly along the motion direction, thereby improving the picture quality. If the quantity of motion of the entire screen is unknown, select 0. If the screen size is less than CIF (352 x 288), select 0. The specifiable values and associated fcode settings vary depending on the motion detection search range. Refer to table 27.24.

37.3.26 Weighted Prediction Control Register (VP5_CE_ENC_WPRED)

This register is reserved. Set each item to 1.

Bit	Name	Setting value	Description
63 to 56	Reserved	1	Always set to 1.
55 to 48	Reserved	1	Always set to 1.
47 to 40	Reserved	1	Always set to 1.
39 to 32	Reserved	1	Always set to 1.
31 to 24	Reserved	1	Always set to 1.
23 to 16	Reserved	1	Always set to 1.

37.3.27 Encode Control Register (VP5_CE_ENC_CTRL)

This register contains the encode control parameters. These parameters are required when starting the CE for encoding. Bits which are omitted here are reserved. The bits are set to 0.

Bit	Name	Setting value	Description
60	ac_pred_off	0, 1	0: Enables AC prediction. 1: Disables AC prediction. Be sure to select 1 for MPEG-4 encoding which involves one CE.
56	transform_8 × 8	0, 1	8 × 8 conversion enable 0: Only 4 × 4 integer conversion used (for encoding with Baseline, Main profiles). 1: 4 × 4 or 8 × 8 integer conversion used (for encoding with High profiles)
55 to 48	intra_th_act	0 to 255	Intra/inter decision threshold 2 If the activity evaluation value for a macroblock exceeds this setting, it is determined to be an inter macroblock. intra_th_act takes preference over intra_th_high. (Recommended value: 255)
47 to 40	intra_th_high	0 to 65535	Intra/inter decision threshold 1 If the inter coding cost evaluation value (based on the Sum of Absolute Differences (SAD) for a macroblock exceeds this setting, it is determined to be an intra macroblock. (Recommended value: 32)
39 to 32	intra_th_offset	0 to 65535	Intra/inter decision offset Specifies the offset value for intra macroblock encoding cost. The greater this setting, the smaller the intra macroblock rate. (Recommended value: 64) Set to 0 when data is coded into a stream which complies with standards other than H.264.

Bit	Name	Setting value	Description
31 to 24	motion_pel_h	(-128)-(+127)	Horizontal motion quantity (in pixel units) Specifies in pixel units the quantity of horizontal motion of the entire screen. This improves the picture quality for encoding PAN pictures. If the quantity of motion of the entire screen is unknown, select 0. For P picture multi-referencing, it is recommended to specify the quantity of motion relative to the Ref0 reference picture. Select 0 for B pictures. The selected value should be consistent with VP5_CE_SPAR.motion_mb_h settings.
23 to 16	motion_pel_v	(-48)-(+47)	Vertical motion quantity (in pixel units) Specifies in pixel units the quantity of vertical motion of the entire screen. This improves the picture quality for encoding PAN pictures. If the quantity of motion of the entire screen is unknown, select 0. For P picture multi-referencing, it is recommended to specify the quantity of motion relative to the Ref0 reference picture. Select 0 for B pictures. The selected value should be consistent with VP5_CE_SPAR.motion_mb_v settings.
15	(reserved)	1	Always set to 1.

Bit	Name	Setting value	Description
12	dq_disable	0, 1	DQ disable 0: Controls the macroblock-level quantization parameters based on TM5 step 2. 1: Does not control the macroblock-level quantization parameters based on TM5 step 2. (Recommended.) Select 1 if a constant amount of code is required throughout the sequence when the line speed is fixed for wireless or other communication technologies. In this case, virtual buffer feedback control based on TM5 step 2 is provided. Note that the picture quality is not enhanced by activity picture quality control.
10	umv_disable	0, 1	UMV disable 0: Screen outside reference made 1: Screen outside reference not made Select 1 if data is coded into a stream which complies with the MPEG2 and H.263 Baseline standards; otherwise, select 0.
9	force_forward	0, 1	Forcible forward reference 0: Normal 1: Forcible forward reference
8	force_backward	0, 1	Forcible backward reference 0: Normal 1: Forcible backward reference

Bit	Name	Setting value	Description
6 to 4	search_range		Motion detection search range 0: ±16(HV) 1: ±32(HV) 2: ±32(H)±16(V) 3: ±64(H)±16(V) 4: ±64(H)±32(V) The specifiable motion detection search range varies depending on the picture type and the number of reference areas. Refer to tables 27.24 and 27.25. The minimum picture size supported varies depending on the settings. Refer to table 27.26.
1	ref_bottom_l0	0, 1	L0 reference picture bottom field flag 0: Top field 1: Bottom field Select the same parity field for B picture.
0	ref_bottom_l1	0, 1	L1 reference picture bottom field flag 0: Top field 1: Bottom field Select the same parity field for B picture.

Table 37.1 Relationship between the Motion Detection Search Ranges, Picture Types and Number of Reference Areas

	VP5_CE_PPAR	VP5_CE_ENC_CTRL
pic_type Setting	**refidx_last0 Setting**	**search_range Setting**
0 (I pictrure)	Don't care	Don't care
1 (P picture)	0 (single-reference)	0, 1, 2, 3, 4
	1 (multi-reference)	0, 2, 3
2 (B picture)	0 (single-reference)	0, 2, 3

Table 37.2 Settings by Motion Detection Search Range

Search Range	**search_range Settings (Motion Detection Search Range)**	
	P Picture (Single-reference)	**B or P Picture (Multi-reference)**
Narrow	0 (±16(HV))	0 (±16(HV))
Medium	1 (±32(HV))	2 (±32(H) ±16(V))
Wide	4 (±64(H) ±32(V))	3 (±64(H) ±16(V))

Table 27.26 Associated Minimum Picture Size Range in Every Motion Detection Search Range

Search_range Setting Value	**Motion detection Search Range**	**Associated Min. Picture size**
0	± ¥16 (HV)	80 × 80
1	±32 (HV)	80 × 80
2	±32 (H) ±16 (V)	80 × 80
4	±64 (H) ±32 (V)	144 × 80
Others	Reserved	Reserved

37.3.28 Activity Control Register (VP5_CE_ACQ_CTRL)

This register contains the picture quality control parameters which depend on the picture activities. The VPU5HG controls the quantization coefficient between q_min and q_max for activities of macroblock data to be coded. Bits which are omitted here are reserved. The bits are set to 0.

Bit	Name	Setting value	Description
61 to 56	q_max	0 to 51	Specifies the maximum quantization coefficient within a picture. Condition q_max >= q_min should always be satisfied.
53 to 48	q_min	0 to 51	Specifies the minimum quantization coefficient within a picture. Condition q_max >= q_min should always be satisfied.
42 to 32	act_avg	0 to 2040	Average activity value (recommended initial setting: 60) It is recommended to set the average activity value (calculated from VP5_CE_ASUM) for the previous frame.
26 to 16	act_max	0 to 2040	Maximum activity value (recommended initial setting: 40) It is recommended to set the maximum activity value (AMAX bit in the VP5_CE_ACT register) for the previous frame.
10 to 0	act_min	0 to 2040	Minimum activity value (recommended initial setting: 20) It is recommended to set the minimum activity value (AMIN bit in the VP5_CE_ACT register) for the previous frame.

37.3.29 Inter Mode Judgment Control Register (VP5_CE_ME_COST)

This register contains the parameters for determining the inter macroblock block sizes. It also contains clip values for quantization parameter changes between macroblocks. The VPU5HG selects the optimal block size based on the inter SAD and vector cost (evaluation value which is an estimated value of the amount of motion vector code). The inter SAD and vector cost weight are changed according to the quantization parameter. Bits which are omitted here are reserved. The bits are set to 0.

Bit	Name	Setting value	Description
53 to 48	cost_thq1	0 to 51	Threshold 1 for the scale factor for the amount of inter mode judgment motion vector code Upper limit on Q which sets Vector cost:Inter SAD = 4:1 (recommended value: 23) Set to 0 unless data is coded into a stream which complies with the H.264 standard.
45 to 40	cost_thq2	0 to 51	Threshold 2 for the scale factor for the amount of inter mode judgment motion vector code Upper limit on Q which sets Vector cost:Inter SAD = 8:1 (recommended value: 29) Set to 0 unless data is coded into a stream which complies with the H.264 standard.
37 to 32	cost_thq3	0 to 51	Threshold 3 for the scale factor for the amount of inter mode judgment motion vector code Upper limit on Q which sets Vector cost:Inter SAD = 16:1 (recommended value: 35) Set to 0 unless data is coded into a stream which complies with the H.264 standard.

Bit	Name	Setting value	Description
29 to 24	cost_Qthq4	0 to 51	Threshold 4 for the scale factor for the amount of inter mode judgment motion vector code Upper limit on Q which sets Vector cost:Inter SAD = 32:1 (recommended value: 41) Set to 0 unless data is coded into a stream which complies with the H.264 standard.
21 to 16	cost_thq5	0 to 51	Threshold 5 for the scale factor for the amount of inter mode judgment motion vector code Upper limit on Q which sets Vector cost:Inter SAD = 64:1 (recommended value: 46)If the quantization parameter exceeds the maximum of values cost_thq1 through cost_thq5, Vector cost:Inter SAD = 128:1 is used for processing. (Refer to figure 27.3.) Set to 0 unless data is coded into a stream which complies with the H.264 standard.
3 to 0	dq_clip	0 to 51	Clip value for the change in the quantization parameter 0: No limit 1-15: Limits the change in the quantization parameter between macroblocks. Set to 2 when data is coded into a stream which complies with the MPEG-4 or H.263 standard; otherwise, set to 0.

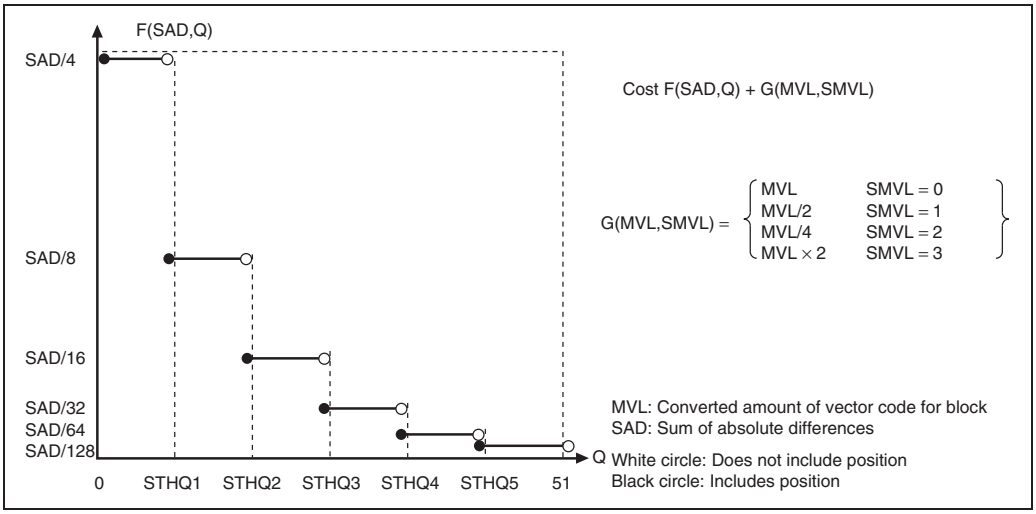

Figure 27.4 MB Partition Cost Calculation

37.3.30 VLCF Control Register (VP5_CE_VLCF)

This register sets the operational mode of VLCF.The parameters in this register are required when starting the CE. Bits which are omitted here are reserved. The bits are set to 0.

- Bit Fields for Encoding (H.264)

Bit	Name	Setting value	Description
29 to 24	slice_qp	0 to 51	pic_init_qp + slice_qp_delta
17 to 16	cabac_init_idc	0 to 2	cabac_init_idc
13 to 8	InitialQpY	0 to 51	InitialQpY(PPS : pic_init_qp)
2	Qnc_disable	0, 1	Always set to 1
1	mv_info	0, 1	MV information output specification 0: Information output 1: Information not output)

- Bit Fields for Encoding (MPEG-2/MPEG-4/H.263)

Bit	Name	Setting value	Description
29 to 24	InitialQpY	0 to 31	InitialQpY
23 to 20	fcode00	Described in the right column.	Specifies fcode[0][0] values MPEG-4 enc: 1 to 4(forward fcode is set) H.263 enc: 1 MPEG-1/-2 enc: 1 to 5 Others: Setting unnecessary
19 to 16	fcode01	Described in the right column.	Specifies fcode[0][1] values (For MPEG-4, forward fcode is set)
15 to 12	fcode10	Described in the right column.	Specifies fcode[1][0] values (For MPEG-4, forward fcode is set)
11 to 8	fcode11	Described in the right column.	Specifies fcode[1][1] values (For MPEG-4, forward fcode is set)

Bit	Name	Setting value	Description
2	qnc_disable	0, 1	Always set to 1.
1	mv_info	0, 1	Specifies the MV information output 0: The information is to be output. 1: The information is not to be output.

- Bit Fields for Decoding

Bit	Name	Setting value	Description
63 to 32	currPicOrderCnt	0 to 2,147,483,647	current PicOrderCnt (POC)
1	mv_info	0, 1	Specifies the MV information output 0: The information is to be output. 1: The information is not to be output.
0	ec_mode	0, 1	Error Conceal Mode Specification 0: Intra conceal (concealing in frame) In a frame, performs the conceal processing to the macroblock after an error generation. At decoding time in H.264, performs the pixel padding with the interpolated value calculated from the edge pixel value. When an error is generated at the upper-left block, performs the pixel padding with the intermediate value. The setting is only for H.264. For setting, use the inter conceal mode by specifying the reference picture address. 1:1 Inter Conceal (concealing between frames) Performs the switch processing the macroblock after an error generation to a skip macroblock, MV = (0, 0). This setting is enable when a reference image is specified even one picture. In B picture, use the direct mode.

Table 27.27 Motion Quantity and fcode Settings by Motion Detection Search Range

Search range	Element	H : motion_mb_h V : motion_mb_v	fcode Setting			
			MPEG-2		MPEG-4(H.263)	
			P Picture	B Picture	P Picture	B Picture
0 (±16 (HV))	H	0	2	←	1(1)	←
	V	0				
1 (±32 (HV))	H	0	3		2	
	V	0				
2 (±32 (H) ±16 (V))	H	-1	4	←	2 if motion_mb_h is 0, 3 otherwise.	←
		0	3	←		
		1	4	←		
	V	0	2	←		
3 (±64 (H) ±16 (V))	H	-3 to -1	5	←	3 if motion_mb_h is 0, 4 otherwise.	←

		1	4			
Other than above	Other than above	Other than above	Reserved		Reserved	

Set fcode[*][0] to the horizontal element (H) value. Set fcode[0][0] and fcode[1][0] to the same value.

Set fcode[*][1] to the vertical element (V) value. Set fcode[0][1] and fcode[1][1] to the same value.

37.3.31 Slice Size Register (VP5_CE_SLC_SIZE)

The VP5_CE_SLC_SIZE register controls the size of a slice or video packet. Bits which are omitted here are reserved. The bits are set to 0.

Bit	Name	Setting value	Description
59 to 48	psmb	0 to 68	Slice MB count (initial value: 0) Inserts the next slice or packet header when the number of MB lines exceeds the set value. If the value is 0, control with the number of MB lines is not provided. Set PSMB or PS to 0 for encoding with slices or video packets. In the case of MPEG-2, select 1.
46 to 32	ps	0 to 32, 767	Slice bit count (initial value: 0) Select 0 for encoding which involves the two CEs. For MPEG-4/H.263 encoding which involves one CE, calculate the intermediate-stream size in 16-bit units by using the target video packet size and specify the calculation result. When the intermeidate-stream size exceeds the set value of these bits, termination processing with the video packet size is performed (the actual output intermidate-stream size might exceed the set value in this register). If the value is 0, control with the number of MB lines is not provided. Any value from 1 through 32,767 (for 16 to 524,272 bits) can be specified. Set PSMB or PS to 0 for encoding with video packets.

Note: Intermediate-stream Size Calculation:
It is recommended to calculate the settings by using the formula below.
Target viedo packet size × 2/3 × R + 96
R = 1.00(I-VOP), 1.67(P-VOP), 2,00(B-VOP)

37.3.32 Target Bit Rate Control Register (VP5_CE_TBIT)

This register contains parameters for bit rate control. It does not need to be set when controlling the picture quality by activities. Bits which are omitted here are reserved. The bits are set to 0.

Bit	Name	Setting value	Description
44 to 32	mb_num	0 to 8,160	Macroblock count
15 to 0	mb_target	0 to 65,535	Target amount of coding per macroblock. This parameter specifies the target number of bits per macroblock for encoding. The setting should be the result of dividing the target bit count per picture by the macroblock count. The VPU5HG controls the quantization coefficient so the amount of coding per macroblock can become the bit count setting.

37.3.33 Virtual Buffer Control Register (VP5_CE_RCDJ)

This register contains parameters for bit rate control. It does not need to be set when controlling the picture quality by activities. Bits which are omitted here are reserved. The bits are set to 0.

Bit	Name	Setting value	Description
52 to 32	reac_param	1 to 2,2097,151	Reaction parameter. This parameter specifies 2 × Bit rate ÷ Frame rate.
31 to 0	rcdj	–2,147,483,658 to 2,147,483,657	Virtual buffer. This parameter specifies the singed value which indicates the amount of virtual buffer. The value should be a 2's complement number.

37.3.34 Intra Refresh Control Register (VP5_CE_MBRF)

This register controls the intra refresh of macroblock. Only a macroblock which is specified an intra macroblock start and end location is encoded to an intra macroblock. This register is valid only at encoding. Bits which are omitted here are reserved.

Bit	Name	Setting value	Description
63 to 56	irst_h	0 to 119	Specifies the intra refresh start macroblock horizontal location.
55 to 48	irst_v	0 to 67	Specifies the intra refresh start macroblock vertical location.
47 to 40	ired_h	0 to 119	Specifies the intra refresh end macroblock horizontal location.
39 to 32	ired_v	0 to 67	Specifies the intra refresh end macroblock vertical location.
31	ir_en	0, 1	Intra refresh enable

37.3.35 Inverse Quantization Matrix (VP5_CE_IQMAT)

This register specifies the quantization matrix for inverse quantization. The parameters in this register are required when starting the CE. For VPU5H processing, set the EMASK bit to H'10 by using the initial routine format.

Setting a 4 × 4 matrix is not necessary for processing non-H.264 content.

No.	Offset	Description	Remarks
0	000	Intra 4 × 4 luminance Y	Specifies the values in 8-bit units in ascending order for the matrix for big endian mode.
1	010	Intra 4 × 4 chrominance Cb	
2	020	Intra 4 × 4 chrominance Cr	
3	030	Inter 4 × 4 luminance Y	
4	040	Inter 4 × 4 chrominance Cb	
5	050	Inter 4 × 4 chrominance Cr	
6	060	Intra 8 × 8 luminance Y	
7	0A0	Inter 8 × 8 luminance Y	

37.3.36 Quantization Matrix (VP5_CE_QMAT)

This register specifies the reciprocal of the quantization matrix for inverse quantization. The parameters in this register are required when starting the CE. For VPU5H processing, set the EMASK bit to H'10 by using the initial routine format.

The range of specifiable quantization matrix values is from 6 to 255 for H.264 content and from 1 to 255 for non-H.264 content.

Setting a 4 x 4 matrix is unnecessary for processing non-H.264 content.

Calculate the reciprocal of a quantization matrix as follows.

[H.264]

IQmat (8-bit width, 8-bit accuracy) = Quantization matrix value

Qmat (16-bit width, 13-bit accuracy) = 8192 (= 2 U 13) / IQmat

/: Round down to the nearest integer

[MPEG-2 or MPEG-4]

IQmat (8-bit width, 8-bit accuracy) = Quantization matrix value

Qmat (16-bit width, 14-bit accuracy) = 8192 (= 2 U 13) // IQmat

//: Round off to the nearest integer

In VPUHG2, this register is used to set coefficient cut flags if the quantization type (VP5_CE_SPAR.q_type) is 0 for MPEG-4/H.263 encoding which involves one CE. Specify 0x0000 (invalid) and 0xFFFF (valid) in ascending order for the matrix. The coefficient in the position where 0x0000 is specified is forcibly encoded as 0. A separate coefficient cut flag should be set for each quantization type (intra or inter). For H.263 processing, be sure to set the DC position to 0xFFFF.

No.	Offset	Description	Remarks
0	000	Intra 4 × 4 luminance Y	Specifies the values in 16-bit units in ascending order for the matrix for big endian mode.
1	020	Intra 4 × 4 chrominance Cb	
2	040	Intra 4 × 4 chrominance Cr	
3	060	Inter 4 × 4 luminance Y	
4	080	Inter 4 × 4 chrominance Cb	
5	0A0	Inter 4 × 4 chrominance Cr	
6	0C0	Intra 8 × 8 luminance Y	
7	140	Inter 8 × 8 luminance Y	

37.3.37 CE Intermediate Stream 0 Buffer Size Register (VP5_CE_IS_BS0)

Bit	Name	Setting Value	Description
31 to 25	reserved	0	Reserved
24	CNT0	0, 1	Set to 1 when start-up the continue.
23 to 9	CIS0		CE intermediate stream 0 buffer size specification. This parameter specifies the intermediate stream 0 buffer size in 256-byte units (with the low-order eight bits being 0). For encoding, the CE stops writing after it has written intermediate stream 0 of the specified size. For decoding, the CE stops reading after it has read intermediate stream 0 of the specified size. In either case, it stops writing or reading and generates an interrupt. The interrupt is a CE error termination interrupt if the CIE0 bit in VP5_IRQ_ENB is 0 or a CE intermediate stream 0 buffer end interrupt if that bit is 1. The bits should be set before the start of the VPU5HG CE and after the generation of a CE intermediate stream 0 buffer end interrupt.
8 to 0	reserved	0	Reserved

37.3.38 FME0QNC0 Control Register (VP5_CE_FME0_QNC0)

This register controls the quantization parameter. This parameter is required for starting one CE for encoding. Select 0.

Bit	Name	Setting Value	Description
63 to 0	qnc	0	Always set to 1.

37.3.39 FME0QNC1 Control Register (VP5_CE_FME0_QNC1)

This register controls the quantization parameter. This parameter is required for starting one CE for encoding. Select 0.

Bit	Name	Setting Value	Description
63 to 0	qnc	0	Always set to 1.

37.3.40 TRF0QNC0 Control Register (VP5_CE_TRF0_QNC0)

This register controls the quantization parameter. This parameter is required for starting one CE for encoding. Select 0.

Bit	Name	Setting Value	Description
63 to 0	qnc	0	Always set to 1.

37.3.41 TRF0QNC1 Control Register (VP5_CE_TRF0_QNC1)

This register controls the quantization parameter. This parameter is required for starting one CE for encoding. Select 0.

Bit	Name	Setting Value	Description
63 to 0	qnc	0	Always set to 1.

37.3.42 VLCS Sequence Level Control Register (VP5_VLC_SPAR)

This register contains a parameter necessary for syntax interpretation by the VLCS STX. The parameter is required when starting the VLCS. The parameter should be specified using the VLCS initialization routine. Table 27.27 shows the bit fields. Bits which are omitted here are reserved. The bits are set to 0.

Table 27.27 VP5_VLC_SPAR Bit Fields

Name	Bit	Setting		Description
		DEC	ENC	
63	mode	01	0	Operation mode 0: Encoding 1: Decoding
62	interlace	0, 1	0, 1	Frame /field encoding method 0: Frame structure 1: Field structure For MPEG-4 processing, select one of the following: 0: Progressive encoding 1: Interlaced encoding Table 27.23 shows the combinations of interlace setting.

Name	Bit	Setting		Description
		DEC	ENC	
61	field_pic_if	0, 1	0, 1	Field picture input/output flag. Specifies the format for pictures in the external RAM. 0: Frame picture 1: Field picture Select 1 when the frame pictures are encoded as field pictures or when the field structure streams are decoded to output frame pictures. Table 27.23 shows the combinations of interlace settings.
60	mb_aff	0, 1	0, 1	For encoding: Specifies the use of adaptive frame/field prediction or frame/field DCT for each MB in frame pictures. Select 0 for H.264 processing. For decoding: Select 0 for processing non-H.264 content. Specify the picture structure for processing H.264 content. 0: FLD/FRM 1: AFRM
59	entropy_coding_mode_flag	0, 1	0, 1	Information source coding specification 0: CAVLC 1: CABAC
57	q_scale_type	0, 1	0, 1	Q scale type (MPEG2)
56	q_type	0, 1	0, 1	Quantization type When using H.264; 0: Quantization matrix not used 1: Quantization matrix used
54	frame_mbs_only_flag_inv	0, 1	0, 1	When using H.264; 0: Progressive sequence 1: Interlace sequence When using MPEG-2; (set same value with field_pic_if) 0: Frame picture

Name	Bit	Setting		Description
		DEC	ENC	
				1: Field picture
				When using MPEG-4,H.263; Set 0
				When using VC-1;
				0: Progressive
				1: Interlace Frame and Interlace Field
53	monochrome	0, 1	0, 1	0: 420, 1: 400 (monochrome
				e)
47	avc_profile	0, 1	0, 1	Specifies a profile
				0: Baseline, Main
				1: High
44 to 40	num_ref_frames	0 to 16	0 to 16	Specifies num_ref_frames (for H.264).
				Can only be set to 1 for interaction with VBLx.
39, 38	Ce	1	1	Always set to 1.
34 to 32	stream_type			Stream type
				0: MPEG4
				1: H.263
				2: H.264
				4: VC-1
				6: MPEG-2
				7: MPEG-1

Name	Bit	Setting		Description
		DEC	ENC	
31 to 24	mb_width			Horizontal macroblock count (in MB units). Includes MBs distributed across the screen boundary if the horizontal pixel count is not a multiple of 16.
19 to 16	hsize_odd	0 to 15	0 to 15	For encoding: Set the horizontal picture size remainder (in pixel units). For decoding: Set to 0 for H.264, MPEG-2, VC-1 SP/MP. Set the horizontal picture size remainder (in pixel units) for MPEG-4, VC-1 AP.
15 to 8	mb_height			Vertical macroblock count (in MB units; Includes the number of MBs distributed across the screen boundary if the vertical pixel count is not a multiple of 16.)
3 to 0	vsize_odd	0 to 15	0 to 15	For encoding: Set the vertical picture size remainder (in pixel units) For decoding:Set to 0 for H.264, MPEG-2, VC-1 SP/MP. Set the vertical picture size remainder (in pixel units) for MPEG-4, VC-1 AP.

37.3.43 VLCS Slice Header Register (VP5_VLC_SH)

The VPU5_VLC_SH register contains parameters for creating a slice header for H.264 encoding. The parameters in this register are required when starting the VLCS. They are set using the VLCS initialization routine. Bits which are omitted here are reserved. The bits are set to 0. Since the MPEG-2 header is byte aligned, setting in bit units is not necessary.

(1) VP5_VLC_SH Word 0

This parameter specifies the offset from the alignment position to the stream storage start position.

Bit	Name	Setting value	Description
4 to 0	offset_byte	0 to 31	Byte count for the stream storage start position offset. This parameter specifies the number of bytes from the alignment position to the stream storage start position. Starting first with VP5_VLC_SH word 1 to VP5_VLC_SH word 4 in sequence, store the words in the area from the alignment position to the stream storage start position.

(2) VP5_VLC_SH Word 1

Bit	Name	Setting value	Description
63 to 0	pad_bytes	0 to 31	Value to be stored in the area from the alignment position to the stream storage start position. (fill from MSB)

(3) VP5_VLC_SH Word 2

Bit	Name	Setting value	Description
63 to 0	pad_bytes		Value to be stored in the area from the alignment position to the stream storage start position. (fill from MSB)

(4) VP5_VLC_SH Word 3

Bit	Name	Setting value	Description
63 to 0	pad_bytes		Value to be stored in the area from the alignment position to the stream storage start position. (fill from MSB)

(5) VP5_VLC_SH Word 4

Bit	Name	Setting value	Description
63 to 0	pad_bytes		Value to be stored in the area from the alignment position to the stream storage start position. (fill from MSB)

(6) VP5_VLC_SH Word 5

- Bit Field (H.264)

Bit	Name	Setting value	Description
52 to 48	slice_header_size	0 to 31	High-order five bits for the slice header bit count (high-order five bits [8:4] for the slice_header bit count (byte count for the valid portions in VP5_VLC_SH words 6 through 13).
35 to 32	slice_header_size	0 to 15	Low-order four bits for the slice header size in bits (low-order four bits [3:0] for the slice_header bit count (valid portions in VP5_VLC_SH words 6 through 13)).
23 to 16	nal_unit_header		nal unit header (stream for the forbidden_zero_bit, nal_ref_idc and nal_unit_type portions)
0	start_code_insertion	0, 1	Start code (H'0000 0001) insertion in the position immediately before NAL. 0: Not inserted 1: Inserted)

- Bit Field (MPEG-4/H.263)

Bit	Name	Setting value	Description
52 to 48	slice_header_size	0 to 31	High-order five bits for the VOP header size in bits (high-order five bits [8:4] for the header bit count (byte count for the valid portions in VP5_VLC_SH words 6 through 13)).
35 to 32	slice_header_size	0 to 15	Low-order four bits for the VOP header size in bits (low-order four bits [3:0] for the header bit count (valid portions in VP5_VLC_SH words 6 through 13)).

(7) VP5_VLC_SH: Words 6 through 13

Bit	Name	Setting value	Description
63 to 0	slice_header		Slice header (which should be stored in big endian order). The emulation prevention byte can be inserted automatically. If the automatic insertion function is turned on, there is no need to insert the emulation prevention byte when setting this register. For H.264 processing, specify the area for slice_header() starting at slice_type and ending at a position immediately before cabac_init_idc (this area does not include cabac_init_idc). For MPEG-4 processing, specify the area for Video Object Plane up to a position immediately before motion_shape_texture(). For H.263 processing, specify the area for Video Plane with Short Header up to a position immediately before gob_layer().

(8) VP5_VLC_SH: Word 14

Bit	Name	Setting value	Description
63 to 0	PicSizeInMbs	1 to 8,160	Number of MBs in each picture

(9) VP5_VLC_SH: Word 16

Bit	Name	Setting value	Description
19 to 16	mb_num_bitlen	1 to 14	macroblock number bit length (setting only at MPEG-4 VP encoding)
15 to 0	dp_size_limit	0 to 65,535	Data Partition At encoding time, if VP exceeds the number of these bits, VLCS issues a warning to CTRL (Inevitable due to that 0 bit is synonymous with infinity, a warning is not issued).

37.3.44 VLCS Mode Register (VP5_VLC_MODE)

This register controls the VLCS operation. The parameters in this register are required when starting the VLCS. They are specified using the VLCS initialization routine. Bits which are omitted here are reserved. The bits are set to 0.

Bit	Name	Setting value	Description
36	Reserved	1	Always set to 1.
33, 32	Reserved	2	Always set to 2.
16	ParallelMode	0, 1	Parallel CE operation mode (for the VPU5H only) 0: 1-CE operation 1: 2-CE operation
12	ColInfoDir	0, 1	MPEG-4 collocation not-coded information stream transfer direction. 0: Read (B picture) 1: Write (I/P picture) Set to 0 for encoding or when the stream complies with other standards.
11	DPWEn	0, 1	MPEG-4 collocation not-coded information stream enable. 0: Disable 1: Enable Set to 0 for encoding or when the stream complies with other standards.
10	BPDPREn	0, 1	MPEG-4 data partition output stream enable. 0: Disable 1: Enable Set to 0 for encoding or when the stream complies with other standards.

Bit	Name	Setting value	Description
9	EPervDelEn	0, 1	H.264 MapColToList setting in MB units or units of MB lines/VC-1 bit plane/MPEG-4 data partition input stream enable. 0: Disable 1: Enable Set to 0 for encoding or when the stream complies with other standards.When using the DP, the DPWEn bit must be set to 1.When using the H.264 MapColToList, set the collist_proc_mode value of command stream word 1.
6	EPrevDelEn	0, 1	H.264 /VC-1 APemulation prevention byte deletion function. (0: Disable, 1: Enable) Select 0 for encoding or 1 for decoding.
5	EPrevInsEn	0, 1	H.264 emulation prevention byte insertion function. 0: Disable 1: Enable Select 0 for encoding or 1 for decoding.
4	CmdEn	0, 1	Command stream enable. Always select 1 for decoding. Select 0 for encoding.
3 to 0	Reserved	14	Set to 14.

37.3.45 Stream A Buffer Size Register (VP5_VLC_STRA_BS)

Bit	Name	Setting value	Description
32 to 24	reserved	0	Reserved
23 to 0	BVSA		Stream A buffer size specification. This parameter specifies the stream A buffer size in units of 256 bytes (with the low-order eight bits being 0). For encoding, the system stops writing after it has written a stream of the specified size. For decoding, the system stops reading after it has read a stream of the specified size. In either case, it stops writing or reading and generates an interrupt. The interrupt is a VLCS error termination interrupt if the VBAE bit in VP5_IRQ_ENB is 0 or a stream A buffer end interrupt if that bit is 1. The bits should be set before the start of the VPU5HG VLCS and after the generation of a stream A buffer end interrupt. For decoding, the stream A buffer size should be specified with command type 8 in the command stream (see section 23.6.2 (3), Command Stream, and thus this register's settings are ignored at activation time.

37.3.46 Stream B Buffer Size Register (VP5_VLC_STRB_BS)

Bit	Name	Setting value	Description
31 to 24	reserved	0	Reserved
23 to 0	VBSB		Stream B buffer size specification This parameter specifies the stream B buffer size in units of 256 bytes (with the low-order eight bits being 0). For decoding, the system stops reading after it has read a stream of the specified size. Also, it stops writing or reading and generates an interrupt. The interrupt is a VLCS error termination interrupt if the VBBE bit in VP5_IRQ_ENB is 0 or a stream B buffer end interrupt if that bit is 1. The bits should be set before the start of the VPU5HG VLCS and after the generation of a stream B buffer end interrupt. At activation time, the stream B buffer size should be specified with command type 8 in the command stream (see section 23.6.2 (3), Command Stream) and thus this register's settings at activation time are ignored.

37.3.47 VLCS Intermediate Stream 0 Buffer Size Register (VP5_VLC_IS_BS0)

Bit	Name	Setting value	Description
31 to 24	reserved	0	Reserved
23 to 0	VIS0		VLCS intermediate stream 0 buffer size specification. This parameter specifies the VLCS intermediate stream 0 buffer size in units of 256 bytes (with the low-order eight bits being 0). For encoding, the VLCS stops reading after it has read intermediate stream 0 of the specified size. For decoding, the VLCS stops writing after it has written intermediate stream 0 of the specified size. In either case, it stops writing or reading and generates an interrupt. The interrupt is a VLCS error termination interrupt if the VISE0 bit in VP5_IRQ_ENB is 0 or a VLCS intermediate stream 0 buffer end interrupt if that bit is 1. The bits should be set before the start of the VPU5HG VLCS and after the generation of a VLCS intermediate stream 0 buffer end interrupt.

37.3.48 VLCS Intermediate Stream 1 Buffer Size Register (VP5_VLC_IS_BS1)

Bit	Name	Setting value	Description
31 to 24	reserved	0	Reserved
23 to 0	VIS1		VLCS intermediate stream 1 buffer size specification. This parameter specifies the VLCS intermediate stream 1 buffer size in units of 256 bytes (with the low-order eight bits being 0). For encoding, the VLCS stops reading after it has read intermediate stream 1 of the specified size. For decoding, the VLCS stops writing after it has written intermediate stream 1 of the specified size. In either case, it stops writing or reading and generates an interrupt. The interrupt is a VLCS error termination interrupt if the VISE1 bit in VP5_IRQ_ENB is 0 or a VLCS intermediate stream 1 buffer end interrupt if that bit is 1. The bits should be set before the start of the VPU5HG VLCS and after the generation of a VLCS intermediate stream 0 buffer end interrupt.

37.3.49 GDMAC Base Address Array Register 1 (VP5_BAAR1)

This register specifies the base address so the VPU5HG can access the external memory. The parameters in this register are required when starting the VLCS or CE. Table 27.29 lists the specifiable base addresses. Common bit fields are available for the base addresses shown in the table 27.29.

Table 27.28 Description of Base Address Array 1

No.	Address offset	Setting category	Associated DMA channel	Description	Remarks
8	H'040	CE	DECY1	Decode picture luminance base address	
9	H'048	CE	DECC1	Decode picture chrominance base address	
10	H'050	CE	DECBY1	Decode picture luminance base address (bottom field)	For frame structure and field picture arrangement only
11	H'058	CE	DECBC1	Decode picture chrominance base address (bottom field)	For frame structure and field picture arrangement only
12	H'060	CE	TMP1	Encode picture luminance base address	For encoding only
13	H'068	CE	TMP1	Encode picture chrominance base address	For encoding only
18	H'090	CE	MVINFO1	MV information (write) base address	
19	H'098	CE	MVINFOB1	MV information (odd MB line) (write) base address	PIC-AFF/MB-AFF
20	H'0A0	CE	MVR1	Anchor picture MV information (read) base address	
21	H'0AB	CE	MVRB1	Anchor picture MV information (odd MB line) (read) base address	PIC-AFF/MB-AFF
22	H'0B0	CE	CEIS1	CE1 intermediate stream base address	

No.	Address offset	Setting category	Associated DMA channel	Description	Remarks
23	H'0B8	CE	CEIC1	CE1 intermediate control stream base address	
28	H'0E0	VLCS	VLIS1	VLCS intermediate stream base address	
29	H'0E8	VLCS	VLCI1	VLCS intermediate control stream base address	
32	H'100	CE	DISPY1	Filter picture luminance base address	
33	H'108	CE	DISPC1	Filter picture chrominance base address	
34	H'110	CE	DISPBY1	Filter picture luminance base address (bottom field)	For frame structure and field picture arrangement only
35	H’118	CE	DISPBC1	Filter picture chrominance base address (bottom field)	For frame structure and field picture arrangement only

Table 27.29 VP5_BAAR1 Bit Fields

Bit	Name	Setting value	Description
63 to 32	BAA	Base address	32-bit base address.The smallest unit of external memory accessed at once by the VPU5HG is eight bytes. Be sure to set the low-order three bits for the address specified in BAAR to 0. The unit of alignment might be 32 bytes or more depending on the base address. Specify the base address according to the alignment.
31 to 0	reserved	Reserved	Reserved

In encoding and decoding, the intermediate stream and the intermediate stream control base address should be specified according to the case listed as follows.

At encoding time, CE output address is specified in the base address of the intermediate stream and the intermediate stream control to be set in VLCS as follows.

VP5_BAAR0.CEIS0 → VP5_BAAR1.VLIS1

VP5_VAAR0.CEIC0 → VP5_BAAR1.VLIC1

VP5_BAAR1.CEIS1 → VP5_BAAR0.VLIS0

VP5_BAAR1.CEIC1 → VP5_BAAR0.VLIC0

At decoding time, VLCS output address is specified in the base address of the intermediate stream and the intermediate stream control to be set CE as follows.

VP5_BAAR0.VLIS0 → VP5_BAAR0.CEIS0

VP5_BAAR0.VLIC0 → VP5_BAAR0.CEIC0

VP5_BAAR1.VLIS1 → VP5_BAAR1.CEIS1

VP5_BAAR1.VLIC1 → VP5_BAAR1.CEIC1

In encoding and decoding, the MV information base address should be specified according to the case listed as follows.

At encoding time, MV information base address is specified as follows.

Anchor flame: VP5_BAAR0.MVINFO0 → VP5_BAAR1.MVR1

Anchor flame: VP5_VAAR0. MVINFOB0 → VP5_BAAR1. MVRB1

Anchor flame: VP5_BAAR1. MVINFO1 → VP5_BAAR0. MVR0

Anchor flame: VP5_BAAR1. MVINFOB1 → VP5_BAAR0. MVRB0

At decoding time, MV information base address is specified as follows.

Anchor flame: VP5_BAAR0. MVINFO 0 → VP5_BAAR0. MVR0

Anchor flame: VP5_BAAR0. MVINFOB0 → VP5_BAAR0. MVRB0

Anchor flame: VP5_BAAR1. MVINFO1 → VP5_BAAR1. MVR1

Anchor flame: VP5_BAAR1. MVINFOB1 → VP5_BAAR1. MVRB1

37.3.50 Decode Luminance Picture DMA Channel Register 1 (VP5_CE_DCHR_DECY1)

This register specifies the operation of the DMA channel (DECY1) to output decode luminance pictures or local decode luminance pictures. The parameters in this register are required when starting the CE.This register contains the same bit fields as those in VP5_CE_DCHR_DEY0. Set the bit fields to the values which are the same as those for VP5_CE_DCHR_DEY0.

37.3.51 Decode Chrominance DMA Channel Register 1 (VP5_CE_DCHR_DECC1)

This register specifies the operation of the DMA channel (DECC1) to output decode chrominance pictures or local decode chrominance pictures. The parameters in this register are required when starting the CE.This register contains the same bit fields as those in VP5_CE_DCHR_DECC0. Set the bit fields to the values which are the same as those for VP5_CE_DCHR_DECC0.

37.3.52 Filter Luminance Picture DMA Channel Register 1 (VP5_CE_DCHR_DISPY1)

This register specifies the operation of the DMA channel (DECY1) to output filter luminance pictures.

The parameters in this register are required when starting the CE by using the post filter for MPEG-2/MPEG-1/MPEG-4/H.263 processing. They are also required when starting the CE for VC-1 RangeReduction and RangeMapping stream decoding.

This register contains the same bit fields as VP5_CE_DCHR_DISPY0. Set the same values as those for VP5_CE_DCHR_DISPY0.

37.3.53 Filter chrominance Picture DMA Channel Register 1 (VP5_CE_DCHR_DISPC1)

This register specifies the operation of the DMA channel (DECC1) to output filter chrominance pictures.

The parameters in this register are required when starting the CE by using the post filter for MPEG-2/MPEG-1/MPEG-4/H.263 processing. They are also required when starting the CE for VC-1 RangeReduction and RangeMapping stream decoding.

This register contains the same bit fields as VP5_CE_DCHR_DISPC0. Set the same values as those for VP5_CE_DCHR_DISPC0.

37.3.54 Coded-Picture DMA Channel Register (VP5_CE_DCHR_TMP1)

This register specifies the operation of the DMA channel (TMP1) to read encoded pictures (templates). The parameters in this register are required when starting the CE. This register need not be set for decoding.

Bit	Name	Setting value	Description
63 to 48	(reserved)	H'B000	Always set to this value.
47 to 43	(reserved)	0	Always set to this value.
42 to 32	hsize		Horizontal size of the picture area. (The bits are set to a value rounded up to a multiple 16 and divided by 8.) Set to twice the horizontal size of the picture area when the encode pictures are stored as frame pictures in external memory for field encoding.
31 to 16	(reserved)	H'0000	Always set to this value.
15 to 13	endian	0 to 7	Endian. (Refer to table 27.22)
12 to 9	src_offset	0	Set to 0.
8 to 0	(reserved)	0	Always set to this value.

37.3.55 MV Information Output DMA Channel Register 1 (VP5_CE_DCHR_MBINFO1)

This register specifies the operation of the DMA channel to output MV information. The parameters in this register are required when starting the CE. Set the EMASK bit to H'0 by using the initialization routine format. This register contains the same bit fields as those in VP5_CE_DCHR_MVINFO0. Set the bit fields to the values which are the same as those for VP5_CE_DCHR_MVINFO0.

37.3.56 Odd MB Line MV Information Output DMA Channel Register 1 (VP5_CE_DCHR_MVINFOB1)

This register specifies the operation of the DMA channel (MVINFOB1) to output MV information about odd-numbered MB lines for the H.264 PIC-AFF or MB-AFF. The parameters in this register are required when starting the CE. This register need not be set when no MV information is output. This register contains the same bit fields as those in VP5_CE_DCHR_MVINFOB0. Set the bit fields to the values which are the same as those for VP5_CE_DCHR_MVINFOB0.

37.3.57 Anchor Picture MV Information DMA Channel register 1 (VP5_CE_DCHR_MVR1)

This register specifies the operation of the DMA channel (MVR1) to read anchor picture MV information. The parameters in this register are required when starting the CE. When this register is set, the external memory is accessed at the same time. Thus, it must not be set when no anchor picture MV information is used. This register contains the same bit fields as those in VP5_CE_DCHR_MVR0. Set the bit fields to the values which are the same as those for VP5_CE_DCHR_MVR0.

37.3.58 Anchor Picture Odd MB Line MV Information DMA Channel register 1 (VP5_CE_DCHR_MVRB1)

This register specifies the operation of the DMA channel (MVRB1) to read anchor picture MV information about odd-numbered MB lines for the H.264 PIC-AFF or MB-AFF. The parameters in this register are required when starting the CE. When this register is set, the external memory is accessed at the same time. Thus, it must not be set when no anchor picture MV information is used. This register contains the same bit fields as those in VP5_CE_DCHR_MVRB0. Set the bit fields to the values which are the same as those for VP5_CE_DCHR_MVRB0.

37.3.59 CE Intermediate Stream DMA Channel Register 1 (VP5_CE_DCHR_CEIS1)

This register specifies the operation of the DMA channel (CEIS1) which allows the CE to input/output intermediate streams. The parameters in this register are required when starting the CE.

This register contains the same bit fields as those in VP5_CE_DCHR_CEIS0. Set the bit fields to the values which are the same as those for VP5_CE_DCHR_CEIS0.

- Decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'8980 7000	Always set this value.
31 to 16	(reserved)	H'0000	Always set this value.
15 to 13	endian	0 to 7	Endian (See table 27.22)
12 to 9	Src_offset	8	Set to 8.
8 to 0	(reserved)	22	Always set this value.

37.3.60 CE Intermediate Control Stream DMA Channel Register 1 (VP5_CE_DCHR_CEIC1)

This register specifies the operation of the DMA channel (CEIS1) which allows the CE to input/output intermediate control streams. The parameters in this register are required when starting the CE.

This register contains the same bit fields as those in VP5_CE_DCHR_CEIC0. Set the bit fields to the values which are the same as those for VP5_CE_DCHR_CEIC0.

- Decoding

Bit	Name	Setting value	Description
63 to 32	(reserved)	H'88B0 7000	Always set this value.
31 to 16	(reserved)	H'0000	Always set this value.
15 to 13	endian	0 to 7	Endian (See table 27.22)
12 to 9	Src_offset	8	Set to 8.
8 to 0	(reserved)	23	Always set this value.

37.3.61 CE Intermediate Stream 1 Buffer Size Register (VP5_CE_IS_BS1)

Bit	Name	Setting value	Description
31 to 25	reserved	0	Reserved
24	CNT1	0, 1	When starts the continue, set to 1.
23 to 9	CIS1		CE intermediate stream 1 buffer size specification. This parameter specifies the intermediate stream 1 buffer size in 256-byte units (with the low-order eight bits being 0). For encoding, the CE stops writing after it has written intermediate stream 1 of the specified size. For decoding, the CE stops reading after it has read intermediate stream 1 of the specified size. In either case, it stops writing or reading and generates an interrupt. The interrupt is a CE error termination interrupt if the CIE1 bit in VP5_IRQ_ENB is 0 or a CE intermediate stream 1 buffer end interrupt if that bit is 1. The bits should be set before the start of the VPU5HG CE and after the generation of a CE intermediate stream 1 buffer end interrupt.
8 to 0	reserved	0	Reserved

37.3.62 DEB1 LMDMA Synchronization Register (VP5_CE_DEB_LMDMASR1)

Bit	Name	Setting value	Description
63 to 36	(reserved)	0	Reserved
35 to 32	GRC	4	Set to 4 for VPU5HG.
31 to 0	(reserved)	0	Reserved

37.3.63 VLCS Intermediate Stream DMA Channel Register 1 (VP5_VLC_DCHR_VLIS1)

This register specifies the operation of the DMA channel which allows the VLCS to input/output intermediate streams.

This register contains the same bit fields as those in VP5_CE_DCHR_VLIS0. Set the bit fields to the values which are the same as those for VP5_CE_DCHR_VLIS0.

37.3.64 VLCS Intermediate Control Stream DMA Channel Register 1 (VP5_VLC_DCHR_VLIC1)

This register specifies the operation of the DMA channel which allows the VLCS to input/output intermediate control streams. The parameters in this register are required when starting the VLCS. Set the EMASK bit to H'0 by using the initialization routine format.

This register contains the same bit fields as those in VP5_VLC_DCHR_VLIC0. Set the bit fields to the values which are the same as those for VP5_VLC_DCHR_VLIC0.

37.4 Command Stream Parameter Descriptions

The command stream parameters are slice-level parameters for H.264 decoding. They should be specified using a command stream. They constitute a single word with 64 bits. For decoding based on standards other than the H.264 standard, specify only VP5_VLC_CMD words 0 and 1 at the beginning of the frame.

37.4.1 Slice-Level Command Register (VP5_VLC_CMD)

This register contains parameters required for the STX to interpret the H.264 syntax. The parameters are required when starting the VLCS. They are set using a command stream. They make up the first parameter group in the command stream.

(1) VP5_VLC_CMD: Word 0

- H.264 Bit Field

Bit	Name	Setting value	Description
63 to 61	pic_type	0 to 2	Picture type 0: I 1: P 2: B Select 0 when concealing the entire picture. Set not only the other parameters in the command stream but also the internal registers assuming that I pictures are to be decoded. For information about concealing the entire picture, refer to section 28.6.2 (3), Command Stream.
60 to 56	refidx_last0	0 to 31	Valid number of L0 reference areas
52 to 48	refidx_last1	0 to 31	Valid number of L1 reference areas
47	bottom_field	0, 1	Bottom field flag 0: Top field 1: Bottom field
46	col_field_pic	0, 1	Anchor picture field flag 0: Frame 1: Field
45	rounding_type	0, 1	vop_rounding_type
44	wpred_flag	0, 1	Weighted-prediction flag 0: Weighted-prediction not used 1: Weighted-prediction used
42 to 40	wpred_wd_l	0 to 7	Weighted-prediction luminance scale (luma_log2_weight_denom)
38 to 36	wpred_wd_c	0 to 7	Weighted-prediction chrominance scale (chroma_log2_weight_denom)
33	alt_vscan	0, 1	alternate_vertical_scan
32	const_intra_pred	0, 1	constrained_intra_pred_flag
28 to 24	qp_c_offset0	(-12) to (+12)	qp_chroma_index_offset value (Cb for high profiles)

Bit	Name	Setting value	Description
23 to 19	qp_c_offset1	(-12) to (+12)	qp_chroma_index_offset value (Cr for high profiles)
17, 16	deblock_filter_idc	0 to 2	disable_deblocking_filter_idc
15 to 12	alpha_offset	(-6) to (+6)	slice_alpha_c0_offset_div2
11 to 8	beta_offset	(-6) to (+6)	slice_beta_offset_div2

- MPEG-2/MPEG-1 Bit Field

Bit	Name	Setting value	Description
63 to 61	pic_type	0 to 2	Picture type 0: I 1: P 2: B 4: D Select 0 when concealing the entire picture. Set not only the other parameters in the command stream but also the internal registers assuming that I pictures are to be decoded. For information about concealing the entire picture, refer to section 28.6.2 (3), Command Stream.
47	bottom_field	0, 1	Bottom field flag 0: Top field 1: Bottom field
35	full_pel_backward_vector	0, 1	full_pel_b_vector value (0 for MPEG-1/MPEG-2 processing)
34	full_pel_forward_vector	0, 1	full_pel_f_vector value (0 for MPEG-1/MPEG-2 processing)
33	alt_vscan	0, 1	alternate_vertical_scan
25	top_field_first	0, 1	0: Bottom field first 1: Top field first
24	concealment_motion_vector	0, 1	concealment_motion_vector Select 0 when concealing the entire picture. For information about concealing the entire picture, refer to section 28.6.2 (3), Command Stream.
23	frame_pred_frame_dct	0, 1	frame_pred_frame_dct
22	intra_vlc_format	0, 1	MPEG-2 intra-VLC table changeover
21, 20	intra_dc_precision	0 to 2	MPEG-2 intra-DC precision

- MPEG-4/H.263 Bit Field

Bit	Name	Setting value	Description
63 to 61	pic_type	0 to 2	Picture encode type 0: I 1: P 2: B Select 0 when concealing the entire picture. Set not only the other parameters in the command stream but also the internal registers assuming that I pictures are to be decoded. For information about concealing the entire picture, refer to section 28.6.2 (3), Command Stream.
45	rounding_type	0, 1	vop_rounding_type
42	resync_marker	0, 1	Always set to 1.
41	data_partitioned	0, 1	DP ON/OFF
40	reversible_vlc	0, 1	RVLC ON/OFF
38 to 26	intra_dc_vlc_thr	0, 1	intra_dc_vlc_thr value (VLCtable changeover QP threshold setting)
33	alt_vscan	0, 1	alternate_vertical_scan 0: zigzag scan 1: alternate scan
25	top_field_first	0, 1	0: Bottom field first 1: Top field first

- VC-1 Bit Field

Bit	Name	Setting value	Description
63 to 61	pic_type	0 to 2	Picture type 0: I 1: P 2: B Use 0 for selecting BI. Select 0 when intra-concealing the entire picture. Set not only the other parameters in the command stream but also the internal registers assuming that I pictures are to be decoded. Select 1 when inter-concealing the entire picture. Set not only the other parameters in the command stream but also the internal registers assuming that P pictures are to be decoded. For information about concealing the entire picture, refer to section 28.6.2 (3), Command Stream.
55	ref_interlace0	0, 1	Reference area type for baa_pointer value 0 0: Progressive 1: Int-Frame/Field
54	ref_interlace1	0, 1	Reference area type for baa_pointer value 1 0: Progressive 1: Int-Frame/Field
53	ref_interlace2	0, 1	Reference area type for baa_pointer value 2 0: Progressive 1: Int-Frame/Field
52	ref_interlace3	0, 1	Reference area type for baa_pointer value 3 0: Progressive 1: Int-Frame/Field
51	range_mapy_flag	0, 1	RANGE_MAPY_FLAG
50	range_mapuv_flag	0, 1	RANGE_MAPUV_FLAG
48	second_field	0, 1	2nd field flag 0: 1st field 1: 2nd field

Bit	Name	Setting value	Description
47	bottom_field	0, 1	Bottom field flag 0: Top field 1: Bottom field
46	col_field_pic	0, 1	Anchor picture field flag 0: Frame 1: Field
45	rounding_type	0, 1	vop_rounding_type
43, 42	range_mapy	0 to 3	RANGE_MAPY low-order two bits
41 to 39	range_mapuv	0 to 7	RANGE_MAPUV
38	range_red	0, 1	Range reduction 0: Invalid 1: Valid
37	range_red_cur	0, 1	RANGEREDFRM for the current frame 0: Invalid 1: Valid
36	range_red_ref	0, 1	RANGEREDFRAM for the forward reference frame 0: Invalid 1: Valid
35	intensity comp	0, 1	Intensity compensation 0: Invalid 1: Valid
34	uniform_quantizer	0, 1	0: uniform quantizer 1: non-uniform quantizer
33	alt_vscan	0, 1	alternate_vertical_scan 0: zigzag scan 1: alternate scan
31 to 26	pquant	1 to 31	PQUANT value
25	bi_linear	0, 1	Specifies whether the filter for half pel interpolation is bi-linear or bi-cubic. 0: Bi-Cubic 1: Bi-Linear
24	vc1_loopfilter	0, 1	VC-1 loop filter
23	fastuvmc	0, 1	FASTUVMC enable

Bit	Name	Setting value	Description
22	overlap	0, 1	OVT enable for VC-1
21, 20	condover	0, 2, 3	CondOver 0: None 2: All 3: Some (selected based on the bit plane)
15	intcomp_double	0, 1	First-stage IntComp valid flag for the top field
14	intcomp_double2	0, 1	First-stage IntComp valid flag for the bottom field
13 to 8	lumascale	0 to 63	LUMSCALE for the progressive sequence or forward reference top field The default is 32.
7	intcomp_bwd	0, 1	IntComp valid flag for backward reference
5 to 0	lumashift	0 to 63	LUMSHIFT for the progressive sequence or forward reference top field The default is 0.

(2) VP5_VLC_CMD: Word 1

- H.264 Bit Field

Bit	Name	Setting value	Description
63 to 32	slice_size	—	Slice data size
29 to 24	slice_qp	0 to 51	Specifies the quantization parameter (included in PPS) for the first macroblock in the slice. Specifies pic_init_qp + slice_qp_delta.
23, 22	weighted_bipred_idc	0 to 2	Specifies weighted_bipred_idc.
21	direct_bot_use_flag	0, 1	Selected for the frame picture B_Slice in an MBAFF sequence. (topAbsDiffPOC<botAbsDiffPOC) ?0:1
20	direct_8x8_inference_ flag	1	Specifies direct_8 × 8_interface_flag.
19	direct_spatial_mv_ pred_flag	1	Specifies direct_spatial_mv_pred_flag.
18	transform_8x8_ mode_flag	0, 1	Specifies whether to use 8 × 8 integer conversion. 0: No 1: Yes
17, 16	cabac_init_idc	0 to 2	Specifies cabac_init_idc.
15, 14	collist_proc_mode	0 to 2	Specifies how to process mapcoltolist. 0: Uses a command stream for processing. 1: Processes data in MB line units. 2: Processes data in MB units. If 1 or 2 is selected, setting both a separate channel and VP5_VLC_MODE is necessary. Select 0 when concealing the entire picture. For information about concealing the entire picture, refer to section 28.6.2 (3), Command Stream.
13 to 8	InitialQpY	0 to 51	Specifies pic_init_qp included in PPS.

- MPEG-2/MPEG-4/H.263 Bit Field

Bit	Name	Setting value	Description
63 to 32	frame_size	—	Frame data size Select 0 when concealing the entire picture. For information about concealing the entire picture, refer to section 28.6.2 (3), Command Stream.
29 to 24	InitialQpY	1 to 31	InitialQpY (for MPEG-4 only)
23 to 20	fcode00	1 to 9	Specifies the fcode[0][0] value. MPEG-4 dec: 1 to 7 (forward fcode) H.263 dec: 1 MPEG-2 dec: 1 to 9 Others: Need not be selected.
19 to 16	fcode01	1 to 9	Specifies the fcode[0][1] value (or forward fcode for MPEG-4 processing).
15 to 12	fcode10	1 to 9	Specifies the fcode[1][0] value (or forward fcode for MPEG-4 processing).
11 to 8	fcode11	1 to 9	Specifies the fcode[1][1] value (or forward fcode for MPEG-4 processing).

- VC-1 Bit Field

Bit	Name	Setting value	Description
63 to 32	frame_size	—	Frame data size Select 0 when concealing the entire picture for decoding Advanced Profile. For information about concealing the entire picture, refer to section 28.6.2 (3), Command Stream.
29 to 24	InitialQpY	1 to 31	ALTPQUANT value
21, 20	mvrange	0 to 3	0: (H[-64,63.f] × V[-32,31.f]) 1: (H[-128,127.f] × V[-64,63.f]) 2: (H[-512,511.f] × V[-128,127.f]) 3: (H[-1024,1023.f] × V[-256,255.f])
19, 18	dmvrange	0 to 3	DMVRANGE value
17	REFFIELD	1, 0	REFFIELD value
16	HALFPEL value	1, 0	HALFPEL (0:Halfpel, 1: HalfpelBilinear)
15	numref	1, 0	NUMREF value
14	tff	1, 0	Top Field First value
13, 12	refdist_fwd	0 to 3	REFDIST FWD value (reduced to 3 if it is 4 or more)
11, 10	refdist_bwd	1, 0	REFDIST BWD value (reduced to 3 if it is 4 or more)
9	curfld	1, 0	first field = 0, second field = 1
8	ref0_bottom	1, 0	REF0_BOTTOM
7 to 0	pic_header_len	0 to 255	Picture Header length (0 to 255) Used for multi-slice images.

(3) VP5_VLC_CMD: Word 2

- H.264 Bit Fields

These bits specify whether the L0 and L1 reference pictures are top or bottom fields.

Bit	Name	Setting value	Description
63	ref_bottom_field[63]	0, 1	L0 prediction ref0 0: Top field 1: Bottom field
62	ref_bottom_field[62]	0, 1	L0 prediction ref1 0: Top field 1: Bottom field
61	ref_bottom_field[61]	0, 1	L0 prediction ref2 0: Top field 1: Bottom field
60	ref_bottom_field[60]	0, 1	L0 prediction ref3 0: Top field 1: Bottom field
:	:	0, 1	:
bit	ref_bottom_field[bit]	0, 1	L0 prediction ref[63-bit] 0: Top field 1: Bottom field
:	:	0, 1	:
33	ref_bottom_field[33]	0, 1	L0 prediction ref30 0: Top field 1: Bottom field
32	ref_bottom_field[32]	0, 1	L0 prediction ref31 0: Top field 1: Bottom field
31	ref_bottom_field[31]	0, 1	L0 prediction ref0 0: Top field 1: Bottom field

Bit	Name	Setting value	Description
30	ref_bottom_field[30]	0, 1	L0 prediction ref1 0: Top field 1: Bottom field
:	:	0, 1	:
bit	ref_bottom_field[bit]	0, 1	L0 prediction ref[31-bit] 0: Top field 1: Bottom field
:	:	0, 1	:
3	ref_bottom_field[3]	0, 1	L0 prediction ref28 0: Top field 1: Bottom field
2	ref_bottom_field[2]	0, 1	L0 prediction ref29 0: Top field 1: Bottom field
1	ref_bottom_field[1]	0, 1	L0 prediction ref30 0: Top field 1: Bottom field
0	ref_bottom_field[0]	0, 1	L0 prediction ref31 0: Top field 1: Bottom field

- MPEG-4 Bit Fields

Bit	Name	Setting value	Description
49 to 32	TRD		TRD[i] for B_direct (except δ[i])
17 to 0	TRB		TRB[i] for B_direct (except δ[i])

- VC-1 Bit Field

Bit	Name	Setting value	Description
63 to 58	lumascale5	0 to 63	LUMASCALE for backward reference (refer to figure 27.5)
			The default is 32.
57 to 52	lumashift5	0 to 63	LUMASHIFT for backward reference (refer to figure 27.5)
			The default is 0.
51 to 46	lumascale4	0 to 63	First-stage LUMASCALE for the forward reference bottom field (refer to figure 27.5)
			The default is 32.
45 to 40	lumashift4	0 to 63	First-stage LUMASHIFT for the forward reference bottom field (refer to figure 27.5)
			The default is 0.
39 to 34	lumascale3	0 to 63	First-stage LUMASCALE for the forward reference top field (refer to figure 27.5)
			The default is 32.
33 to 28	lumashift3	0 to 63	First-stage LUMASHIFT for the forward reference top field (refer to figure 27.5)
			The default is 0.
27 to 22	lumascale2	0 to 63	LUMASCALE for the forward reference bottom field (refer to figure 27.5)
			The default is 32.
21 to 16	lumashift2	0 to 63	LUMASHIFT for the forward reference bottom field (refer to figure 27.5)
			The default is 32.
15 to 0	ScaleFactor		Scale factor used for B_direct

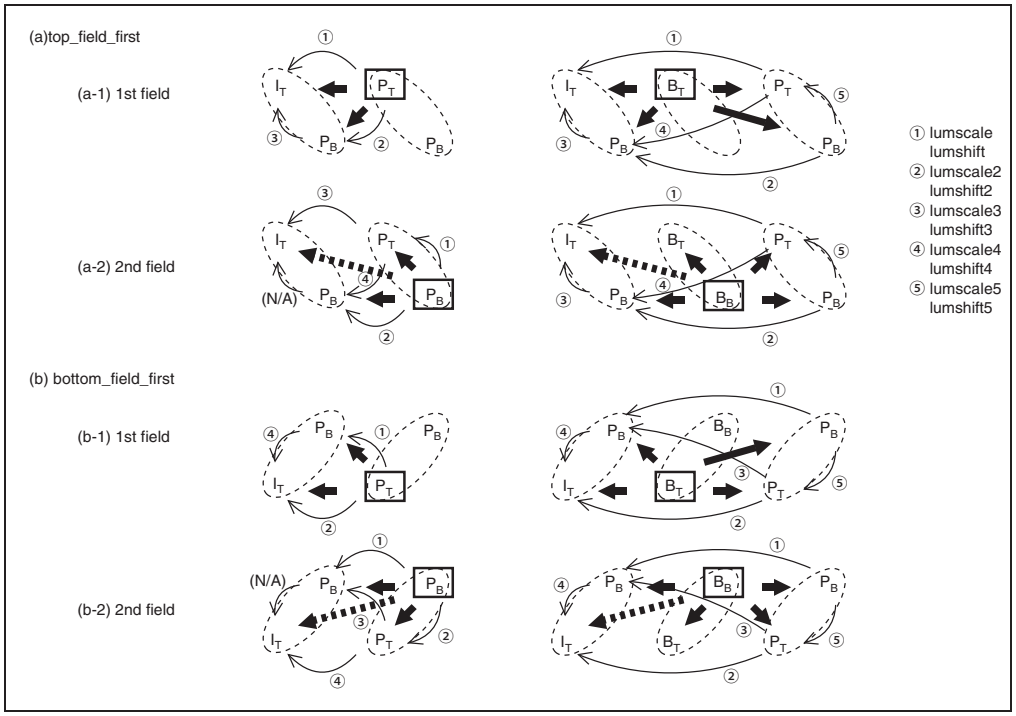

Figure 27.5 VC-1 intenity_compensation Parameter Settings

(4) VP5_VLC_CMD: Word 3

- VC-1 Bit Field

Bit	Name	Setting value	Description
63	TRANSDCTAB	0, 1	TRANSDCTAB
62	TRANSACTAB1	0 to 2	TRANSACTAB coding set
60, 59	TRANSACTAB2	0 to 2	TRANSACTAB2 coding set
58, 57	MVMODE	0 to 3	0: 1-MV Half-pel bilinear 1: 1-MV Half-pel 2: 1-MV 3: Mixed-MV
56, 55	MVTAB	0 to 3	MVTAB (Table 51 in the standard)
54, 53	CBPTAB	0 to 3	CBPTAB (Table 52 in the standard)
52	TTMBF	0, 1	TTMBF 0: MB or frame level 1: MB level
51, 50	TTFRM	0 to 3	Transform Type for TTMBF = 1 0: 8 × 8 1: 8 × 4 2: 4 × 8 3: 4 × 4

Bit	Name	Setting value	Description
0	SKIPFRAME	0, 1	Specifies how to conceal the entire pictue for VC-1 processing. 0: Intra concealment 1: Inter concealment For information about concealing the entire picture, refer to section 28.6.2 (3), Command Stream. Other options 0: Non-skipped frame 1: Skipped frame

37.4.2 Reference Address Conversion Table (VP5_VLC_REF_TBL)

For H.264 decoding, these bits provide parameters for updating the offset for the association between the list after REF_idx update for each slice and VP5_BAAR at the beginning of a picture and for respecifying the long or short term for each reference. These bits are specified in a command stream. They are added for P and B pictures. The number of words can vary depending on num_ref_frames.

If a reference picture with field_pic_flag = 0 is located in a separate address for each field, these bits specify the BAA pointer for the top field.

- VP5_REF_TBL Structure

Description	
if (pic_type != I_Pic) {	
for(i = 0; i <= ((num_ref_frames*2-1)/8); i++) {	
VP5_REF_TBL [i];	BAA pointer conversion table for L0 prediction with ref_idx = i
}	
}	
if (pic_type == B_Pic) {	
for(i = 0; i <= ((num_ref_frames*2-1)/8); i++) {	
VP5_REF_TBL [num_ref_frames+i];	BAA pointer conversion table for L1 prediction with ref_idx = i
}	
}	

- VP5_REF_TBL Words 0 through 7

Address offset	Name	Description
0000	VP5_REF_TBL[0]	BAA pointer conversion table for L0 prediction with ref_idx = 0 to 7
0008	VP5_REF_TBL[1]	BAA pointer conversion table for L0 prediction with ref_idx = 8 to 15
0010	VP5_REF_TBL[2]	BAA pointer conversion table for L0 prediction with ref_idx = 16 to 23
0018	VP5_REF_TBL[3]	BAA pointer conversion table for L0 prediction with ref_idx = 24 to 31
0020	VP5_REF_TBL[4]	BAA pointer conversion table for L1 prediction with ref_idx = 0 to 7
0028	VP5_REF_TBL[5]	BAA pointer conversion table for L1 prediction with ref_idx = 8 to 15

14 to 8	0 to 31	BAA pointer for L1 prediction reference picture ref_idx[i*8+6]
7	0, 1	Flag for L1 prediction reference picture ref_idx[i*8+7] 0: Short term 1: Long term
6 to 0	0 to 31	BAA pointer for L1 prediction reference picture ref_idx[i*8+7]

37.4.3 Anchor Picture MV Information Address (VP5_VLC_MVR_ADDR)

At H.264 decoding time, this register specifies the anchor picture MV information address in every slice using a command stream.

The setting is necessary at picture decoding time including B-slice.

1word setting for the 1CE.

Bit	Name	Setting value	Description
63 to 32	mvr_addr	—	Frame or top field anchor picture MV information address
31 to 0	mvr_addr_odd	—	Bottom field anchor picture MV information address

37.4.4 VP5_VLC_MCTL: MapColToList

These bits specify MapColToList for each slice for H.264 decoding. It is a mapping table of ref_idx values for the current picture which uses colPic ref_idx as the index. The number of words can vary depending on num_ref_frames.

Set these bits for temporal direct prediction used for B slices (when direct_spatial_mv_pred_flag = 0).

Address offset	Name	Description
H'0004_8068	VP5_VLC_MCTL[i:i=0]	ref_idx conversion table for the current picture for colPic L0 prediction ref_idx = 0 to 7
H'0004_8070	VP5_VLC_MCTL[i:i=1]	ref_idx conversion table for the current picture for colPic L0 prediction ref_idx = 8 to 15
H'0004_8078	VP5_VLC_MCTL[i:i=2]	ref_idx conversion table for the current picture for colPic L0 prediction ref_idx = 16 to 23
H'0004_8080	VP5_VLC_MCTL[i:i=3]	ref_idx conversion table for the current picture for colPic L0 prediction ref_idx = 24 to 31

- Bit Field Description

Bit	Setting Value	Description
63 to 56	0 to 31	ref_idx for the current picture for colPic ref_idx[i*8+0]
55 to 48	0 to 31	ref_idx for the current picture for colPic ref_idx[i*8+1]
47 to 40	0 to 31	ref_idx for the current picture for colPic ref_idx[i*8+2]
39 to 32	0 to 31	ref_idx for the current picture for colPic ref_idx[i*8+3]
31 to 24	0 to 31	ref_idx for the current picture for colPic ref_idx[i*8+4]
23 to 16	0 to 31	ref_idx for the current picture for colPic ref_idx[i*8+5]
15 to 8	0 to 31	ref_idx for the current picture for colPic ref_idx[i*8+6]
7 to 0	0 to 31	ref_idx for the current picture for colPic ref_idx[i*8+7]

37.4.5 VP5_VLC_POC: POC List

These bits specify the POC list for H.264 decoding. The number of words can vary depending on num_ref_frames.

Set these bits for temporal direct prediction used for B slices (when direct_spatial_mv_pred_flag = 0) or implicit weighted prediction.

- VP5_VLC_POC Structure

Description

```
if (pic_type == B_Pic) {
if (direct_spatial_mv_pred_flag == 0 || weighted_bipred_idc==implicit ) {
            for( i = 0; i <= (num_ref_frames+2); i++ ) {
          VP5_VLC_POC[i];                                          POC list
            }
      }
}
```

- Frame Used as the Current Picture

37.4.6 Weighing Control Conversion Table (VP5_VLC_WP_TBL)

These bits provide parameters for updating the weighted prediction offset for each slice for H.264 decoding. Even when ref_idx is updated, specify the weighted prediction parameter consistent with ref_idx at the beginning of the picture. These bits should be set in a command stream.

The size specified in VP5_WP_TBL depends on num_ref_idx_10 and num_ref_idx_11. That size ranges from 2 words to 64 words (each consisting of 64 bits).

- VP5_WP_TBL Structure

Description	
for(I = 0; i <= num_ref_idx_l0_active_minus1; i++) {	
VP5_WP_TBL[i];	Weighted prediction parameter for L0 prediction with ref_idx = i.
}	
for(i = 0; i <= num_ref_idx_l1_active_minus1; i++) {	
VP5_WP_TBL[num_ref_idx_l0_active_minis1+i];	Weighted prediction parameter for L1 prediction with ref_idx = i.
}	

- Bit Fields in Each Word

Bit	Name	Setting Value	Description
63 to 48	reserved		Reserved
58 to 56	luma_log2_weight_denom	0 to 7	luma_log2_weight_denom (Don't care except for i = 0)
55	reserved		Reserved
54	luma_weight_ln_128	0, 1	luma_weight_ln[i] (n = 0 or 1) 128 flags 0: luma_weight_ln[i] = (-128) to 127 1: luma_weight_ln[i] = 128
53	chroma_weight_ln_128[0]	0, 1	chroma_weight_ln[i][0](Cb) (n = 0 or 1) 128 flags 0: chroma_weight_ln[i][0] = (-128) to 127 1: chroma_weight_ln[i][0] = 128
52	chroma_weight_ln_128[1]	0, 1	chroma_weight_ln[i][1](Cr) (n = 0 or 1) 128 flags 0: chroma_weight_ln[i][1] = (-128) to 127 1: chroma_weight_ln[i][1] = 128
51	reserved		Reserved
50 to 48	chroma_log2_weight_denom	0 to 7	chroma_log2_weight_denom (Don't care except for i = 0)
47 to 40	luma_weight_ln[i]	(-128) -127	luma_weight_ln[i] (n: 0/1)
39 to 32	luma_offset_ln[i]	(-128) -127	luma_offset_ln[i] (n: 0/1)
31 to 24	chroma_weight_ln[i][0]	(-128) -127	chroma_weight_ln[i][0](Cb) (n: 0/1)
23 to 16	chroma_offset_ln[i][0]	(-128) -127	chroma_offset_ln[i][0] (Cb) (n: 0/1)
15 to 8	chroma_weight_ln[i][1]	(-128) -127	chroma_weight_ln[i][1] (Cr) (n: 0/1)
7 to 0	chroma_offset_ln[i][1]	(-128) -127	chroma_offset_ln[i][1] (Cr) (n: 0/1)

37.4.7 Next-slice First-MB Number (VP5_VLC_NEXT_FMS_ADDR)

This register specifies the first MB number in the next slice with a command stream for H.264 decoding. Select 0 for the last slice of a picture.

Bit	Name	Setting value	Description
12 to 0	first_mb_number_in_next_slice	0 to 8159	First MB number in the next slice

37.4.8 MPEG-4 VP Header Decoding Parameter (VP5_VLC_BITLEN0)

Bit	Name	Setting value	Description
63 to 32	ldmac_base_adr		Decoding DP buffer start address (set only at MPEG-4 DP decoding time)
19 to 16	mb_num_bitlen	1 to 14	macroblock number bit length (set only at MPEG-4 decoding time)
4 to 0	vop_time_inc_bitlen	1 to 16	VOP time increment bit length (set only at MPEG-4 decoding time)

37.4.9 MPEG-4 VP Header Decoding Parameter (VP5_VLC_BITLEN1)

Bit	Name	Setting value	Description
39 to 32	modulo_time_base_bitlen	0 to 255	modulo time base bit length (set only at MPEG-4 decoding time)
14 to 0	total_number_of_mbs	1 to 16384	macroblock number in VOP (set only at MPEG-4 decoding time)

37.5 Data Stored in External RAM and Its Format

37.5.1 Encode Picture

An encode picture is an original picture encoded by the VPU5HG. It is required when starting the VPU5HG CE for encoding.

The VPU5HG uses 4:2:0 sampling to process pictures. This sampling involves one Cb (blue chrominance) pixel and one Cr (red chrominance) pixel for four Y (luminance) pixels. That is, there is one pixel of chrominance information for two vertical pixels x two horizontal pixels of luminance information. Human eyes are more sensitive to changes in luminance than they are to those in chrominance. Thus, information can be successfully compressed by using four pixels of luminance information and one pixel of chrominance information. Figure 27.6 shows the format for encoded pictures. The picture origin is in the upper left-hand corner.

The start address of an input/output picture should be aligned on a 32-byte boundary. In the address register for the VPU5HG, specify the physical memory address space which can be accessed from the bus controller connected to the VPU5HG.

If the horizontal size of a picture is insufficient and its rightmost edge does not reach a 16-byte boundary, add an empty area to the rightmost edge of each line to ensure that the line starts on the 16-byte boundary (the size of the empty area should be the same for each line). Even if the vertical size of a picture is not a multiple of 16 lines, a multiple of 16 lines are accessed. Thus, an accessible area including a coded picture consisting of a multiple of 16 lines is required. Chrominance blue (Cb) and chrominance red (Cr) should be stored alternately in units of sampling pixels (for details, refer to the chrominance format shown in figure 27.6).

Specify the horizontal size of an encode picture stored in memory as hsize in VP5_CE_DCHR_TMP. This size should be a value (horizontal size/8) in units of eight pixels. When the VPU5HG is used with the VBLx, the horizontal size can be set to 512, 1024 or 2048. Thus, hsize should be 64, 128 or 256.

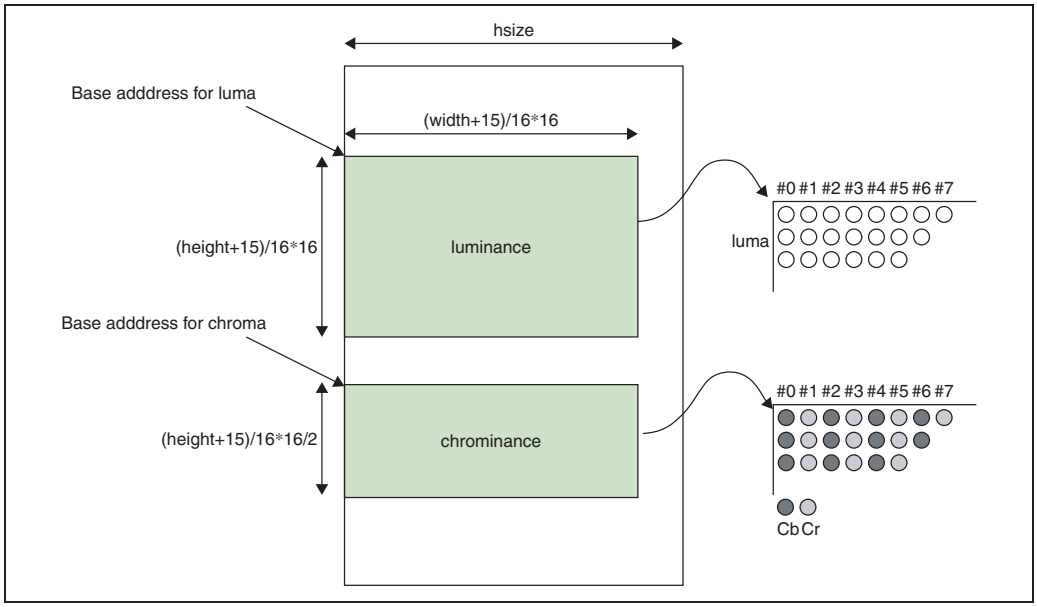

Figure 27.6 Picture Format

37.5.2 Reference Picture

A reference picture is required when starting the CE for encoding or decoding. Its format is shown in figure 27.6.

Specify the horizontal size of a reference picture stored in memory as hsize in VP5_CE_DCHR_REF. This size should be a value (horizontal size/8) in units of eight pixels. When the VPU5HG is used with the VBLx, the horizontal size can be set to 512, 1024 or 2048. Thus, hsize should be 64, 128 or 256.

37.5.3 Decode Picture

A decode picture is required when starting the CE for encoding or decoding. Its format is shown in figure 27.6.

Specify the horizontal size of a decode picture stored in memory as hsize in both VP5_CE_DCHR_DECY and VP5_CE_DCHR_DECC. This size should be a value (horizontal size/8) in units of eight pixels. When the VPU5HG is used with the VBLx, the horizontal size can be set to 512, 1024 or 2048. Thus, hsize should be 64, 128 or 256.

37.5.4 Stream

This is a data area required for starting the VLCS. Data are output for encoding and input for decoding.

The start address of the stream buffer should be aligned on a 32-byte boundary. Secure a stream data area whose size is in units of 256 bytes. Specify also the buffer size.

Streams are variable-length data. The VLCS accesses a position at a distance in 256 byte units from the start address of the buffer. When buffer end interrupts are disabled, the VLCS operation is forcibly terminated if an attempt is made to write or read data at a position after the last buffer address. An error is reported via the VP5_VLC_ERRH and VP5_VLC_ERRL registers. When buffer end interrupts are enabled, the VLCS operation is suspended if an attempt is made to write or read data at a position after the last buffer address. The VLCS waits until it resumes operation. If the end of the stream is 2048 bytes or less away from the last buffer address at the time of reading, a buffer end interrupt might occur and cause the VLCS to wait until it resumes operation.

Regardless of whether buffer end interrupts are enabled or disabled, a DMA prefetch is performed to read 512 additional bytes from the area after the last buffer address. Be careful not to make this area inaccessible.

At the time of decoding, specify the last buffer address for startup by using a command stream. To specify the last buffer address for resuming operation, use the VP5_VLC_STRA_BS register. For H.264 decoding, stream A and stream B are alternated for each slice so the streams can be read. Select the VP5_VLC_STRA_BS or VP5_VLC_STRB_BS register according to the buffer end interrupt source, and specify the last buffer address in the selected register.

At the time of encoding, stream A is used for writing streams. Thus, specify the last buffer address in the VP5_VLC_STRA_BS register.

37.5.5 Command Stream

A command stream is required when starting the VLCS for decoding.

A command stream is input for decoding by the VLCS. Specify a control parameter for each slice.

The start address of the command stream buffer should be aligned on a 32-byte boundary. Command stream data area should be established in 256-byte units. The VLCS access the area in 256-byte units starting at the buffer start address.

Allocate the command stream in consecutive memory areas.

37.5.6 Intermediate Stream

An intrermediate stream is used for buffering data between the VLCS and CE. It is a data area required for starting the VLCS and CE. At the time of encoding, an intermeidate stream is ouput from the CE and serves as an input for the VLCS. At the time of decoding, an intermediate stream is output from the VLCS and serves as an input for the CE.

The start address of the intermediate-stream buffer should be aligned on a 32-byte boundary. Secure an intermediate-stream data area whose size is in units of 512 bytes. Specify also the buffer size.

Intermediate streams are variable-length data. The VLCS accesses a position at a distance in 256 byte units from the start address of the buffer. When buffer end interrupts are disabled, the VLCS operation is forcibly terminated if an attempt is made to write or read data at a position after the last buffer address. An error is reported via the VP5_VLC_ERRH and VP5_VLC_ERRL registers.

When buffer end interrupts are enabled, the VLCS operation is suspended if an attempt is made to write or read data at a position after the last buffer address. The VLCS waits until it resumes operation. If the end of the stream is 2048 bytes or less away from the last buffer address at the time of reading, a buffer end interrupt might occur and cause the VLCS to wait until it resumes operation.

Regardless of whether buffer end interrupts are enabled or disabled, a DMA prefetch is performed to read 512 additional bytes from the area after the last buffer address. Be careful not to make this area inaccessible.

The CE accesses a position at a distance in units of 512 bytes for encoding (writing) or in units of 256 bytes for decoding (reading) from the buffer start address. If an attempt is made to write or read data at a position after the last buffer address, the CE suspends its operation and waits until it resumes operation. If the end of an intermediate stream is 2048 bytes or less away from the last buffer address at the time of reading, a buffer end interrupt might occur and cause the CE to wait until it resumes operation. At the time of reading, a DMA prefetch is performed to read 512 additional bytes from the area after the last buffer address. Be careful not to make this area inaccessible.

37.5.7 Intermediate Control Stream

An intermediate control stream is required when starting the VLCS and CE. It indicates encoded information about macroblocks for each CE.

An intermediate control stream is a fixed-length data stream consisting of 64 bits/MB for buffering data between the VLCS and CE. It occupies a buffer area whose size is 64 bits × MB count per frame. Figure 27.7 shows the format for intermediate control streams during normal processing (i.e., when ERR = 0). Figure 27.11 shows the format for intermediate control streams when an error occurs (i.e., when ERR = 1).

An intermediate control stream is input for encoding by the VLCS and output for decoding by the VLCS. It is output for encoding by the CE and input for decoding by the CE. An intermediate control stream is required for each CE. For the VPU5HG, two memory areas are required. An intermediate control stream consists of 64 bits/MB and its size depends on the picture size. A data area whose size is the number of macroblocks to be processed × 64 bits is accessed for each CE.

The start address of the intermediate control stream buffer should be aligned on a 32-byte boundary. The intermediate control stream data area should be established in 256-byte units.

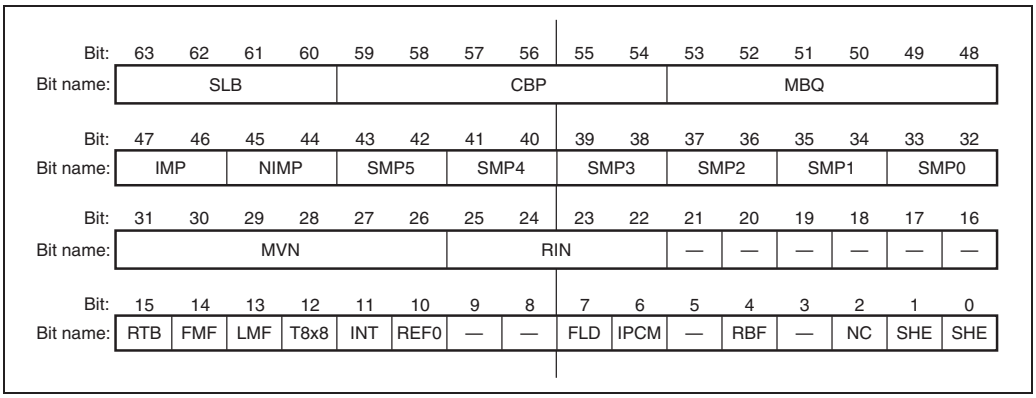

Figure 27.7 Intermediate Control Stream Format (for Normal Processing: H.264)

Bit	Bit Name	Description
63 to 60	SLB	Slice bound (0 to 15) MB slice boundary information (Bit 3: Left MB, Bit 2: Upper left MB, Bit 1: Upper MB, Bit 0: Upper right MB)
59 to 54	CBP	Coded Block Pattern (0 to 63) Coded block pattern ({CHROMA[1:0], Y3, Y2, Y1, Y0})
53 to 48	MBQ	MB Quant (0 to 51) MB quant value
47, 46	IMP	00: MB division is intra_16 × 16. (Only intra 16 × 16 is selected.) 01: MB division is intra_4 × 4. Inter_4 × 4 conversion is performed for inter MBs. 10: MB division is intra_8 × 8. Inter_8 × 8 conversion is performed for inter MBs. 11: Reserved
45, 44	NIMP	00: MB division is inter_16 × 16. 01: MB division is inter_16 × 8. 10: MB division is inter_8 × 16. 11: MB division is inter_8 × 8.

31 to 26	MVN	Mv num 0: MV is not added. 1 to 4: MV count (for H or V set)

25, 24	FMT	FMT (0 to 3)
		(frame/field)_motion_type value. It is set to 0 if there is not macroblock_motion_forward/backward for the MB (INTRA). If no MC is specified, it is processed as described below.
		Additional Description:
		frame_motion_type is used for field pictures and field_motion_type is used for frame picture as the FMT value. Whether they are field or frame pictures can be determined as follows:
		if(macroblock_motion_forward||macroblock_motion_backward){ i
		f(picture_structue=='Frame'){
		if(frame_pred_frame_dct==0)
		frame_motion_type
		}else{
		field_motion_type
		}
		}
		
		In this determination, if frame_motion_type/field_motion_type cannot be found, field and frame pictures are processed as frame-based and field-based respectively.

0	ERR	Error Flag 0: Normal MB. If the ERR is 0, the bit field is the one shown in figure 27.9. 1: Error MB.

37.5.8 Motion Vector

It indicates encoded information about a macroblock.

Direct prediction in a B-VOP/slice requires the motion vector for referenced pictures. Thus, the external RAM should contain 2 buffer areas for each frame (field pair) that hold motion vectors. Two buffer areas are required for each frame (field pair) if PIC_AFF is not used while four buffer areas are required for each frame (field pair) if PIC_AFF is used. For MPEG-4/H.263 encoding which involves one CE, one buffer area is required for each frame (field pair). Each buffer area must be established as a consecutive area. This is because it is to be used as one area for even and odd lines in decoding the frame structure.

The buffer area should be established in 256-byte units with the size that can accommodate the data size shown in table 27.31, aligning to a 32-byte boundary. The data size and number of banks to be established per MB for each picture structure are shown in table 27.32.

Table 27.31 Motion Vector Buffer Size

Picture structure	Buffer area	Data size per buffer
Frame	TOP	MB_DATA_SIZE*mb_width*(mb_height + 1)/2
	BOTTOM	MB_DATA_SIZE*mb_width*(mb_height + 1)/2
Frame (1CE encoding)	—	MB_DATA_SIZE*mb_wdth*mb_height
field	TOP	MB_DATA_SIZE*mb_width*(mb_height + 1)/2
	BOTTOM	MB_DATA_SIZE*mb_width*(mb_height + 1)/2
PIC_AFF	TOP EVEN	MB_DATA_SIZE*mb_width*(mb_height + 3)/4
	TOP ODD	MB_DATA_SIZE*mb_width*(mb_height + 3)/4
	BOTTOM EVEN	MB_DATA_SIZE*mb_width*(mb_height + 3)/4
	BOTTOM ODD	MB_DATA_SIZE*mb_width*(mb_height + 3)/4

Table 27.32 Motion Vector Data Size and Number of Bank

Stream Type (w/Profile Name)	Data size per MB (MB_DATA_SIZE)	Number of bank
H.264 decode	64 Bytes	num_ref_rames + 1
H.264 decode	16 Bytes	num_ref_rames + 1
the others decode	64 Bytes	2
the others decode	16 Bytes	2

When a sequence including a B-VOP/slice is decoded or encoded, a motion vector is output by setting the buffer start address to No. 18 (offset H'090) MV information (write) base address in the base address array and setting the VP5_CE_VLCF mv_info bit (motion vector information output specification) to 1. When a B-VOP/slice is decoded or encoded, the start address of the buffer which contains motion vector output used for decoding or encoding the reference picture (or anchor picture for H.264) is set to No. 20 (offset H'0A0) anchor picture MV information (read) base address. Input and output operations are independent of each other. They might take place at the same time.

Table 27.33 Motion Vector Channel Setting Examples(Decode)

	current Frame Pic		Current Field Pic(Top) *	
	read	write	read	write
col frame Pic	CE0 ch0: BOT EVEN	CE0 ch0: BOT EVEN	CE0 ch0: TOP ODD	CE0 ch0: TOP ODD

Below are examples of address settings for motion vectors for H.264 encoding.

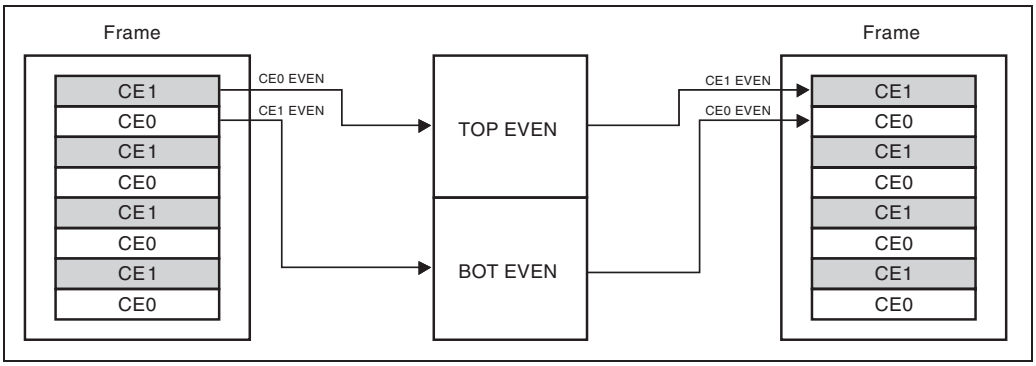

Figure 27.12 Examples of Motion Vector Settings (Current Picture: Frame, Anchor Picture: Frame)

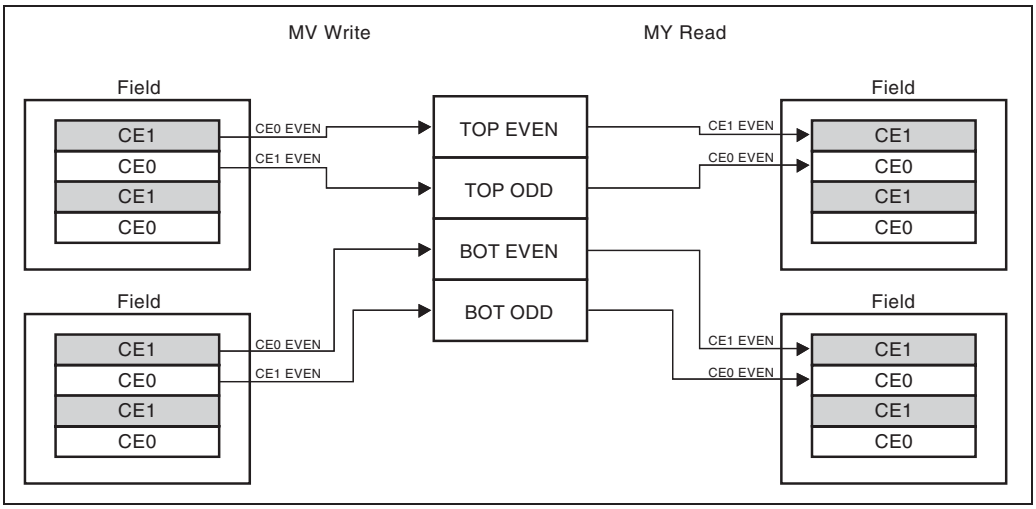

Figure 27.13 Examples of Motion Vector Settings (Current Picture: Field, Anchor Picture: Field)

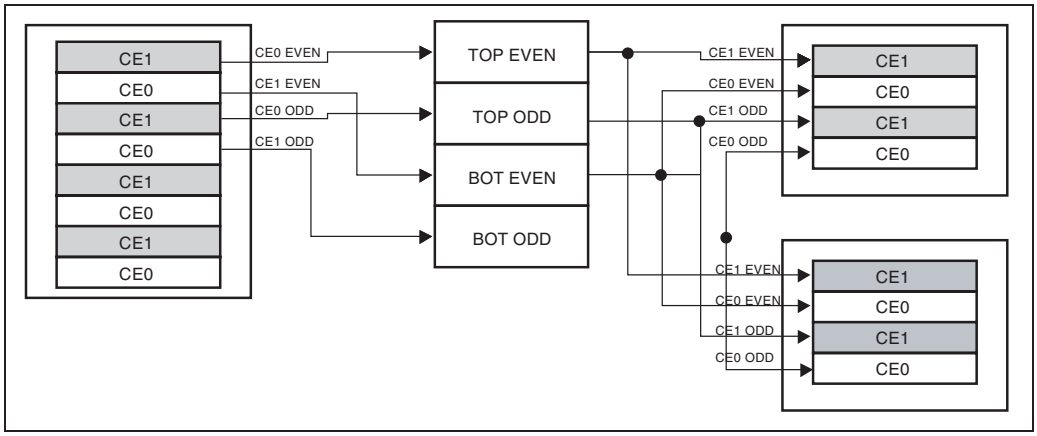

Figure 27.14 Examples of Motion Vector Settings (Current Picture: Field, Anchor Picture: Frame)

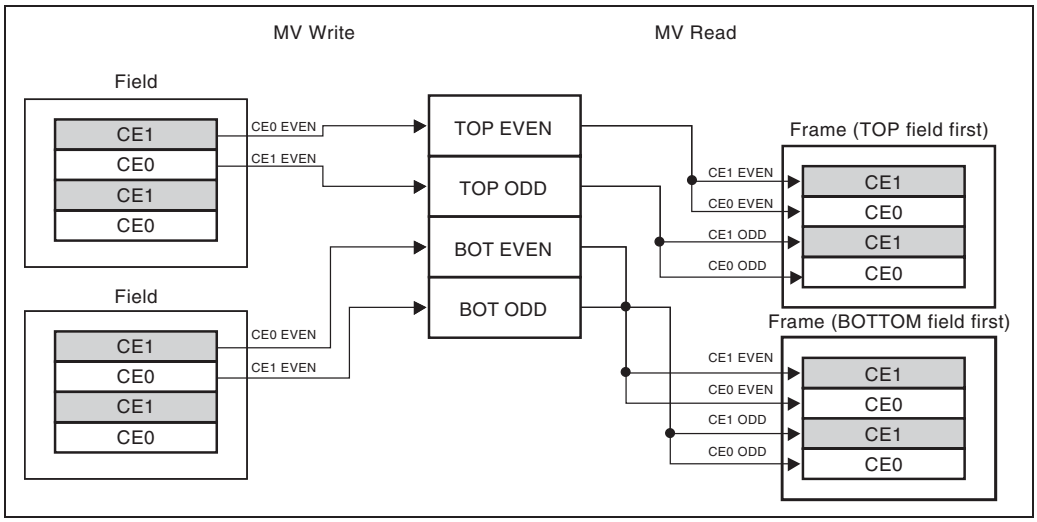

Figure 27.15 Examples of Motion Vector Settings (Current Picture: Frame, Anchor Picture: Field)

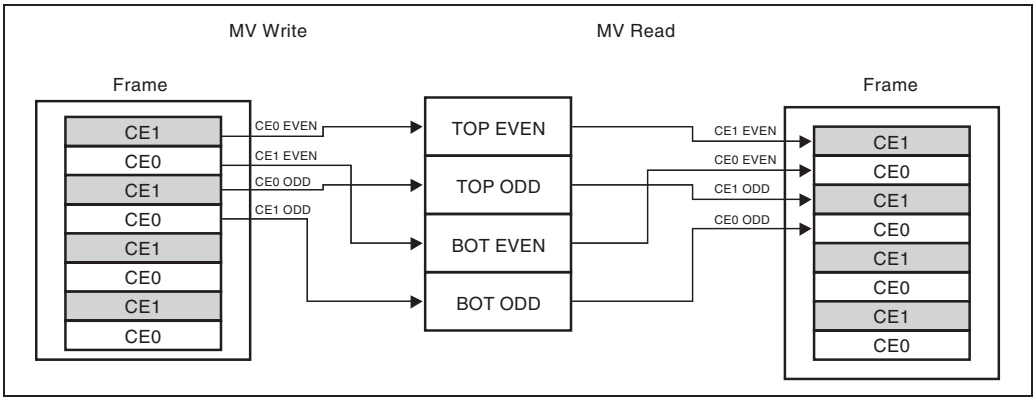

Figure 27.16 Examples of Motion Vector Settings (Current Picture: Frame, Anchor Picture: Frame (frame_mbs_only_flag = 0))

For H.264 decoding, a 32-bit motion vector for each submacroblock and a 64-byte motion vector (16 vectors) for each macroblock are output. For H.264 encoding, a 32-bit motion vector for each 8 × 8 block and a 16-byte motion vector (four vectors) for each macroblock are output.

Figure 27.10 shows the format of one motion vector for H.264/MPEG-2/VC-1 and figure 27.11 shows also the format of one motion vector for MPEG-4/H.263.

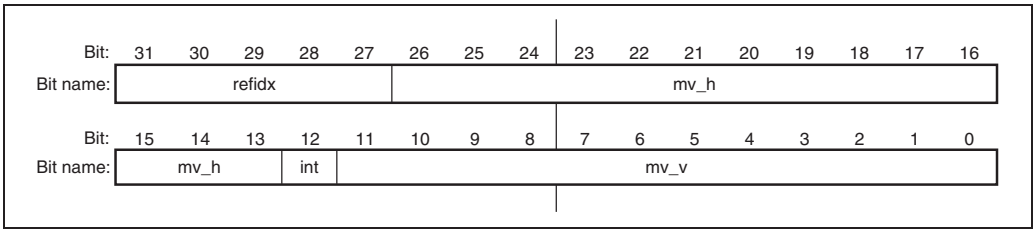

Figure 27.17 Motion Vector format (H.264/MPEG-2/VC-1)

Bit	Bit Name	Description
31 to 27	ref_idx	ref_idx 0: Indicates ref_idx
26 to 13	mv_h	Horizontal Motion Vector 0: Horizontal motion vector (1/4 pixel accuracy)
12	int	Intra/Inter Flag 0: Inter MB encoding 1: Intra MB encoding
11 to 0	mv_v	Vertical Motion Vector 0: Vertical motion vector (1/4 pixel accuracy)

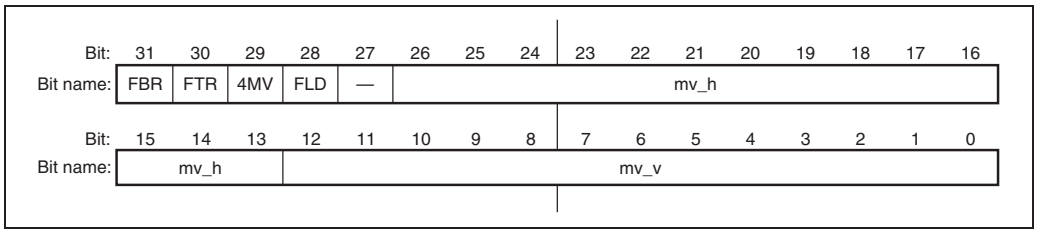

Figure 27.18 Motion Vector format (MPEG-4/H.263)

Bit	Bit Name	Description
31	FBR	forward_bottom_field_reference 0: forward_bottom_field_reference value (refer to FWD-bot MV 0:Top, 1:Bottom)
30	FTR	forward_top_field_reference 0: forward_top_field_reference value (refer to FWD-bot MV 0:Top, 1:Bottom)
29	4MV	4MV 0: 1MV MB 1: 4MV MB
28	FLD	FLD 0: Frame MB 1: Field MB
27	—	reserved
26 to 13	mv_h	Horizontal Motion Vector（-8,192 to 8,191） Horizontal motion vector (1/4 pixel accuracy)
12 to 0	mv_v	Vertical Motion Vector（-4,096 to 4,095） Vertical motion vector (1/4 pixel accuracy)

In the VPU5HG, one CE outputs a motion vector for odd-numbered macroblock lines and the other CE a motion vector for even-numbered macroblock lines. Figure 27.12 shows the motion vector format.

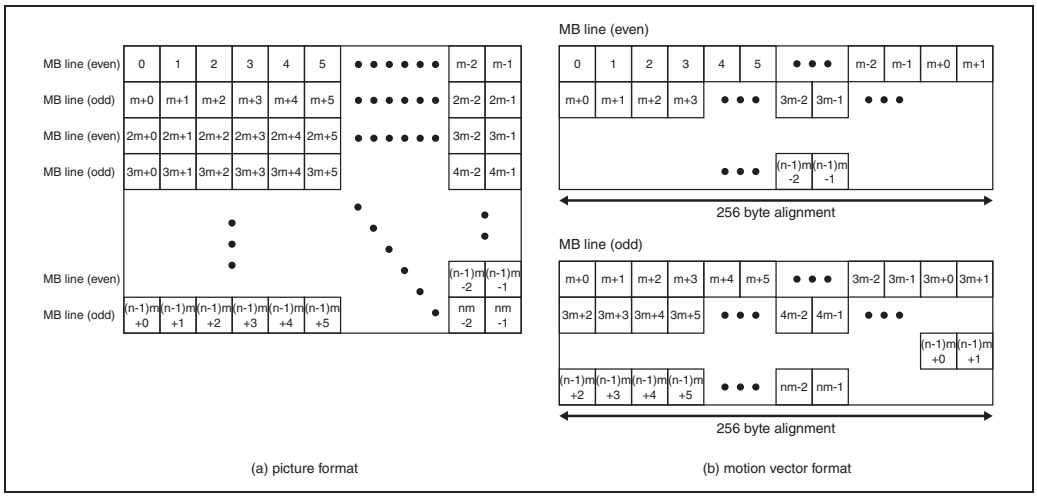

Figure 27.19 Motion Vector Format

37.5.9 Data Partition

If the coding tool data partition is used to improve error durability during MPEG-4 decoding, an area is required to store information on the data partition. The VPU5 accesses this information to reorder encoding data.

The required size for the area is (48 bytes × number of macroblocks + { 8 bytes).Secure a buffer area that accommodates this data size in 256-byte units, aligning to a 32-byte boundary.

37.5.10 Colocation Not Coded Information

When the VLCS processes a sequence including a B-VOP in MPEG-4 decoding, an area for storing the colocation not coded information is needed. The VPU5 outputs information to the area when decoding a P-VOP and inputs information from the area when decoding a B-VOP. An area of ((number of macroblocks + 63) / 64) × 64 bits is required. The buffer area that can contain this size of data should be aligned on a 32-byte boundary and established in 256-byte units.

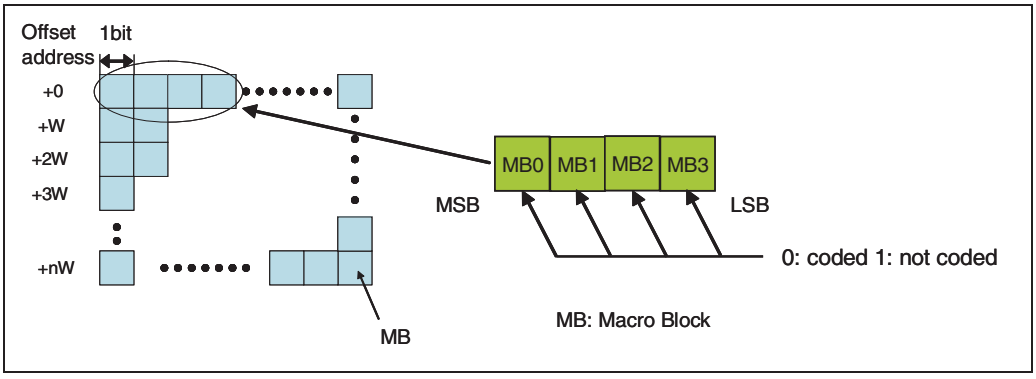

Figure 27.20 Colocation Not Coded Information Format

37.5.11 Bit Plane

A bit plane is required when starting the VLCS for decoding. Its contents are input for decoding by the VLCS. It includes control parameters for each slice.

The size of a bit plane depends on the picture size. Before starting the VLCS, establish a data area for four bits/macroblock.

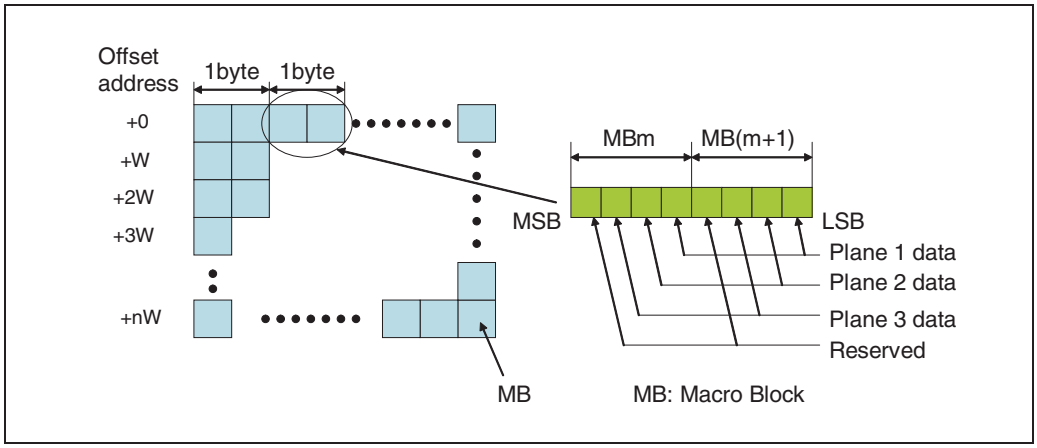

Figure 27.21 4 Bit Plan Data Format

Field P							

Note: The number which follows a white circle indicates the number of a storage position in a bit plane.

37.5.12 MapColToList Information

BPDPREn in the VP5_VLC_MODE (VLCS mode register) is set to 1; that is, when MapColToList is processed in MB line units or MB units. The required area size is size S (bytes) shown in the following × (number of MB lines or MBs). Size S is determined by whether conditions MbAffFlag == 1 and anchor picture = field picture are satisfied.

Note that when MapColToList data is provided for each MB or MB line, an intermediate stream of up to 7,104 bits is added to that MB or MB line. If, for example, MapColToList data is provided for each MB line for a stream produced at 1,920 × 1,080 resolution, up to 68 × 7,104 = 483,072 bits are added for each frame.

37.6 Operational Description

37.6.1 Overview

The VPU5HG is 1-way CODEC hardware IP which implements H.264, MPEG-2, MPEG-4, H.263, and VC-1 encoding and decoding. This section describes the VPU5HG processing flow.

The VPU5HG consists of two modules. One is the VLC responsible for encoding and the other is the CE responsible for picture processing. The modules can operate independently of each other. The VPU5HG performs the processing for the levels shown in table 27.37. Software processing is required for the higher levels.

37.6.2 VPU5HG Operation Control Setting

To control the VPU5HG operation, it is necessary to combine setting methods shown in table 27.38.

Table 27.38 VPU5HG Operation Setting Methods

No.	Setting method	Description
(1)	Register	The VPU5HG operation control is specified in the register mapped to the host space. This register includes the system settings.
(2)	Initialization routine	Stores into external RAM both the firmware for operating the TRF, FME and DEB, which use the STX and PIPE architectures in the VLCS, and control information from a layer above the picture layer according to the video encoding scheme. After the VPU5HG is activated, it executes the initialization routine. Processing starts when the settings in the external RAM are already downloaded into the internal RAM or register in the VPU5HG. The data format for the initialization routine contains 128-bit data which is a combination of VPU5HG internal space address and data shown in figure 27.23.
(3)	Command stream	The external RAM stores control information included in the slice header for H.264 decoding. After the VPU5HG is activated, the VLCS reads that information from the external RAM for decoding of each slice. Figure 27.24 shows the data format for command streams.

(1) Registers

Necessary data is set in the VPU5HG register mapped to the host space. The VPU5HG register contents can only be accessed as long words (each consisting of 32 bits). Table 27.6 shows the VPU5HG registers.

The VPU5HG registers contain system settings. Information about the operating status and processing results for each process is available from the status register.

(2) Initialization Routine

The setting method which uses the initialization routine involves storing the VPU5HG control parameters into the external RAM.

The setting parameters for the initialization routine excluding the STX and PIPE microcode are called the initialization routine parameters. Their format is shown in figure 27.23.

Figure 27.23 shows the storage format for 32-bit external RAM. Each packet contains a multiple of four words (128 bits). One packet corresponds to one internal register (64 bits). The first one word contains: the VPU address [21:17] of a register shown in section 27.3, Internal Register Descriptions; mask bits for broadcasting (EMASK: H'0 unless otherwise specified) and transfer direction bits (D = 1: Counterclockwise rotation). RSVD is a reserved area which should be set to 0. The second word contains the VPU address [16:0] of a register shown in section 27.3, Internal Register Descriptions. Because the register data length specified by the initialization routine is 64 bits, the low-order three bits (TRM) for the address specified in the second word are always 0. The subsequent two words (64 bits) specify the actual data to be stored. The packets should be in consecutive addresses.

The last packet (end packet) for the initialization routine parameters is VPU address H'0000 1007 (set by DMAC channel 1) or VPU address H'0020 1007 (set by DMAC channel 0). Select 0 for the DATA field. Select 1 for resuming the operation. Tables 27.5 and 27.6 show the internal registers to be set for the initialization routine.

For encoding which involves one CE, only the internal registers of CE0 are used. Select 1 for the DATA field for CE0’s end packet. There is no need to specify the initialization parameters for CE1.

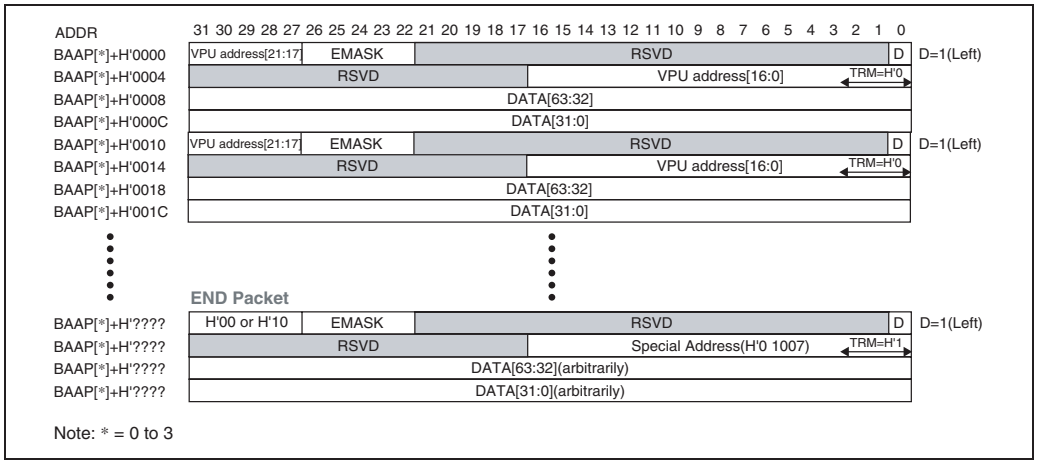

Figure 27.23 Initialization Routine Parameter Format

(3) Command Stream

A command stream is intended to automatically specify the slice setting parameters in the VLCS when starting the slice processing. This stream is available for decoding. If a command stream is enabled, the VLCS reads the stream by using the GDMAC automatic mode when starting the slice processing. Then, it sets the basic parameters for the slice and transfers additional data to the STX data memory.

Note: A command stream containing one frame of slice information should be stored in the external RAM before the VLCS is activated.

A command stream consist of a command header and subsequent data areas required. Figure 27.17 shows the command header configuration. Two or more commands can be given for each slice. The boundary bit (B bit) in the command header in the last command for each slice should be set to 1. The command is prefetched to reduce the overhead involved in reading the command stream on the slice boundary. However, the command capacity should be 128 bytes or less per slice due to the prefetch buffer size. If the command capacity exceeds that limit, the command stream read time cannot be decreased and the performance might be degraded.

One command of command type 0 is always required for each slice. This command should specify the stream start position and start macroblock address. This command should be the first to be specified for each slice. This command contains: the E bit which indicates the last slice to be processed; the S bit which indicates that the slice-level parameter is abbreviated; the I bit which indicates the initial processing of the picture is required; and the T bit which indicates the final processing of the picture is required.

If the E bit is 1, the next slices are not processed. The VLCS processing terminates after the current slice is processed.

If the S bit is 1, the same slice parameter as that for the previous slice is used for addresses other than the macroblock address or stream start address. If any of the parameters excluding this bit are changed, all the slice parameters should be specified.

If the I bit is 1, the current macroblock address is initialized to the address specified in command type 0. The slices are processed in the order of the scanned macroblocks. This bit is set to 0 when an error macroblock is inserted if an absent macroblock is detected. The VLCS manages the position of the currently processed macroblock. If the I bit is 0 and if the macroblock position at the beginning of the slice (i.e., the macroblock address specified in command type 0) differs from the currently processed macroblock position, then an error macroblock is inserted, thereby advancing the current macroblock position to the beginning of the slice.

If the T bit is 1, the VLCS inserts error macroblocks into slices ending with the last one in the picture after the completion of the current slice processing. Typically, this bit is specified for the last slice in the picture.

Table 27.39 shows the functions of the E, S, I and T bits. Table 27.40 shows the normal settings. Use the settings shown in table 27.39 for the VPU5HG.

Table 27.39 Functions of the Operation Control Bits of Command Type 0

Bit name	Function	Description
E	Specification of the last command	0: Does nothing. 1: Terminates the VLCS operation after slice processing.
S	Specification of the use of the same slice parameter	0: Uses the newly specified slice parameter. 1: Uses the same slice parameter as that for the previous slice. (This value should not be selected for the VPU5HG.)
I	Forced specification of the macroblock address	0: Processes the slices after inserting error conceal MBs in the positions between the last MB in the previous slice and the first MB in the current slice. 1: Does nothing. Performs processing after a seek to the start MB address in the slice. (This value should not be selected for the VPU5HG.)
T	Specification of insertion of error macroblocks in MBs ending with the lower right one	0: Does nothing. 1: Inserts error conceal MBs in the positions ending with the lower right one in the picture after slice processing. (This value should be the same as that for the E bit for the VPU5HG.)

Table 27.40 Normal Settings for the Control Bits of Command Type 0

	Bit status			
Slice position	**E**	**S**	**I**	**T**
First slice in the picture	0	0	0	0
Last slice in the picture	1	0	0	1
First and last slices in the picture	1	0	0	1
Other slices	0	0	0	0

Command type 8 is specified after command type 0. Command type 8 is used to specify the stream buffer size and initial buffer offset. The stream buffer size can be specified in units of 256 bytes, and thus the low-order eight bits should always be set to 0. The initial buffer offset can be specified in units of eight bytes, and thus the low-order three bits should always be set to 0. A stream is read starting at a position determined by the specified initial offset. If the VLCS has read an amount of data equal to the specified buffer size, it stops reading the stream. Then, an error is reported via the VP5_VLC_ERRH and VP5_VLC_ERRL registers. The initial offset should be less than the specified buffer size. If interrupts for the stream channel are enabled by the VP5_INT_ENB register settings, the VLCS stops its operation and generates an interrupt which results in continuing the operation.

DMA prefetch occurs when a stream or other data is read. Thus, extra data is read. (This extra data is not processed.)

If the buffer size is infinite, command type 8 can be omitted. However, it should be specified when control such as continuation with the stream buffer size is required. When specifying command type 8 is necessary, it should always be specified for all slices.

Command type 16 is used for storing a set of data in consecutive areas. It should be stored in units of 64 bits. The low-order three bits for the start address should always be 0. The number of 64-bit words should be specified in Length. For command type 16, the command header is followed by a data row with a length equal to the number of 64-bit words specified in Length. Specify 1 in Length when data in one position is to be changed. If the size of stored data is one word, Length should be 1.

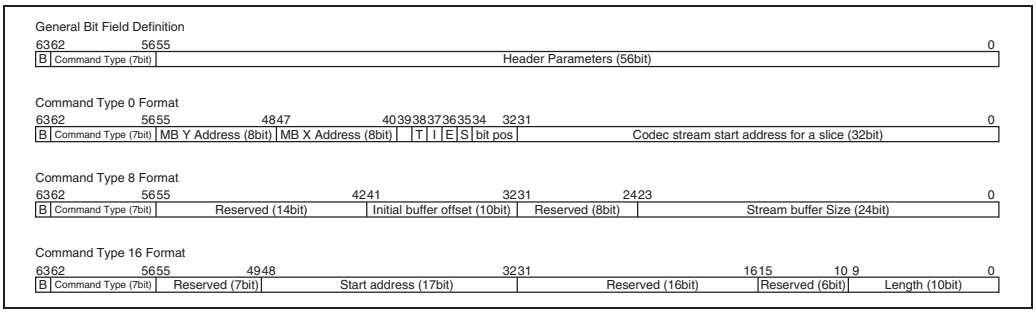

Figure 27.24 Command Header Format

Figure 27.25 shows the overall configuration of a command stream. This stream contains a series of parameters for each slice in a single picture. There are three command headers for each slice: the first of type 0, the second of type 8 and the third of type 16. The command header of type 16 is followed by parameters to be stored in addresses specified in that header. For details about these parameters, refer to the description of the command stream parameters in section 28.4, Command Stream Parameter Descriptions. The command header of type 16 is optional. Usually, one command header of type 16 is required for each slice. Two or more command headers of type 16 can be provided for each slice. The B bit in the last command header for each slice should always be set to 1. By this setting, the VPU5HG VLCS can identify the separation between slices.

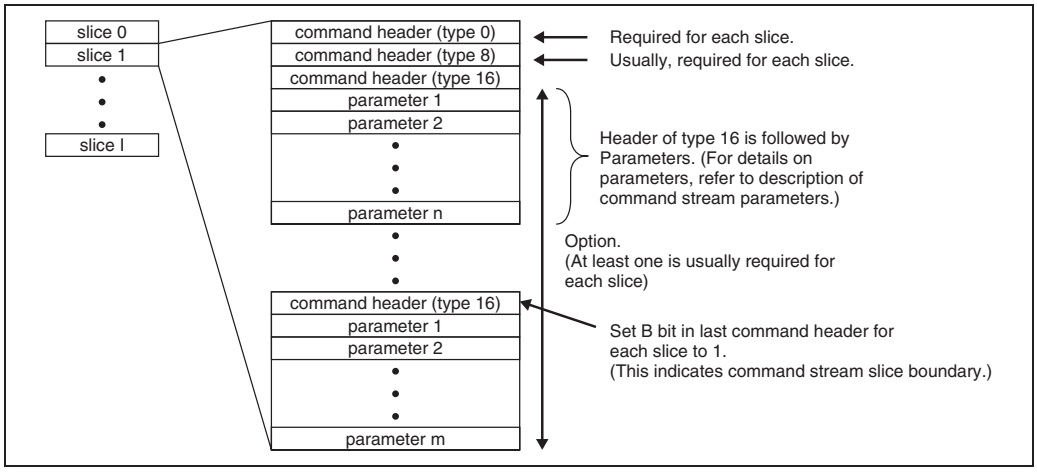

Figure 27.25 Command Stream Configuration

Described below is the stream start position specified in a command stream of type 0. Also described are the related parameters for decoding. These descriptions are based on figure 27.26.

In a command stream of type 0, specify the stream start address as an address of the byte including the start bit for slice data. This address should be Sadr shown in the figure. For bit pos, specify the position of the start bit for slice data. This position should be Sbitpos shown in the figure. Specify the horizontal MB position and vertical MB position for MB X addr and MB Y addr, respectively.

To obtain entirely concealed pictures, set both MB X addr and MB Y addr to 255 for the first slice of each picture. For processing non-H.264 content, set both the E and T bits to 1 at this time so each picture can be processed as one slice. For processing H.264 content, each picture is processed as two irregular slices. Set the E and T bits to 0 for the first slice and set both of them to 1 for the second slice. Except for the values of the E and T bits, all the settings for the second slice should be the same as those for the first slice.

If there is an error in H.264 multi-slice encoding/decoding, make settings as follows.

If the first slice or an intermeidate slice in the frame is missing, set the command stream for the normal slices only. The hardware's concealment feature conceals the starved area. If the last slice in the frame is missing, set the command stream for the last-but-one normal slice. At this time, be sure to set both the E and T bits to 1.

The skip bit in word 1 for the command stream parameter should always be 0. For slice_size, specify the number of bytes between the align address (= AAdr) and end address (= EAdr). If the

system does not wrap around memory addresses for continuing operation, slice_size = EAdr - AAdr +1. Be sure to select 0 when concealing the entire picture for processing non-H.264 content.

Calculate AAdr as follows.

AAdr = SAdr&~H'1F (32-byte align mode (established by setting BAAlign = 1 for VP5_VLCS_MODE))

Using figure 27.27, the following describes the parameters which can be specified for command streams of type 8. Use type 8 for specifying the stream buffer area. If data outside of this area are accessed, the VLCS stops reading from the memory and behaves the same way as it does when internally reading data 0.

Use the Stream Buffer Size parameter to specify the buffer area size in units of 256 bytes. The low-order eight bits should always be 0. Be sure to select 0 when concealing the entire picture for processing non-H.264 content.

Use the Stream Buffer Size parameter to specify the buffer area size in units of 256 bytes. The low-order eight bits should always be 0.

Use the Initial Buffer Offset parameter to specify the number of bytes from the beginning of the buffer whose size is in 256-byte units to the align address (= AAdr). This number is a multiple of eight bytes, and thus the low-order three bits should always be 0. This number should always be smaller than the Stream Buffer Size parameter. The VLCS reads from a memory address which is the number of bytes specified in the Initial Buffer Offset parameter away from the align address. Thus, the buffer area can be correctly specified in the Stream Buffer Size parameter by properly setting the Initial Buffer Offset parameter.

The beginning of the buffer whose size is in 256-byte units should be aligned on a 32-byte boundary. The VLCS does not read from the area which follows the stream buffer. However, note that DMA prefetch results in reading extra data. The total amount of such extra data in the overall VPU5HG configuration is equal to the DMA buffer size (512 bytes for the VPU5HG).

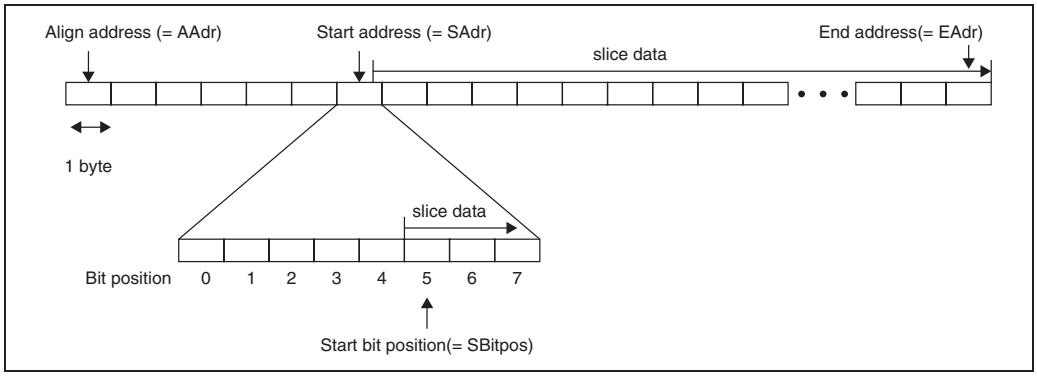

Figure 27.26 Parameters for Specifying a Stream Address for Decoding

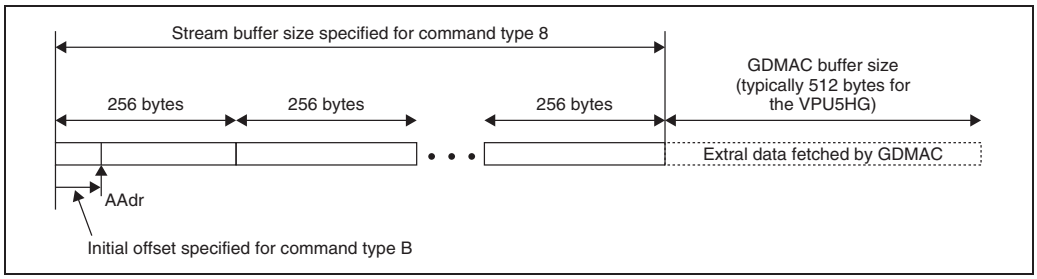

Figure 27.27 Parameters Specified for a Command Stream of Type 8

37.6.3 Encoding

(1) Encoding

The VPU5HG encoding process is divided into two stages. In the first stage, the CE encodes picture data into intermediate data. In the second stage, the VLCS converts the input into variable-length data. First, the CE is activated to perform intra/inter prediction, frequency conversion, etc., thereby converting data into intermediate data. Then, the VLCS is activated to convert the intermediate data into a variable-length encoded bit stream. The CE and VLCS encode data in picture units. A termination interrupt can be output to provide notification when each module terminates its processing.

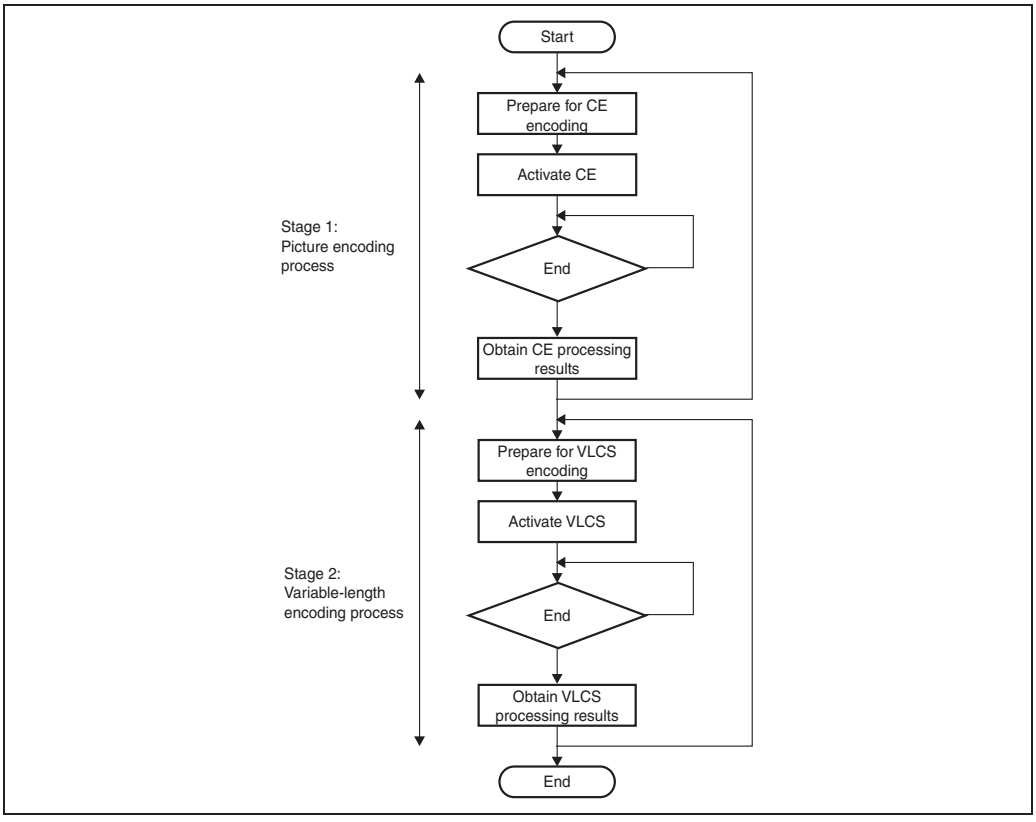

Figure 27.28 Overview of the Encoding Process Flow

(2) Picture Encoding by CE Activation

Encode pictures, reference pictures and encoding control parameters are input for VPU5HG picture encoding by CE activation (stage 1). After this encoding, an intermediate stream and intermediate control stream are output. The CE encodes data in picture units. A termination interrupt can be output to provide notification when the CE terminates its processing.

To encode picture data by CE activation, first set the sequence-level control parameters, picture-level control parameters and encoding mode by using software. Table 27.41 shows the input parameters and data required for this encoding. It also shows the setting methods for the VPU5HG. Table 27.42 shows the output parameters and data for the CE as well as output destinations. The software obtains the control parameters for variable-length encoding (stage 2) by VLCS activation and those for picture encoding (stage 1) by CE activation for the next picture.

Table 27.41 Input Parameters and Data for the CE

Item	Setting method	Description
System settings	Register	Settings for system control of the interrupt, etc., and for execution of the initialization routine
Microcode	Initialization routine	CE microcode
CE operation setting parameter	Initialization routine	Picture-level control parameter and GDMAC settings
Reference picture	External RAM	Reference picture (other than I picture)
Encode picture	External RAM	Picture to be encoded

Table 27.42 Output Parameters and Data for the CE

Item	Output destination	Description
System status	Register	Operation status
Picture status	Register	Encoding result status
Reference picture	External RAM	Reference picture for next-picture encoding
MV information	External RAM	Motion vector information
Intermediate stream	External RAM	Intermediate data stream. (Output for each CE.)
Intermediate control stream	External RAM	Control information required for VLCS processing. (Output for each CE.)

Figure 27.22 shows the software for picture data encoding by CE activation. It also shows the VPU5HG operation flow.

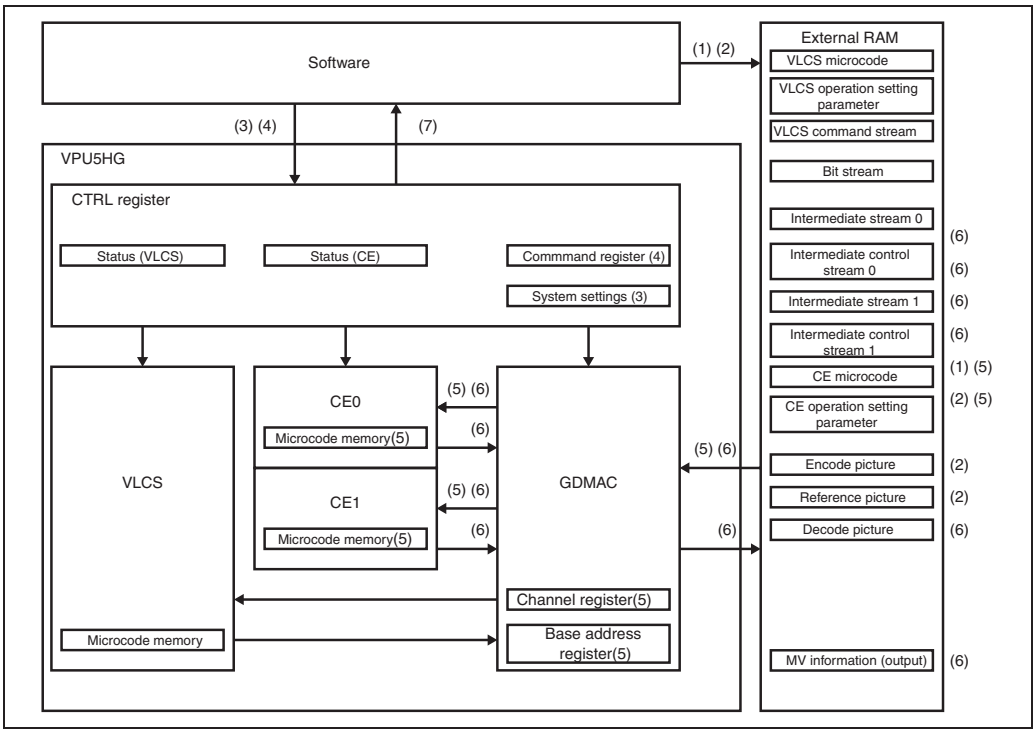

Figure 27.29 Conceptual Diagram of the Software for Picture Encoding and the CE Operation Flow

No.	Encoding Sequence by the CE
(1)	Store predetermined microcode into the external RAM. This code complies with the encoding standard.
(2)	The software stores the encode picture, reference picture, reference picture motion vector and CE operation setting parameters into the external RAM for picture data encoding.
(3)	The software sets the VPU5HG registers for system control and initialization routine execution.
(4)	The software activates the CE by writing 1 to the VPU5HG VP5_CMD register.
(5)	The VPU5HG executes the initialization routine according to the system settings. This routine first downloads the microcode into the microcode memory in the CE. Then, it transfers the CE operation setting parameters to predetermined registers/RAM in the CE and GDMAC.
(6)	After the initialization routine execution, the CE reads the MB-level encoding control parameters, encode picture and reference picture from the external RAM. Then, the it performs the encoding process which includes motion vector detection, frequency conversion, quantization and coefficient prediction. Finally, it outputs an intermediate stream and intermediate control stream. At the same time, it outputs MB and MV information. It may also output MB and MV information to the external RAM depending on the settings.
(7)	After the CE processing, the software checks the encoding result status.

(3) Variable-Length Encoding by VLCS Activation

The intermediate stream is input for VPU5HG variable-length encoding by VLCS activation (stage 2). After this encoding, an encoded bit stream is output. The VLCS encodes data in picture units. A termination interrupt can be output to provide notification when the VLCS terminates its processing.

When encoding involves the use of the VLCS, the software performs encoding above the picture level. After the last data and offset are set as the header information created by the software, the VLCS creates a bit stream which follows the header.

Table 27.44 shows the input parameters and data required for variable-length encoding by VLCS activation. It also shows the setting methods for the VPU5HG. The inputs to the VLCS for encoding are system control information, microcode, picture parameters, GDMAC settings, intermediate streams and intermediate control streams. The picture parameters should be set to the same values as those for CE activation in stage 1. Table 27.45 shows the output parameters and data for the VLCS as well as the output destinations.

Table 27.43 Layers for Bitstream Creation by Hardware

Stream Type(w/ Profile Name)	Layer
MPEG-4	Video packet header or motion shape texture and lower
H.264	Slice data and lower
H.263	gob_layer and lower
MPEG-2	picture_data and lower
MPEG-1	picture_data and lower

Table 27.44 Input Parameters and Data for the VLCS

Item	Setting method	Description

Figure 27.30 shows the software for variable-length encoding by VLCS activation. It also shows the VPU5HG operation flow.

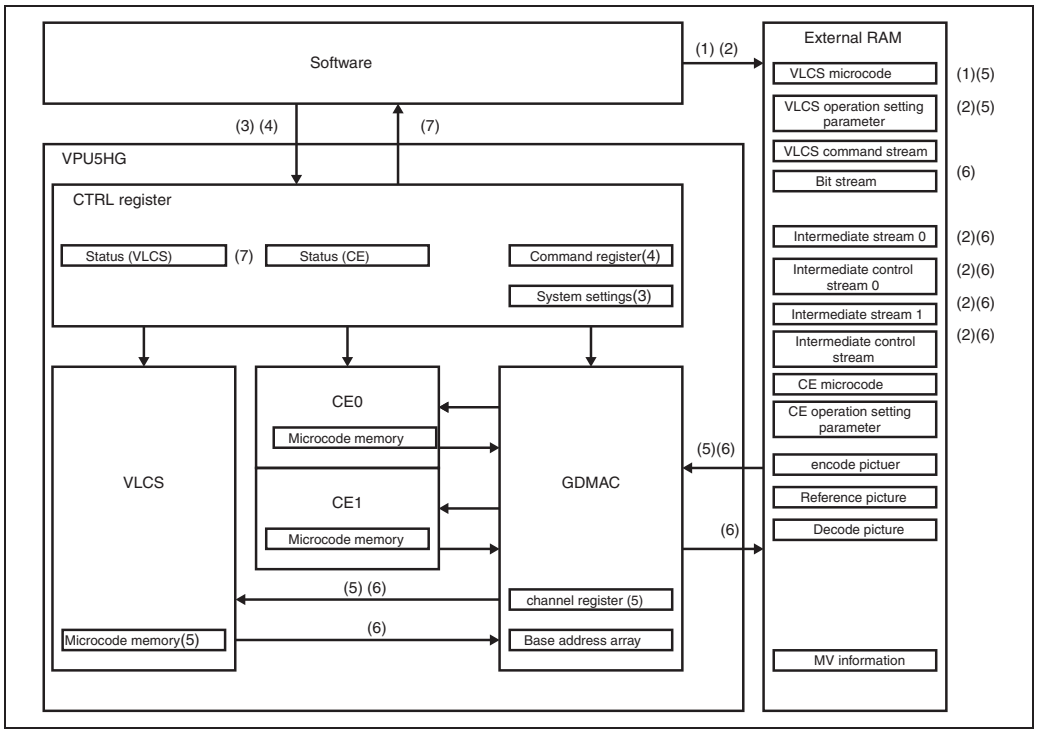

Figure 27.30 Conceptual Diagram of the Software for Variable-Length Encoding and the VLCS Operation Flow

No.	Encoding Sequence by the VLCS
(1)	The software stores predetermined microcode into the external RAM. This code complies with the encoding standard.
(2)	The software stores the VLCS operation setting parameters, intermediate stream and intermediate control stream into the external RAM.
(3)	The software sets the VPU5HG registers for system control and initialization routine execution.
(4)	The software activates the VLCS by writing 1 to VPU5HG VP5_CMD register.
(5)	The VPU5HG executes the initialization routine according to the system settings. This routine first downloads the microcode into the microcode memory in the VLCS. Then, it transfers the VLCS operation setting parameters to predetermined registers/RAM in the VLCS and GDMAC.
(6)	After the initialization routine execution, the VLCS performs variable-length encoding while at the same time reading the intermediate stream and intermediate control stream from the external RAM. The VLCS outputs a bits stream by variable-length encoding.
(7)	After the VLCS processing, the software checks the variable-length encoding result status.

(4) H.264 Encoding Procedures (720 Pixels × 480 Lines Progressive Sequence)

The following describes the steps for H.264 encoding. The examples below assume that the intermediate streams and intermediate control streams are configured with a double buffer. The SDRAM stored data and parameter settings are represented in big endian form. The endian settings for each DMAC channel register and those for VP5_CTRL are 0.

(a) Encoding by the CE (First I Picture)

1. Store the microcode into the external memory. Its base address is H'1000 0000 (set in VP5_CE_MBA) for this example.
2. Create CE0 operation control parameters and store them into the external memory. Their base address is H'1021 0000 (set in VP5_CE_PBA0) for this example.

Table 27.46 Sample CE0 Operation Control Parameters for 720 × 480 I Picture Encoding

Settings																Description

00	00	00	01	00	00	00	a8	00	00	00	00	00	00	00	00	VP5_CE_SLC_SIZE
00	00	00	01	00	00	00	b0	00	00	05	46	ff	ff	00	01	VP5_CE_TBIT
00	00	00	01	00	00	00	b8	00	00	85	55	00	00	00	00	VP5_CE_RCDJ
48	00	00	01	00	00	04	40	00	00	00	00	00	1e	86	00	VP5_CE_IS_BS0 CE intermediate stream 0 buffer size register
80	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Last packet for the initialization routine

Specify the base addresses in VP5_BAAR0. Set the DMA channel registers for encoding. With hsize in the decode picture and reference picture DMA channel registers, specify 1024/8 which is greater than a horizontal picture size of 720. Set VP5_GDMAC_ARDPR1 and VP5_GDMAC_SHWARBT when starting the CE for the first I picture. Specify num_ref_frame = 1, ce = 1, dec_out_disable = 0, stream_type = 2(H.264), mb_width = H2D (= 720/16) and mb_height = H'1E (= 480/16) in VP5_CE_SPAR. Specify pic_type = 0 and refidx_last0 = 0 in VP5_CE_PPAR. Specify the recommended values in VP5_CE_ENC_WPRED, VP5_CE_ENC_CTRL, VP5_CE_ACQ_CTRL and VP5_CE_ME_COST. Set H'0000 0000 in VP5_CE_FME*n*_QNC*m* and VP5_CE_TRF*n*_QNC*m* (*n* = 0, *m* = 1). Specify VPU address[21:17] = H'00 for the last packet for the CE0 initialization routine.

3. Create CE1 operation control parameters and store them into the external memory. Their base address is H'1013 6400 (set in VP5_CE_PBA1) for this example.

Table 27.47 Sample CE1 Operation Control Parameters for 720 × 480 I Picture Encoding

Setting																Description
d0	00	00	01	00	00	40	40	12	a2	00	00	00	00	00	00	VP5_BAAR1 decode picture luminance base address

d0	00	00	01	00	00	00	90	c0	00	00	00	00	00	0c	12	VP5_CE_DCHR_MVINFO1 MV information output DMA channel register 1
d0	00	00	01	00	00	00	b0	c0	00	00	00	00	00	10	16	VP5_CE_DCHR_CEIS1 CE intermediate stream DMA channel register 1
d0	00	00	01	00	00	00	b8	c0	00	00	00	00	00	10	17	VP5_CE_DCHR_CEIC1 CE intermediate control stream DMA channel register 1
c8	00	00	01	00	00	04	40	00	00	00	00	00	1e	86	00	VP5_CE_IS_BS1 CE intermediate stream 1 buffer size register
c0	00	00	01	00	00	00	50	00	00	00	04	00	00	00	00	VP5_CE_DEB_LMDMASR1 DEB1LMDMA synchronous register
00	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Late packet for the initialization routine

Specify the base addresses in VP5_BAAR1. Set the DMA channel registers for encoding. Specify VPU address[21:17] = H'00 for the last packet for the CE1 initialization routine.

4. Make settings for system control and initialization routine activation. Then, start the CE. Below are sample register settings. Start the CE with the CME bit = 1 and the CE bit = 1 in the VP5_CTRL register.

```
register_write ( VP5_CTRL,      H'0000 00B5 ); // Overall operation settings
register_write ( VP5_IRQ_ENB,   H'0000 0101 ); // Interrupt enable
register_write ( VP5_CE_MBA,    H'1000 0000 ); // Microcode base address
register_write ( VP5_CE_PBA0,   H'1002 1000 ); // Parameter base address
register_write ( VP5_CE_PBA1,   H'1013 6400 ); // Parameter base address
register_write ( VP5_CMD,       H'0000 0001 ); // Activation
```

where arguments #0 and #1 for register_write() indicate a register name and data to be set, respectively.

5. Check the results.

The CS bit in the VP5_STATUS register indicates the VPU5HG CE is active. When it terminates its operation, this bit is set to 0 and the CE bit in the VP5_IRQ_STA register is set to 1, indicating the termination status.

After the operation, check the following status registers:

VP5_CE_ERR
VP5_CE_INT_TB0

VP5_CE_INT_TB1
VP5_CE_MB_ATTR
VP5_CE_MB_SADA
VP5_CE_MB_SADR
VP5_CE_MB_USAD
VP5_CE_ASUM
VP5_CE_ACT}
VP5_CE_QSUM
VP5_CE_DJS
VP5_CE_YSUM

(b) Encoding by the VLCS (First I Picture)

1. Store the microcode into the external memory. Its base address is H'100a 3000 (set in VP5_CE_MBA) for this example.
2. Store the microcode into the external memory. Its base address is H'100a 3000 (set in VP5_CE_MBA) for this example.

Table 27.48 Sample VLCS DMAC Channel 0 Operation Control Parameters for 720 × 480 I Picture Encoding

Setting																Description
50	00	00	01	00	00	40	c0	13	44	00	00	00	00	00	00	VP5_BAAR0 stream A base address

08	00	00	01	00	00	80	20	00	00	00	00	00	00	00	00	VP5_VLC_SH word 4
08	00	00	01	00	00	80	28	00	02	00	01	00	65	00	01	VP5_VLC_SH word 5
08	00	00	01	00	00	80	30	11	01	00	00	00	00	00	00	VP5_VLC_SH word 6
08	00	00	01	00	00	80	70	00	00	00	00	00	00	05	46	VP5_VLC_SH word 14
08	00	00	01	00	00	0f	50	00	00	00	12	00	01	00	2e	VP5_VLC_MODE
08	00	00	01	00	00	0f	80	00	00	00	00	00	0f	43	00	VP5_VLC_STRA_BS stream buffer size register
08	00	00	01	00	00	0f	a0	00	00	00	00	00	1e	86	00	VP5_VLC_IS_BS0 VLCS intermediate stream 0 buffer size register
08	00	00	01	00	00	0f	b0	00	00	00	00	00	1e	86	00	VP5_VLC_IS_BS1 VLCS intermediate stream 1 buffer size register
80	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Last packet for the initialization routine

Specify the base addresses in VP5_BAAR0. Set the base addresses of the intermediate stream and intermediate control stream equal to the addresses output by the CE as follows.

VP5_BAAR0.CEIS0→VP5_BAAR1.VLIS1

VP5_BAAR0.CEIC0→VP5_BAAR1.VLIC1

VP5_BAAR1.CEIS1→VP5_BAAR0.VLIS0

VP5_BAAR1.CEIC1→VP5_BAAR0.VLIC0

Set the DMA channel registers for decoding. Set VP5_GDMAC_ARDPRI and VP5_GDMAC_SHWARBT when activing the VLCS for the first I picture. Specify mode=1 (decoding), num_ref_frame = 1, ce = 1, dec_out_disable = 0, stream_type = 2(H.264), mb_width = H'2d (= 720/16) and mb_height = H'1e (= 480/16) in VP5_VLC_SPAR. Specify EPrevDelEn = 0, EPrevInsEn = 1 and CmdEn = 0 in VP5_VLC_MODE for encoding. Specify VPU address[21:17] = H'10 for the last packet for the DMAC channel 0 initialization routine.

3. Create VLCS operation control parameters and store them into the external memory. Their base address is H'101B 7400 (set in VP5_CE_PBA1) for this example.

Table 27.49 VLCS DMAC Channel Operation Control Parameters for 720 × 480 I Picture Encoding

Setting																Description
d0	00	00	01	00	00	40	e0	13	b7	4f	00	00	00	00	00	VP5_BAAR1 VLCS intermediate stream base address
d0	00	00	01	00	00	40	e8	13	d5	d5	00	00	00	00	00	VP5_BAAR1 VLCS intermediate control stream base address
d0	00	00	01	00	00	00	e0	88	a0	70	00	00	00	12	1c	VP5_VLC_DCHR_VLIS1 VLCS intermediate stream DMA channel register 1
d0	00	00	01	00	00	00	e8	88	a8	70	00	00	00	12	1d	VP5_VLC_DCHR_VLIC1 VLCS intermediate control stream DMA channel register 1
00	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Last packet for the initialization routine

Specify the base addresses in VP5_BAAR1. Set the DMA channel registers for decoding. Set the base addresses of the intermediate stream and intermediate control stream equal to the addresses output by the CE as follows.

VP5_BAAR0.CEIS0→VP5_BAAR1.VLIS1

VP5_BAAR0.CEIC0→VP5_BAAR1.VLIC1

VP5_BAAR1.CEIS1→VP5_BAAR0.VLIS0

VP5_BAAR1.CEIC1→VP5_BAAR0.VLIC0

Specify the base addresses in VP5_BAAR1. Set the DMA channel registers for decoding. Specify VPU address[21:17] = H'00 for the last packet for the DMAC channel 1 initialization routine.

4. Make settings for system control and initialization routine activation. Then, start the VLCS. When the VLCS is activated, the CE processing should already be terminated. Below are sample register settings. Start the VLCS with the VME bit = 1 and the VE bit = 1 in the VP5_CTRL register.

```
register_write ( VP5_CTRL,      H'0000 C500 ); // Overall operation settings
register_write ( VP5_IRQ_ENB,   H'0000 0101 ); // Interrupt enable
register_write ( VP5_VLC_MBA,   H'100A 3000 ); // Microcode base address
register_write ( VP5_VLC_PBA0,  H'100B 4000 ); // Parameter base address
register_write ( VP5_VLC_PBA1,  H'101B 7400 ); // Parameter base address
register_write ( VP5_CMD,       H'0000 0001 ); // Activation
```

5. Check the results.

   The VS bit in the VP5_STATUS register indicates the VPU5HG VLCS is active. When it terminates its operation, this bit is set to 0 and the VLE bit in the VP5_IRQ_STA register is set to 1, indicating the termination status.

   After the operation, check the following status registers:

   VP5_VLC_TB
   VP5_VLC_ERRH
   VP5_VLC_ERRL

(c) Encoding by the CE (P Picture)

The following shows an example of encoding by the CE for P pictures.

1. When the CE is used to encode a P picture after an I picture, there is no need to reset the microcode.
2. Create CE0 operation control parameters and store them into the external memory. Their base address is H'1021 0000 (set in VP5_CE_PBA0) for this example

Table 27.50 Sample CE0 Operation Control Parameters for 720 × 480 P Picture Encoding

Setting																Description
50	00	00	01	00	00	40	40	12	d8	00	00	00	00	00	00	VP5_BAAR0 decode picture luminance base address

80	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Last packet for the initialization routine

Specify the base addresses in VP5_BAAR0. This example assumes that the intermediate stream and intermediate control stream are configured with a double buffer, and that the specified base addresses are different from those for the I picture encoding. Set the DMA channel registers for encoding. With hsize in the decode and reference picture DMA channel registers, specify 1024/8 which is greater than a horizontal picture size of 720. Specify num_ref_frame = 1, ce = 1, dec_out_disable = 0, stream_type = 2(H.264), mb_width = H'2D (= 720/16) and mb_height = H'1E (= 480/16) in VP5_CE_SPAR. Specify pic_type = 0 and refidx_last0 = 0 in VP5_CE_PPAR. Specify the recommended values in VP5_CE_ENC_WPRED, VP5_CE_ENC_CTRL, VP5_CE_ACQ_CTRL and VP5_CE_ME_COST. Set H'0000 0000 in VP5_CE_FME*n*_QNC*m*

and VP5_CE_TRF*n*_QNC*m* (*n* = 0, *m* = 1). Specify VPU address[21:17] = H'10 for the last packet for the CE0 initialization routine.

3. Create CE1 operation control parameters and store them into the external memory. Their base address is H'1013 6400 (set in VP5_CE_PBA1) for this example.

Table 27.51 Sample CE0 Operation Control Parameters for 720 × 480 P Picture Encoding

Setting																Description

00	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Last packet for the initialization routine

Specify the base addresses in VP5_BAAR1. This example assumes that the intermediate stream and intermediate control stream are configured with a double buffer, and that the specified base addresses are different from those for the I picture encoding. Set the DMA channel registers for encoding. Specify VP5_CE_DEB_LMDMASR1 for the CE1 operation control parameter. Specify VPU address[21:17] = H'00 for the last packet for the CE1 initialization routine.

4. Make settings for system control and initialization routine activation. Then, start the CE. Below are sample register settings. Start the CE with the CME bit = 0 and the CE bit = 1 in the VP5_CTRL register.

```
register_write ( VP5_CTRL,      H'0000 00B1 ); // Overall operation settings
register_write ( VP5_IRQ_ENB,   H'0000 0101 ); // Interrupt enable
register_write ( VP5_CE_PBA0,   H'1002 1000 ); // Parameter base address
register_write ( VP5_CE_PBA1,   H'1013 6400 ); // Parameter base address
register_write ( VP5_CMD,       H'0000 0001 ); // Activation
```

5. Check the results as described for the I picture processing.

(d) Encoding by the VLCS (P Picture)

1. When the VLCS is used to encode a P picture after an I picture, there is no need to reset the microcode.
2. Create VLCS operation control parameters and store them into the external memory. Their base address is H'100B 4000 (set in VP5_CE_PBA0) for this example.

Table 27.52 Sample VLCS DMAC Channel 0 Operation Control Parameters for 720 × 480 P Picture Encoding

Setting																Description
50	00	00	01	00	00	40	c0	13	44	00	00	00	00	00	00	VP5_BAAR0 stream A base address

08	00	00	01	00	00	0f	50	00	00	00	12	00	01	00	2e	VP5_VLC_MODE
08	00	00	01	00	00	0f	80	00	00	00	00	00	0f	43	00	VP5_VLC_STRA_BS stream buffer size register
08	00	00	01	00	00	0f	a0	00	00	00	00	00	1e	86	00	VP5_VLC_IS_BS0 VLCS intermediate stream 0 buffer size register
08	00	00	01	00	00	0f	b0	00	00	00	00	00	1e	86	00	VP5_VLC_IS_BS1 VLCS intermediate stream 1 buffer size register
80	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Late packet for the initialization routine

Specify the base addresses in VP5_BAAR0. Set the base addresses of the intermediate stream and intermediate control stream equal to the addresses output by the CE as follows.

VP5_BAAR0.CEIS0→VP5_BAAR1.VLIS1

VP5_BAAR0.CEIC0→VP5_BAAR1.VLIC1

VP5_BAAR1.CEIS1→VP5_BAAR0.VLIS0

VP5_BAAR1.CEIC1→VP5_BAAR0.VLIC0

Set the DMA channel registers, VP5_VLC_SPAR and VP5_VLC_MODE to the same values as those for the I picture encoding. Specify VPU address[21:17] = H'10 for the last packet for the DMAC channel 0 initialization routine.

3. Create VLCS operation control parameters and store them into the external memory. Their base address is H'101B 7400 (set in VP5_CE_PBA1) for this example.

Table 27.53 Sample VLCS DMAC Channel 1 Operation Control Parameters for 720 × 480 P Picture Encoding

Setting																Description
d0	00	00	01	00	00	40	e0	13	96	cb	00	00	00	00	00	VP5_BAAR1 VLCS intermediate stream base address
d0	00	00	01	00	00	40	e8	13	b5	51	00	00	00	00	00	VP5_BAAR1 VLCS intermediate control stream base address
d0	00	00	01	00	00	00	e0	88	a0	70	00	00	00	12	1c	VP5_VLC_DCHR_VLIS1 VLCS intermediate stream DMA channel register 1
d0	00	00	01	00	00	00	e8	88	a8	70	00	00	00	12	1d	VP5_VLC_DCHR_VLIC1 VLCS intermediate control stream DMA channel register 1
00	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Late packet for the initialization routine

Specify the base addresses in VP5_BAAR1. Set the base addresses of the intermediate stream and intermediate control stream equal to the addresses output by the CE as follows.

VP5_BAAR0.CEIS0→VP5_BAAR1.VLIS1

VP5_BAAR0.CEIC0→VP5_BAAR1.VLIC1

VP5_BAAR1.CEIS1→VP5_BAAR0.VLIS0

VP5_BAAR1.CEIC1→VP5_BAAR0.VLIC0

Set the DMA channel registers for decoding. Specify VPU address[21:17] = H'00 for the last packet for the DMAC channel 1 initialization routine.

4. Make settings for system control and initialization routine activation. Then, start the VLCS. When the VLCS is activated, the CE processing should already be terminated. Below are sample register settings. Start the VLCS with the VME bit = 1 and the VE bit = 1 in the VP5_CTRL register.

```
register_write ( VP5_CTRL,      H'0000 C500 ); // Overall operation settings
register_write ( VP5_IRQ_ENB,   H'0000 0101 ); // Interrupt enable
register_write ( VP5_VLC_MBA,   H'100A 3000 ); // Microcode base address
register_write ( VP5_VLC_PBA0,  H'100B 4000 ); // Parameter base address
register_write ( VP5_VLC_PBA1,  H'101B 7400 ); // Parameter base address
register_write ( VP5_CMD,       H'0000 0001 ); // Activation
```

5. Check the results.

37.6.4 Decoding

(1) Overview of Decoding

The VPU5HG decoding process is divided into two stages. In the first stage, the VLCS performs variable-length decoding. In the second stage, the CE performs picture decoding. Figure 27.24 outlines the decoding process flow. First, the VLCS is activated to convert an encoded bit stream into intermediate data by variable-length decoding (stage 1). Then, the CE is activated to decode the picture data (stage 2). During these stages, the VLCS and CE decode data in picture units. They operate independently of each other. This permits forming a pipeline from the two stages. A termination interrupt can be output to provide notification when each module terminates its processing.

To make the VPU5HG work at its maximum processing capacity, the VLCS and CE should operate asynchronously. The CE is activated synchronously with the arrival of a picture.
The performance of the VLCS depends on the bit rate of bit streams, and because of this, the VLCS is activated asychronously with the arrival of a picture. Acquire an intermediate stream buffer large enough to contain an intermediate stream which is decoded by the VLCS before being decoded by the CE (the recommended size of that buffer is four times the VBV buffer size).

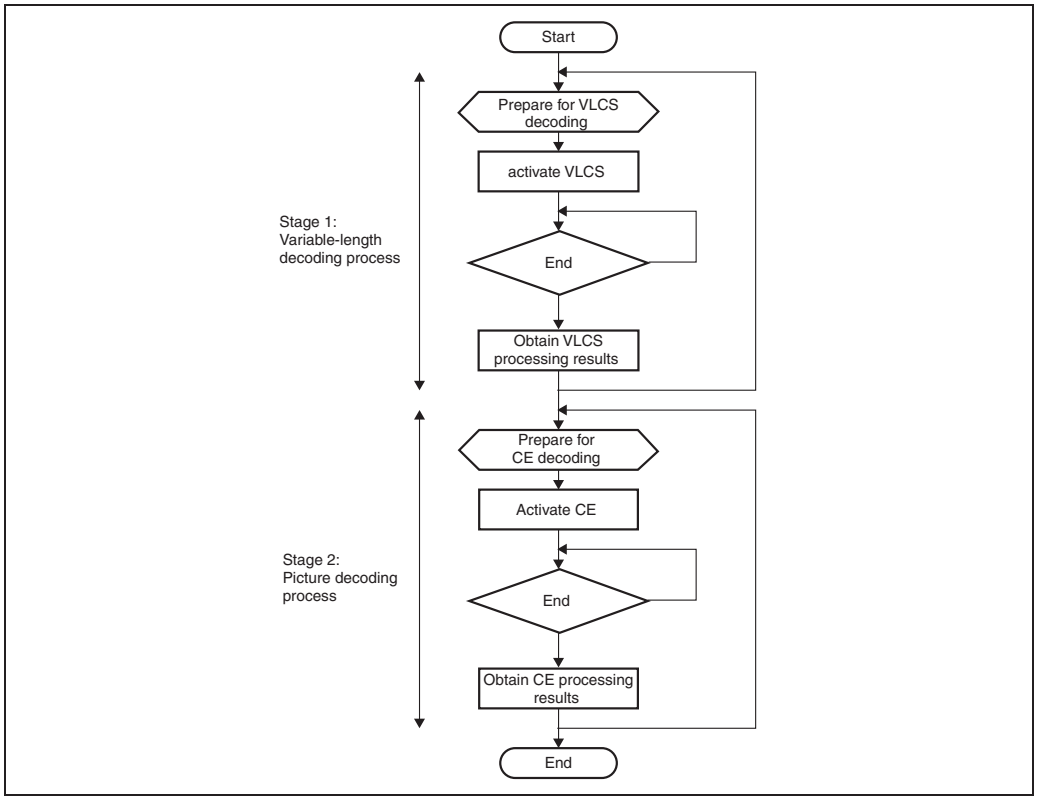

Figure 27.31 Overview of the Decoding Process Flow

(2) Variable-Length Decoding by VLCS Activation

An encoded bits stream is input for VPU5HG variable-length decoding by VLCS activation (stage 1). After this decoding, an intermediate stream is output. The VLCS decodes data in picture units. A termination interrupt can be output to provide notification when the VLCS terminates its processing.

To perform variable-length decoding by VLCS activation, first analyze the layers above the picture header level by using software and obtain the sequence-level and picture-level control parameters for the bit stream which should be decoded. H.264 decoding further involves analyzing the slice header and obtaining the additional control parameters.

Table 27.54 shows the input parameters and data required for variable-length decoding by VLCS activation. It also shows the setting methods for the VPU5HG. The inputs to the VLCS for decoding are system control information, microcode, picture parameters, GDMAC settings, command streams, bit streams and bit streams. The system control information, picture parameters, command streams and bit streams should be based on the results of header analysis by the software. Table 27.55 shows the output parameters and data for the VLCS as well as the output destinations. The software obtains the control parameters for picture decoding (stage 2) by CE activation and those for variable-length decoding (stage 1) by VLCS activation for the next picture.

Table 27.54 Input Parameters and Data for the VLCS

Item	Setting method	Description
System settings	Register	Settings for system control of the interrupt, etc., and for execution of the initialization routine
Microcode	Initialization routine	CE microcode
Operation setting parameter	Initialization routine	Picture-level control parameter and GDMAC settings
Command stream	Command stream	Parameter for the slice settings and the stream start address information
Bit stream	External RAM	Encode bit stream

Table 27.55 Output Parameters and Data for the VLCS

Item	Output destination	Description
System status	Register	Operation status
Picture status	Register	Encoding result status
Intermediate stream	External RAM	Intermediate data stream. (Output for each CE.)
Intermediate control stream	External RAM	Control information required for VLCS processing. (Output for each CE.)

Figure 27.32 shows the software for variable-length decoding by VLCS activation. It also shows the VPU5HG operation flow.

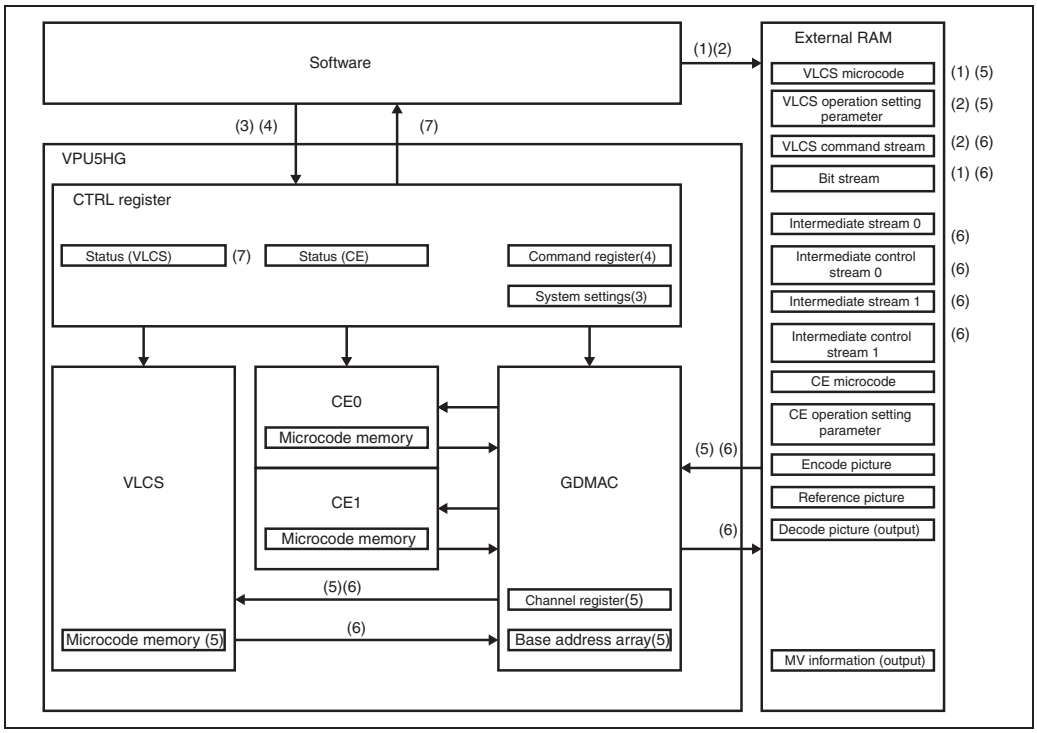

Figure 27.32 Conceptual Diagram of the Software for Variable-Length Decoding and the VLCS Operation Flow

No.	Decoding Sequence by the VLCS
(1)	The software stores the bit stream to be decoded into the external RAM. It also stores predetermined microcode into that memory. This code complies with the encoding standard.
(2)	The software analyzes the upper layers and stores the VLCS operation setting parameters and command streams into the external RAM.
(3)	The software sets the VPU5HG registers for system control and initialization routine execution according to the results of analyzing the upper layers.
(4)	The software activates the VLCS by writing 1 to VPU5HG VP5_CMD register.
(5)	The VPU5HG executes the initialization routine according to the system settings. This routine first downloads the microcode into the microcode memory in the VLCS. Then, it transfers the VLCS operation setting parameters to predetermined registers/RAM in the VLCS and GDMAC.
(6)	After the initialization routine execution, the VLCS performs decoding while at the same time reading the bit stream bit streams and command stream from the external RAM. It outputs an intermediate stream and intermediate control stream by this decoding.
(7)	After the VLCS processing, the software checks the decoding result status.

(3) Picture Decoding by CE Activation

An intermediate stream, subjected to variable-length encoding by the VLCS, is input for VPU5HG picture decoding by CE activation (stage 2). After this decoding, a decoded picture is output. The CE decodes data in picture units. A termination interrupt can be output to provide notification when the CE terminates its processing.

To decode picture data by CE activation, first set the sequence-level and picture-level control parameters for the intermediate stream to be decoded. Use software for setting them. Table 27.56 shows the input parameters and data required for this decoding. It also shows the setting methods for the VPU5HG. The inputs to the CE for decoding are system settings, microcode, CE operation setting parameters, intermediate streams, intermediate control streams, reference pictures and MV information. Table 27.57 shows the output parameters and data for the CE as well as the output destinations. The software obtains the control parameters for variable-length encoding (stage 2) by CE activation for the next picture.

Table 27.56 Input Parameters and Data for the CE

Item	Setting method	Description
System settings	Register	Settings for system control of the interrupt, etc., and for execution of the initialization routine
Microcode	Initialization routine	CE microcode
CE operation setting parameter	Initialization routine	Picture-level control parameters and GDMAC settings
Intermediate stream	External RAM	Intermediate data stream. (Required for each CE.)
Intermediate control stream	External RAM	Control information for CE processing. (Required for each CE.)
MV information	External RAM	Motion vector information (for B picture decoding only)
Reference picture	External RAM	Reference picture

Table 27.57 Output Parameters and Data for the CE

Item	Output destination	Description
System status	Register	Operation status
Picture status	Register	Decoding result status
Decoded picture	External RAM	Picture which is already decoded
MV information	External RAM	Motion vector information

Figure 27.33 shows the software for picture decoding by CE activation. It also shows the VPU5HG operation flow.

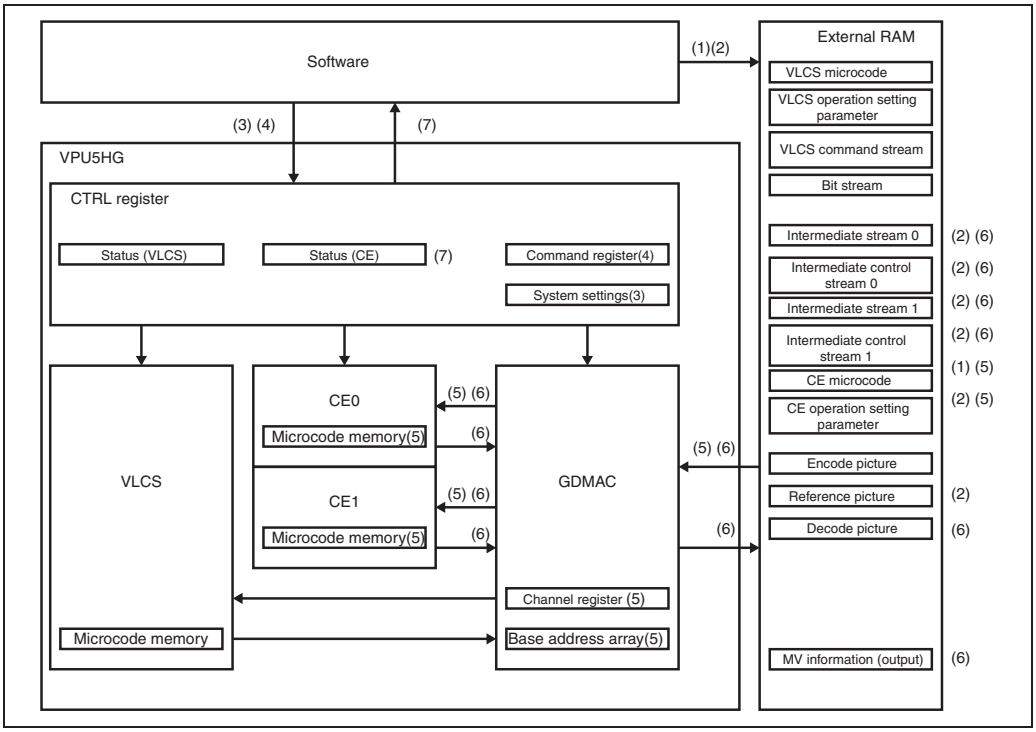

Figure 27.33 Conceptual Diagram of the Software for Picture Decoding and the CE Operation Flow

No.	Decoding Sequence by the CE
(1)	Store predetermined microcode into the external RAM. This code complies with the encoding standard.
(2)	The software stores the encode picture, reference picture, reference picture motion vector and CE operation setting parameters into the external RAM for picture data encoding.
(3)	The software sets the VPU5HG registers for system control and initialization routine execution.
(4)	The software activates the CE by writing 1 to VPU5HG VP5_CMD register.
(5)	The VPU5HG executes the initialization routine according to the system settings. This routine first downloads the microcode into the microcode memory in the CE. Then, it transfers the CE operation setting parameters to predetermined registers/RAM in the CE and GDMAC.
(6)	After the initialization routine execution, the CE reads the intermediate stream, intermediate control stream, reference picture and reference picture motion vector from the external RAM while at the same time performing decoding. The CE outputs a decoded picture after decoding. It also outputs MV information to the external RAM as required.
(7)	After the CE processing, the software checks the decoding result status.

(4) H.264 Decoding Procedures (720 Pixel × 480 Line Progressive Sequence)

The following describes the steps for H.264 decoding. The example below assumes that the stream is placed in H'1200 0000 and that the intermediate streams and intermediate control streams are configured with a double buffer. The SDRAM stored data and parameter settings are represented in big endian form. The endian settings for each DMAC channel register and those for VP5_CTRL are 0.

(a) Decoding by the VLCS (First I Picture)

1. Store the microcode into the external memory. Its base address is H'100A 3000 (set in VP5_CE_MBA) for this example.
2. Create VLCS DMAC channel 0 operation control parameters and store them into the external memory. Their base address is H'100B 4000 (set in VP5_CE_PBA0) for this example.

Table 27.58 Sample VLCS DMAC Channel 0 Operation Control Parameters for 720 × 480 I Picture Decoding

Setting																Description

Specify the base addresses in VP5_BAAR1. Set the DMA channel registers for decoding. Specify VPU address[21:17] = H'00 for the last packet for the CE1 initialization routine.

4. Create command streams and store them into the external memory. Their base address is H'1455 4200 (set in VP5_BAAR0) for this example.

Table 27.57 Sampel Command Stream Settings for 720 × 480 I Picture Decoding

Setting																Description
00	00	00	53	12	00	00	1f	08	00	00	00	00	00	00	00	Command header (type0,type8)
90	00	80	00	00	00	00	03	00	00	00	00	00	00	00	00	Command header (type16,Length=3)
00	00	a8	05	1e	00	1e	00	00	00	00	00	00	00	00	00	Command header (type16). Continued from above.

Set the command stream by referring to section 27.5.5. For this example, set the operation control bits for the command headers of type 0 to the values (T = E = 1, S = I = 0) for the first and last slices of the picture. For command type 0, set Stream Start Address to the byte address (H'1200 001F) including the first bit of slice data and set bit_pos to bit position 3. For command headers of type 16, set three words (Length = 3) which are words 0 through 2 included in VP5_VLC_CMD (address H'0 8000). Also, set these words for I picture decoding.

5. Make settings for system control and initialization routine activation. Then, start the VLCS. When the VLCS is activated, the CE processing should already be terminated. Below are sample register settings. Start the VLCS with the VME bit = 1 and the VE bit = 1 in the VP5_CTRL register.

```
register_write ( VP5_CTRL,      H'0000 C500 ); // Overall operation settings
register_write ( VP5_IRQ_ENB,   H'0000 0101 ); // Interrupt enable
register_write ( VP5_VLC_MBA,   H'100C 3000 ); // Microcode base address
register_write ( VP5_VLC_PBA0,  H'100B 4000 ); // Parameter base address
register_write ( VP5_VLC_PBA1,  H'101B 7400 ); // Parameter base address
register_write ( VP5_CMD,       H'0000 0001 ); // Activation
```

6. Check the results.

   The VS bit in the VP5_STATUS register indicates the VPU5HG VLCS is active. When it terminates its operation, this bit is set to 0 and the VLE bit in the VP5_IRQ_STA register is set to 1, indicating the termination status.

   After the operation, check the following status registers:

   VP5_VLC_ERRH
   VP5_VLC_ERRL
   VP5_VLC_INT_TB0
   VP5_VLC_INT_TB1

(b) Decoding by the CE (First I Picture)

1. Store the microcode into the external memory. Its base address is H'1000 0000 (set in VP5_CE_MBA) for this example.
2. Create CE0 operation control parameters and store them into the external memory. Their base address is H'1021 0000 (set in VP5_CE_PBA0) for this example.

Table 27.58 Sample CE0 Operation Control Parameters for 720 × 480 I Picture Decoding

Setting																Description
50	00	00	01	00	00	40	40	12	5a	bc	00	00	00	00	00	VP5_BAAR0 decoding picture luminance base address
50	00	00	01	00	00	40	48	12	62	bd	00	00	00	00	00	VP5_BAAR0 decoding picture chrominance base address
50	00	00	01	00	00	40	90	12	67	73	80	00	00	00	00	VP5_BAAR0 MV information base address
50	00	00	01	00	00	40	b0	13	cd	3e	00	00	00	00	00	VP5_BAAR0 intermediate stream base address
50	00	00	01	00	00	40	b8	14	4d	40	00	00	00	00	00	VP5_BAAR0 intermediate control stream base address
50	00	00	01	00	00	42	00	00	00	00	00	00	00	00	00	VP5_BAAR0 reference picture luminance address 0
50	00	00	01	00	00	42	08	00	00	00	00	00	00	00	00	VP5_BAAR0 reference picture chrominance address 0
50	00	00	01	00	00	00	40	d0	00	00	80	00	00	08	08	VP5_CE_DCHR_DECY0 decode luminance picture DMA channel register 0
50	00	00	01	00	00	00	48	d0	00	00	80	00	00	08	09	VP5_CE_DCHR_DECC0 decode chrominance picture DMA channel register 0
50	00	00	01	00	00	00	60	b0	00	00	80	00	00	02	00	VP5_CE_DCHR_REF reference picture DMA channel register
50	00	00	01	00	00	00	90	c0	00	00	00	00	00	0c	12	VP5_CE_DCHR_MVINFO0 MV information output DMA channel register 0
50	00	00	01	00	00	00	b0	88	80	70	00	00	00	10	16	VP5_CE_DCHR_CEIS0 CE intermediate stream DMA channel register 0
50	00	00	01	00	00	00	b8	88	88	70	00	00	00	10	17	VP5_CE_DCHR_CEIC0 CE intermediate control stream DMA channel register 0
00	00	00	01	00	00	00	00	80	00	01	42	2d	00	1e	00	VP5_CE_SPAR
00	00	00	01	00	00	00	08	00	00	00	00	00	00	00	00	VP5_CE_PPAR
00	00	00	01	00	00	00	a0	00	00	00	00	00	00	00	02	VP5_CE_VLCF
48	00	00	01	00	00	04	40	00	00	00	00	00	40	01	00	VP5_CE_IS_BS0 CE intermediate stream 0 buffer size register
80	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Late packet for the initialization routine

Specify the base addresses in VP5_BAAR0. Set the base addresses of the intermediate stream and intermediate control stream equal to the addresses output by the VLCS as follows.

VP5_BAAR0.VLIS0→VP5_BAAR1.CEIS0

VP5_BAAR0. VLIC0→VP5_BAAR1.CEIC0

VP5_BAAR1. VLIS1→VP5_BAAR0.CEIS1

VP5_BAAR1. VLIC1→VP5_BAAR0.CEIC1

Set the DMA channel registers for decoding. Specify num_ref_frame = 1, ce = 1, dec_out_disable = 0, stream_type = 2(H.264), mb_width = H'2D (=720/16) and mb_height = H'1E (=480/16) in VP5_CE_SPAR. Specify pic_type = 0 and refidx_last0 = 0 in VP5_CE_PPAR. Specify VPU address[21:17] = H'10 for the last packet for the CE0 initialization routine.

3. Create CE1 operation control parameters and store them into the external memory. Their base address is H'1013 6400 (set in VP5_CE_PBA1) for this example.

Table 27.59 Sample CE1 Operation Control Parameters for 720 × 480 I Picture Decoding

Setting																Description
d0	00	00	01	00	00	40	40	12	5a	bc	00	00	00	00	00	VP5_BAAR1 decode picture luminance base address
d0	00	00	01	00	00	40	48	12	62	bd	00	00	00	00	00	VP5_BAAR1 decode picture chrominance base address
d0	00	00	01	00	00	40	90	12	66	bd	80	00	00	00	00	VP5_BAAR1 MV information base address
d0	00	00	01	00	00	40	b0	14	0d	3f	00	00	00	00	00	VP5_BAAR1 intermediate stream base address
d0	00	00	01	00	00	40	b8	14	4f	41	00	00	00	00	00	VP5_BAAR1 intermediate control stream base address
d0	00	00	01	00	00	00	40	d0	00	00	80	00	00	08	08	VP5_CE_DCHR_DECY1 decode luminance picture DMA channel register 1
d0	00	00	01	00	00	00	48	d0	00	00	80	00	00	08	09	VP5_CE_DCHR_DECC1 decode chrominance picture DMA channel register 1
d0	00	00	01	00	00	00	90	c0	00	00	00	00	00	0c	12	VP5_CE_DCHR_MVINFO1 MV information output DMA channel register 1
d0	00	00	01	00	00	00	b0	88	80	70	00	00	00	10	16	VP5_CE_DCHR_CEIS1 CE intermediate stream DMA channel register 1
d0	00	00	01	00	00	00	b8	88	88	70	00	00	00	10	17	VP5_CE_DCHR_CEIC1 CE intermediate control stream DMA channel register 1
c8	00	00	01	00	00	04	40	00	00	00	00	00	40	01	00	VP5_CE_IS_BS1 CE intermediate stream 1 buffer size register
c0	00	00	01	00	00	00	50	00	00	00	04	00	00	00	00	VP5_CE_DEB_LMDMASR1 DEB1LMDMA synchronous register
00	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Late packet for the initialization routine

Specify the base addresses in VP5_BAAR1. Set the base addresses of the intermediate stream and intermediate control stream equal to the addresses output by the VLCS as follows.

VP5_BAAR0.VLIS0→VP5_BAAR1.CEIS0

VP5_BAAR0. VLIC0→VP5_BAAR1.CEIC0

VP5_BAAR1. VLIS1→VP5_BAAR0.CEIS1

VP5_BAAR1. VLIC1→VP5_BAAR0.CEIC1

Set the DMA channel registers for decoding. Specify VP5_CE_DEB_LMDMASR1 for the CE1 operation control parameter. Specify VPU address[21:17] = H'00 for the last packet for the CE1

4. Make settings for system control and initialization routine activation. Then, start the CE. When the CE is activated, the VLCS processing for the picture should already be terminated. Below are sample register settings. Start the CE with the CEMD bit = 1, the CME bit = 1 and the CE bit = 1 in the VP5_CTRL register.

```
register_write ( VP5_CTRL,      H'0080 00B5 ); // Overall operation settings
register_write ( VP5_IRQ_ENB,   H'0000 0101 ); // Interrupt enable
register_write ( VP5_CE_MBA,    H'1000 0000 ); // Microcode base address
register_write ( VP5_CE_PBA0,   H'1002 1000 ); // Parameter base address
register_write ( VP5_CE_PBA1,   H'1013 6400 ); // Parameter base address
register_write ( VP5_CMD,       H'0000 0001 ); // Activation
```

5. Check the results.
   The CS bit in the VP5_STATUS register indicates the VPU5HG CE is active. When it terminates its operation, this bit is set to 0 and the CE bit in the VP5_IRQ_STA register is set to 1, indicating the termination status.
   After the operation, check the following status register:
   VP5_CE_ERR

(c) Decoding by the VLCS (P Picture)

1. When the VLCS is used to decode a P picture after an I picture, there is no need to reset the microcode.
2. When the VLCS is used to decode a P picture after an I picture, there is no need to reset the microcode.

Table 27.60 Sample VLCS DMAC Channel 0 Operation Control Parameters for 720 × 480 P Picture Decoding

Setting																Description
50	00	00	01	00	00	40	d0	14	55	42	00	00	00	00	00	VP5_BAAR0 command stream base address
50	00	00	01	00	00	40	e0	13	49	3a	00	00	00	00	00	VP5_BAAR0 VLCS intermediate stream base address
50	00	00	01	00	00	40	e8	13	c9	3c	00	00	00	00	00	VP5_BAAR0 VLCS intermediate control stream base address
50	00	00	01	00	00	00	c0	08	a0	70	00	00	00	14	18	VP5_VLC_DCHR_STRA stream A DMA channel register
50	00	00	01	00	00	00	d0	88	b0	70	00	00	00	14	1a	VP5_VLC_DCHR_CMDS command stream DMA channel register
50	00	00	01	00	00	00	e0	c0	00	00	00	00	00	12	1c	VP5_VLC_DCHR_VLIS0 VLCS intermediate stream DMA channel register 0
50	00	00	01	00	00	00	e8	c0	00	00	00	00	00	12	1d	VP5_VLC_DCHR_VLIC0 VLCS intermediate control stream DMA channel register 0
08	00	00	01	00	00	00	00	80	00	01	42	2d	00	1e	00	VP5_VLC_SPAR
08	00	00	01	00	00	0f	50	00	00	00	12	00	01	00	5e	VP5_VLC_MODE
08	00	00	01	00	00	0f	80	00	00	00	00	00	40	01	00	VP5_VLC_STRA_BS stream buffer size register
08	00	00	01	00	00	0f	a0	00	00	00	00	00	40	01	00	VP5_VLC_IS_BS0 VLCS intermediate stream 0 buffer size register
08	00	00	01	00	00	0f	b0	00	00	00	00	00	40	01	00	VP5_VLC_IS_BS1 VLCS intermediate stream 1 buffer size register
80	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Late packet for the initialization routine

Specify the base addresses in VP5_BAAR0. This example assumes that the VLCS intermediate stream and VLCS intermediate control stream are configured with a double buffer, and that the specified base addresses are different from those for the I picture decoding. Set the DMA channel register, VP5_VLC_SPAR and VP5_VLC_MODE to the same values as those for the I picture decoding. Specify VPU address[21:17] = H'10 for the last packet for the DMAC channel 0 initialization routine.

3. Create VLCS operation control parameters and store them into the external memory. Their base address is H'101B7 400 (set in VP5_CE_PBA1) for this example.

Table 27.61 Sample VLCS DMAC Channel 1 Operation Control Parameters for 720 × 480 P Picture Decoding

Setting																Description
d0	00	00	01	00	00	40	e0	13	89	3b	00	00	00	00	00	VP5_BAAR1 VLCS intermediate stream base address
d0	00	00	01	00	00	40	e8	13	cb	3d	00	00	00	00	00	VP5_BAAR1 VLCS intermediate control stream base address
d0	00	00	01	00	00	00	e0	c0	00	00	00	00	00	12	1c	VP5_VLC_DCHR_VLIS1 VLCS intermediate stream DMA channel register 1
d0	00	00	01	00	00	00	e8	c0	00	00	00	00	00	12	1d	VP5_VLC_DCHR_VLIC1 VLCS intermediate control stream DMA channel register 1
00	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Late packet for the initialization routine

Specify the base addresses in VP5_BAAR1. This example assumes that the VLCS intermediate stream and VLCS intermediate control stream are configured with a double buffer, and that the specified base addresses are different form those for the I picture decoding. Set the DMA channel register for decoding. Specify VPU address[21:17] = H'00 for the last packet for the DMAC channel 1 initialization routine.

4. Create command streams and store them into the external memory. Their base address is H'1455 4200 (set in VP5_BAAR0) for this example.

Table 27.62 Sample Command Stream Settings for 720 × 480 P Picture Decoding

Setting																Description
00	00	00	51	12	00	a8	0e	08	00	00	00	00	00	00	00	Command header (type0,type8)
10	00	80	18	00	00	00	01	00	00	00	00	00	00	00	00	Command header (type16Length=1)
90	00	80	00	00	00	00	03	20	00	00	00	00	00	00	00	Command header (type16Length=3)
00	00	32	c0	1e	00	1e	00	00	00	00	00	00	00	00	00	Command header (type16). Continued from above.

Set the command stream by referring to section 27.5.5, command stream. For this example, set the operation control bits for the command headers of type 0 to the values (T = E = 1, S = I = 0) for the first and last slices of the picture. Also, set Stream Start Address to the byte address (H'1200 00A8) including the first bit of slice data and set bit_pos to bit position 1.

For the first command header of type 16, set one word (Length = 1) included in VP5_VLC_REF_TBL (address H'0 8018). For the remaining command headers of type 16, set three words (Length = 3) which are words 0 through 2 included in VP5_VLC_CMD (address H'0 8000). For the progressive sequence, set word 2 in VP5_VLC_CMD to H'0000 0000.

5. Make settings for system control and initialization routine activation. Then, start the VLCS. Below are sample register settings. Start the VLCS with the VME bit = 0 and the VE bit = 1 in the VP5_CTRL register.

```
register_write ( VP5_CTRL,      H'0000 C100 ); // Overall operation settings
register_write ( VP5_IRQ_ENB,   H'0000 0101 ); // Interrupt enable
register_write ( VP5_VLC_PBA0,  H'100B 4000 ); // Parameter base address
register_write ( VP5_VLC_PBA1,  H'101B 7400 ); // Parameter base address
register_write ( VP5_CMD,       H'0000 0001 ); // Activation
```

6. Check the results as described for the I picture processing.

(d) Decoding by the CE (P Picture)

The following shows an example of decoding by the CE for P pictures.

1. When the CE is used to decode a P picture after an I picture, there is no need to reset the microcode.
2. Create CE0 operation control parameters and store them into the external memory. Their base address is H'10210000 (set in VP5_CE_PBA0) for this example.

Table 27.63 Sample CE0 Operation Control Parameters for 720 × 480 P Picture Decoding

Setting																Description
50	00	00	01	00	00	40	40	12	68	c3	00	00	00	00	00	VP5_BAAR0 decode picture luminance base address

50	00	00	01	00	00	00	90	c0	00	00	00	00	00	0c	12	VP5_CE_DCHR_MVINFO0 MV information output DMA channel register 0
50	00	00	01	00	00	00	b0	88	80	70	00	00	00	10	16	VP5_CE_DCHR_CEIS0 CE intermediate stream DMA channel register 0
50	00	00	01	00	00	00	b8	88	88	70	00	00	00	10	17	VP5_CE_DCHR_CEIC0 CE intermediate control stream DMA channel register 0
00	00	00	01	00	00	00	00	80	00	01	42	2d	00	1e	00	VP5_CE_SPAR
00	00	00	01	00	00	00	08	20	00	00	00	00	00	00	01	VP5_CE_PPAR
00	00	00	01	00	00	00	a0	00	00	00	00	00	00	00	02	VP5_CE_VLCF
48	00	00	01	00	00	04	40	00	00	00	00	00	40	01	00	VP5_CE_IS_BS0 CE intermediate stream 0 buffer size register
80	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Late packet for the initialization routine

Specify the base addresses in VP5_BAAR0. Set the base addresses of the intermediate stream and intermediate control stream equal to the addresses output by the VLCS as follows.

VP5_BAAR0.VLIS0→VP5_BAAR1.CEIS0
VP5_BAAR0. VLIC0→VP5_BAAR1.CEIC0
VP5_BAAR1. VLIS1→VP5_BAAR0.CEIS1
VP5_BAAR1. VLIC1→VP5_BAAR0.CEIC1

Specify the reference picture address as the decode picture base address for the I picture. Set the DMA channel registers for decoding. Specify pic_type = 1 (P picture) and refidx_last0 = 0 in VP5_CE_PPAR. Specify VPU address[21:17] = H'10 for the last packet for the CE0 initialization routine.

3. Create CE1 operation control parameters and store them into the external memory. Their base address is H'1013 6400 (set in VP5_CE_PBA1) for this example.

Table 27.64 Sample CE1 Operation Control Parameters for 720 × 480 P Picture Decoding

Setting																Description
d0	00	00	01	00	00	40	40	12	68	c3	00	00	00	00	00	VP5_BAAR1 decode picture luminance base address
d0	00	00	01	00	00	40	48	12	70	c4	00	00	00	00	00	VP5_BAAR1 decode picture chrominance base address

00	00	00	01	00	00	10	07	00	00	00	00	00	00	00	00	Late packet for the initialization routine

Specify the base addresses in VP5_BAAR1. Set the base addresses of the intermediate stream and intermediate control stream equal to the addresses output by the VLCS as follows.

VP5_BAAR0.VLIS0→VP5_BAAR0.CEIS0
VP5_BAAR0. VLIC0→VP5_BAAR0.CEIC0
VP5_BAAR1. VLIS1→VP5_BAAR1.CEIS1
VP5_BAAR1. VLIC1→VP5_BAAR1.CEIC1

Specify the reference picture address as the decode picture base address for the I picture. Set the DMA channel registers for decoding. Specify VP5_CE_DEB_LMDMASR1 for the CE1 operation control parameter. Specify VPU address[21:17] = H'00 for the last packet for the CE0 initialization routine.

4. Make settings for system control and initialization routine activation. Then, start the CE.
   Below are sample register settings. Start the CE with the CEMD bit = 1, the CME bit = 0 and the CE bit = 1 in the VP5_CTRL register.

```
register_write ( VP5_CTRL,          H'0080 00B1 ); // Overall operation settings
register_write ( VP5_IRQ_ENB,       H'0000 0101 ); // Interrupt enable
register_write ( VP5_CE_PBA0,       H'1002 1000 ); // Parameter base address
register_write ( VP5_CE_PBA1,       H'1013 6400 ); // Parameter base address
register_write ( VP5_CMD,           H'0000 0001 ); // Activation
```

5. Check the results as described for the I picture processing.

37.7 Notes on Usage

Notes on usage of the VPU5HG are described below.

(1) Processing End

When the VPU5 detects a stream error during decoding other than H.264, it skips streams to the next resynchronization marker or start code. Therefore, if the VPU5 detects an error during decoding a stream that does not have the end code at the end of sequence and the error is found after a location, such as the last picture in the sequence, where no resynchronization marker or start code is appended, it may keep trying to find it in the stream forever. To prevent this, add a 4-byte code starting with "H'00" to the end of the stream depending on the stream standard when decoding a stream that has no end code at the end of the sequence of Streams Stream Standard Code to be added.

Stream Standard	Code to be Added
MPEG-2/MPEG-1	H'00 00 01 B7
MPEG-4	H'00 00 01 B1
H.263	H’00 00 FC 00
VC-1	H'00 00 01 0A

(2) Timing of Terminating Operations

In the LSI incorporating the VPU5 and ICB, the ICB may continue accessing memory after the VPU5HG operation is ended; there is a time lag until the end of ICB operation because the ICB buffers the data output from the VPU5HG and then writes it to external memory.

Accordingly, detect the end of VPU5HG operation through an interrupt or status register polling and then confirm that the corresponding status register of the ICBshows the end of ICB operation before checking the operation result.

For the LSI incorporating the VPU5 and ICB, refer to the ICB specifications.

Section 38 Image Extraction Direct Memory Access Controller (2D-DMAC)

This LSI has an image extraction direct memory access controller (2D-DMAC). This module reads the image data in the frame buffer memory, performs image extraction/shift/simple magnification and format conversion, and then rewrites the processed image data to the frame buffer memory.

38.1 Features

- Image extraction
  2D-DMAC extracts an image in the rectangular area from a point (Sx, Sy) shifting from the source image data origin to a point in the frame memory, and then writes the extracted image data to another frame memory. Extraction of data is possible in one-pixel units for YCbCr formats and in one-pixel units for RGB formats. This function is available for image clipping and image motion compensation.
- Image rotation/inversion
  Vertical/horizontal inversion and the 90°/270° rotation can be performed.
- Simple enlargement
  When writing a destination image, it can simply be enlarged twice in the X and Y directions.
- Format conversion
  RGB formats can be converted to each other.
  YCbCr formats (YCbCr4:2:0 and YCbCr4:2:2) can be converted to each other.
  No format conversion is possible between RGB and YCbCr.
  The format conversion method is equivalent to that of VIO.
- Channels
  Settings for eight channels are enabled. For the YCbCr formats, settings for one channel for each Y plane and C plane are enabled. Therefore, concurrent processing is possible for up to four planes (YCbCr formats) or up to eight planes (RGB formats).
  Provided with an outstanding buffer for each channel, even if data transfer of a channel is blocked, 2D-DMAC can continue operation of other channels. Transition of processing between channels is performed upon completion of each line processing.
- Interrupt
  Each channel has interrupt request signals that can be output at the time of data transfer half end and data transfer end respectively.

Figure 38.1 shows a block diagram of 2D-DMAC and figure 38.2 shows a flow for the pixel processing block.

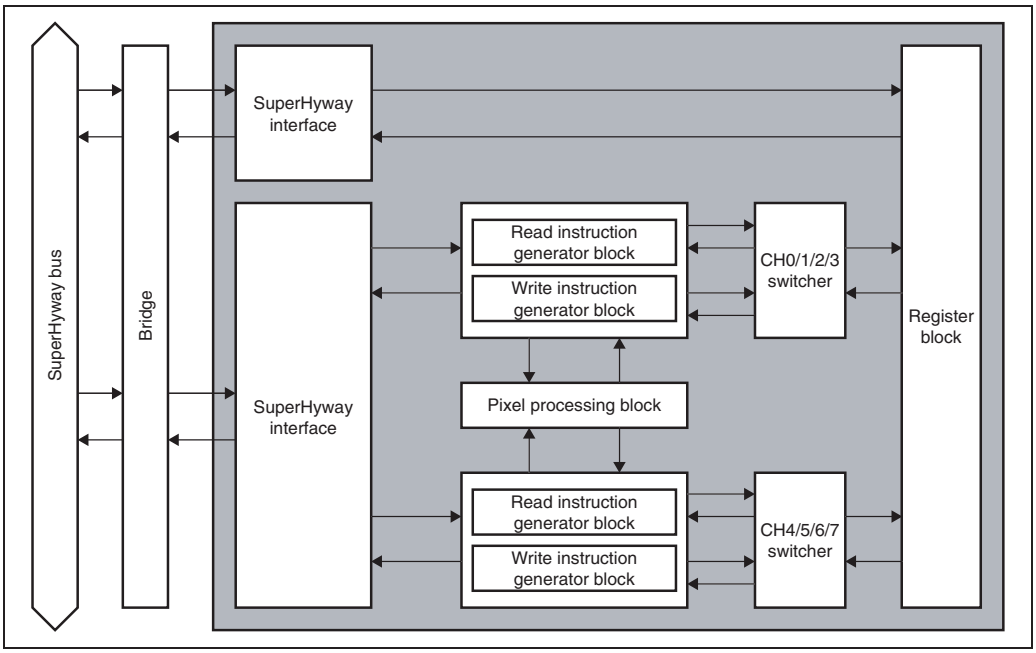

Figure 38.1 Block Diagram of 2D-DMAC

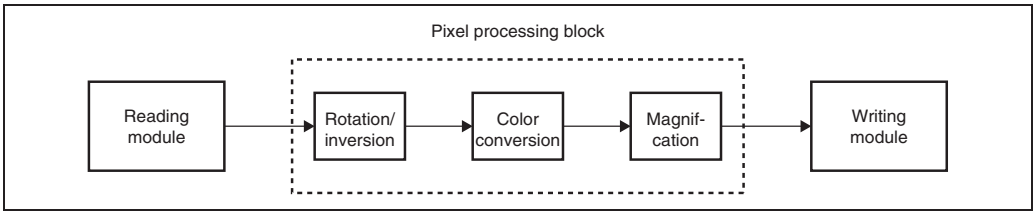

Figure 38.2 Block Flow of Pixel Block

38.2 Register Descriptions

Table 38.1 lists the registers used in 2D-DMAC. Table 38.2 shows the register status in each processing mode.

Table 38.1 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
Interrupt status clear register	CHSTCLR	R/W	H'FEA0 0010	32

n: 0 to 7

38.2.1 Control Registers (CHnCTRL)

CHnCTRL (n = 0 to 7) is a 32-bit readable/writable register that controls transfer mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HMRR	VMRR	ROTL	ROTR	—	MX	—	MY	HIE	HE	TIE	TE	—	—	STP	DMAEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	HMRR	0	R/W	Horizontal Inversion (symmetric to the vertical axis) The source image inverted horizontally is output. See table 38.5 details on the relations between this bit and inversion/rotation. 0: Horizontal inversion is not performed. 1: Inverted horizontally source image is output.
14	VMRR	0	R/W	Vertical Inversion (symmetric to the horizontal axis) The source image inverted vertically is output. See table 38.5 details on the relations between this bit and inversion/rotation. 0: Vertical inversion is not performed. 1: Inverted vertically source image is output.
13	ROTL	0	R/W	270° Rotation (clockwise) The source image rotated 270° is output. When this bit is 1, set the ROTR bit to 0. See table 38.5 details on the relations between this bit and inversion/rotation. 0: 270° rotation is not performed. 1: Rotated 270° source image is output.

Bit	Bit Name	Initial Value	R/W	Description
12	ROTR	0	R/W	90° Rotation (clockwise) The source image rotated 90° is output. When this bit is 1, set the ROTR bit to 0. See table 38.5 details on the relations between this bit and inversion/rotation.

				0: 90° rotation is not performed. 1: Rotated 90° source image is output.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10	MX	0	R/W	Magnify X Direction 0: No magnification 1: Outputs with double magnification in the X direction. When ROTR or ROTL is 1, set this bit to 0.
9	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
8	MY	0	R/W	Magnify Y Direction 0: No magnification 1: Outputs with double magnification in the Y direction. When ROTR or ROTL is 1, set this bit to 0.
7	HIE	0	R/W	Half End Interrupt Enable Specifies whether to output the half end flag as an interrupt request. 0: A half end interrupt is disabled. 1: A half end interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
6	HE	0	R/W	Half End Indicates that data transfer for half the setting lines has been completed. This bit is set to 1 when the DVPXLE bit in CHnDPXLE becomes half (a value of 1-bit right shift) of the DVPXL bit value in CHnDPXL that was set before starting transfer. If CHnCTRL.ROTR=1 or CHnCTRL.ROTL=1, this bit is set to 1 when the DHPXLE bit in CHnDPXLE becomes half of the DHPXL bit value in CHnDPXL that was set before starting transfer. Only clearing to 0 after reading 1 is enabled. Clearing by the CHSTCLR register is also enabled.

5	TIE	0	R/W	Transfer End Interrupt Enable Specifies whether to output the transfer end flag as an interrupt request. 0: A transfer end interrupt is disabled. 1: A transfer end interrupt is enabled.
4	TE	0	R/W	Transfer End This bit is set to 1 when the DVPXL bit in CHxDPXL that was set by the DVPXLE bit in CHxDPXLE before starting transfer and the entire DMA transfer are completed. When this bit is set to 1 while the RPT bit is 0, the DMAEN bit is automatically cleared. Only clearing to 0 after reading 1 is enabled. Clearing by the CHSTCLR register is also enabled.
3, 2	LINK[1:0] (n=0,2,4,6) — (n=1,3,5,7)	00	R/W (n=0,2,4,6) R (n=1,3,5,7)	(n=0,2,4,6) Link Transfer Mode This mode enables alternate block line transfers between a master channel (CHn) and a slave channel (CHn+1). When these bits are set to 10, specify the DVPXL bit in CH(n+1)DPXL equal to half of the DVPXL in CHnDPXL. When these bits are set to 11, specify the DVPXL bit in CH(n+1)DPXL equal to the DVPXL in CHnDPXL. In this mode, start the transfer of the master channel before that of the slave channel. 00: Link transfer mode is disabled. 01: Setting prohibited. 10: A block line transfer of a slave channel is performed every two block line transfers of a master channel. 11: Alternate transfers are performed. (n=1,3,5,6) Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1	STP	0	R/W	Transfer Stop Stops DMA transfer temporarily. When this bit is set to 1, DMA transfer is suspended upon completion of the line that is being transferred, and the DMAEN bit is cleared to 0. At this time, this bit is also cleared. To restart DMA transfer after that, set the DMAEN bit to 1. To reset the operation of a channel, rewrite data to the SAR, DAR, and DPXL registers of the channel. [Writing] 0: NOP 1: Stops DMA transfer temporarily. [Reading] 0: Transfer is in progress or suspended. 1: Pending until the line being transferred is completed
0	DMAEN	0	R/W	DMA Transfer Enable Enables DMA transfer. Only writing 1 is enabled. This bit shows 1 during transfer, and is automatically cleared when a DMA transfer is completed. Writing 0 to this bit is disabled. A DMA transfer can be suspended by setting the STP bit to 1. [Writing] 0: NOP 1: Performs DMA transfer. [Reading] 0: No DMA transfer is in progress. 1: A DMA transfer is in progress.

38.2.2 Input/Output Swap Register (CHnSWAP)

CHnSWAP (n = 0 to 7) controls 64-bit data swapping in the data input/output section of 2D-DMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	OLS	OWS	OBS	—	ILS	IWS	IBS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	OLS	0	R/W	Output Longword Swap Setting In the output section of 2D-DMAC, 64 bits of data are swapped with 32 bits of the MSB and 32 bits of the LSB in longword units. 0: Output longword swap is not performed. 1: Output longword swap is performed.
5	OWS	0	R/W	Output Word Swap Setting In the output section of 2D-DMAC, 64 bits of data are swapped with 32 bits of the MSB and 32 bits of the LSB in word units. 0: Output word swap is not performed. 1: Output word swap is performed.
4	OBS	0	R/W	Output Byte Swap Setting In the output section of 2D-DMAC, 64 bits of data are swapped with 16-bit groups in byte units. 0: Output byte swap is not performed. 1: Output byte swap is performed.

Bit	Bit Name	Initial Value	R/W	Description
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

2	ILS	0	R/W	Input Longword Swap Setting In the input section of 2D-DMAC, 64 bits of data are swapped with 32 bits of the MSB and 32 bits of the LSB in longword units. 0: Input longword swap is not performed. 1: Input longword swap is performed.
1	IWS	0	R/W	Input Word Swap Setting In the input section of 2D-DMAC, 64 bits of data are swapped with 32 bits of the MSB and 32 bits of the LSB in word units. 0: Input word swap is not performed. 1: Input word swap is performed.
0	IBS	0	R/W	Input Byte Swap Setting In the input section of 2D-DMAC, 64 bits of data are swapped with 16-bit groups in byte units. 0: Input byte swap is not performed. 1: Input byte swap is performed.

When the system is operated in little-endian mode, this register should be used to select the swapping method conforming to the input/output format. The data relationships available when swapping methods are set are shown in figure 38.3, figure 38.4, and figure 38.5.

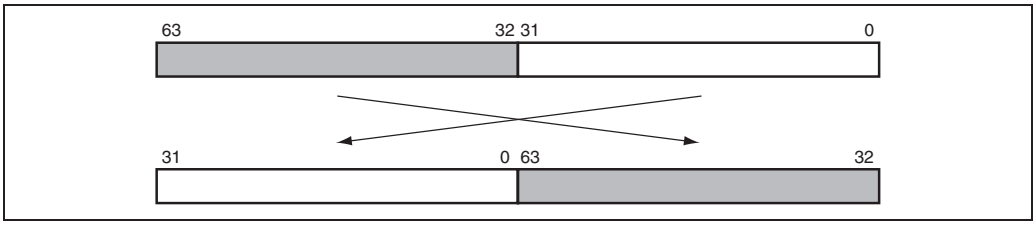

Figure 38.3 Data Relationship Before and After Longword Swapping

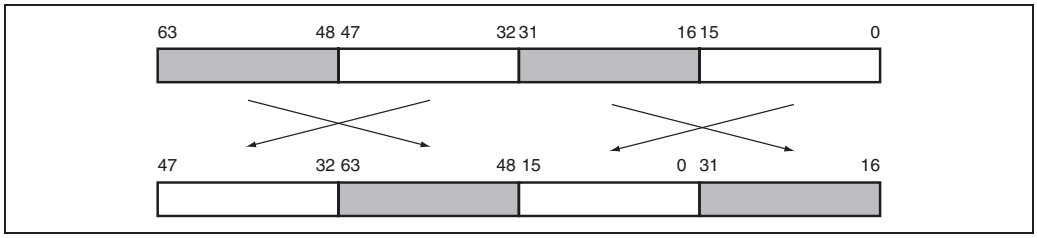

Figure 38.4 Data Relationship Before and After Word Swapping

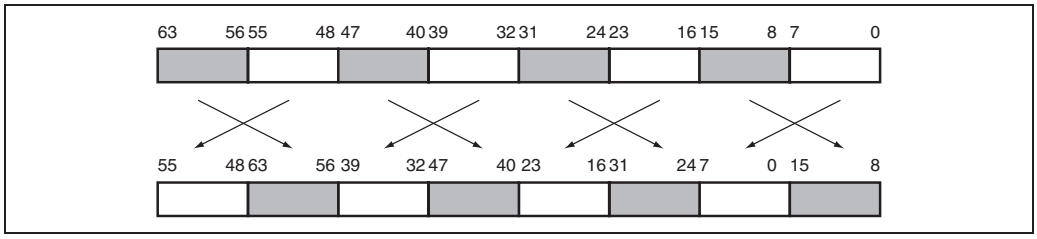

Figure 38.5 Data Relationship Before and After Byte Swapping

38.2.3 Source Format Registers (CHnSFMT)

CHnSFMT (n = 0 to 7) is a 32-bit readable/writable register for setting the source image.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	HWTH[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	MD[1:0]		PKF[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	HWTH[15:0]	H'0000	R/W	Source Image Horizontal Byte Size Specify the one-line width of the source image in units of bytes. This value should be a multiple of the pack size. When ROTR or ROTL is 1, set these bits to 16n.
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6, 5	MD[1:0]	00	R/W	Source Image Format 00: RGB data 01: Y data 10: CbCr data (YcbCr4:2:0) 11: CbCr data (YcbCr4:2:2)
4 to 0	PKF[4:0]	00000	R/W	Source Image RGB Data Packed Format Specify the packed format for source image data in the RGB format. These bits are available only when MD = 00. Table 38.3 shows the packed RGB formats.

Table 38.3 Packed RGB Formats

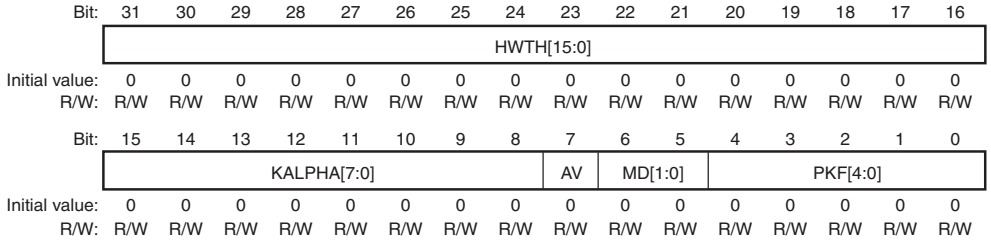
| PKF [4:0] | Format | Bit Rate [bpp] | Phase | Bit | | |

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SAR[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SAR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SAR[31:0]	H'00000000	R/W	Source Image Extraction Start Address Specify the address of the extraction start pixel in the source image data.

When the source image fills CHnSAR≠16n and cutting out effective pixel bytes



number ≦16byte , line finality access = address where line terminal address is rounded up to 16n + 16byte .

Address where source image final pixel address of cutting out object is rounded up to 16n + 16,

secure it as an input image area.

38.2.5 Destination Format Registers (CHnDFMT)

CHnDFMT (n = 0 to 7) is a 32-bit readable/writable register for setting a destination image format and so on.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	HWTH[15:0]	H'0000	R/W	Destination Image Horizontal Byte Size Specify the one-line width of the destination image in units of bytes. Set a multiple of 16. When CTRL.MX is 1, set a value after magnification.
15 to 8	KALPHA [7:0]	H'00	R/W	Alpha Value Specify an alpha value used for output when the source image is in a format with or without alpha and the AV bit is set to 1.
7	AV	0	R/W	Alpha Enable 0: Disables the alpha value when the source image is in a format with alpha. When the output is in a format with alpha, the KALPHA value is output. 1: Enables the alpha value when the source image is in a format with alpha, and outputs the alpha value when the output is in a format with alpha.
6, 5	MD[1:0]	00	R/W	Destination Image Format 00: RGB data 01: Y data 10: CbCr data (YCbCr4:2:0) 11: CbCr data (YCbCr4:2:2)

Bit	Bit Name	Initial Value	R/W	Description
4 to 0	PKF[4:0]	00000	R/W	Destination Image RGB Data Packed Format Specify the packed format for destination image data in the RGB format. These bits are available only when MD = 00. Table 38.3 shows the packed RGB formats.

38.2.6 Destination Pixel Registers (CHnDPXL)

CHnDPXL (n = 0 to 7) is a 32-bit readable/writable register for setting the horizontal pixel size and vertical pixel size of the destination image.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DHPXL[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DVPXL[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	DHPXL[15:0]	H'0000	R/W	Destination Image Horizontal Pixel Size Specify the horizontal pixel size of the destination image. When the MX bit in CTRL is 1, set a value before magnification. For the CbCr plane in YCbCr4:2:2 or YCbCr4:2:0, set a value of half of the number of pixels. The minimum pixel size will be 1; set 1 or a larger value.
15 to 0	DVPXL[15:0]	H'0000	R/W	Destination Image Vertical Pixel Size Specify the vertical pixel size of the destination image. When the MX bit in CTRL is 1, set a value before magnification. For the CbCr plane in YCbCr4:2:0, set a value of half of the number of lines. The minimum pixel size will be 1; set 1 or a larger value.

38.2.7 Destination Address Registers (CHnDAR)

CHnDAR (n = 0 to 7) is a 32-bit readable/writable register for setting the transfer start address of the destination image.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DAR[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DAR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DAR [31:0]	H'00000000	R/W	Specify the start address of the destination image. Only a multiple of 16 can be set. The specified address point is to be changed according to the settings to the VMRR, HMRR, ROTR, ROTL, and MY bits. See the section 38.3.2, Image Rotation/Inversion, for the setting instructions.

38.2.8 Source Line Address Registers (CHnSARE)

CHnSARE (n = 0 to 7) is a 32-bit read-only register that shows the start address of the line in processing of the source image.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SARE[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SARE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SARE [31:0]	H'00000000	R	This read-only register used for internal processing shows the start address of the line in processing of the source image.

38.2.9 Destination Line Address Registers (CHnDARE)

CHnDARE (n = 0 to 7) is a 32-bit read-only register that shows the start address of the line in processing of the destination image.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DARE[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DARE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DARE [31:0]	H'00000000	R	This read-only register used for internal processing shows the start address of the line in processing of the destination image.

38.2.10 Destination Pixel Processing Registers (CHnDPXLE)

CHnDPXLE (n = 0 to 7) is a 32-bit read-only register that shows the number of unprocessed lines of the destination image.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DHPXLE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DVPXLE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	DHPXLE [15:0]	H'0000	R	This read-only register used for internal processing shows the number of unprocessed horizontal lines of the destination image.
15 to 0	DVPXLE [15:0]	H'0000	R	This read-only register used for internal processing shows the number of unprocessed vertical lines of the destination image.

38.2.11 Interrupt Status Clear Register (CHSTCLR)

CHSTCLR is a register that indicates the status of HE and TE bits in each channel. By writing 1 in a bit in CHSTCLR, HE or TE bit in the corresponding channel is to be cleared.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CHnHE[7:0]								CHnTE[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	CHnHE[7:0]	H'00	R/W	Indicates the status of the HE bit in CHnCTRL (n = 0 to 7). Writing 1 in this bit, the HE bit in corresponding channel is to be cleared. [Writing] 0: NOP 1: HE bit is cleared. [Reading] 0: 0 is set in the HE bit. 1: 1 is set in the HE bit.
7 to 0	CHnTE[7:0]	H'00	R/W	Indicates the status of the TE bit in CHnCTRL (n = 0 to 7). Writing 1 in this bit, the TE bit in corresponding channel is to be cleared. [Writing] 0: NOP 1: TE bit is cleared. [Reading] 0: 0 is set in the TE bit. 1: 1 is set in the TE bit.

38.3 Operation

This module can extract image data of required size from the source image and store it as a destination image, and also can convert the format, rotation/inversion, and magnify the image at that time.

38.3.1 Image Extraction

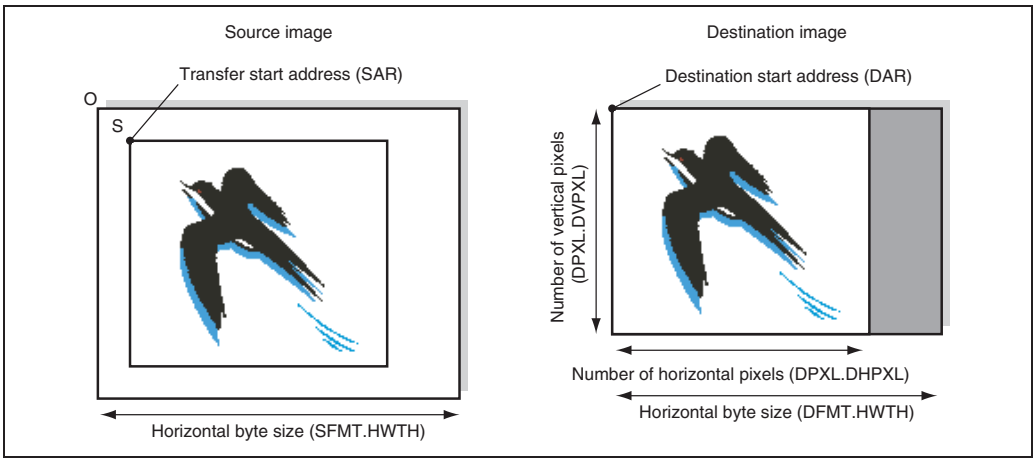


Figure 38.6 Schematic Diagram of Image Extraction

Figure 38.6 shows a schematic diagram of image extraction.

The image format conforms to the YCbCr4:2:0, YCbCr4:2:2, and RGB formats. Extraction of data is possible in two-pixel units for YCbCr formats and in one-pixel units for RGB formats. However, since the Y data and C data are independently stored in the memory in the YCbCr format, set them in different channels respectively.

For source images, the address of extraction start coordinates S and the horizontal byte size must be set in respective registers. Set the start address of the extraction start pixel in SAR. If the X coordinate of extraction start coordinates S (SAR) is an odd number with origin O in the YCbCr format, a deviation is generated between Y data and C data in the horizontal direction. Furthermore, in the YCbCr4:2:0 format, if the Y coordinate of extraction start coordinates S is an odd number with origin O, a deviation is generated between Y data and C data in the vertical direction. For each case, extract image data from the even pixel coordinates where truncation is made.

For destination images, destination start address, numbers of horizontal and vertical pixels, and the horizontal byte size must be set. Set an integer multiple of 16 (≥ DHPXL in DPXL x bytes per pixel) for the horizontal byte size (HWTH in DFMT). Discard the gray area in figure 38.6 as invalid data. For YCbCr formats, set an even number for the number of Y data horizontal pixels. In addition, for the YCbCr4:2:0 format, the number of vertical pixels must also be set to an even number.

Table 38.4 lists these restrictions.

Table 38.4 Restrictions for Each Format

Format	Item	Restrictions
Common	Destination image horizontal byte size (CHnDFMT.HWTH)	Set an integer multiple of 16.
Y data (YCbCr4:2:2)	Source image horizontal extraction start position (CHnSAR.SAR)	In a case that the X-coordinate of starting coordinate-S (SAR) relative to the coordinate origin 0 of source image is odd number, a deviation is generated between Y data and C data in the horizontal direction.
	Destination image horizontal pixel size (CHnDPXL.DHPXL)	In a case that the horizontal pixel size is odd number of the destination image, the invalid data might be generated right side in the image.
Y data (YCbCr4:2:0)	Source image horizontal extraction start position (CHnSAR.SAR)	In a case that the X-coordinate of starting coordinate-S (SAR) relative to the coordinate origin 0 of source image is odd number, a deviation is generated between Y data and C data in the horizontal direction.
	Source image vertical extraction start position (CHnSAR.SAR)	In a case that the Y-coordinate of starting coordinate-S (SAR) relative to the coordinate origin 0 of source image is odd number, the vertical throw between Y and CbCr is to be generated.
	Destination image horizontal pixel size (CHnDPXL.DHPXL)	In a case that the horizontal pixel size is odd number of the destination image, the invalid data might be generated right side in the image.
	Destination image vertical pixel size (CHnDPXL.DVPXL)	In a case that the vertical pixel size is odd number of the destination image, the invalid data might be generated bottom in the image.

38.3.2 Image Rotation/Inversion

Table 38.5 The Combination of the Bits, VMRR, HMRR, ROTL, and ROTR and the Rotation/Inversion

VMRR bit	HMRR bit	ROTL bit	ROTR bit	DAR specified point	Rotation/Inversion Performance
0	0	0	0	A	Rotation/Inversion is not performed
0	0	0	1	C	Clockwise 90 degrees rotation
0	0	1	0	B	Clockwise 270 degrees rotation
0	1	0	1	A	After rotating clockwise 90 degrees, inverse horizontally
1	0	1	0		(After rotating clockwise 270 degrees, inverse vertically)
1	0	0	1	D	After rotating clockwise 90 degrees, inverse vertically
0	1	1	0		(After rotating clockwise 270 degrees, inverse horizontally)
0	1	0	0	C	Inversing horizontally
1	0	0	0	B	Inversing vertically
1	1	0	0	D	180 degrees rotation
Others				—	Setting prohibited

The rotation/inversion performance in 90 degrees units can be executed arbitrarily effects of combination of the bits, VMRR, HMRR, ROTR, and ROTL as shown in table 38.5. Figure 38.7 shows the relations between the source image and the destination image in operating with rotation/inversion performance and Figure 38.8 shows only with inversion performance.

During the rotation/ inversion operating, the address specified point setting in CHnDAR is to be changed according to the setting of the bits, VMRR, HMRR, ROTR, and ROTL. See figure 38.9 for details on the specified address point corresponding to the processing respectively.

Lists the formulas for the address settings as follows.

offset_add	Address at the left above end of the destination image.
dest_hwidth	Horizontal byte size of the destination image (CHnDFMT.DHWTH)
dest_vpxl	Vertical pixel size of the destination image (CHnDPXL.DVPXL)

A DAR = offset_add

B DAR = offset_add + (dest_hwidth × (dest_vpxl − 1))

C DAR = offset_add + dest_hwidth

D DAR = offset_add + (dest_hwidth × dest_vpxl)

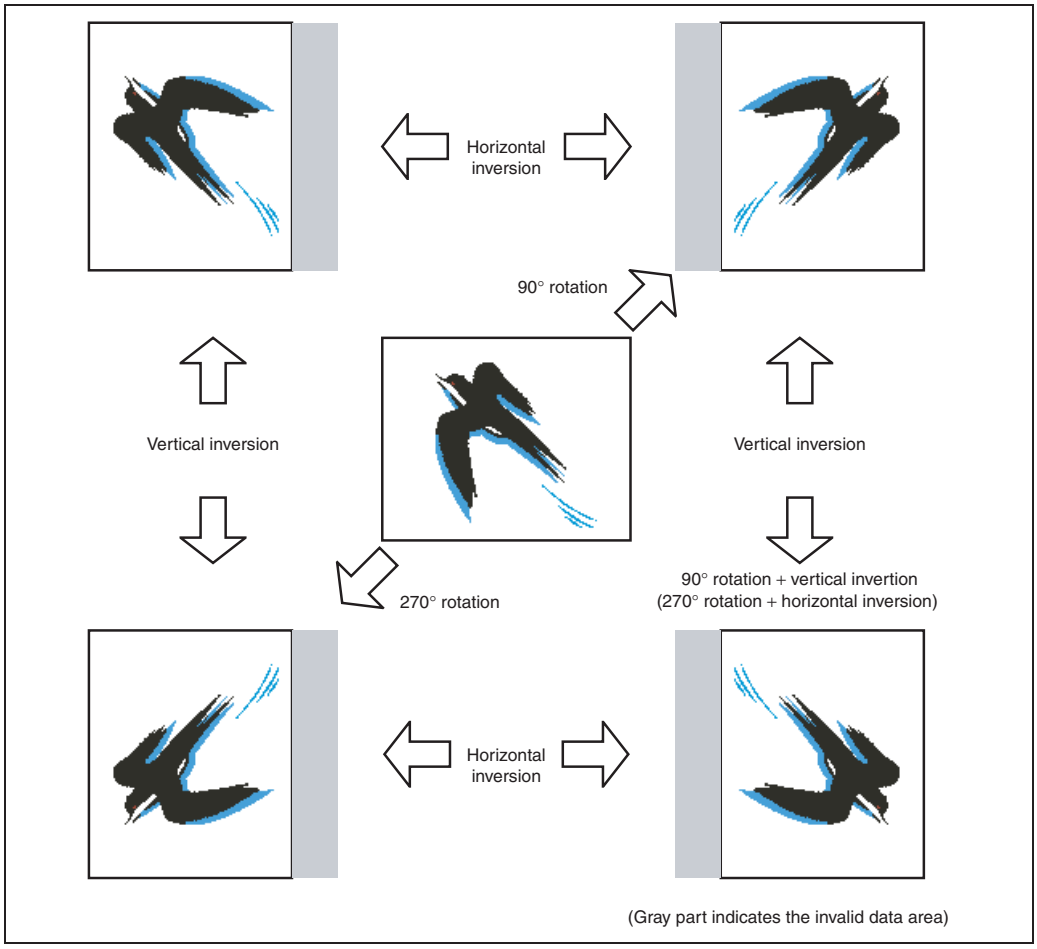

Figure 38.7 Relations between the Source Image and the Destination Image in Operating with Rotation/Inversion Performance

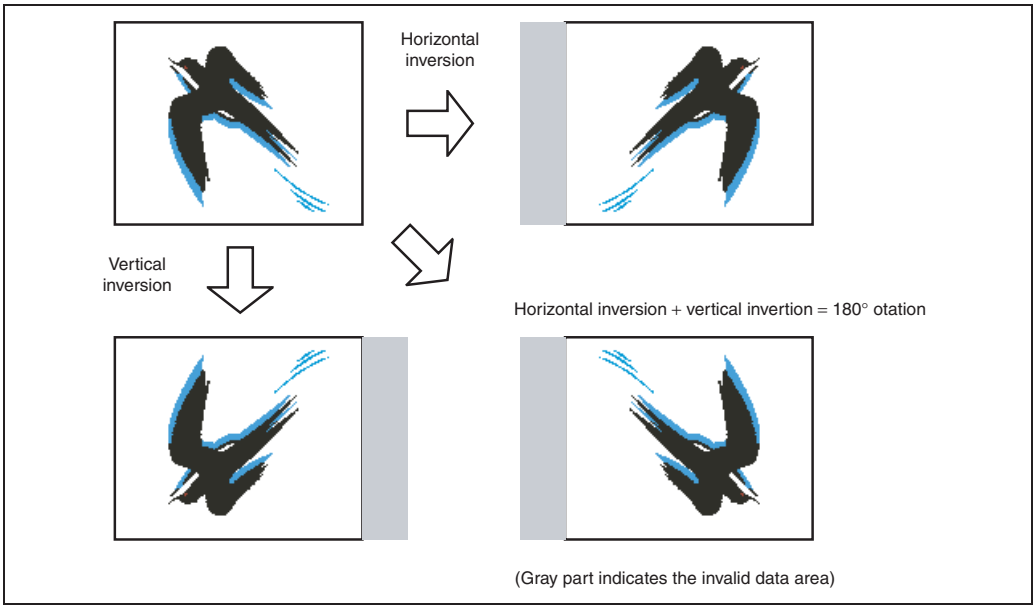

Figure 38.8 Relations between the Source Image and the Destination Image in Operating with Inversion Performance

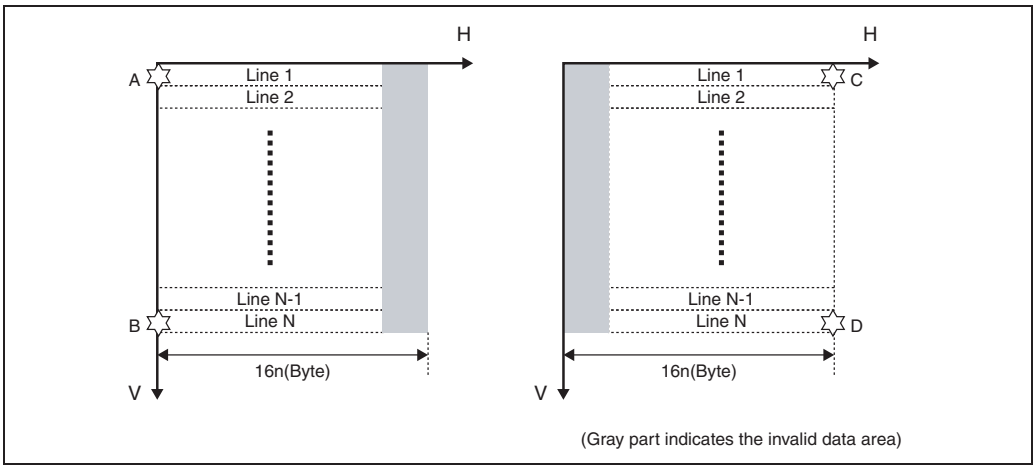

Figure 38.9 The specified Address point of CHnDAR

38.3.3 Format Conversion

Conversions are possible between RGB formats and between YCbCr formats (YCbCr4:2:0 and YCbCr4:2:2). For available RGB formats, see table 38.3. However, no format conversion is possible between RGB and YCbCr.

38.3.4 Simple Magnification

Setting the MX and MY bits in CTRL allows enlarged output in the X and Y directions respectively.

Simple magnification method is used for the magnification processing where the pixels in the source image are copied in the X and Y directions and are then output.

Figure 38.10 is a schematic diagram of simple magnification of pixels.

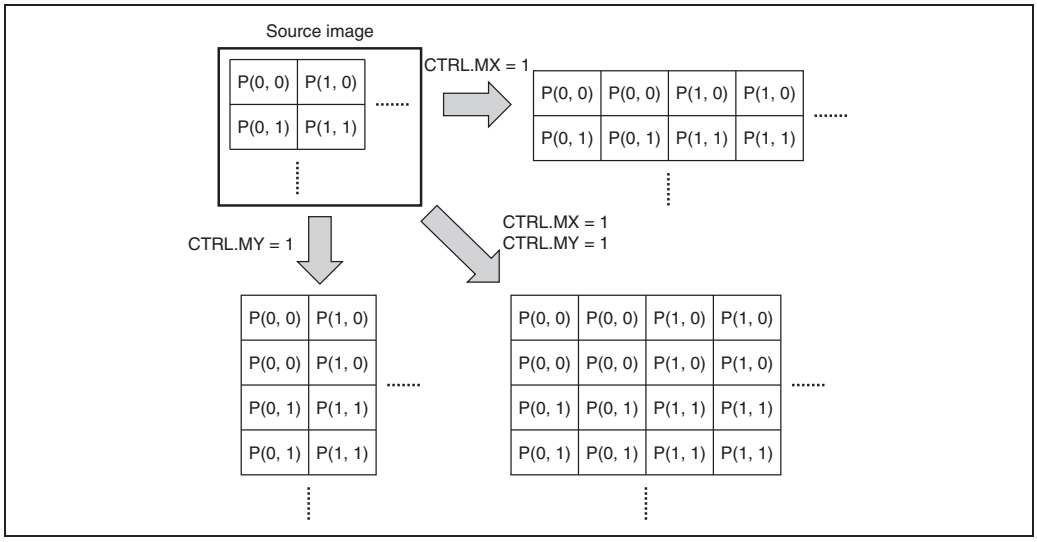

Figure 38.10 Enlarged Output of Pixels

38.4 Transfer Flow

Figure 38.11 shows a flowchart of DMAC transfer using 2D-DMAC.

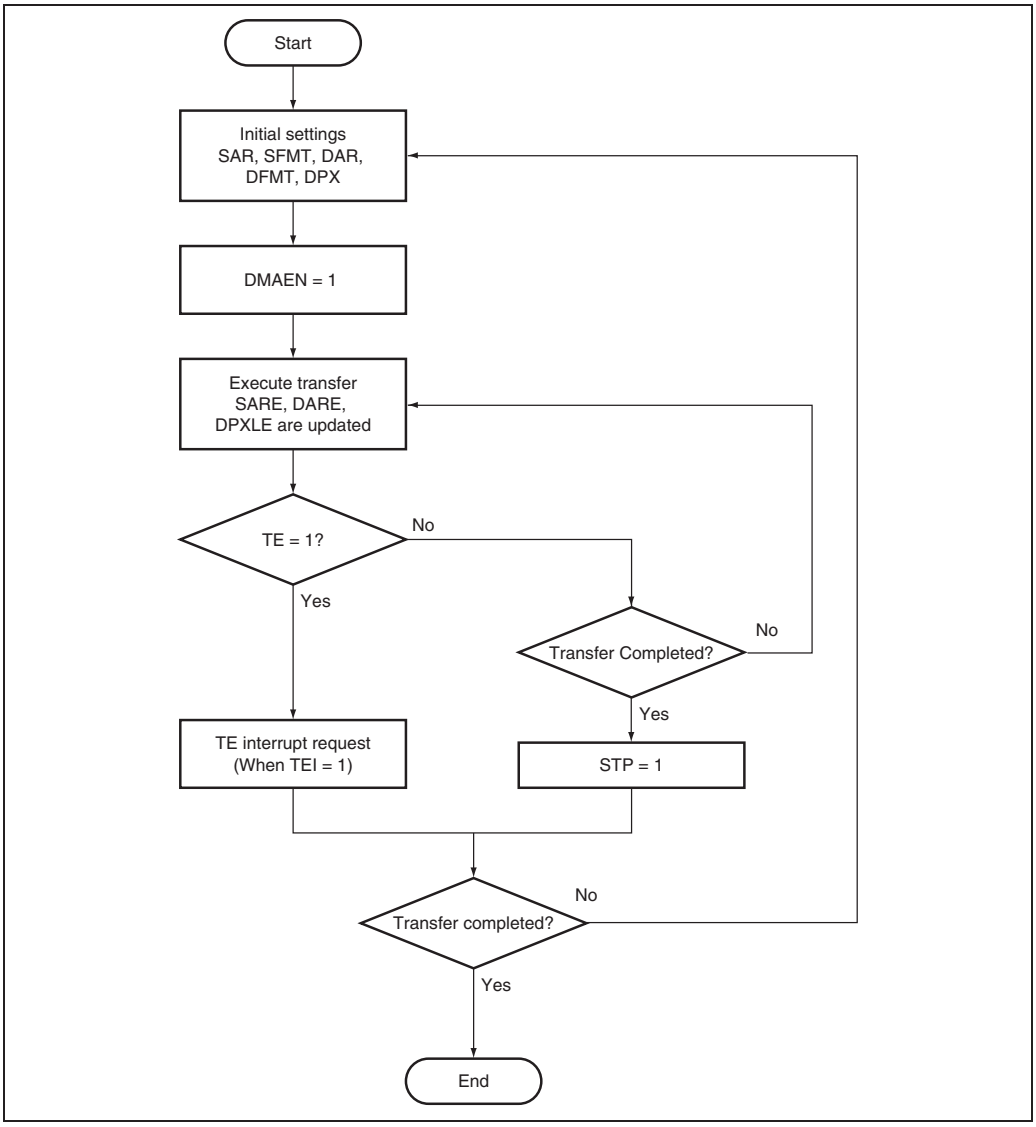

Figure 38.11 Flowchart of DMAC Transfer Using 2D-DMAC

Section 39 Media RAM (MERAM)

This LSI has a 1536-Kbyte media RAM (MERAM). Up to 32 interconnect buffers (ICB) can be defined on the MERAM. Each ICB functions as a read buffer or write buffer for transactions of an image module, and also allows data transmission/reception between image modules through the ICB. The use of ICBs enables the number of accesses to the SDRAM to be reduced and the access efficiency to be improved.

Furthermore, by combining multiple areas in the MERAM, it can be defined as a frame buffer cache. When the LCDC accesses data through the frame buffer cache, the data is cached and the second access and the following accesses are made from the MERAM, which reduces accesses to the SDRAM.

This LSI also has an LCD refresh controller, allowing to temporarily store display data, which is formerly read from the SDRAM in the refresh mode, in the MERAM and to display it on the LCD by simply performing internal bus transfer.

Accesses from the following modules are supported: CEU, CSI-RX, VEU × 4, BEU × 3, 2D-DMAC, ISP, VPU, JPU, DSI-TX × 2, LCDC × 2.

Note: 1. Set the RTMSTPCR007 bit in RTMSTPCR0 of the CPGA to 0 (operation started) in any of the following conditions:

Condition 1	When using any of those modules listed above (or accessing their registers)
Condition 2	When accessing the registers of IPMMU (I)
Condition 3	When directly accessing the MERAM as the internal memory

When all conditions 1 to 3 are not met, RTMSTPCR007 in the RTMSTPCR0 register of the CPGA can be set to 1 (stop).

2. When accessing the MERAM as the internal memory, or when using the interconnect buffer function, set the RTMSTPCR113 bit in the RTMSTPCR1 register to 0 (operation started). Otherwise, set the RTMSTPCR113 bit to 1 (operation stopped). When the LCDC0/1 accesses the MERAM in the LCD refresh mode, the RTMSTPCR113 bit may be 0 (operation started).

39.1 Features

(1) Features of Interconnect Buffers (ICB)

- Up to 32 buffers can be defined.
- Each ICB functions as a read buffer, which prefetches data from the specified area of the SDRAM and then stores the data in the buffer according to read transactions from a module. The ICB can also start reading before a transaction from the module occurs.
- Each ICB also functions as a write buffer, which receives write transactions from a module and stores them in the buffer. Whether to write data back to the SDRAM or not is selectable.
- The write buffer for a module can be used as the read buffer for another module, which allows data transfer in the MERAM. Data write to the SDRAM is also possible.

(2) Features of Frame Buffer Cache

- An area of combined ICBs can be defined as a frame buffer cache.
- Data from the frame buffer within the SRAM is supplied to the LCDC while also being used to fill the frame buffer cache. When the data doesn't change, data is simply supplied from the frame buffer to the LCDC.

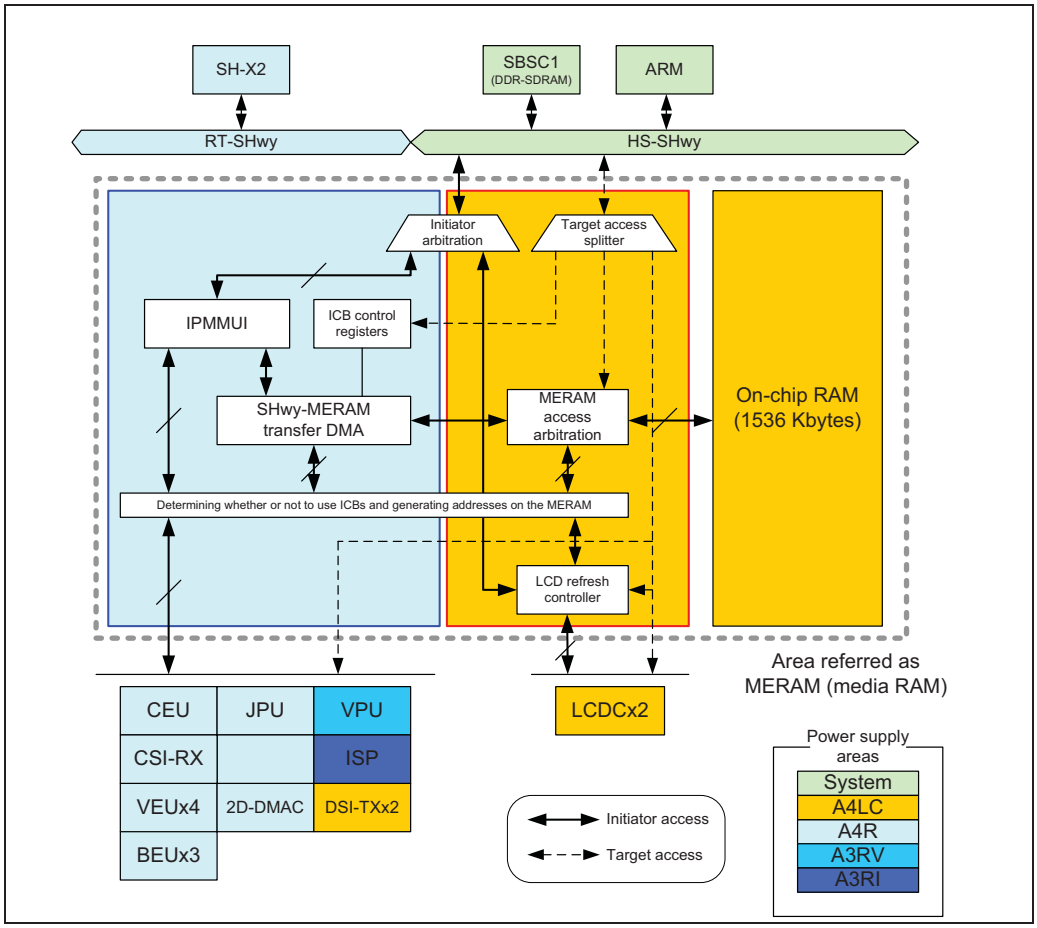

Figure 39.1 Block Diagram of MERAM and Other Modules

39.2 Register Descriptions

Table 39.1 shows the register configuration and memory configuration of the MERAM. Table 39.2 shows the register status in each processing mode.

Table 39.1 Register Configuration and Memory Configuration

Register Name	Abbreviation	R/W	Address	Access Size
ICB control register 0	MEVCR0	R/W	H'E550 0000	32
ICB control register 1	MEVCR1	R/W	H'E550 0004	32
ICB transfer end interrupt set register 0	METEIE0	R/W	H'E550 0008	32

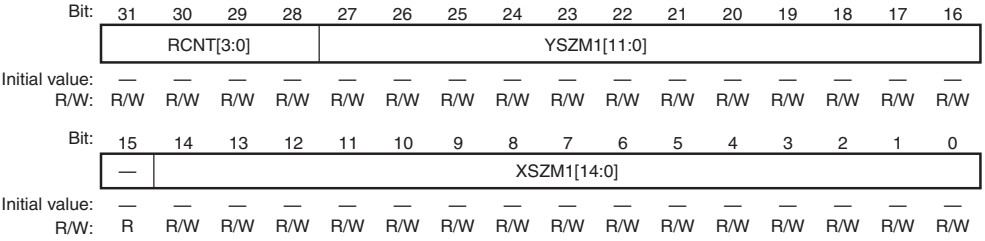
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	BV	0	R/W	Block Line processing Valid This bit is used along with the XBV bit in MEnnMCNF register to specify the unit of transfer between the external memory/corresponding image modules and the MERAM. • If the BV bit in the MEnnCTRL register is 1 and the XBV bit in the MEnnMCNF is 0: The transfer is performed in block line units that is is specified by the BSZ2 to BSZ0 bits in the MEnnCTRL register (block line transfer mode). • If the BV bit in the MEnnCTRL register and the XBV bit in the MEnnMCNF are 1: The transfer is performed in units of blocks into which the block line specified by the BSZ2 to BSZ0 bits in the MEnnCTRL register is divided by up to (2^BSZ[2:0]) horizontally (block transfer mode). • If the BV bit in the MEnnCTRL is 0: The transfer is performed in line units regardless of the setting in the BSZ2 to BSZ0 bits in the MEnnCTRL register (line transfer mode).

Bit	Bit Name	Initial Value	R/W	Description
30 to 28	BSZ[2:0]	000	R/W	Indicate the number of lines that compose a block line. The 2^BSZ2 to BSZ0 line is treated as a block line. These bits specify a block line consisting of 1, 2, 4, 8, 16, 32, 64 lines.
27	—	Undefined	R	Reserved The write value should always be 0.
26 to 16	MSAR[10:0]	H'000	R/W	Specify the start address of a memory area reserved in the MERAM in units of Kbytes (0 to 1535). Set a multiple of the number of block lines specified by bits BSZ2 to BSZ0. For the memory area size used in the MERAM, see section 39.2.3, ICBnnMERAM Set Register (MEnnMCNF).
15 to 11	NXT[4:0] (LNM[4:0])	00000	R/W	Specify the next ICB number when configuring a frame buffer cache. Setting the current buffer number indicates that the buffer is the end buffer of the frame buffer cache. The value of these bits is used only when the MD2 to MD0 bits are B'111. For details, see section 39.4.4, Settings as Frame Buffer Cache. Specify the ICB number for the connection destination in combination with MEnnMCNF.LNM[5:4] when the buffering mode has been enabled.
10, 9	WD[1:0]	00	R/W	Set B'11 in this field to use.
8	WS	0	R/W	Set B'1 in this field to use.
7	CB	0	R/W	Indicates 0 while the ICB is using register set A, and indicates 1 while the ICB is using register set B. The write value should always be 0. Unless otherwise specified with a special application example, the value of this bit will not be used.

Bit	Bit Name	Initial Value	R/W	Description
6	WBF	0	R/W	When the MD2 to MD0 bits are B'001 or B'111, this bit indicates that the data read fill operation in the ICB is completed. When the MD2 to MD0 bits are B'010 or B'011, this bit indicates that the write back operation of the ICB data is completed. The write value should always be 0. If 1 is written while the ICB is operating, the MERAM terminates the operation upon completion of the ongoing read fill or write back operation. Note: If 1 is written to this bit while the ICB is operating, the data written back to the SDRAM and the data filled into the ICB are not guaranteed. When writing 1 to this bit, also write 1 to the WF and RF bits to quit using the buffer.

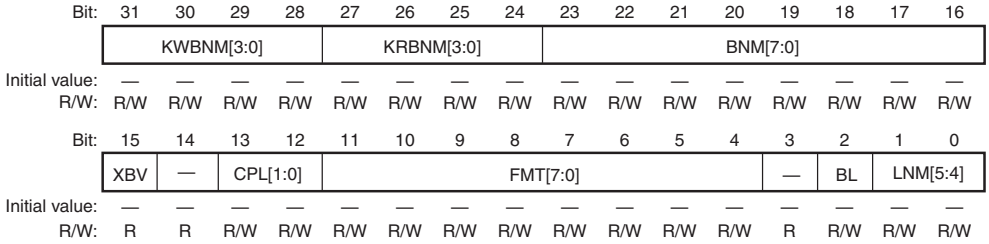


Bit	Bit Name	Initial Value	R/W	Description
5	WF	0	R/W	When the MD2 to MD0 bits are B'010, B'011, or B'100, this bit indicates that the data write operation in the ICB is completed. Upon detection of write operation end by the WD1 and WD0 bits, this bit is automatically set to 1. The write value should always be 0. If 1 is written while the ICB is operating, it is regarded that the completion of data write to the ICB has been notified. For modules that cannot automatically detect write operation end using the WD1 and WD0 bits, write 1 to this bit after receiving the operation completion of the module, and then notify manually that the data write to the ICB is completed. Setting this bit to 1 when the MD2 to MD0 bits are B'010 or B'011 starts write back operation of the data remaining in the ICB. Setting this bit to 1 when the MD2 to MD0 bits are B'011 or B'100 allows data reading up to the last line. When this bit is 1 and the following conditions are met, the use of the ICB is regarded as completed, the ACnn bit in MEACTST is negated, and the TEnn bit in METEST is set to 1. At the same time, the WBF, WF, and RF bits are cleared. [Conditions] When MD2 to MD0 = B'010: The WBF bit is 1 (write back completed). When MD2 to MD0 = B'011: The WBF bit is 1 (write back completed) and the RF bit is 1 (read operation completed). When MD2 to MD0 = B'100: The RF bit is 1 (read operation completed). Note: Even if an address with an offset (line N) has been written as the start address, data including line 0 to N is written back when operation is completed.

Bit	Bit Name	Initial Value	R/W	Description
4	RF	0	R/W	When the MD2 to MD0 bits are B'001, B'011, or B'100, this bit indicates that the data read operation in the ICB is completed. Upon detection of data read completion by the RCNT3 to RCNT0 bits in MEnnBSIZE, this bit is automatically set to 1. The write value should always be 0. If 1 is written while the ICB is operating, it is regarded that the completion of data read from the ICB has been notified. For modules that cannot automatically detect read operation end using the RCNT3 to RCNT0 bits in MEnnBSIZE, write 1 to this bit after receiving the operation completion of the module, and then notify that the data read from the ICB is completed. When this bit is 1 and the following conditions are met, the use of the ICB is regarded as completed, the ACnn bit in MEACTST is negated, and the TEnn bit in METEST is set to 1. At the same time the WBF, WF, and RF bits are cleared. [Conditions] When MD2 to MD0 = B'001: The WBF bit is 1 (read fill completed). When MD2 to MD0 = B'011: The WBF bit is 1 (write back completed) and the WF bit is 1 (write operation completed). When MD2 to MD0 = B'100: The WF bit is 1 (write operation completed). When MD2 to MD0 = B'111: The WBF bit is 1 (read fill completed).

Bit	Bit Name	Initial Value	R/W	Description
3	CM	0	R/W	Consecutive address mode. Specify how addresses are converted to line numbers and in-line offsets. For details, see section 39.3, Making Access to MERAM. 0: XSZM1 in MEnnBSIZE<4096: Bit 11 to bit 0 of the address indicate the in-line offset, and the bits after bit 12 indicate the line number. 4096<=XSZM1 in MEnnBSIZE: Bit 14 to bit 0 of the address indicate the in-line offset, and the bits after bit 15 indicate the line number. 1: XSZM1 in MEnnBSIZE<1024: Bit 9 to bit 0 of the address indicate the in-line offset, and the bits after bit 10 indicate the line number. 1024<=XSZM1 in MEnnBSIZE<2048: Bit 10 to bit 0 of the address indicate the in-line offset, and the bits after bit 11 indicate the line number. 2048<=XSZM1 in MEnnBSIZE<4096: Bit 11 to bit 0 of the address indicate the in-line offset, and the bits after bit 12 indicate the line number. 4096<=XSZM1 in MEnnBSIZE<8192: Bit 11 to bit 0 of the address indicate the in-line offset, and the bits after bit 13 indicate the line number. Note: When CM in MEnnCTRL is 1, set XSZM1 in MEnnBSIZE to less than 8192.
2 to 0	MD[2:0]	000	R/W	Specify ICBnn usage mode. 000: No ICB is used. 001: Read buffer mode 010: Write buffer mode 011: Interconnect buffer (with write back) mode* 100: Interconnect buffer (without write back) mode* 111: Frame buffer cache mode** Note: In block transfer mode, setting other than the read buffer mode and write buffer mode is prohibited. * When using the interconnect buffer mode with extended ICBs, enable the buffering mode. ** Setting prohibited when the extended ICB function is enabled.

39.2.2 ICBnn Frame Size Register (MEnnBSIZE)



MEnnBSIZE (nn = 00 to 127) specifies the size of the frame buffer corresponding to ICBnn.

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	Undefined	R	Reserved The write value should always be 0.
28 to 16	YSZM1 [12:0]	Undefined	R/W	Specify the number of lines -1 (nn = 00 to 31: 0 to 4095, nn = 32 to 127: 8192) of the frame buffer corresponding to ICBnn (nn = 00 to 127).
15	—	Undefined	R	Reserved The write value should always be 0.
14 to 0	XSZM1 [14:0]	Undefined	R/W	Specify the actual data size -1 in units of bytes (0 to 32767 bytes) in one line of the frame buffer corresponding to ICBnn (nn = 0 to 127). Note: When CM in MEnnCTRL is 1, set XSZM1 in MEnnBSIZE to less than 8192.

39.2.3 ICBnn MERAM Set Register (MEnnMCNF)

MEnnMCNF (nn = 00 to 127) is used for settings of buffer areas in the MERAM used by ICBnn.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	KWBNM [3:0]	Undefined	R/W	Specify the number of lines to be retained during writing when the MD2 to MD0 bits in MEnnCTRL are B'010, B'011, or B'100. • Specify the number of lines in units of block lines specified by the BSZ2 to BSZ0 bits in MEnnCTRL, and the number of lines to be retained during writing is treated as (KWBNM3 to KWBNM0 +1) << BSZ2 to BSZ0 in MEnnCTRL. • When the MERAM detects data write to line n, it determines that the data on the line (n - number of lines retained during writing) is fixed, and no more data writing to the line (n - number of lines retained during writing) is generated. Note: The value of these bits depends on the characteristics or operation settings of associated modules. For details, see section 39.5, Setting for Each Associated Module.

Bit	Bit Name	Initial Value	R/W	Description
27 to 24	KRBNM [3:0]	Undefined	R/W	Specify the number of lines to be retained during reading when the MD2 to MD0 bits in MEnnCTRL are B'001, B'011, B'100, or B'111. • Specify the number of lines in units of block lines specified by the BSZ2 to BSZ0 bits in MEnnCTRL, and the number of lines to be retained during reading is treated as (KRBNM3 to KRBNM0 +1) << BSZ2 to BSZ0 in MEnnCTRL. • When the MERAM detects data read on line n, it determines that the data on the line (n - number of lines retained during reading) can be released, and no more data reading on the line (n - number of lines retained during reading) is generated. Note: The value of these bits depends on the characteristics or operation settings of associated modules. For details, see section 39.5, Setting for Each Associated Module.

Bit	Bit Name	Initial Value	R/W	Description
23 to 16	BNM[7:0]	Undefined	R/W	• Line transfer mode, block line transfer mode: Specify the number of lines to be secured in the MERAM. (Lines of the set number +1 are secured.) Specify the number of lines irrespective of the value of the BSZ2 to BSZ0 bits in MEnnCTR. Secure at least the following number of lines. MD = B'001: (Number of lines retained during reading +1: Number of block lines) MD = B'010: (Number of lines retained during writing +1: Number of block lines) MD = B'011, B'100: (Number of lines retained during writing + number of lines retained during reading +1: Number of block lines) MD = B'111: See the following, (1) Calculating Memory Area Reserved in the MERAM. • Block transfer mode: Specify the number of lines to be secured in the MERAM. (Lines of the set number +1 are secured.) Secure at least the following number of lines. MD = B'001: (Number of lines retained during reading +1: Number of block lines) MD = B'010: (Number of lines retained during writing +1: Number of block lines) When YC combining mode is enabled, the number of lines actually secured for the value set by the above-mentioned is YCbCr420: (BNM+1) x 1.5 YCbCr422: (BNM+1) x 2 YCbCr444: (BNM+1) x 3 Please set for (BNM+1) to become an even number for YCbCr420
15	XBV	Undefined	R/W	• Block transfer mode: When both bits, MEnnCTRL.BV and MEnnCTRL.XBV are set to 1, a transfer is performed in every block between the external memory and the MERAM, and also the associated image module and the MERAM. (block transfer mode)

Bit	Bit Name	Initial Value	R/W	Description
14	—	Undefined	R	Reserved The write value should always be 0.
13, 12	CPL[1:0]	Undefined	R/W	YC combining mode When MEnnMCNF.CPL ! = B'00, the values of MEnnSSARA and MEnnSSARB are used as the Y surface address and the C surface address, respectively, to perform transfer in which these surfaces are linked. 00: This mode is not used. 01: YCbCr444 10: YCbCr420 11: YCbCr422
11 to 4	FMT[7:0]	Undefined	R/W	Data packed format Specify the data packed format in the external memory for performing transfer in the YC combining mode. Refer to tables 39.3 and 39.4 for the planar format and packed format, respectively. FMT[7:5] Specify the format for YCbCr data. 000: Semi-planar format 010: Planar-Padding format 011: Planar-Fitting format 100, 101: Packed format Other settings: Prohibited. FMT[4] Exchange the data position of Cb for that of Cr. 0: No effects 1: Exchange the data position of Cb for that of Cr FMT[5], FMT[3:2] Specify the packed format when the packed format mode is selected. FMT[1:0] Reserved The write value shoud always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3	—	Undefined	R	Reserved The write value should always be 0.
2	BL	Undefined	R/W	Buffering mode Must be set when two different ICBnns are used for interconnection. Set this bit to 0 other than when the MD values for these two ICBnns are set to 'B011 or 'B100.
1, 0	LNM[5:4]	Undefined	R/W	Specify the ICB number for the connection destination in combination with MEnnCTRL.LNM[3:0] when the buffering mode has been enabled.

(1) Calculating Memory Area Reserved in the MERAM

The memory area in the MERAM is used as follows:

- Line transfer mode:
  Unit of area used for buffer (KB) = value rounded up (MEnnBSIZE.XSZM1[14:0]+1) to the nearest 2^n KB (including 1 KB)
  Total size of area used for buffer (KB) = (unit of area used for buffer) × (MEnnMCNF.BNM[7:0]+1)
- Block line transfer mode:
  Unit of area used for buffer (KB) = value rounded up (MEnnBSIZE.XSZM1[14:0]+1) to the nearest 2^n KB (including 1 KB) × 2^MEnnCTRL.BSZ[2:0]
  Total size of area used for buffer (KB) = (unit of area used for buffer) × ((MEnnMCNF.BNM[7:0]+1)/(2^MEnnCTRL.BSZ[2:0]))
- Block transfer mode:
  Unit of area used for buffer (KB) = value rounded up (MEnnBSIZE.XSZM1[14:0]+1) to the nearest 2^n KB (including 1 KB) × 2^MEnnCTRL.BSZ[2:0]/MEnnCTRL.BSZ[2:0]
  Total size of area used for buffer (KB) = (unit of area used for buffer) × (MEnnMCNF.BNM[7:0]+1)

  When YCbCr dual transfer mode is enabled, the following memory area is used.

  YCbCr420 : Total size of area used for buffer (KB) = (the size of area calculated for Y data) × 1.5

  YCbCr422 : Total size of area used for buffer (KB) = (the size of area calculated for Y data) × 2

  YCbCr444 : Total size of area used for buffer (KB) = (the size of area calculated for Y data) × 3

When ICBnn is defined the amount of memory area calculated as "Total size of area used for buffer" above which begins with the start address specified by the MSAR10 to MSAR0 bits in MEnnCTRL is secured. Since no detection is performed with respect to whether or not the memory area overlaps with the memory area secured by another ICB, write a multiple of the "total size of area used for buffer" value to the MSAR10 to MSAR0 bits to avoid such an overlap.

Note: Specify a value so that the total number of "lines secured in the MERAM","lines held during reads", and "lines held during writes" is less than 256.

(2) Data Packed Format on External Memory in YC Combining Mode

When YCbCr-format image data is transferred from the external memory to the MERAM via an ICB for which the YC combining mode has been enabled, the format specified in MEnnMCNF.FMT is converted into the semi-planar format that can be processed in image modules, before the data is stored in MERAM. Also, when data is transferred from the MERAM to the external memory via an ICB for which the YC combining mode has been enabled, the semi-planar format of the data stored in the MERAM is converted into the format specified in MEnnMCNF.FMT.

- Semi-planar format

  In this format, Y and CbCr are stored at different addresses. The start addresses of the Y data and the CbCr data must be specified in MEnnSSARA and MEnnSSARB, respectively.
- Planar-Padding format

  In this format, Y, Cb, and Cr are stored at different addresses. The start addresses of the Y data and the Cb data must be specified in MEnnSSARA and MEnnSSARB, respectively. The Cr data is placed from the end of the Cb data, and the start address, SSARC, is calculated using the following expressions:

  YCbCr420 : SSARC = MEnnSSARB + (MEnnSSARB - MEnnSSARA) / 2

  YCbCr422, 444 : SSARC = MEnnSSARB + (MEnnSSARB - MEnnSSARA)
- Planar-Fitting format

  In this format, Y data, Cb data, and Cr data are stored at different addresses. The start addresses of the Y data and the Cb data must be specified in MEnnSSARA and MEnnSSARB, respectively. The Cr data is placed from the end of each line of the Cb data, and the start address, SSARC, is calculated using the following expressions:

  YCbCr420,422 : SSARC = MEnnSSARB + MEnnSBSIZE / 2

  YCbCr444 : SSARC = MEnnSSARB + MEnnSBSIZE

  Table 39.3 shows the method of storing data in the planar formats.
- Packed format

In this format, Y, Cb, and Cr are packed on a pixel basis and stored at a single address. Table 39.4 shows the corresponding packed format.

Table 39.3 YCbCr Planar Format

XSZ = MEnnBSIZE.XSZM1 + 1, YSZ = MEnnBSIZE.YSZM1 + 1
SSARA = MEnnSSARA, SSARB = MEnnSSARB, SBSIZE = MEnnSBSIZE.SBSIZE
SSARC = SSARB + (SSARB - SSARA) / 2 [YCbCr420, Planar-Padding],
SSARB + SSARB - SSARA [YCbCr422, YCbCr444, Planar-Padding],
SSARB + SBSIZE/2 [YCbCr420, YCbCr422, Planar-Fitting]

SSARB + SBSIZE [YCbCr444, Planar-Fitting]

Note: When FMT[4] has been set to 1'b1, the data position of Cb is exchanged for that of Cr.

Table 39.4 Packed Format for YCbCr

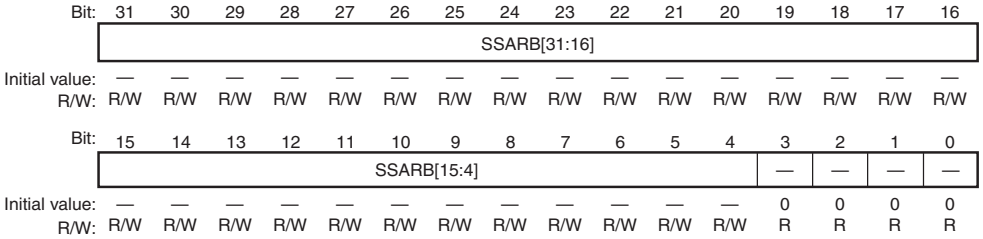
	FMT[5], FMT[3:2]	Phase	Bit			
			31 to 24	23 to 16	15 to 8	7 to 0
YCbCr444 (CPL = 2'b01)	000	0	Y0	Cb0	Cr0	Y1
		1	Cb1	Cr1	Y2	Cb2
		2	Cr2	Y3	Cb3	Cr3
	001	0	Cb0	Y0	Cr0	Cb1
		1	Y1	Cr1	Cb2	Y2
		2	Cr2	Cb3	Y3	Cr3
	010	0	Cb0	Cr0	Y0	Cb1
		1	Cr1	Y1	Cb2	Cr2
		2	Y2	Cb3	Cr3	Y3
YCbCr420 (CPL = 2'b10)	000	–	Y0	Y1	Cb0	Cr0
	001	–	Cb0	Y0	Y1	Cr0
	010	–	Cb0	Cr0	Y0	Y1
	100	–	Y0	Cb0	Y1	Cr0
	110	–	Cb0	Y0	Cr0	Y1
YCbCr422 (CPL = 2'b11)	000	0	Y0	Y1	y0	y1
		1	Cb0	Cr0	Y2	Y3
		2	y2	y3	Cb2	Cr2
	010	0	Cb0	Cr0	Y0	Y1
		1	y0	y1	Cb2	Cr2
		2	Y2	Y3	y2	y3
	100	0	Y0	Y1	Cb0	y0
		1	y1	Cr0	Y2	Y3
		2	Cb2	y2	y3	Cr2
	101	0	Cb0	Y0	Y1	Cr0
		1	y0	y1	Cb2	Y2
		2	Y3	Cr2	y2	y3
	110	0	Y0	Cb0	Y1	y0
		1	Cr0	y1	Y2	Cb2
		2	Y3	y2	Cr2	y3

The capital letter Y and small letter y in YCbCr422 indicate Y data of the upper-layer pixels and the lower-layer pixels, respectively.

Note: When FMT[4] has been set to 1'b1, the data position of Cb is exchanged for that of Cr.

39.2.4 ICBnn External Memory Start Address Register A (MEnnSSARA)

MEnnSSARA (nn = 00 to 127) indicates the start address of the frame buffer (register set A) corresponding to ICBnn in the external memory. The value of the SSARA bits must be a multiple of 16.



Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SSARA[31:16]															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SSARA[15:4]												—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	SSARA [31:4]	Undefined	R/W	Indicate the start address (in 16-byte units) of the frame buffer (register set A) corresponding to ICBnn (nn = 0 to 127) in the external memory. In YCbCr dual transfer mode, indicate the start address of Y data.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

39.2.5 ICBnn External Memory Start Address Register B (MEnnSSARB)

MEnnSSARB (nn = 00 to 127) indicates the start address of the frame buffer (register set B) corresponding to ICBnn in the external memory. The value of the SSARB bits must be a multiple of 16.

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	SSARB [31:4]	Undefined	R/W	Indicate the start address (in 16-byte units) of the frame buffer (register set B) corresponding to ICBnn (nn = 0 to 127) in the external memory. In YCbCr dual transfer mode, indicate the start address of C data.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

39.2.6 ICBnn External Memory Buffer Size Register (MEnnSBSIZE)

MEnnSBSIZE (nn = 00 to 127) indicates the one-line width of the frame buffer corresponding to ICBnn in the external memory in units of bytes. The one-line width must be a multiple of 8.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	HDV	HSZ[2:0]			—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SBSIZE[15:4]												—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	HDV	0	R/W	Horizontally-Divided Access setting This bit is valid when the BV bit in the MEnnCTRL register is 1. It allows transfer between a block line or block in the MERAM and the external memory to be performed in units of blocks into which the block line or block is divided horizontally with the size specified by the HSZ2 to HSZ0 bits. If the destination external memory space is specified for T-L conversion by the IPMMU(I), set the HSZ2 to HSZ0 bits to the same horizontal size as the one of a block in the external memory. If these settings do not match, transfer is not performed normally.
30 to 28	HSZ[2:0]	000	R/W	Indicate the horizontal division unit in horizontally-divided access setting. 000: 16 bytes 001: 32 bytes 010: 64 bytes 011: 128 bytes Others: Setting prohibited
27 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	SBSIZE [15:4]	Undefined	R/W	Indicate the one-line width (in 16-byte units) of the frame buffer.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

39.2.7 ICB Control Register 0 (MEVCR0)

MEVCR0 is a 32-bit read-only register for the future extension. Data write to this register is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	RST	0	R/W	ICB Reset When this bit is set to 1, all ICBs are initialized, and then this bit is automatically cleared. Reset all the modules using an ICB, and then set this bit to 1. Use this bit when an error occurs in the software program that uses an ICB.
30	WD	0	R/W	Write Direction When writing to MEACTSTn, METESTn, MEILWST, or MEILRST, MEILSTn, the bits to which 1 has been written are cleared usually. But when this bit is set to 1, the bits to which 1 has been written are set.
29	AMD1	0	R/W	Address Mode Switch 0: The ICB function is used when the addresses from modules are within H'80000000 to H'BFFF FFFF. 1: The ICB function is used when the addresses from modules are within H'C0000000 to H'DFFF FFFF. For details, see section 39.3, Making Access to MERAM.

Bit	Bit Name	Initial Value	R/W	Description
28	AMD0	0	R/W	Extended ICB Enable 0: The addresses H'E000 0000 to H'EFFF FFFF are output on the SHwy. 1: The extended ICB function is used when the addresses from modules are within H'E0000000 to H'EFFF FFFF. For details, see section 39.3, Making Access to MERAM.
28 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

39.2.9 ICB Transfer End Interrupt Set Register n (METEIEn)

METEIEn (n = 0 to 3) controls interrupt requests made by the transfer end flag (TEnn bits in METEST) of each ICB (nn = 00 to 127).

For modules that cannot detect a write operation, when the WF bit in MEnnCTRL is manually set to 1, the MERAM can wait until the write back operation ends using this interrupt function.

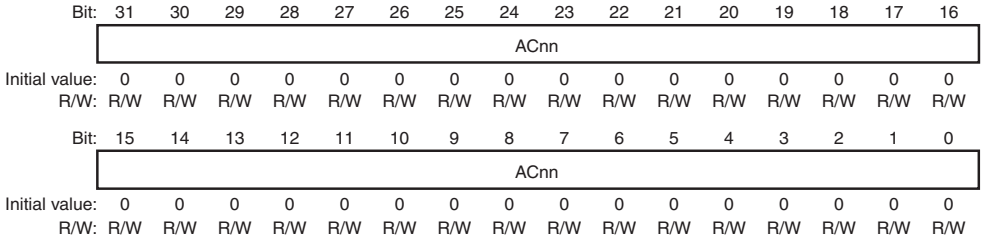
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TInn (n = 0: nn = 00 to 31 N = 1: nn = 32 to 63 N = 2: nn = 64 to 95 N = 3: nn = 96 to 127)	H'0000 0000	R/W	When any of the TInn (nn = 00 to 127) bits is set to 1, an interrupt occurs while the ICB transfer end flag (TEnn) in METESTn is 1. After an interrupt occurs, it can be canceled by clearing the TEnn flag or the Tinn bits in this register.

39.2.10 ICB Transaction Error Interrupt Set Register n (MEILIEn)



MEILIEn (n = 0 to 3) controls interrupt requests made by the error status flag (IWnn in MEILWST, IRnn in MEILRST, and IWRnn in MEILSTn) of each ICB (nn = 00 to 127). For error status conditions, see the descriptions on the MEILWST and MEILRST and MEILSTn registers.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IInn (n = 0: nn = 00 to 31 n = 1: nn = 32 to 63 n = 2: nn = 64 to 95 n = 3: nn = 96 to127)	H'0000 0000	R/W	When any of these bits (nn = 00 to 127) is set to 1 and the error end flag (IWnn or IRnn or IWRnn) of each ICB in MEILWST or MEILRST or MEILST is 1, an interrupt occurs. An interrupt is generated by the flag on the write side or read side. After an interrupt occurs, it can be canceled by clearing the IWnn and IRnn and IWRnn flags or clearing the corresponding IInn bits in this register.

39.2.11 ICB Active Status Register n (MEACTSTn)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	ACnn (n = 0: nn = 00 to 31 n = 1: nn = 32 to 63 n = 2: nn = 64 to 95 n = 3: nn = 96 to 127)	H'0000 0000	R/W	Indicate that ICBnn (nn = 00 to 127) is in use. When 1 is written to this register while the WD bit in MEVCR1 is 0, the bits to which 1 has been written are cleared and the other bits remain unchanged. When 1 is written to this register while the WD bit in MEVCR1 is 1, the bits to which 1 has been written are set to 1 and the other bits remain unchanged.

(1) State Transitions of ICBnn

The ACnn bits (nn = 00 to 127) indicate that ICBnn (nn = 00 to 127) is in use.

When a transaction occurs successfully from an associated module to ICBnn, the ACnn bit is set to 1 and the ICBnn becomes active.

The active ICBnn must be driven to inactive mode upon completion of processing for one plane. The completion of processing for one plane means the following.

- When MD = B'001 or B'111: The WBF and RF bits in MEnnCTRL are 1.
  The RF bit indicates that the read operation of the module using ICBnn is completed. WBF = 1 shows that the read fill operation for ICBnn is completed up to the last line.

- When MD = B'010: The WBF and WF bits in MEnnCTRL are 1.
  The WF bit indicates that the write operation of the module using ICBnn is completed. WBF = 1 shows that the write back of the data written to ICBnn to the external memory is completed up to the last line.
- When MD = B'011: The WBF, WF, and RF bits in MEnnCTRL are 1.
- When MD = B'100: The WF and RF bits in MEnnCTRL are 1.

When the processing for one plane of ICBnn is completed, the WBF, WF, and RF bits in MEnnCTRL are cleared and the corresponding bit (TEnn) in METESTn is set to 1. At the same time, the corresponding bit (ACnn) in MEACTSTn is cleared and ICBnn enters inactive mode.

The WF and RF bits can be set by manually writing 1 to the WF and RF bits of all active ICBnn when the end interrupt of the associated module occurs. Do not set the WBF bit to 1 to avoid discontinuation of write back operation.

Furthermore, the function to automatically detect the completion of processing for one plane is available for each write and read operation in some cases. For details of the function, see the descriptions on the WD1 and WD0 bits in MEnnCTRL, the WS bit in MEnnCTRL, and the RCNT3 to RCNT0 bits in MEnnBSIZE, and also see section 39.5, Settings for Each Associated Module. When the auto-detect function is available, the WF and RF bits in MEnnCTRL are automatically set to 1 by the execution of the last transaction in the write or read operation, which does not require manual setting.

ICBnn that returns to inactive mode can deal with the next-plane transaction sent from the associated module. If the next-plane transaction is generated while ICBnn is active, a transaction error occurs usually. But the processing can be continued in the following cases.

- When the register set A/register set B specification of a transaction to ICBnn differs from the register set A/register set B indication of the active ICBnn
- When the register set A/register set B specification of a transaction to ICBnn matches the register set A/register set B indication of the active ICBnn, but the transaction line number is 0 and the transaction processing to the last line is already completed and line 0 is not included in the lines to be retained during reading/writing

With these conditions, an occurrence of this transaction is regarded as the completion of use of ICBnn, and therefore the completion processing starts automatically. In the case of a read transaction, the MERAM sets the RF bit in one or two buffers that the module is using for read operation, waits until the buffers become inactive, and then processes the generated transaction. In the case of a write transaction, the MERAM sets the WF bit in one or two buffers that the module is using for write operation, waits until the buffers become inactive, and then processes the generated transaction.

Note: Two or more ICBs are available for reading in the BEU, for reading/writing in the 2D-DMAC. But the completion processing for an ICB used for another purpose may be performed upon occurrence of the next-plane transaction to an ICBnn. For this reason, this function is not available when using two or more ICBs for each read and write operation of the associated module.

When a transaction error is detected, the corresponding bits (IWnn/IRnn/IWRnn) in MEILWST, MEILRST, and MEILSTn are set to 1 and the corresponding bit (ACnn) in MEACTSTn is negated. For transaction errors, see the descriptions on the MEILWST, MEILRST, and MEILSTn registers.

(2) Writing to Register for Active ICB

When writing data to MEACTSTn, the AC bits corresponding to the bits to which 1 has been written are usually negated. When the WD bit in MEVCR1 is 1, the AC bits corresponding to the bits to which 1 has been written are set. Unless otherwise specified with a special application example, the AC bits need not be controlled by writing to this register.

While ACnn is 1, writing to the set register of ICBnn is made as follows:

- During the MEnnCTRL write operation, only writing 1 to the WBF, WF, and RF bits is effective and the other bits remain unchanged. When 0 is written to all the WBF, WF, and RF bits, every bit remains unchanged, but the set register of ICBnn is reevaluated, the buffers are restarted, and the read fill operation is started in advance.

  For restarting the buffers, see the description on clearing the error flag in MEILRST and restarting. For starting the read fill operation in advance of this, see (3) Starting Read Fill Operation in Advance.
- Writing to other set registers of ICBnn is possible, but only the register on the opposite plane from the register (MEnnSSARA or MEnnSSARB) specified by the CB bit in MEnnCTRL can be modified. The other registers should not be modified.

(3) Starting Read Fill Operation in Advance

When the MD2 to MD0 bits in MEnnCTRL is B'001, the read fill operation to the MERAM is started after a read transaction is generated from a module to ICBnn and then the ACnn bit in MEACTSTn is set to 1. Starting the read fill operation before such a read transaction occurs is made possible by the following procedure.

1. Set ICBnn.
2. Set the ACnn bits in MEACTSTn manually with the WD bit in MEVCR1 set to 1.
3. Write 0 to all bits in MEnnCTRL.

Since the ACnn bit in MEACTSTn is 1, no data is written to MEnnCTRL, but the read fill operation is started by reevaluating the ICBnn setting.

Note: When using ICBnn for the first time, write H'00000000 at addresses of MEnnCTRL + H'0C and MEnnCTRL + H'1C in step 1.

39.2.12 ICB Transfer End Status Register n (METESTn)

The TEnn bit (nn = 00 to 127) in this register indicates that the processing for one plane of ICBnn (nn = 00 to 127) is completed.

For the definition of the completion of processing for one plane of ICBnn, see the descriptions on the WF and RF bits in MEnnCTRL.

In writing to METEST, the TE bits corresponding to the bits to which 1 has been written are usually negated. When the WD bit in MEVCR1 is 1, the TE bits corresponding to the bits to which 1 has been written are set.

When the interrupt function of METEIEn is used and an interrupt occurs, clear the bit that generated the interrupt. When the interrupt function is not used, the Tenn bit needs not be cleared.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TEnn (n = 0: nn = 00 to 31 n = 1: nn = 32 to 63 n = 2: nn = 64 to 95 n = 3: nn = 96 to 127)	H'0000 0000	R/W	Indicate that the processing for one plane of ICBnn (nn = 00 to 127) is completed. The bits in this register to which 1 has been written are cleared.

39.2.13 ICB Write Transaction Error Status Register (MEILWST)

The IWnn bit (nn = 0 to 31) indicates that an unprocessable write transaction to ICBnn (nn = 0 to 31) has occurred. When this bit is set to 1, the ACnn bit in MEACT0 is negated. A write transaction error occurs under the following conditions.

Conditions for write transaction error:

- When a write transaction occurs to ICBnn for which the MD2 to MD0 bits in MEnnCTRL are set to B'000
- When a write transaction occurs to ICBnn in which a read transaction error or write transaction error has already occurred (IRnn bit in MEILRST or IWnn bit in MEILWST is 1)
- When a write transaction occurs to ICBnn in the state where the ACnn bit in MEACTST0 of active ICBnn is negated by writing to MEACTSTn
- When a write transaction occurs to a plane different from the register set A/register set B indication (value of the CB bit in MEnnCTRL) of an active ICBnn (ACnn in MEACTST0 = 1). However, when a module uses the same ICBnn repeatedly, the mismatch of register set A/register set B means the completion of processing for the former plane, which is not an error.

In writing to MEILWST, the IW bits corresponding to the bits to which 1 has been written are usually negated. When the WD bit in MEVCR1 is 1, the IW bits corresponding to the bits to which 1 has been written are set.

When the interrupt function of MEILIE0 is used and an interrupt occurs, clear the bit that generated the interrupt. Although the interrupt function is not used, no transaction to ICBnn for which the IWnn bit is set to 1 is processed after that. Therefore, the IWnn bit needs to be cleared. See section 39.2.14 (1), Clearing the Error Flag and Restarting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IWnn	H'0000 0000	R/W	Indicate that an error occurred during a write transaction to ICBnn (nn = 0 to 31). The bits to which 1 has been written are cleared.

39.2.14 ICB Read Transaction Error Status Register (MEILRST)

The IRnn bit (nn = 0 to 31) indicates that an unprocessable read transaction to ICBnn (nn = 0 to 31) has occurred. When this bit is set to 1, the ACnn bit in MEACTST0 is negated. A read transaction error occurs under the following conditions.

Conditions for read transaction error:

- When a read transaction occurs to ICBnn for which the MD2 to MD0 bits in MEnnCTRL are set to B'000
- When a read transaction occurs to ICBnn in which a write transaction error or read transaction error has already occurred (IRnn bit in MEILRST or IWnn bit in MEILWST is 1)
- When a read transaction occurs to ICBnn in the state where the ACnn bit in MEACTST0 of active ICBnn is negated by writing to MEACTST
- When a read transaction occurs to a plane different from the register set A/register set B indication (value of the CB bit in MEnnCTRL) of an active ICBnn (ACnn in MEACTST0 = 1). However, when a module uses the same ICBnn repeatedly, the mismatch of register set A/ register set B means the completion of processing for the former plane, which is not an error.

In writing to MEILRST, the IR bits corresponding to the bits to which 1 has been written are usually negated. When the WD bit in MEVCR1 is 1,the IR bits corresponding to the bits to which 1 has been written are set. When the interrupt function of MEILIE0 is used and an interrupt occurs, clear the bit that generated the interrupt. Although the interrupt function is not used, no transaction to ICBnn for which the IRnn bit is set to 1 is processed after that. Therefore, the IRnn bit needs to be cleared.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRnn															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRnn															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IRnn	H'0000 0000	R/W	Indicate that an error occurred during a read transaction to ICBnn (nn = 0 to 31). The bits to which 1 has been written are cleared.

(1) Clearing the Error Flag and Restarting

A transaction where the IWnn bit in MEILWST or the IRnn bit in MEILRST has been set to 1 remains in the ICB module and is not cleared until the transaction is processed or all ICBs are initialized. Therefore, the error module and all ICBs must be initialized except for the special case where the property of the transaction that has set the error flag can be anticipated.

1. If there is any module that uses an ICB other than ICBnn, change the register setting of the module so as not to use any ICB temporarily.
2. Issue the software reset command to all modules that use ICBnn and may cause an error.
3. Set the RST bit in MEVCR1 to 1 to reset all ICBs.

When the property of the transaction that has set the error flag can be anticipated and the transaction can be completed, the following procedure is available.

[Example] In the case of an error due to issuing of a transaction with the MD2 to MD0 bits in MEnnCTRL set to 000:

1. Set the ICBnn so that the transaction can be handled with the IWnn flag in MEILWST or the IRnn flag in MEILRST set to 1, and then write a value other than B'000 to the MD2 to MD0 bits.
2. Clear the IWnn bit in MEILWST and the IRnn bit in MEILRST.
3. Set the WD bit in MEVCR1 to 1, and then set the corresponding ACnn bit in MEACTST to 1.
4. Write 0 to all bits in MEnnCTRL. Since the ACnn bit is 1, no data writing is made actually, but the ICBnn setting is reevaluated by writing to MEnnCTRL, and the remaining transaction is processed.

39.2.15 ICB Transaction Error Status Register n (MEILSTn)

The IWR bit (nn = 32 to 127) indicates that an unprocessable read transaction or write transaction has occurred in ICBnn (nn = 32 to 127). When this bit is set to 1, the ACnn bit in MEACTSTn is negated.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	IWRnn (n = 1: nn = 32 to 63 n = 2: nn = 64 to 95 n = 3: nn = 96 to 127)	H'0000 0000	R/W	Indicate that an error occurred during a read or write transaction to ICBnn (nn = 32 to 127). The bits to which 1 has been written are cleared.

39.2.16 ICB Request Queue Priority Select Register 1, 2 (MEQSEL1, 2)

Each ICB buffer makes requests to the external memory for read fill operation or write back operation. These read-fill and write-back requests (hereafter referred to as external memory access requests) are stored in three kinds of queues that have different priority levels.
The QSEL1nn[47:16] bits and QSEL2nn[47:16] bits determine whether external memory access requests from ICB16 to ICB47 are stored in queue 1 or queue 2. For details, refer to 39.2.16 (1) External Memory Access Processing Order.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	QSEL1nn[31:16] QSEL1nn[47:32]	H'00FF 0000	R/W	Store external memory access requests made by an ICBnn (nn = 16 to 47) in queue 1. The upper 16 bits and the lower 16 bits correspond to nn = 16 to 31 and nn = 32 to 47, respectively. Total 8 bits must be set to 1. It is prohibited to set QSEL1nn and QSEL2nn to 1 for a single buffer at the same time.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	QSEL2nn[31:16] QSEL2nn[47:32]	H'FF00 0000	R/W	Store external memory access requests made by an ICBnn (nn = 16 to 47) in queue 2. The upper 16 bits and the lower 16 bits correspond to nn = 16 to 31 and nn = 32 to 47, respectively. Total 8 bits must be set to 1. It is prohibited to set QSEL1nn and QSEL2nn to 1 for a single buffer at the same time.

(1) External Memory Access Processing Order

Each ICB buffer makes requests to the external memory for read fill operation or write back operation. The order of processing these read-fill and write-back requests (hereafter referred to as external memory access requests) is described below:

1. External memory access requests made by ICBs are processed on a 1-line basis. After processing for a single line is completed, processing for another ICB is started.
2. External memory access requests made by ICBs are accumulated in three kinds of queues. Once external memory access requests are accumulated in the queues, the next request is prevented from being made until processing for the requests is completed.
   - Queue 2: External memory access requests made by the buffer specified in QSEL2 are accumulated.
   - Queue 1: External memory access requests made by the buffer specified in QSEL1 are accumulated.
   - Queue 0: External memory access requests made by buffers other than above are accumulated.

   Note that requests made by ICBs that are used as a cache buffer in the frame buffer cache mode are accumulated in the queue corresponding to the ICB number of the marker buffer.
3. External memory access requests accumulated in queue 2 are always given the highest priority. While there are no requests accumulated in queue 2, external memory access requests in queue 1 and 0 are processed alternately. The frequency of processing requests in queue 0 is the same as that of processing requests in queue 1. However, the numbers of requests accumulated in queue 0 and 1 are 16 and 8, respectively, and because of the difference between the numbers, requests in queue 1 are processed faster.

   Therefore, the buffer allocated to QSEL2 must have a higher priority than that allocated to QSEL1.

39.3 Making Access to MERAM

39.3.1 Direct Access from Shwy Initiator

The 1536-Kbyte space of the addresses H'E808 0000 to H'E81F FFFF is directly accessible to the MERAM memory. However, accesses are made irrespective of the ICB active status. Therefore, make accesses only to areas that are not used as ICBs.

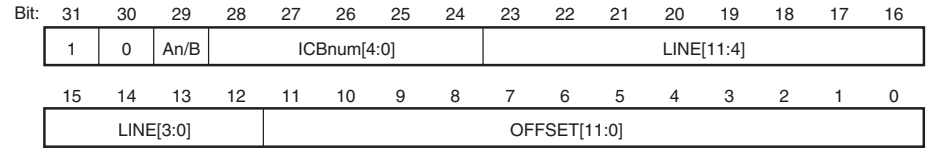
39.3.2 Direct Access from Associated Image Module

The addresses H'0000 0000 to H'7FFF FFFF and H'C000 0000 to H'FFFF FFFF from an associated module are output on the SHwy. Therefore, when making a direct access from an associated module to the MERAM, specify the 1536-Kbyte space of addresses H'E558 0000 to H'E56F FFFF or H'E808 0000 to H'E81F FFFF. However, accesses are made irrespective of the ICB active status. Therefore, make accesses only to areas that are not used as ICBs.

39.3.3 Access to ICB from Associated Image Module

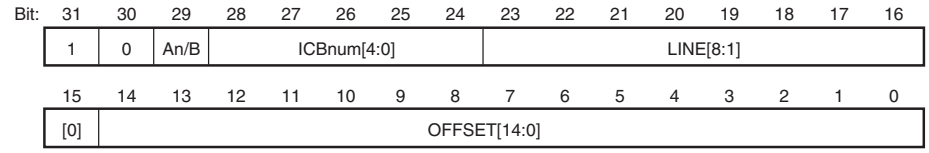
When AMD1 in MEVCR1 = 0, accesses from an associated module to addresses H'8000 0000 to H'BFFF FFFF are treated as accesses to ICBs (nn = 00 to 31).

When AMD1 in MEVCR1 = 1, accesses from an associated module to addresses H'C000 0000 to H'DFFF FFFF are treated as accesses to ICBs (nn = 00 to 31).



The ICB is used by interpreting the address from an associated image module as follows:

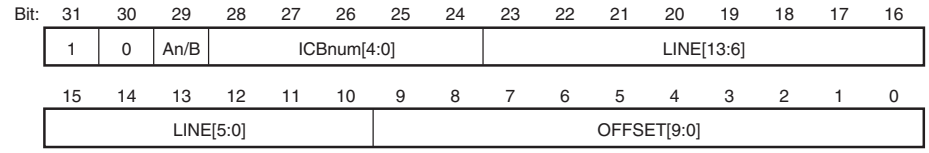
Bit field meaning;



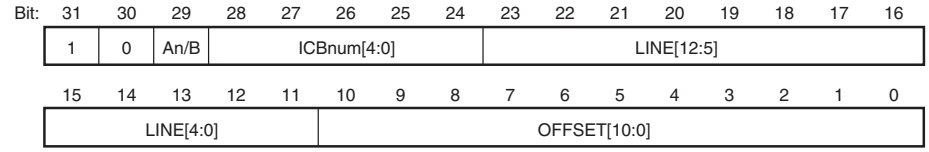
- An/B — Indicates register set A by 0 and register set B by 1. Note, however, that in the YC combining mode, 0 and 1 indicate Y surface indication and C surface indication, respectively.
- ICBnum4 to ICBnum0 — Indicate the ICB buffer number.
- LINEn to LINE0 — Indicate the line number.
- OFFSETm to OFFSET0 — Indicate the in-line offset (in 1-byte units).

(a) AMD1 in MEVCR1=0, CM in MEnnCTRL=0

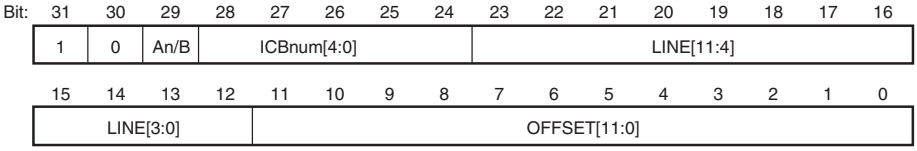
(a-1) XSZM in MEnnBSIZE < 4096



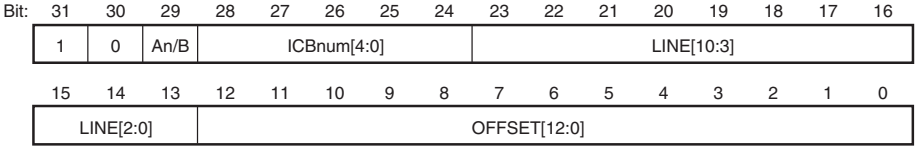
(a-2) 4096 ≤ XSZM in MEnnBSIZE



(b) AMD1 in MEVCR1=0, CM in MEnnCTRL=1

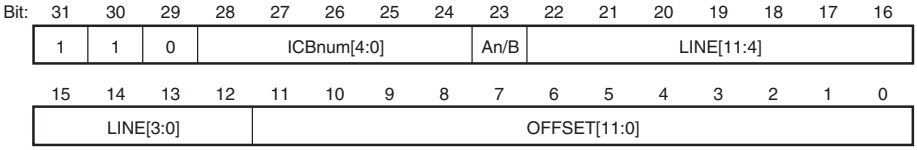


(b-1) XSZM1 in MEnnBSIZE < 1024

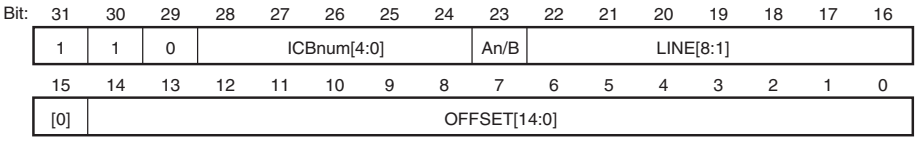


(b-2) 1024 ≤ XSZM1 in MEnnBSIZE < 2048

(b-3) 2048 ≤ XSZM1 in MEnnBSIZE < 4096



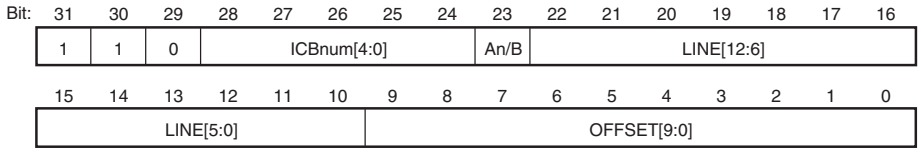
(b-4) 4096 ≤ XSZM1 in MEnnBSIZE < 8192



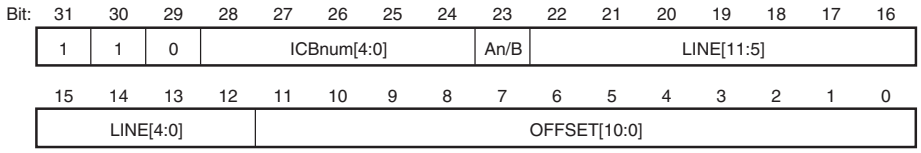
Note: When CM in MEnnCTRL is 1, set XSZM1 in MEnnBSIZE to less than 8192.

(c) AMD1 in MEVCR1 = 1, CM in MEnnCTRL = 0

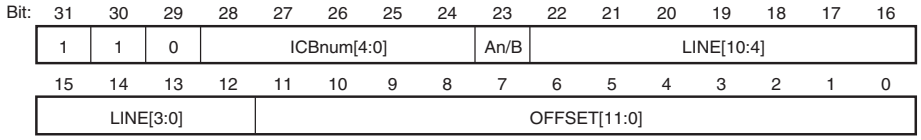
(c-1) XSZM1 in MEnnBSIZE < 4096



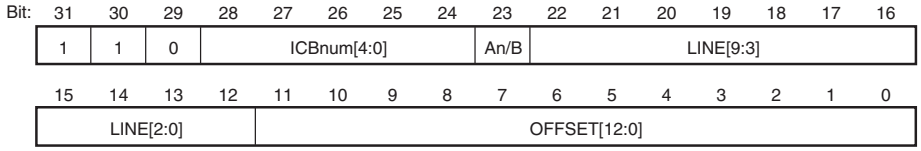
(c-2) 4096 ≤ XSZM1 in MEnnBSIZE



(d) AMD1 in MEVCR1 = 0, CM in MEnnCTRL = 1



(d-1) XSZM1 in MEnnBSIZE < 1024

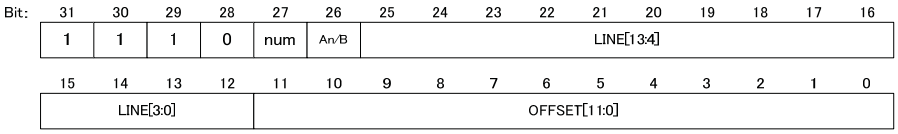


(d-2) 1024 ≤ XSZM1 in MEnnBSIZE 2048

(d-3) 2048 ≤ XSZM1 in MEnnBSIZE<4096

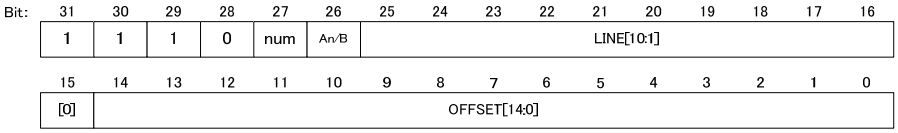
(d-4) 4096 ≤ XSZM1 in MEnnBSIZE<8192

Note: When CM in MEnnCTRL is 1, set XSZM1 in MEnnBSIZE to less than 8192.



39.3.4 Access to Extended ICB from Associated Image Module

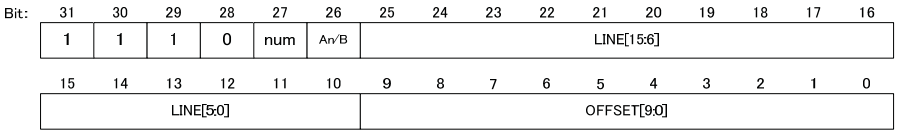
A unique extended ICB (nn = 32 to 127) is allocated to each associated image module. When MEVCR1.AMD0 = 1, accesses to H'E000 0000 to H'EFFF FFFF correspond to those to extended ICBs. Table 39.5 lists the extended ICB numbers corresponding to each image module.



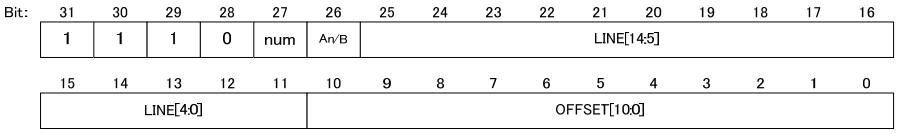
Addresses from image modules are interpreted as follows to use extended ICBs.

(e) AMD0 in MEVCR1 = 1, CM in MEnnCTRL = 0

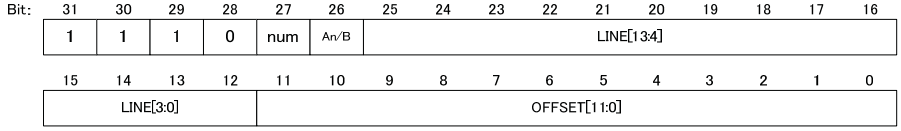
(e-1) XSZM1 in MEnnBSIZE < 4096



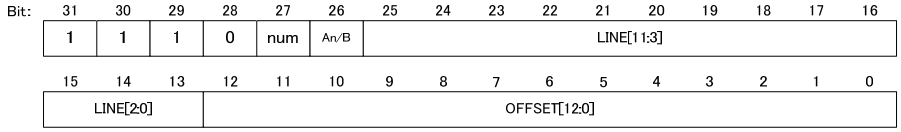
(e-2) 4096 ≤ XSZM1 in MEnnBSIZE



(f) AMD0 in MEVCR1 = 1, CM in MEnnCTRL = 1



(f-1) XSZM1 in MEnnBSIZE < 1024



(f-2) 1024 ≤ XSZM1 in MEnnBSIZE < 2048

(f-3) 2048 ≤ XSZM1 in MEnnBSIZE < 4096

(f-4) 4096 ≤ XSZM1 in MEnnBSIZE < 8192

Note: When CM in MEnnCTRL is 1, set XSZM1 in MEnnBSIZE to less than 8192.

Table 39.5 Image Modules and their Corresponding Extended ICB Numbers

Image Module	R/W	Extended ICB number (ICBnn)
CEU, LCDC0, LCDC1 *	W	40, 41
LCDC0 *	R	32, 33
LCDC1 *	R	34, 35

2D-DMAC	R	CH0 to 3: 104, 105 CH4 to 7: 106, 107
	W	CH0 to 3: 108, 109 CH4 to 7: 110, 111
ISP (capture, RAW pre-processing)	R	112, 113
	W	114, 115
ISP (YC processing)	R	116, 117
	W	118, 119

* Buffer priority levels can be changed using MEQSEL1 and MEQSEL2.

39.3.5 Additional remarks on line numbers and offset addresses

The descriptions in (a) to (f) above are about how the output addresses from an image module which is not the VPU are interpreted to be used for the ICB function. Addresses are generated in the image module in the following two methods:

(1) Adjusting the stride length of image modules to the interpretation as the ICB function

The modules other than the VPU have registers for setting the stride length. The addresses output from modules can be interpreted as the ICB function by setting H'1000 or H'8000 in these registers ((a-1)(a-2), (c-1)(c-2), (e-1)(e-2)). (Where appropriate, examples are provided in this chapter to assist the description.) The actual data width and stride length are set in XSZM1 in MEnnBSIZE and SBSIZE in MEnnSBSIZE.

In this method, the volume of transfers between the MERAM and external memory is equal to the amount of the screen data set in XSZM1 in MEnnBSIZE and SBSIZE in MEnnSBSIZE. Since a buffer area with a size of 1KB/2KB/4KB. that is obtained by rounding up (XSZM1 in MEnnBSIZE + 1) is secured for each line in the MERAM, some of those areas may be wasted depending on the value of XSZM1 in MEnnBSIZE.

(2) Adjusting the stride length of image modules to the values in the external memory

Set the same value for the stride length of an image module as in the external memory (hereafter called as W). This allows the addresses from the image module to be generated in the form of ICB buffer identifiers and in-frame offsets.

An example below describes how to set values in this method when CM in MEnnCTRL is set to 1 and XSZM1 in MEnnBSIZE = H'3FF and SBSIZE in MEnnSBSIZE = H'400 are set. The ICB interprets the offset from the start of frame contained in the output address from the image module as a line in 1-KB units to perform transfers with the external memory.

In this method, the source of the MERAM to SDRAM transfer includes invalid data areas (W minus H, where H is the actual data width) in the memory. This means that the larger the size of W-H is, the more volume of transfers is wasted. The buffer area in the MERAM is used effectively in 1-KB units except for the invalid data area in it. Consequently, the buffer area in the MERAM can be smaller by using the method (A-2) when W-H is small. The following summarizes how to use the ICB in this method.

- Set CM in MEnnCTRL = 1 to specify the consecutive address mode.
- Set XSZM1 in MEnnBSIZE = H'3FF to specify the line width of ICBs to 1KB.
- Set SBSIZE in MEnnSBSIZE = H'400 to specify the line width of ICBs to 1KB.

- Set YSZM1 in MEnnBSIZE = roundup ((W*(V-1) + H)/1KB)-1 to include the 1-KB that contains the last pixel, where V is the line number in the external memory and roundup(f) is the calculation to round up f to an integer.
- Specify the buffer line number to be secured in BNM in MEnnBSIZE in 1-KB units.
- Set the values calculated as follows in KRBNM in MEnnBSIZE and KWBNM in MEnnBSIZE. Use n as the desired number of lines to be retained for each module that is described in section 39.5, Settings for Each Associated Module.
  - Calculate the desired number of lines to be retained (N) that is converted in 1-KB units, assuming N = roundup(n*W/1KB)+1. Note, however, that in the YC combining mode (YCbCr420), it is necessary to assume N = roundup(n*W/1KB) + 2
  - When 16 ≥ N, assume BSZ in MEnnCTRL = 0 and Ns = N.
  - When 32 ≥ N>16, assume BSZ in MEnnCTRL = 1 and Ns = roundup(N/2).
  - When 64 ≥ N>32, assume BSZ in MEnnCTRL = 2 and Ns = roundup(N/4).
  - (Hereinafter the same applies. Set the BSZ value so that Ns ≤ 16 is satisfied.)
  - Set KRBNM in MEnnBSIZE and KWBNM in MEnnBSIZE to Ns-1.

Note the followings:

- In the last line, access made to the external memory reaches the area that is rounded up the last pixel of an image to a 1-KB boundary. So, make sure to secure areas in the external memory to include the range.

39.4 Setting ICB

Note: The examples described in this section are based on the method listed in section 39.3.4 (1), Adjusting the stride length of image modules to the interpretation as the ICB function. See the section 39.3.4 (2), Adjusting the stride length of image modules to the values in the external memory that is also enable to be used for the setting ICB.

39.4.1 Settings as Read Fill Buffer

The following example shows the setting when ICBs are used as a read buffer for read accesses to the VEU (0).

- ICB00 setting (for Y data)

```
ME00CTRL     =   H'0000 0701 ;// Read fill mode, no completion detection
                             // Allocate the buffer area from H'E808 0000
ME00BSIZE    =   H'005F 007F ;// Vertical 96 lines and horizontal 128 pixels
ME00MCNF =       H'0F1F 0000 ;// Number of lines retained during reading=16, total number
                                 of buffer lines=32
ME00SSARA    =   H'5800 0000 ;// Start address of Y data in the external memory (register
                                 set A)
ME00SSARB    =   H'5900 0000 ;// Start address of Y data in the external memory (register
                                 set B)
ME00SBSIZE   =   H'0000 0080 ;// Screen width in the external memory (128 bytes)
```

- ICB01 setting (for C data)

```
ME01CTRL     =   H'0020 0701 ;// Read fill mode, no completion detection
                             // Allocate the buffer area from H'E808 8000
ME01BSIZE    =   H'005F 007F ;// Vertical 96 lines and horizontal 128 pixels
ME01MCNF     =   H'0F1F 0000 ;// Number of lines retained during reading=16,
                                 total number of buffer lines=32
ME01SSARA    =   H'5800 8000 ;// Start address of C data in the external memory
                                 (register set A)
ME01SSARB    =   H'5900 8000 ;// Start address of C data in the external memory
                                 (register set B)
ME01SBSIZE   =   H'0000 0080 ;// Screen width in the external memory (128 bytes)
```

- VEU(0) setting

```
VE0SSR   =   H'0060 0080  ;   // Vertical 96 lines and horizontal 128 pixels
V0SAYR   =   H'8000 0000  ;   // Use ICB00 (register set A) for reading Y data
V0SACR   =   H'8100 0000  ;   // Use ICB01 (register set A) for reading C data
VE0SWR   =   H'0000 1000  ;   // Set H'1000 as screen width when using ICBs
V0RFSR   =   H'0060 0080  ;   // Clip the output. Vertical 96 lines and horizontal 128
pixels
V0DAYR   =   H'5801 0000  ;   // Start address in the external memory to store Y data
                              (register set A)
V0DACR   =   H'5801 8000  ;   // Start address in the external memory to store C data
                              (register set A)
VE0DWR   =   H'0000 0080  ;   // Screen width in the external memory (128 bytes)
VE0IER   =   H'0000 0001  ;   // Enable interrupts
```

(Other registers should be set according to the desired VEU0 functions.)

After setting these, start the VEU0 by setting VE1STR1 = H'0000 0001. The read access request from the VEU0 points to the addresses using ICB00 (register set A)/ICB01 (register set A), so the MERAM starts a read fill operation from the external memory address (H'5800 0000/H'5800 8000). This read fill operation continues to be performed automatically until all read fill operations for the lines specified in YSZM1 in ME00BSIZE/YSZM1 in ME01BSIZE completes or the buffer areas for the buffer lines specified in BNM in ME00BSIZE/BNM in ME01BSIZE get full.

If the read access request from the VEU0 is to the lines that are already filled into the buffer area, the MERAM returns data to the VEU0. Otherwise, the request is suspended until the lines have been filled into the buffer area.

The VEU0 sometimes performs read fill operations on per-block basis, so the line number is not always incremented serially and the line at up to 16 lines ago may be filled again. For this reason, the numbers of lines retained during reading that are set in KRBNM in ME00MCNF should be more than 16. If the MERAM returns the first n lines corresponding to an access request from the VEU0, the data in "n-(number of lines retained during reading)" lines is considered as unnecessary and discarded from the buffer area. The area is reused for another read fill operation.

When an interrupt from the VEU0 is detected, notify the MERAM of the completion of the read operation to ICB00/ICB01 by setting as follows:

```
ME00CTRL =   H'0000 0711 ;    // RF bit=1
ME01CTRL =   H'0020 0711 ;    // RF bit=1
```

When the RF bits are set, ICB00/ICB01 are freed and the bit 1 to bit 0 in the MEACT register return to 0. This enables the VEU0 to be set for the next operation or ICB00/ICB01 to be set for other modules.

When the start addresses of read operations for the VEU0 are set as follows, data is filled from H'5900 0000/ H'5900 8000 in the external memory:

```
V0SAYR   =   H'A000 0000  ;   // Use ICB00 (register set B) for reading Y data
V0SACR   =   H'A100 0000  ;   // Use ICB01 (register set B) for reading C data
```

By combining with the setting of the VEU0 two-set register can reduce resetting of the MERAM or VEU0 registers.

39.4.2 Settings as Write Back Buffer

The following example shows the setting when ICBs are used as a write back buffer for write accesses to the VEU1.

- ICB02 setting (for Y data)

```
ME02CTRL     =   H'0040 0702 ;// Write back mode, no completion detection
                             // Allocate the buffer area from H'E808 8000
ME02BSIZE    =   H'005F 007F ;// Vertical 96 lines and horizontal 128 pixels
ME02MCNF     =   H'F01F 0000 ;// Number of lines retained during writing=16, total number of
                                 buffer lines=32
ME02SSARA    =   H'5802 0000 ;// Start address in the external memory to store Y data
                                 (register set A)
ME02SSARB    =   H'5902 0000 ;// Start address in the external memory to store Y data
                                 (register set B)
ME02SBSIZE   =   H'0000 0080 ;//Screen width in the external memory (128 bytes)
```

- ICB03 setting (for C data)

```
ME03CTRL     =   H'00600702 ; // Write back mode, no completion detection
                             // Allocate the buffer area from H'E809 0000
ME03BSIZE    =   H'005F007F ; // Vertical 96 lines and horizontal 128 pixels
ME03MCNF     =   H'F01F0000 ; // Number of lines retained during writing=16,
                                 total number of buffer lines=32
ME03SSARA    =   H'58028000 ; // Start address in the external memory to store C data
                                 (register set B)
ME03SSARB    =   H'59028000 ; // Start address in the external memory to store C data
                                 (register set B)
ME03SBSIZE   =   H'00000080 ; // Screen width in the external memory (128 bytes)
```

- VEU(1) setting

```
VE1SSR      =   H'0060 0080  ;// Vertical 96 lines and horizontal 128 pixels
V1SAYR      =   H'580 10000  ;// Start address of Y data in the external memory
                             // (This is an example of setting when the output result from
                                the VEU0 is to be processed further.)
V1SACR      =   H'5801 8000  ;// Start address of C data in the external memory
                             // (This is an example of setting when the output result from
                                the VEU0 is to be processed further.)
VE1SWR      =   H'0000 0080  ;// Screen width in the external memory (128 bytes)
V1RFSR      =   H'0060 0080  ;// Clip the output. Vertical 96 lines and horizontal 128
                                pixels
V1DAYR      =   H'8200 0000  ;// Use ICB02 (register set A) for writing Y data
V1DACR      =   H'8300 0000  ;// Use ICB03 (register set A) for writing C data
VE1DWR      =   H'0000 1000  ;// Set H'1000 as screen width when using ICBs
VE1IER      =   H'0000 0001  ;// Enable interrupts
```

(Other registers should be set according to the desired VEU1 functions.)

After setting these, start the VEU1 by setting VE1STR = H'0000 0001. The write access request from the VEU1 points to the addresses using ICB02 (register set A)/ICB03 (register set A), so the MERAM processes write data in a write operation to the buffer area secured in the MERAM. This write data can be written until the buffer areas for the buffer lines specified in BNM in ME02BSIZE/BNM in ME03BSIZE get full.

The VEU1 sometimes performs write operations on per-block basis, so the target line number is not always incremented serially and the target line at up to 16 lines ago may be written again. For this reason, the numbers of lines retained during writing that are set in KWBNM in ME02MCNF/KWBNM in ME03MCNF should be more than 16. If the MERAM returns the first n lines corresponding to an access request from the VEU1, the data in "n-(number of lines retained during writing)" is considered to have been written and it is written back to the external memory. The area that contains data that has been written back is freed and reused for write data. Thus, processing the write operation from the VEU(1) continues with reusing buffer areas until the last line specified in YSZM1 in ME02BSIZE/YSZM1 in ME03BSIZE is reached.

When an interrupt from the VEU1 is detected, notify the MERAM of the completion of the write operation to ICB02/ICB03 by setting as follows:

```
ME02CTRL =   H'0040 0722 ;    // WF bit=1
ME03CTRL =   H'0060 0722 ;    // WF bit=1
```

When the WF bits are set, ICB02/ICB03 are freed and the bit 3 to bit 2 in the MEACT register return to 0 after the MERAM writes back data that has not been done yet to the external memory (note that the data on the lines to be retained during writing before the last line is not written back unless the WF bit is set). This enables the VEU1 to be set for the next operation or ICB02/ICB03 to be set for other modules.

When the start addresses of write operations for the VEU1 are set as follows, data is written back from H'5902 0000/ H'5902 8000 in the external memory:

```
VSAYR2   =   H'A200 0000  ;   // Use ICB02 (register set B) for writing Y data
VSACR2   =   H'A300 0000  ;   // Use ICB03 (register set B) for writing C data
```

By combining with the setting of the VEU1 two-set register can reduce resetting of the MERAM or VEU1 registers.

39.4.3 Settings as Interconnect Buffer

The following example shows the setting when the VEU0 and VEU1 are interconnected via ICBs.

- ICB04 setting (for Y data)

```
ME04CTRL     =   H'0080 0703 ;// Interconnect mode with write back, no completion detection
                             // Allocate the buffer area from H'E808 0000
ME04BSIZE    =   H'005F 007F ;// Vertical 96 lines and horizontal 128 pixels
ME04MCNF     =   H'FF2F 0000 ;// Number of lines retained during writing=16, number of lines
                                 retained during reading=16,
                             // Total number of buffer lines=32
ME04SSARA    =   H'5801 0000 ;// Start address (register set A) in the external memory to
                                 store the Y data
                             // of the processing result from the VEU0
ME04SSARB    =   H'5901 0000 ;// Start address in the external memory to store Y data
                                 (register set B)
ME04SBSIZE   =   H'0000 0080 ;// Screen width of the processing result from the VEU0 in
                                 the memory (128 bytes)
```

- ICB05 setting (for C data)

```
ME05CTRL     =    H'00A0 0703 ;// Interconnect mode with write back, no completion detection
                               // Allocate the buffer area from H'E808 8000
ME05BSIZE    =    H'005F 007F ;// Vertical 96 lines and horizontal 128 pixels
ME05MCNF     =    H'FF2F 0000 ;// Number of lines retained during writing=16, number of lines
                                  retained during reading=16,
                               // Total number of buffer lines=48
ME05SSARA    =    H'5803 8000 ;// Start address (register set A) in the external memory to
                                  store the Y data
                               // of the processing result from the VEU0
ME05SSARB    =    H'5903 8000 ;// Start address in the external memory to store C data
                                  (register set B)
ME05SBSIZE   =    H'0000 0080 ;// Screen width of the processing result from the VEU0 in
                                  the memory (128 bytes)
```

- VEU(0) setting (differences only)

```
VDAYR1       =    H'84000000  ;  // Use ICB04 (register set A) for writing Y data
VDACR1       =    H'85000000  ;  // Use ICB05 (register set A) for writing C data
VEDWR1       =    H'00001000  ;  // Set H'1000 as screen width when using ICBs
```

- VEU(1) setting (differences only)

```
VSAYR2       =    H'84000000  ;  // Use ICB04 (register set A) for reading Y data
VSACR2       =    H'85000000  ;  // Use ICB05 (register set A) for reading C data
VESWR2       =    H'00001000  ;  // Set H'1000 as screen width when using ICBs
```

After setting these, start the VEU0 and VEU1 by setting VE0STR = H'0000 0001 and VE1STR = H'0000 0001. With these settings, the output data from the VEU0 is input to the VEU1 via buffer areas in the MERAM. The output data from the VEU0 is also written back to the external memory. When MD in ME04CTRL/MD in ME05CTRL are set to 100, the output data from the VEU0 is stored in the MERAM only temporarily and no access is made to the external memory.

The VEU0 completes its operation and an interrupt is generated. But at this point, the data from the VEU0 that is on the lines to be retained during writing before the last line is considered not to be fixed, so the operation for the VEU1 is not complete. When an interrupt from the VEU0 is detected, notify the MERAM of the completion of the write operation to ICB04/ICB05 by setting as follows:

```
ME04CTRL =   H'0080 0723 ;    // WF bit=1
ME05CTRL =   H'00A0 0723 ;    // WF bit=1
```

When the WF bits are set, the MERAM determines that all data is fixed and the VEU1 starts its remaining operation to write back the data that has not been done yet to the external memory. When an interrupt is generated from the VEU1, notify the MERAM of the completion of the read operation to ICB04/ICB05 by setting as follows:

```
ME04CTRL =    H'0080 0713 ;     // RF bit=1
ME05CTRL =    H'00A0 0713 ;     // RF bit=1
```

If the RF bits are set to 1 and the write back to the external memory is complete, ICB04/ICB05 are freed and bit 5 to bit 4 in the MEACT register return to 0. This enables the VEU1 to be set for the next operation or ICB04/ICB05 to be set for other modules.

It is distinguished whether the output result from the VEU0 is written back to the register ser A or B of ICB04/ICB05, but the same register set should be selected for the VEU0/VEU1.

39.4.4 Settings as Interconnect Buffer Using Extended ICBs

Shown below is an example of settings for interconnection between the VEU0 and the VEU1 via extended ICBs.

- ICB66 Setting (for the VEU0 and Y data)

```
ME66CTRL    = H'0080 2703      ; // Interconnect mode with write back, no completion
                                   detection
                                 // Buffer link with ICB68. Allocate the buffer area from
                                   H'E808 0000.
ME66BSIZE   = H'005F 007F      ; // Vertical 96 lines and horizontal 128 pixels
ME66MCNF    = H'F02F 0006      ; // Number of lines retained during writing = 16, total
                                   number of buffer lines = 32
                                 // Enable buffer link mode
ME66SSARA   = H'5801 0000      ; // Start address of an area in the external memory, in which
                                   the Y data of processing result from the VEU0 is to be
                                   stored (A surface)
ME66SSARB   = H'5901 0000      ; // Start address of an area in the external memory, in which
                                   the Y data is to be stored (B surface)
ME66SBSIZE  = H'0000 0080      ; // Screen width of processing result from the VEU0 in the
                                   memory (128 bytes)
```

- ICB67 Setting (for the VEU0 and C data)

```
ME67CTRL    = H'00A0 2F03      ; // Interconnect mode with write back, no completion
                                   detection
                                 // Buffer link with ICB69. Allocate the buffer area from
                                   H'E808 8000.
ME67BSIZE   = H'005F 007F      ; // Vertical 96 lines and horizontal 128 pixels
ME67MCNF    = H'0F2F 0006      ; // Number of lines retained during writing = 16, total
                                   number of buffer lines = 48
                                 // Enable buffer link mode
ME67SSARA   = H'5803 8000      ; // Start address of an area in the external memory, in which
                                   the C data of processing result from the VEU0 is to be
                                   stored (A surface)
ME67SSARB   = H'5903 8000      ; // Start address of an area in the external memory, in which
                                   the C data is to be stored (B surface)
ME67SBSIZE  = H'0000 0080      ; // Screen width of processing result from the VEU0 in the
                                   memory (128 bytes)
```

- ICB68 Setting (for the VEU1 and Y data)

```
ME68CTRL    = H'0080 1703      ; // Interconnect mode with write back, no completion
                                   detection
                                 // Buffer link with ICB66. Allocate the buffer area from
                                   H'E808 0000.
ME68BSIZE   = H'005F 007F      ; // Vertical 96 lines and horizontal 128 pixels
ME68MCNF    = H'0F2F 0006      ; // Number of lines retained during reading = 16, total
                                   number of buffer lines = 32
                                // Enable buffer link mode
ME68SSARA   = H'5801 0000      ; // Start address of an area in the external memory, in which
                                   the Y data of processing result from the VEU0 is to be
                                   stored (A surface)
ME68SSARB   = H'5901 0000      ; // Start address of an area in the external memory, in which
                                   the Y data is to be stored (B surface)
ME68SBSIZE  = H'0000 0080      ; // Screen width of processing result from the VEU0 in the
                                   memory (128 bytes)
```

- ICB69 Setting (for the VEU1 and C data)

```
ME69CTRL    = H'00A0 1F03      ; // Interconnect mode with write back, no completion
                                   detection
                                 // Buffer link with ICB67. Allocate the buffer area from
                                   H'E808 8000.
ME69BSIZE   = H'005F 007F      ; // Vertical 96 lines and horizontal 128 pixels
ME69MCNF    = H'F02F 0006      ; // Number of lines retained during reading = 16, total
                                   number of buffer lines = 48
                                 // Enable buffer link mode
ME69SSARA   = H'5803 8000      ; // Start address of an area in the external memory, in which
                                   the C data of processing result from the VEU0 is to be
                                   stored (A surface)
ME69SSARB   = H'5903 8000      ; // Start address of an area in the external memory, in which
                                   the C data is to be stored (B surface)
ME69SBSIZE  = H'0000 0080      ; // Screen width of processing result from the VEU0 in the
                                   memory (128 bytes)
```

- VEU0 Setting (differences only)

```
V0DAYR      = H'E000 0000      ; // Use ICB66 (A surface) for writing Y data
V0DACR      = H'E800 0000      ; // Use ICB67 (A surface) for writing C data
VE0DWR      = H'0000 1000      ; // Set H'1000 as screen width when using ICBs
```

- VEU1 Setting (differences only)

```
V1SAYR      = H'E000 0000      ; // Use ICB68 (A surface) for reading Y data
V1SACR      = H'E800 0000      ; // Use ICB69 (A surface) for reading C data
VE1SWR      = H'0000 1000      ; // Set H'1000 as screen width when using ICBs
```

When using the interconnection function with extended ICBs, the settings described in section 39.4.3, Settings as Interconnect Buffer cannot be used because a unique ICB is allocated to each module. Enabling the buffering mode allows interconnection between two different ICBs.

39.4.5 Settings as Frame Buffer Cache

ICBs can be used as a frame buffer cache by combining two ICBs. One is called marker buffer, and the other is called cache buffer.

However, when the LCDC handles YCbCr screens, it uses four ICBs in total (two for each Y image and C image). The following descriptions are based on the assumption that the LCDC handles RGB images.

- Marker buffer

  Set the LCDC for using the marker buffer. That is, the addresses that are output from the LCDC include the ICB number of the marker buffer, and therefore it seems that only the marker buffer is accessed. Only ICB28 to ICB31 buffers can be used as the marker buffer. In other words, when MD = B'111 in MEmmCTRL (mm = 28 to 31 in this case) is set for any of ICB28 to ICB31, such an ICB is treated as a marker buffer. Set the corresponding cache buffer number to the NXT4 to NXT0 bits in MEmmCTRL of the marker buffer.
- Cache buffer

  When the line number 0 access is made to the marker buffer, the NXT4 to NXT0 bits in MEmmCTRL are referenced, and the set value (cc) is regarded that ICBcc is used.

  ICBcc functions like the read fill buffer. When the read fill operation for the buffer lines specified by the BNM7 to BNM0 bits in MEccMCNT is completed, the control is shifted to the buffer specified by the NXT4 to NXT0 bits in MEccCTRL so that the filled data remains in the MERAM memory without being overwritten. Specify the marker buffer number (mm) again in the NXT4 to NXT0 bits in MEccCTRL.

When processing shifts from ICBcc to ICBmm, the active bit (ACcc in MEACTST) of ICBcc remains 1. When the ACcc bit in MEACTST is 1 at an access to the cache buffer and the register set A/register set B indication by the CB bit in MEccCTRL matches the register set A/register set B shown at the address accessed, it is regarded that data is already contained in ICBcc, and therefore the read fill operation is not performed. If the register set A/register set B indication does not match or when the ACcc bit in MEACTST is 0, it is regarded that the data is updated or the access is the first one, and therefore the ACTcc bit is set, the CB bit is modified, and the read fill operation is performed again.

If the control is returned to the marker buffer for other than line number 0, the marker buffer continues operation as a read fill buffer. The marker buffer keeps operating to the last line while reusing the MERAM buffers in the same way as the normal read fill buffer. Secure at least two lines for the marker buffer to function as a read fill buffer. The marker buffer is necessary even if the frame buffer for all screens can be secured in the cache buffer.

The following describes settings specific to frame buffer cache mode for the marker buffer and cache buffer.

- Marker buffer settings

MEmmCTRL:	Set the MD2 to MD0 bits to B'111, and the NXT4 to NXT0 bits to cc. Specify the start address of the buffer in the MERAM to be used by the marker buffer in the MSAR8 to MSAR0 bits.
MEmmBSIZE:	Set the total number of lines in minus 1 in the YSZM111 to YSZM10 bits. Set the RCNT3 to RCNT0 bits to 1 to enable to detect the completion of read operation. The completion can also be notified manually.
MEmmMCNF:	Set B'001 or larger (to secure two lines or more) in the BNM7 to BNM0 bits. Specify 0 or larger (to secure one line or more) in the KRBNM3 to KRBNM0 bits.
MEmmSSARA/MEmmSSARB:	Set the start address for each register set A and register set B on the external memory, which cannot be retained in the cache buffer.
MEmmSBSIZE:	Specifies the screen width in the external memory in units of bytes in the same way as other modes.

- Cache buffer settings

MEccCTRL:	Set the MD2 to MD0 bits to B'111, and the NXT4 to NXT0 bits to mm. Specify the start address in units of Kbytes in the MERAM to be secured as a cache area in the MSAR8 to MSAR0 bits.
MEccBSIZE:	Set the total number of lines of the frame buffer (all screens) minus 1 in the YSZM111 to YSZM10 bits. When a cache buffer size enough for the data of the previous screen is secured, set the RCNT3 to RCNT0 bits to 1 to enable detection of the completion of read operation in the cache buffer.
MEccMCNF:	Set the number of lines that can be secured in the MERAM in the BNM7 to BNM0 bits. Specify 0 or larger (to secure one line or more) in the KRBNM3 to KRBNM0 bits.
MEccSSARA/MEccSSARB:	Set the start address each for register set A and register set B on the external memory.
MEccSBSIZE:	Specifies the screen width in the external memory in units of bytes in the same way as other modes.

To perform processing manually for one register set for the frame buffer cache, write 1 to the RF bit in MEmmCTRL of the marker buffer. At this time, the active state ACcc bit in MEACTST of ICBcc is not cleared. To stop using the entire frame buffer cache or to change the frame buffer cache setting, manually clear the ACcc bit in MEACTST.

- Additional Remarks: Reusing a data in the Cash Buffer.

  When a frame buffer dash is to be used in a condition that the image data is still contained in the MERAM, the initial read fill can be skipped by setting the cash buffer for already filled in advance. In this case, addition to the normal setting of the cash buffer is required as follows:

```
MEccCTRL                ← Normal initial setting | H'0000 0040;//WBF bit settings
MEccCTRL + H'0C address  ← H'0000 0000                          ;//
MEccCTRL + H'1C address  ← H'0000 0000                          ;//
MEVCR1          ← H'4000 0000                                   ;//Transit to the set
                                                                   mode in the ACT bit.
MEACTST[CC]     ← B'1                                           ;//Cash buffer active bit
                                                                   settings.
MEVCR1          ← H'0000 0000                                   ;//Returns to the clear
                                                                   mode of the ACT bit.
```

39.5 Setting for Each Associated Module

This section shows the registers that can use the interconnect buffer function and the required parameters to define the associated ICB buffers for each module.

This section is described based on the description in section 39.3.4 (1), Adjusting the stride length of image modules to the interpretation as the ICB function. See also section 39.3.4 (2), Adjusting the stride length of image modules to the values in the external memory since this method is also available.

In addition, this section assumes that line/block line transfer modes are used. Modules that can use block transfer mode are described individually.

Image Module: Indicates the name of the image module.

Usage Condition: Indicates the availability of the ICB function depending on the usage condition of the image module and the usage condition with different parameters defined. For details on the usage condition, refer to the footnotes below the table.

Address Register: Indicates the name of the register that can use the ICB function. The ICB function can be used by setting the address indicating that the function is to be used (refer to section 39.3.3, Access to ICB from Associated Image Module) in this register.

Associated Stride Register: When the register in this column is used as shown in 39.3.4(1), Adjusting the stride length of image modules to the interpretation as the ICB function, specify H'1000 or H'8000 in the register.

R/W: "R" indicates that the register(s) contains the input address. "W" indicates that the register(s) contains the output address.

Number of Lines Retained: Indicates the minimum number of lines required for the ICB buffer associated with the register. The KWBNM or KRBNM field in the MEnnMCNF register should be set to a value so that it is greater than the number of lines retained as shown in table 39.3.

Unit of Processing: The BNM field in the MEnnMCNF register should be set to a value that is obtained by adding at least 1 to the number of lines retained shown in table 39.3. Setting the field to at least "number of lines retained + unit of processing" prevents the image module from being stalled due to waiting for data buffers.

General Notes:

1. When the YCbCr format is used, the Y/C address registers are used. These registers cannot be used in such a way that one of them is set to use the ICB function and the other is set not to use it.
2. As the stride register value is interpreted differently for the YCbCr444 format, it cannot be used as shown in 39.3.4(1), Adjusting the stride length of image modules to the interpretation as the ICB function.

Table 39.6 Settings for Associated Module

Image Module	Conditions	Address Register	Associated Slide Register	R/W	Number of retained line	Process Units
CEU		CDAYR, CDACR	CDWDR	W	1	1
		CDBYR, CDBCR	CDWDR	W	1	1
VEU	V2	VEnSAYR, VEnSACR	VEnSWR	R	*V1	1
		VEnDAYR, VEnDACR	VEnDWR	W	×	×
	V3	VEnSAYR, VEnSACR	VEnSWR	R	*V1	1
	V4	VEnDAYR, VEnDACR	VEnDWR	W	*V1	1
	V5	VEnSAYR, VEnSACR	VEnSWR	R	×	×
		VEnDAYR, VEnDACR	VEnDWR	W	×	×
BEU		BSAYR1, BSACR1	BSMWR1	R	1	1
		BSAYR2, BSACR2	BSMWR2	R	1	1
		BSAYR3, BSACR3	BSMWR3	R	1	1
		BDAYR, BDACR	BDMWR	W	1	1
2D-DMAC	T1	CHnSAR	CHnSFMT.HWTH	R	1	1
		CHnDAR	CHnDFMT.HWTH	W	1	1
	T2	CHnSAR	CHnSFMT.HWTH	R	1	1
		CHnDAR	CHnDFMT.HWTH	W	2	2
	T3	CHnSAR	CHnSFMT.HWTH	R	1	1
		CHnDAR	CHnDFMT.HWTH	W	×	×
	T4	CHnSAR	CHnSFMT.HWTH	R	16	16
		CHnDAR	CHnDFMT.HWTH	W	×	×
JPU		JIFESYA1/2, JIFESYC1/2	JIFESMW	R	8	8
		JIFDDYA1/2, JIFDDYC1/2	JIFDDMW	W	8	8
DSI-TX		CMTIADR0/1/2/3	CMTIADRI0/1/2/3	R	1	1
LCDC	LC1	MLDSA1R, MLDSA2R	MLMLSR	R	1	1

Image Module	Conditions	Address Register	Associated Slide Register	R/W	Number of retained line	Process Units
VPU	VP1	BAAR0/1	DCHCR_DECY0	W	32	32
		BAAR0/1	DCHCR_DECC0	W	16	16
	VP2	BAAR0/1	DCHCR_TMPY0	R	32	32
		BAAR0/1	DCHCR_TMPC0	R	16	16
	VP3	BAAR0/1	DCHCR_REF	R	96/64	32
		BAAR0/1	DCHCR_REF	R	48/32	16

Notes: 1. The usage conditions of VEU are described below.

V1: The number of retained lines may need to be changed depending on whether the YC combining mode is used or not. When the YC combining mode is disabled, the minimum number of retained lines is 1. When it is enabled, make the following settings according to the number of pixels processed by the VEU.
[Reading]
YUV420: (The value obtained by rounding up “512 ÷ VESSR.VHSS”) + 2
YUV422: (The value obtained by rounding up “512 ÷ VESSR.VHSS”) + 1
[Writing]
YUV420: (The value obtained by rounding up “512 ÷ VRFSR.VHCLP”) + 2
YUV422: (The value obtained by rounding up “512 ÷ VRFSR.VHCLP”) + 1

V2: When (VFMCR.VMRR != 0) (When a vertical reverse filter is in use)

V3: When V2 is not met and VENHR.ENH || VENHR.ENHV || (VRFCR!=0) is true (When a zoom-in/out function or an enhancer is in use)

V4: When V2 and V3 are not met and VFMCR.FLTPI = 1 (When performing high-speed processing with a LPF/deblocking filter or a median filter)

V5: When V2, V3, and V4 are not met

2. The usage conditions of the 2D-DMAC are described below.

T1: If (CHnCTRL.ROTR == 0) && : (CHnCTRL.ROTL == 0) && : (CHnCTRL.VMRR == 0), and CHnCTRL.MY == 0

T2: If (CHnCTRL.ROTR == 0) && : (CHnCTRL.ROTL == 0) && : (CHnCTRL.VMRR == 0), and CHnCTRL.MY == 1

T3: If neither T1 nor T2 are applicable, but (CHnCTRL.ROTR == 0) && : (CHnCTRL.ROTL == 0),

T4: When T1, T2, and T3 are not met, processing is performed on a 16-line basis. The block transfer mode is available.

3. LCDC usage conditions
LC1: When using a marker buffer and a cache buffer, set the number of retained lines to 1.

4. The usage conditions from the VPU are described below.

VP1: Block transfer mode is available. When using it, set BSZ = 5 for Y (32 line) and BSZ = 4 for C (16 lines).

VP2: Block transfer mode is available. When using it, set BSZ = 5 for Y (32 line) and BSZ = 4 for C (16 lines).

VP3: The ICB function is available only during encoding or self-recording/playing. The number of referenced planes that can be used in the ICB function is up to 2 (4 planes for Y/C in total). If the area to be searched for is 32 × 32, 96 lines for Y and 48 lines for C should be retained. If the area to be searched for is 16 × 16, 64 lines for Y and 32 lines for C should be retained (block transfer mode is not available).

39.6 LCD Refresh Controller Overview

The MERAM has an LCD refresh mode.

39.7 Description on Registers related to LCD Refresh Controller

Table 39.7 shows the register configuration for the LCD refresh controller. Also, table 39.8 shows the states of registers in each mode.

Table 39.7 Register Configuration

Register Name	Abbr.	R/W	Address	Access Size
LCD refresh control register	LRCTRL	R/W	H'FE94 8000	32
LCD refresh interrupt enable register	LRIER	R/W	H'FE94 8004	32
LCD refresh interrupt source register	LRISR	R/W	H'FE94 8008	32
LCD refresh status register	LRSR	R/W	H'FE94 800C	32
MERAM operation mode set register	LRLPRSR	R/W	H'FE94 8014	32
LCD refresh interrupt address register 1	LRIAR1	R/W	H'FE94 8018	32
LCD refresh interrupt address register 2	LRIAR2	R/W	H'FE94 801C	32
LCD refresh extended address register 2	LRXAR2	R/W	H'FE94 8024	32
LCD refresh memory boundary address register 1	LRMAR1	R/W	H'FE94 8028	32
LCD refresh memory boundary address register 2	LRMAR2	R/W	H'FE94 802C	32
External access control register	LREBUFC	R/W	H'FE94 8030	32
External access read buffer allocation register	LREBUFP	R/W	H'FE94 8034	32
External access address map register 80	LREMAP80	R/W	H'FE94 8040	32
External access address map register 88	LREMAP88	R/W	H'FE94 8044	32
External access address map register 90	LREMAP90	R/W	H'FE94 8048	32
External access address map register 98	LREMAP98	R/W	H'FE94 804C	32
External access address map register A0	LREMAPA0	R/W	H'FE94 8050	32
External access address map register A8	LREMAPA8	R/W	H'FE94 8054	32
External access address map register B0	LREMAPB0	R/W	H'FE94 8058	32
External access address map register B8	LREMAPB8	R/W	H'FE94 805C	32
Virtual MERAM0A allocation register	LRPG0A	R/W	H'FE94 8080	32

Register Name	Abbr.	R/W	Address	Access Size
Virtual MERAM0A external memory address register	LRSD0A	R/W	H'FE94 8084	32
Virtual MERAM0B allocation register	LRPG0B	R/W	H'FE94 8088	32
Virtual MERAM0B external memory address register	LRSD0B	R/W	H'FE94 808C	32
Virtual MERAM1A allocation register	LRPG1A	R/W	H'FE94 8090	32
Virtual MERAM1A external memory address register	LRSD1A	R/W	H'FE94 8094	32
Virtual MERAM1B allocation register	LRPG1B	R/W	H'FE94 8098	32
Virtual MERAM1B external memory address register	LRSD1B	R/W	H'FE94 809C	32
Virtual MERAM2A allocation register	LRPG2A	R/W	H'FE94 80A0	32
Virtual MERAM2A external memory address register	LRSD2A	R/W	H'FE94 80A4	32
Virtual MERAM2B allocation register	LRPG2B	R/W	H'FE94 80A8	32
Virtual MERAM2B external memory address register	LRSD2B	R/W	H'FE94 80AC	32
Virtual MERAM3A allocation register	LRPG3A	R/W	H'FE94 80B0	32
Virtual MERAM3A external memory address register	LRSD3A	R/W	H'FE94 80B4	32
Virtual MERAM3B allocation register	LRPG3B	R/W	H'FE94 80B8	32
Virtual MERAM3B external memory address register	LRSD3B	R/W	H'FE94 80BC	32

39.7.1 LCD Refresh Control Register (LRCTRL)

LRCTRL switches between the normal operation mode and the refresh mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	CRAB1[3:0] CRAB0[3:0]	00	R/W	LCDC use register surface combination switch Switch the register surface used by the LCDC, in synchronization with the LCDC's state transition between the refresh mode and the normal mode. These bits are automatically cleared to B'0000 when state transition is completed. CRAB0 and CRAB1 are set for the LCDC0 and the LCDC1, respectively. CRAB[3]: Specifies the register surface to be used by the sub LCD after a switch between the modes is made. 0: A surface 1: B surface CRAB[2]: Sub LCD switch enable 0: Does not switch the register surface used by the sub LCD. 1: Switches the register surface used by the sub LCD. CRAB[1]: Specifies the register surface to be used by the main LCD after a switch between the modes is made. 0: A surface 1: B surface CRAB[0]: Main LCD switch enable 0: Does not switch the register surface used by the main LCD. 1: Switches the register surface used by the main LCD.

Bit	Bit Name	Initial Value	R/W	Description
7	LROFF1	0	R	LCDC1 normal operation mode select Writing B'1 to this bit switches the LCDC1 to the normal operation mode. Transition is made during a blanking period, and this bit is automatically cleared to B'0 when the transition is completed. 0: NOP 1: Switches the LCDC1 from the refresh mode to the normal mode
6	LRON1	0	R	LCDC1 Refresh Mode Select Writing B'1 to this bit switches the LCDC1 to the refresh mode. Transition is made during a blinking period, and this bit is automatically cleared to B'0 when the transition is completed. 0: NOP 1: Switches the LCDC1 from the normal operation mode to the refresh mode.
5	LROFF0	0	R	LCDC0 normal operation mode select Writing B'1 to this bit switches the LCDC0 to the normal operation mode. Transition is made during a blinking period, and this bit is automatically cleared to B'0 when the transition is completed. 0: NOP 1: Switches the LCDC0 from the refresh mode to the normal operation mode.
4	LRON0	0	R	LCDC0 refresh mode select Writing B'1 to this bit switches the LCDC0 to the refresh mode. Transition is made during a blinking period, and this bit is automatically cleared to B'0 when the transition is completed. 0: NOP 1: Switches the LCDC0 from the normal operation mode to the refresh mode.
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1	LROFF	0	R/W	Normal operation mode select Writing B'1 to this bit switches the LCDC0 and the LCDC1 to the normal operation mode. Transition is made during a blinking period, and this bit is automatically cleared to B'0 when the transition is completed. 0: NOP 1: Makes the transition from the refresh mode to the normal operation mode
0	LRON	0	R/W	Refresh mode select Writing B'1 to this bit switches the LCDC0 and the LCDC1 to the refresh mode. Transition is made during a blinking period, and this bit is automatically cleared to B'0 when the transition is completed. 0: NOP 1: Makes the transition from the normal operation mode to the refresh mode

Note: Do not set the LROFF bit and the LRON bit to 1 at the same time.

39.7.2 LCD Refresh Interrupt Enable Register (LRIER)

LRIER specifies the start points of interrupts.

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	A2IE	0	R/W	LCDC access address interrupt 2 enable Determines whether to generate an interrupt when the LCDC accesses the address specified in LRIAR2. 0: Does not generate an interrupt when the LCDC accesses the address specified in LRIAR2 1: Generates an interrupt when the LCDC accesses the address specified in LRIAR2
8	AIE	0	R/W	LCDC access address interrupt enable Determines whether to generate an interrupt when the LCDC accesses the address specified in LRIAR. 0: Does not generate an interrupt when the LCDC accesses the address specified in LRIAR 1: Generates an interrupt when the LCDC accesses the address specified in LRIAR
7	OFFIE1	0	R/W	LCDC1 normal operation mode transition completion interrupt enable Determines whether to generate an interrupt when the transition of the LCDC1 to the normal operation mode is completed. 0: Does not generate an interrupt when the transition to the normal operation mode is completed 1: Generates an interrupt when the transition to the normal operation mode is completed

Bit	Bit Name	Initial Value	R/W	Description
6	ONIE1	0	R/W	LCDC1 refresh mode transition completion interrupt enable Determines whether to generate an interrupt when the transition of the LCDC1 to the refresh mode is completed. 0: Does not generate an interrupt when the transition to the refresh mode is completed 1: Generates an interrupt when the transition to the refresh mode is completed
5	OFFIE0	0	R/W	LCDC0 normal operation mode transition completion interrupt enable Determines whether to generate an interrupt when the transition of the LCDC0 to the normal operation mode is completed. 0: Does not generate an interrupt when the transition to the normal operation mode is completed 1: Generates an interrupt when the transition to the normal operation mode is completed
4	ONIE0	0	R/W	LCDC0 refresh mode transition completion interrupt enable Determines whether to generate an interrupt when the transition of the LCDC0 to the refresh mode is completed. 0: Does not generate an interrupt when the transition to the refresh mode is completed 1: Generates an interrupt when the transition to the refresh mode is completed
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	OFFIE	0	R/W	Normal operation mode transition completion interrupt enable Determines whether to generate an interrupt when the transition of the LCDC0 and the LCDC1 to the normal operation mode is completed. 0: Does not generate an interrupt when the transition to the normal operation mode is completed 1: Generates an interrupt when the transition to the normal operation mode is completed

Bit	Bit Name	Initial Value	R/W	Description
0	ONIE	0	R/W	Refresh mode transition completion interrupt enable Determines whether to generate an interrupt when the transition of the LCDC0 and the LCDC1 to the refresh mode is completed. 0: Does not generate an interrupt when the transition to the refresh mode is completed 1: Generates an interrupt when the transition to the refresh mode is completed

39.7.3 LCD Refresh Interrupt Source Register (LRISR)

LRISR indicates the interrupt status.

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	A2IS	0	R/W	LCDC access address interrupt 2 state This bit is B'1 when an LCDC access address interrupt 2 occurs. This bit must be cleared by writing B'0 in an interrupt handling routine. 0: Indicates that an LCDC access address interrupt 2 has not occurred or that notification of completion of handling the interrupt has been received. 1: Indicates that an LCDC access address interrupt 2 has occurred and notification of completion of handling the interrupt has not been received.
8	AIS	0	R/W	LCDC access address interrupt state This bit is B'1 when an LCDC access address interrupt occurs. This bit must be cleared by writing B'0 in an interrupt handling routine. 0: Indicates that an LCDC access address interrupt has not occurred or that notification of completion of handling the interrupt has been received. 1: Indicates that an LCDC access address interrupt has occurred and notification of completion of handling the interrupt has not been received.

Bit	Bit Name	Initial Value	R/W	Description
7	OFFIS1	0	R/W	LCDC1 normal operation mode transition completion interrupt state This bit is B'1 when an LCDC1 normal operation mode transition completion interrupt occurs. This bit must be cleared by writing B'0 in an interrupt handling routine. 0: Indicates that a normal operation mode transition completion interrupt has not occurred or that notification of completion of handling the interrupt has been received. 1: Indicates that a normal operation mode transition completion interrupt has occurred and notification of completion of handling the interrupt has not been received.
6	ONIS1	0	R/W	LCDC1 refresh mode transition completion interrupt state This bit is B'1 when an LCDC1 refresh mode transition completion interrupt occurs. This bit must be cleared by writing B'0 in an interrupt handling routine. 0: Indicates that a refresh mode transition completion interrupt has not occurred or that notification of completion of handling the interrupt has been received. 1: Indicates that a refresh mode transition completion interrupt has occurred and notification of completion of handling the interrupt has not been received.
5	OFFIS0	0	R/W	LCDC0 normal operation mode transition completion interrupt state This bit is B'1 when an LCDC0 normal operation mode transition completion interrupt occurs. This bit must be cleared by writing B'0 in an interrupt handling routine. 0: Indicates that a normal operation mode transition completion interrupt has not occurred or that notification of completion of handling the interrupt has been received. 1: Indicates that a normal operation mode transition completion interrupt has occurred and notification of completion of handling the interrupt has not been received.

Bit	Bit Name	Initial Value	R/W	Description
4	ONIS0	0	R/W	LCDC0 refresh mode transition completion interrupt state This bit is B'1 when an LCDC0 refresh mode transition completion interrupt occurs. This bit must be cleared by writing B'0 in an interrupt handling routine. 0: Indicates that a refresh mode transition completion interrupt has not occurred or that notification of completion of handling the interrupt has been received. 1: Indicates that a refresh mode transition completion interrupt has occurred and notification of completion of handling the interrupt has not been received.
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	OFFIS	0	R/W	Normal operation mode transition completion interrupt state This bit is B'1 when LCDC0 and LCDC1 normal operation mode transition completion interrupt occurs. This bit must be cleared by writing B'0 in an interrupt handling routine. 0: Indicates that a normal operation mode transition completion interrupt has not occurred or that notification of completion of handling the interrupt has been received. 1: Indicates that a normal operation mode transition completion interrupt has occurred and notification of completion of handling the interrupt has not been received.
0	ONIS	0	R/W	Refresh mode transition completion interrupt state This bit is B'1 when LCDC0 and LCDC1 refresh mode transition completion interrupt occurs. This bit must be cleared by writing B'0 in an interrupt handling routine. 0: Indicates that a refresh mode transition completion interrupt has not occurred or that notification of completion of handling the interrupt has been received. 1: Indicates that a refresh mode transition completion interrupt has occurred and notification of completion of handling the interrupt has not been received.

39.7.4 LCD Refresh Status Register (LRSR)

LRSR indicates the status concerning LCD refresh operation.

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	MS1	0	R	LCDC1 mode status This bit indicates the LCDC1 operation mode. 0: Normal operation mode 1: LCD refresh mode
5	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
4	MS0	0	R	LCDC0 mode status This bit indicates the LCDC0 operation mode. 0: Normal operation mode 1: LCD refresh mode
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	MS	0	R	Mode status This bit indicates the operation mode of the LCDC0 and the LCDC1. 0: Normal operation mode 1: LCD refresh mode

39.7.5 MERAM Mode Set Register (LRLPRSR)

LRLPRSR specifies the MERAM operation mode. The resume standby mode (RS mode, memory retained, read/write impossible) can be entered by compulsion or in synchronization with the refresh mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18	FRS2	0	R/W	MERAM (1024 to 1536 KB) compulsory RS mode set Selects whether to force the MERAM area (1024 to 1536 KB) to enter the RS mode. 0: Forces the MERAM (1024 to 1536 KB) to enter the normal mode 1: Forces the MERAM (1024 to 1536 KB) to enter the RS mode
17	FRS1	0	R/W	MERAM (512 to 1024 KB) compulsory RS mode set Selects whether to force the MERAM area (512 to 1024 KB) to enter the RS mode. 0: Forces the MERAM (512 to 1024 KB) to enter the normal mode 1: Forces the MERAM (512 to 1024 KB) to enter the RS mode
16	FRS0	0	R/W	MERAM (0 to 512 KB) compulsory RS mode set Selects whether to force the MERAM area (0 to 512 KB) to enter the RS mode. 0: Forces the MERAM (0 to 512 KB) to enter the normal mode 1: Forces the MERAM (0 to 512 KB) to enter the RS mode
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
14	RRS2	0	R/W	MERAM refresh mode synchronize RS mode set Selects whether to allow the MERAM (1024 to 1536 KB) to enter the RS mode in synchronization with the refresh mode. 0: Makes the MERAM (1024 to 1536 KB) enter the normal mode when the transition from the refresh mode to the normal mode is made 1: Makes the MERAM (1024 to 1536 KB) enter the RS mode when the transition from the normal mode to the refresh mode is made
13	RRS1	0	R/W	MERAM refresh mode synchronize RS mode set Selects whether to allow the MERAM (512 to 1024 KB) to enter the RS mode in synchronization with the refresh mode. 0: Makes the MERAM (512 to 1024 KB) enter the normal mode when the transition from the refresh mode to the normal mode is made 1: Makes the MERAM (512 to 1024 KB) enter the RS mode when the transition from the normal mode to the refresh mode is made
12	RRS0	0	R/W	MERAM refresh mode synchronize RS mode set Selects whether to allow the MERAM (0 to 512 KB) to enter the RS mode in synchronization with the refresh mode. 0: Makes the MERAM (0 to 512 KB) enter the normal mode when the transition from the refresh mode to the normal mode is made 1: Makes the MERAM (0 to 512 KB) enter the RS mode when the transition from the normal mode to the refresh mode is made
11 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

39.7.6 Interrupt Address Register (LRIAR)

LRIAR stores the address that serves as a trigger for generating LCDC access address interrupts. When B'1 is written to the LRIER.AIE bit and the LCDC0 or the LCDC1 accesses the address stored in the LRIAR, an LCDC access address interrupt occurs.

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	IA[31:3]	H'FFFF FFF8	R/W	Indicate the address that causes LCDC access address interrupts.
2 to 0	IA[2:0]		R	

39.7.7 Interrupt Address Register2 (LRIAR2)

LRIAR2 stores address 2 that serves as a trigger for generating LCDC access address interrupts. When B'1 is written to the LRIER.A2IE bit and the LCDC0 or the LCDC1 accesses the address stored in the LRIAR2, an LCDC access address interrupt 2 occurs.

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	IA2[31:3]	H'FFFF FFF8	R/W	Indicate the address that causes LCDC access address interrupt2s.
2 to 0	IA2[2:0]			

39.7.8 Extended Address Register2 (LRXAR2)

LRXAR2 stores the SDRAM address at which additional data is stored when the display data size of the LCDC0 or the LCDC1 exceeds the MERAM capacity.

Note: Refer to the notes on the LRMAR2 register.

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	XA2[31:3]	H'FFFF FFF8	R/W	Indicate the extended LCDC address.
2 to 0	XA2[2:0]		R	This address must be 32-byte aligned.

39.7.9 Memory Boundary Address Register1 (LRMAR1)

When the display data size of the LCDC0 or the LCDC1 exceeds the MERAM capacity, LRMAR1 stores the address of the boundary between the SDRAM and the MERAM in which data is stored.

Note: Refer to the notes on the LRMAR2 register.

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	MA1[31:3]	H'E558 0000	R/W	Indicate the LCDC memory boundary address. An address equal to or larger than the value of this register corresponds to a location in the MERAM. The value must be chosen from the MERAM range from H'E558 0000 to H'E56F FFFF. The address must be specified on a 4-KB basis. If it is not specified on a 4-KB basis, it is rounded down to a 4-KB-unit value.
2 to 0	MA1[2:0]		R	

39.7.10 Memory Boundary Address Register2 (LRMAR2)

When the display data size of the LCDC0 or the LCDC1 exceeds the MERAM capacity, LRMAR2 stores the address of the boundary between the SDRAM and the MERAM in which data is stored.

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	MA2[31:3]	H'E570 0000	R/W	Indicate the LCDC memory boundary address. An address equal to or larger than the value of this register corresponds to a location in the MERAM. The value must be chosen from the MERAM range from H'E558 0000 to H'E56F FFFF. The address must be specified on a 4-KB basis. If it is not specified on a 4-KB basis, it is rounded up to a 4-KB-unit value.
2 to 0	MA2[2:0]		R	

Notes: 1. Access by the LCDC0/LCDC1 to virtual addresses H'E5580000 to H'E56F0000 is converted into access to the virtual MERAM space 0A (H'F0000000 to H'F01F0000), and then is converted into access to the internal MERAM or the external memory according to the settings of the LRPG0A and the LRSD0.

2. When any of the values of LRXAR2, LRMAR1, and LRMAR2 is changed, the values of LRPG0A and LRSD0 are updated to ensure appropriate operation. Note, however, that this conversion processing may not be implemented in future products. Therefore, it is recommended to use the LRPG0A and LRSD0A registers instead of the LRXAR2, LRMAR1, and LRMAR2 registers.

3. The relation of the values of LRXAR2, LRMAR1, and LRMAR2 to the automatically converted values of LRPG0A and LRSD0 is as follows:
LRPG0A.MSA[11:0] = INT((LRMAR1-H'e5580000)/4096)
LRPG0A.MSZ[11:0] = ROUNDUP((LRMAR2-H'e5580000)/4096) - LRPG0A.MSA[11:0]
LRSD0A[31:0] = LRXAR2 - LRPG0A.MSZ[11:0]*4096

4. The function, which was defined in LRXAR1 and LRMAR1, to convert access to an MERAM address less than the value of LRMAR1 into access to the external memory is not supported any more. The LRXAR1 register has been removed.

39.7.11 External Access Control Register (LREBUFC)

When the LCDC0 or the LCDC1 is in the LCD refresh mode and the external memory is accessed for read operation, the MERAM performs read fill operation from the external memory to place data in a read buffer area allocated in the internal MERAM. Then, the LCDC0/LCDC1 accesses the data.

This register controls read fill operation from the external memory.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	PRIF[3:0]	H'9	R/W	Set priority levels for external buses in read fill operation from the external memory. PRIF indicates the priority levels for the first requests in lines, and PRIC indicates the priority levels for the subsequent requests. For details on the priority levels, refer to 6.2 SHwy Bus Functions.
27 to 24	PRIC[3:0]	H'B		
23 to 1	—	All 0	R	Reserved
0	EN	H'1	R/W	Be sure to write 1 to this bit.

39.7.12 External Access Read Buffer Allocation Register (LREBUFP)

When the LCDC0/LCDC1 is in the LCD refresh mode and access to the external memory is required, it is necessary to secure a 4-KB read fill buffer area in the internal MERAM. This register specifies the address of this read fill buffer area.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	H'0	R	Reserved
27 to 16	RBUF1[11:0]	H'17F	R/W	Specify the address of a read fill buffer for the LCDC1 on a 4-KB basis. The address must be (8n + 4) KB.
15 to 12	—	H'0	R	Reserved
11 to 0	RBUF0[11:0]	H'17E	R/W	Specify the address of a read fill buffer for the LCDC0 on a 4-KB basis. The address must be 8n KB.

39.7.13 External Access Map Register 80 to B8 (LREMAP80 to B8)

When the LCDC0/LCDC1 is in the LCD refresh mode and an attempt to access the external memory is made, the virtual address is converted into a physical address according to the settings of these registers if the virtual address is in the PMB conversion target space (H'8000_0000 to H'BFFF_FFFF).

The virtual address space is converted on a 128-MB basis. xx in a register name (LREMAPxx) corresponds to a virtual page number.

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	PPN [31:26]	*1	R/W	Specify the physical page number to be converted.
25 to 0	—	H'0	R	Reserved

Notes: 1. The initial value of LREMAPxx (xx = 80, 90, a0, and b0) is 0, and that of LREMAPyy (yy = 88, 98, a8, and b8) is 5'b0000_1.
2. The virtual addresses in the range from 32'H00000000 to 32'H7FFF_FFFF are not correctly converted. Therefore, they cannot be used as external access addresses in the LCD refresh mode.
3. Even when MEVCR1.AMD = 0, the virtual addresses in the range from 32'H80000000 to 32'HBFFFFFFF are converted according to the settings of these registers, and these addresses provide access to the external memory.

39.7.14 Virtual MERAM Allocation Registers 0A to 3B (LRPG0A to 3B)

Access by the LCDC0/LCDC1 to the virtual address space from H'F0000000 to H'F3FFFFFF is regarded as access to the virtual MERAM space regardless of whether the LCD refresh mode is being used.

The virtual MERAM space is divided into eight 8-MB pages. Access to each virtual MERAM page (MERAM_xx) is address-converted into the internal MERAM or the external memory space by using the virtual MERAM allocation registers xx (LRPGxx) and the virtual MERAM external address registers xx (LRSDxx).

Also, when a frame buffer cache is in use, the transition to the LCD refresh mode is automatically translated as access to the virtual MERAM space. LRPG0A and LRSD0A manage access to the ICB A surface, and LRPG0A and LRSD0B manage access to the ICB B surface.

Virtual Address Range	Virtual MERAM Page Name
H'F000_0000 to H'F07F_0000	MERAM_0A
H'F080_0000 to H'F0FF_0000	MERAM_0B
H'F100_0000 to H'F17F_0000	MERAM_1A
H'F180_0000 to H'F1FF_0000	MERAM_1B
H'F200_0000 to H'F27F_0000	MERAM_2A
H'F280_0000 to H'F2FF_0000	MERAM_2B
H'F300_0000 to H'F37F_0000	MERAM_3A
H'F380_0000 to H'F3FF_0000	MERAM_3B

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	0	R	Reserved
27 to 16	MSA[11:0]	0	R/W	Specify the start address in the actual MERAM, where the in-page offset == 0 is allocated, on a 4-KB basis.
15 to 12	—	0	R	Reserved
11 to 0	MSZ[11:0]	0	R/W	Specify the data size in the actual MERAM on a 4-KB basis. Access to a range exceeding this size is regarded as access to the external memory. When MSZ = 0, all access to pages is regarded as access to the external memory. In this case, the value of MSA is not used.

39.7.15 Virtual MERAM External Address Registers 0A to 3B (LRSD0A to 3B)

These registers specify the external memory address corresponding to the in-page offset = 0 of the virtual MERAM pages (MERAM_xx, xx = 0A, 0B, 1A, 1B, 2A, 2B, 3A, and 3B), as a physical address.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PPN[31:0]	0	R/W	Specify the physical address of an external memory address corresponding to the offset (= 0) of the virtual MERAM pages, on a 256-byte basis. Access where the in-page offset address exceeds LRPGxx.MSZ*4KB is converted into access to (LRSDxx.PPN + in-page offset).

Section 40 LCD Controller (LCDC)

The LCD controller (LCDC) reads display data from an external memory . The LCDC uses the palette memory to determine the colors according to the settings and then sends the data to the LCD module. This LCDC allows connection of TFT LCD modules that support the RGB interface or the 80-Series CPU's bus interface (SYS interface) (excludes LCD modules with the NTSC/PAL type or LVDS interface.).

This LSI has two LCD modules (LCDC0, LCDC1).

40.1 Features

(1) Features of the LCDC

- Supports TFT LCD modules
- Supports two types interfaces as LCD module interface
  RGB interface (8/9/12/16/18/24-bit data bus width)
  80-Series CPU's bus interface (SYS interface, 8/9/12/16/18/24-bit data bus width)
- SYS interface supports the following input/output mode for the LCD module
  LCD module: VSYNC input and output modes
- Supports 8/12/16/18/24-bpp display image data formats
- Display image data is read in continuous or one-shot mode: continuous mode where display image data is continuously read according to the refresh rate of the LCD module and one-shot mode where display image data is read at intervals of the frame rate.
- Display image data is read in full or partial screen mode: full screen mode where the size of the display image data to be read depends on the panel size of the LCD module and partial screen mode where the size of the display image data to be read depends on the size of the screen to be updated.
- Each of the RGB colors can be corrected by the 256-entry, 24-bit-input/output internal color palette memory
- Supports inversion of output signals to agree with the LCD module's signal polarity
- Interrupts can be generated every frame or user-specified line
- YCbCr/RGB signals read are converted into YCbCr/RGB signals for output
- Supports tabular mode (display images are doubled horizontally and vertically)
- The child screen can be arranged in four places maximum in the display image data. The alpha blend function can be used in two systems and the ROP3 function be used in two systems.
- The source of the dot clock can be chosen with the bus clock, external input clock, and two interface clock
  LCDC0: the bus clock, MIPI-DSI byte clock, external input clock
  LCDC1: the bus clock, MIPI-DSI byte clock, HDMI clock, external input clock

Tables 40.1 show the LCDC functions respectively.

Table 40.1 LCDC Functions

Item		Function	Remakes
Input data format	8 bpp	RGB 332	
	12 bpp	RGB 444	
	16 bpp	RGB 565	
	18 bpp	RGB 666	
		BGR 666	
	24 bpp	RGB 888	
		BGR 888	
	YCbCr	YCbCr 4:2:0, 4:2:2, 4:4:4	
Output data format	RGB interface	RGB8	3 cycle/pixel
		RGB9	2 cycle/pixel
		RGB12a	2 cycle/pixel
		RGB12b	1 cycle/pixel
		RGB16	1 cycle/pixel
		RGB18	1 cycle/pixel
		RGB24	1 cycle/pixel
		YCbCr 4:2:2 16-bit output	2 cycle/pixel
	SYS interface	SYS8a/8b/8c	3 cycle/pixel
		SYS8d	2 cycle/pixel
		SYS9	2 cycle/pixel
		SYS12	2 cycle/pixel
		SYS16a	1 cycle/pixel
		SYS16b/16c	2 cycle/pixel
		SYS18	1 cycle/pixel
		SYS24	1 cycle/pixel
	Display data write-back	WB8a	• Packed format available • Write-back operation in units of 32 bits • Byte or word swap
		WB8d	
		WB9	
		WB16	
		WB18	
		WB24	

Item		Function	Remakes
LCD driver interface	RGB interface	Interface with HSYNC and VSYNC • Polarity inversion • Output pulse width and position setting	
	SYS interface	80-Series bus interface • Support of VSYNC input/output	
Dot clock	Source clock	Bus clock, external input clock, two peripheral clock	
	Division ratio	n/m m = 60, 54, 48, 42 $1 \leq n \leq m/3, m/2$	
Interrupt	User setting	Interrupt generated when reading of specified lines of data is completed	
	Frame	Interrupt generated when the first pixel data of a frame starts to be output	
		Interrupt generated when output of the last pixel data of a frame is completed	
	VRAM read	Interrupt generated when access to a frame of data in VRAM is completed	
		Interrupt generated when access to a line of data in VRAM is completed	
	VSYNC	Interrupt generated when VSYNC is asserted	
		Interrupt generated when VSYNC is negated	
Display image	Image data read	Image data read depending on the refresh rate of LCD module	
		Image data read depending on the frame rate of display image	
	Display image size	Full screen	
		Only the specified area is updated.	
	Image data processing	Each color of R, G, and B is converted using the color palette • 256 entries • 24-bit input/output	
Format conversion	YCbCr ⇔ RGB	YCbCr data is converted into RGB for output. RGB data is converted into YCbCr for output	

Figures 40.1 is block diagram of the LCDC respectively.

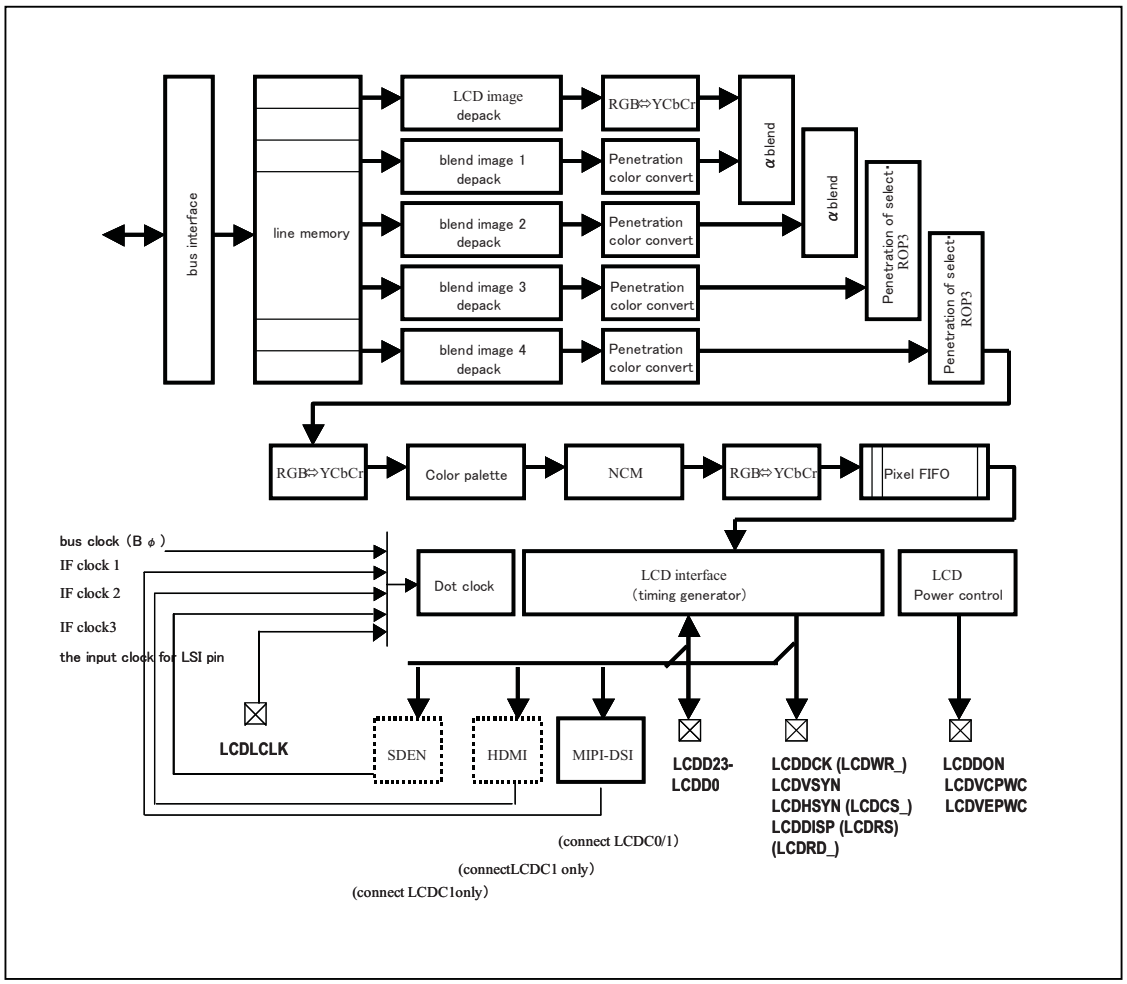

Figure 40.1 Block Diagram of LCDC

40.2 Input/Output Pins

Table 40.2 shows the pin configurations of the LCDC.

Table 40.2 Pin Configurations

Name	Function	I/O	Description
LCDDON	Display on signal	Output	Display start signal (DON) for LCD
LCDVCPWC	Power control	Output	LCD module power control (V_{CC})
LCDVEPWC	Power control	Output	LCD module power control (V_{EE})
LCDDCK/ $\overline{\text{LCDWR}}$	Dot clock/ write strobe	Output	Dot clock signal (RGB interface)/write strobe signal (SYS interface)
LCDVSYN	Vertical sync signal	Output/ I/O	Vertical sync signal (VSYNC) for LCD Output for RGB interface, or I/O for SYS interface
LCDHSYN/ $\overline{\text{LCDCS}}$	Horizontal sync signal/chip select	Output	Horizontal sync signal (RGB interface)/chip select signal for LCD (SYS interface)
LCDDISP/ LCDRS	Display enable/ Register select	Output	Display enable signal (RGB interface)/register select signal (SYS interface)
$\overline{\text{LCDRD}}$	Read strobe	Output	Read strobe signal (SYS interface)
LCDD23 to LCDD0	LCD data bus	Output/ I/O	LCD panel data (output for RGB interface, or I/O for SYS interface)
LCDLCLK	Input clock	Input	LCD source clock (external input, optional)

40.3 Register Descriptions

Table 40.3 shows the register configuration of the LCDC. Table 40.4 shows the states of the registers in each mode.

Most of the LCDC registers have a double-buffered mechanism (register sets A and B, or current and program side). Each register incorporated in the LCDC consists of two sets of registers (excluding some registers). An incorporated register with two sets of registers has a mirror address to access the register set not currently being used. The register which has a name in a register set name makes them one set, and controlled as two structure on a current side and the program side.

*Note

The address of LCDC0 register : H'FE940000 ~ H'FE943FFF
The address of LCDC1 register : H'FE944000 ~ H'FE947FFF

Table 40.3 Register Configurations

- LCDC Register Configurations

			Address			
Register Name	Symbol	R/W	Address (Set A/ current)	Address (Set B/ program)	Mirror Address	Access Size
LCDC palette data registers 00 to FF	LDPR00 to LDPRFF	R/W	H'FE94 0000 to H'FE94 03FC	—	—	32

40.3.1 LCDC Palette Data Registers 00 to FF (LDPR00 to LDPRFF)

LDPRnn specifies palette data in the palette memory. To access the palette memory, use these registers. Each 32-bit register has eight bits assigned to each of the R, G, and B colors. For details on the color palette specifications and settings, see section 40.4.2, Color Palette Specifications.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	PALDnn[23:16]							
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	PALDnn[23:0]	Undefined	R/W	Palette Data

Note: nn = 00 to FF

40.3.2 LCD Dot Clock Pattern Register 1 (MLDDCKPAT1R)

MLDDCKPAT1R specifies the upper 28 bits of a dot clock output pattern for the LCD.

The LCDC operating clock (dot clock) can be generated by dividing the bus clock. For details, see section 40.4.7, Dot Clock Settings.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	DCKPAT1[59:48]											
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DCKPAT1[47:32]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 0	DCKPAT1 [59:32]	H'000 0000	R/W	Dot Clock Pattern 1 [59:32] Specifies the upper 28 bits of the output pattern of the dot clock, which is obtained from the divided source clock. Up to a 60-bit pattern can be specified in combination with these bits and the bits in MLDDCKPAT2R.

40.3.3 LCD Dot Clock Pattern Register 2 (MLDDCKPAT2R)

MLDDCKPAT2R specifies the lower 32 bits of a dot clock output pattern for the LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DCKPAT1[31:16]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DCKPAT1[15:0]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DCKPAT1 [31:0]	H'0000 0000	R/W	Dot Clock Pattern 1 [31:0] Specifies the lower 32 bits of the output pattern of the dot clock, which is obtained from the divided source clock. A maximum of 60-bit pattern can be specified in combination with these bits and bits in MLDDCKPAT1R.

40.3.4 LCDC Dot Clock Register (LDDCKR)

LDDCKR selects the input clock and specifies the division ratio of the dot clock.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	ICKSEL[2:0]		
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	MOSEL	MDCDR[5:0]					
nitial :	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18 to 16	ICKSEL [2:0]	All 0	R/W	Input Clock Select These bits select the source of the dot clock for the LCD. 000: bus clock. 001: MIPI-DSI byte clock 010: HDMI clock (LCDC1 only) 011: External terminal clock input 100 to 111: Setting prohibited
15 to 7	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	MOSEL	0	R/W	LCD Output Clock Select Selects the division ratio of the dot clock (LCD operating clock) from the 1/1 and value specified by bits in this register. 0: A division ratio specified by bits in this register 1: A division ratio of 1/1
5 to 0	MDCDR [5:0]	111100	R/W	Clock Division Ratio These bits specify the denominator when the division ratio of the source clock of the LCD operating clock is denoted as n/m.

Note: If the same frequency is used for the LCDC operation clock (the bus clock under normal operation; the clock selected by the MCKSEL bit in LRCKR) and the dot clock supply clock (the clock selected by the ICKSEL bit of LDDCKR and the ECKSEL bit in LRCKR), neither SOSEL=1 nor MOSEL=1 can be selected. Divide the dot clock supply clock.

* Selecting ICKSEL=10 selects the clock selected by the ECKSEL2 bit in LRCKR.

- Selecting ICKSEL=10 selects the clock selected by the ECKSEL bit in LRCKR.

40.3.5 Dot Clock Stop Register (LDDCKSTPR)

LDDCKSTPR stops or restarts the LCDC dot clock. When temporarily stopping the dot clock and then restarting it, set the DCKSTP bit to 1, check that the DCKSTS bit becomes 1, make necessary settings, and then restart the dot clock.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	DCKSTS
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	DCKSTP
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	DCKSTS	0	R	Dot Clock Status This bit is set to 1 while the dot clock stops. 0: The dot clock is being supplied. 1: The dot clock has stopped.
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DCKSTP	0	R/W	Dot Clock Stop/Restart Control Stops or restarts the dot clock. 0: Supplies the dot clock. 1: Stops the dot clock.

40.3.6 LCD Module Type Register 1 (MLDMT1R)

MLDMT1R selects the module interface of LCD from the RGB and SYS interfaces and the transfer mode for connection to LCD modules, and controls the signal polarity when the RGB interface is used.

The interface mode, the polarity of control signals, the data bus width, and the number of access cycles for LCD can be specified by LCD module type registers 1 to 3

bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	VPOL	HPOL	DW POL	DI POL	DA POL	–	–	–	–	–	–	HS CNT	DW CNT
initial:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VSSM	CSM	YM	IFM	–	–	–	–	–	–	–	–	MIFTYP[3:0]			
initial:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	VPOL	0	R/W	Vertical Sync Signal Polarity Select In VSYNC output mode (when the VSEL bit in MLDMT2R is set to 1), this bit selects the polarity of the VSYNC signal for the main LCD when the RGB or SYS interface is used. In VSYNC input mode (when the VSEL bit in MLDMT2R is cleared to 0), this bit selects whether or not the polarity of the input VSYNC signal is toggled. Note that the polarity of the VSYNC signal is active high. In VSYNC output mode 0: Output VSYNC is active high. 1: Output VSYNC is active low. In VSYNC input mode 0: Polarity is not toggled. 1: Polarity is toggled
27	HPOL	0	R/W	Horizontal Sync Signal Polarity Select Selects the polarity of the HSYNC signal when the RGB interface of the LCD is used. When the RGB interface mode is selected by the IFM bit, this bit is valid. 0: HSYNC signal is active high. 1: HSYNC signal is active low.

Bit	Bit Name	Initial Value	R/W	Description
26	DWPOL	1	R/W	Dot Clock Polarity Select Selects the polarity of the dot clock signal when the RGB interface of the LCD is used. 0: Data latched at the falling edge of the dot clock 1: Data latched at the rising edge of the dot clock
25	DIPOL	0	R/W	Display Enable Polarity Select Selects the polarity of the display enable signal when the RGB interface of the LCD is used. When the RGB interface mode is selected by the IFM bit, this bit is valid. 0: Display enable signal is active high. 1: Display enable signal is active low.
24	DAPOL	0	R/W	Display Data Polarity Select Selects the polarity of display data when the RGB or SYS interface of the LCD is used. The polarity is only for display data and does not affect commands or instructions for connected LCDs. 0: Display data is active high. 1: Display data is active low.
23 to 18	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	HSCNT	0	R/W	HSYNC Signal Output Control Controls the HSYNC output signal during vertical blanking. When the RGB interface mode is selected by the IFM bit, this bit is valid. 0: Outputs HSYNC during vertical blanking. 1: Does not output HSYNC during vertical blanking.
16	DWCNT	0	R/W	Dot Clock Control Controls the dot clock signal output during horizontal or vertical blanking when the RGB interface mode is used. 0: Outputs the dot clock signal during horizontal/vertical blanking. 1: Does not output the dot clock signal during horizontal/vertical blanking.
15	VSSM	0	R/W	VSYNC slide output set 0: no slide 1: slide on The delays are set by MLDIVSNR.DLY.
14	CSM	0	R/W	Camera type SYNC output set 0: LCD panel SYNC signal is output 1: Camera SYNC is output (asserted during the data is valid)
13	YM	0	R/W	YCbCr output mode set Selects the YCbCr output mode. 0: RGB output mode 1: YCbCr output mode If this bit is set to 1, please set MIFTYP[3:0] to 4'b1110 or 4'b1111.

Bit	Bit Name	Initial Value	R/W	Description
12	IFM	0	R/W	Interface Mode Set Selects the interface mode for the connected LCD. 0: RGB interface mode 1: SYS interface mode
11 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	MIFTYP [3:0]	1010	R/W	LCD Module Set These bits select the type of the LCD according to the IFM bit. See table 38.6.

Table 40.5 LCD Module Settings

- IFM = B'0

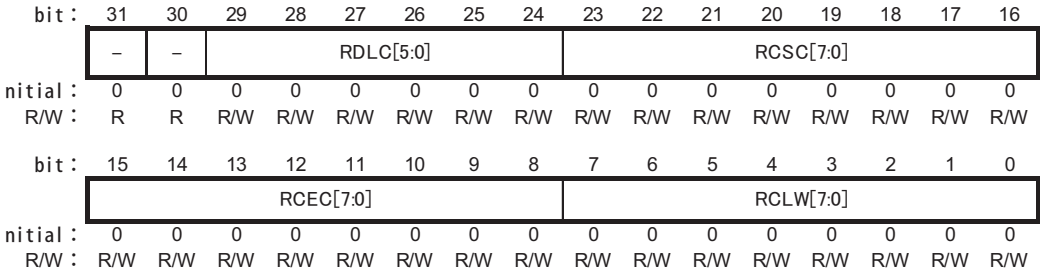
MIFTYP[3:0]	Description
B'0000	RGB8 (24 bpp, three-cycle transfer, 8:8:8)
B'0001	Reserved
B'0010	Reserved
B'0011	Reserved
B'0100	RGB9 (18 bpp, two-cycle transfer, 9:9)
B'0101	RGB12a (24 bpp, two-cycle transfer, 12:12)
B'0110	RGB12b (12 bpp, one-cycle transfer)
B'0111	RGB16 (16 bpp, one-cycle transfer)
B'1000	Reserved
B'1001	Reserved
B'1010	RGB18 (18 bpp, one-cycle transfer)
B'1011	RGB24 (24 bpp, one-cycle transfer)
B'1100 to B'1110	Reserved
B’1111	YCbCr 4:2:2 (16bpp, two-pixel/two-cycle transfer (Y, Cb), (Y, Cr)

- IFM = B'1

MIFTYP[3:0]	Description
B'0000	SYS8a (24 bpp, three-time transfer, 8:8:8)
B'0001	SYS8b (18 bpp, three-time transfer, 8:8:2)
B'0010	SYS8c (18 bpp, three-time transfer, 2:8:8)
B'0011	SYS8d (16 bpp, two-time transfer, 8:8)
B'0100	SYS9 (18 bpp, two-time transfer, 9:9)
B'0101	SYS12 (24 bpp, two-time transfer, 12:12)
B'0110	Reserved
B'0111	SYS16a (16 bpp, one-time transfer)
B'1000	SYS16b (18 bpp, two-time transfer, 16:2)
B'1001	SYS16c (18 bpp, two-time transfer, 2:16)
B'1010	SYS18 (18 bpp, one-time transfer)
B'1011	SYS24 (24 bpp, one-time transfer)
B'1100 to B'1111	Reserved

40.3.7 LCD Module Type Register 2 (MLDMT2R)

MLDMT2R controls the write strobe signal and indicates access status when the SYS interface of LCD is used.



bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	CSUP[2:0]			RSV	VSEL	WCSC[7:0]							
nitial :	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WCEC[7:0]								WCLW[7:0]							
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 26	CSUP[2:0]	001	R/W	Chip Select Setup Time Set These bits specify the setup time of the chip select signal for display data transfer via the SYS interface.
25	RSV	0	R/W	VSYNC Mode Register Select Polarity Set Sets the polarity of the register select signal when display data is transferred via the SYS interface. 0: Register select signal is active low. 1: Register select signal is active high.
24	VSEL	0	R/W	VSYNC I/O Mode Select Selects the input or output mode of the VSYNC signal of the LCD for the SYS interface. This bit is writable when the DO bit in LDCNT2R is cleared to 0. 0: VSYNC output mode (LCDC outputs the VSYNC) 1: VSYNC input mode (LCDC outputs display data or commands according to the VSYNC input from an external device)
23 to 16	WCSC[7:0]	H'00	R/W	Setup Time Set These bits set the setup time of the write strobe signal for the SYS interface on a bus clock basis.
15 to 8	WCEC[7:0]	H'00	R/W	Write Cycle Time Set These bits set the time of a write cycle for the SYS interface on a bus clock basis.
7 to 0	WCLW[7:0]	H'00	R/W	Low Pulse Width Set These bits specify the low level width of the write strobe signal for the SYS interface on a bus clock basis.

40.3.8 LCD Module Type Register 3 (MLDMT3R)

MLDMT3R controls the read strobe signal via the SYS interface of LCD.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 24	RDLC[5:0]	000000	R/W	Read Data Latch Set These bits specify the timing of latching data read via the SYS interface on a bus clock basis.
23 to 16	RCSC[7:0]	H'00	R/W	Setup Time Set These bits specify the setup time of the read strobe signal for the SYS interface on a bus clock basis.
15 to 8	RCEC[7:0]	H'00	R/W	Read Cycle Time Set These bits specify the time of a read cycle for the SYS interface on a bus clock basis.
7 to 0	RCLW[7:0]	H'00	R/W	Low Pulse Width Set These bits specify the low level width of the read strobe signal for the SYS interface on a bus clock basis.

40.3.9 LCD Data Format Register (MLDDFR)

MLDDFR sets the type of image data input to LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	CF1	CF0	CC
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	YF[1:0]		–	–	–	PKF[4:0]				
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18	CF1	0	R/W	set YCbCr format when the data format in memory is ITU-R YCbCr format 0: ITU-R BT.601 YCbCr format 1: ITU-R BT.709 YCbCr format
17	CF0	0	R/W	Set the range of YCbCr format 0: compressed-range YCbCr format [16, 235/240] 1: full-range YCbCr format [0, 255]
16	CC	0	R/W	Set the data format of display data in memory When the data format of display data in memory is YCbCr, set this bit to 1. 0: RGB format 1: YCbCr format
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	YF[1:0]	00	R/W	Input Image YCbCr Data Packed Format These bits select the packed format when the input image data format is YCbCr. When the CC bit in MLDDFR is set to 1, this bit is valid. 00: 4:2:0 YCbCr 01: 4:2:2 YCbCr 10: 4:4:4 YCbCr 11: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	PKF[4:0]	00000	R/W	Input Image RGB Data Packed Format These bits select the packed format when the input image data format is RGB. When the CC bit in MLDDFR is cleared to 0, this bit is valid. Tables 40.6 and 40.7 list the packed formats for the YCbCr and RGB, respectively.

Table 40.6 YCbCr Packed Format

YF[1:0]	YCbCr		Bits 31 to 24	23 to 16	15 to 8	7 to 0
B'00	4:2:0	Y data	Y0	Y1	Y2	Y3
		C data	Cb0	Cr0	Cb2	Cr2
B'01	4:2:2	Y data	Y0	Y1	Y2	Y3
		C data	Cb0	Cr0	Cb2	Cr2
B'10	4:4:4	Y data	Y0	Y1	Y2	Y3
		C data	Cb0	Cr0	Cb1	Cr1
B'11	Reserved

40.3.10 LCD Scan Mode Register 1 (MLDSM1R)

MLDSM1R selects the display data size from full or partial and selects the mode for reading display data from continuous or one-shot. For details of the settings, see section 40.4.4, One-Shot Mode, and section 40.4.5, Partial Screen Mode.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	PRD	–	–	–	–	–	–	–	OS
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	PRD	0	R/W	Partial Size Read Set Selects the size of display data read from external memory. 0: Full screen size (panel size) of data is read. 1: Partial screen size of data is read.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	OS	0	R/W	One-Shot Read Set Selects the mode for reading display data from external memory. 0: Continuous mode (display data is read according to the refresh rate of the panel) 1: One-shot mode (display data is read using the OSTRG bit in MLDSM2R as a trigger)

40.3.11 LCD Scan Mode Register 2 (MLDSM2R)

MLDSM2R sets the one-shot trigger of LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	OSTRG
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	OSTRG	0	R/W	One-Shot Trigger When the one-shot mode is selected for reading display data, setting this bit to 1 starts reading of one frame of data from external memory. This bit is cleared when the display operation is started. 0: — 1: One frame of data read

40.3.12 LCD Display Data Read Start Address Register 1 (MLDSA1R)

MLDSA1R sets the start address of LCD display data in memory. When the data format of display data is YCbCr, these bits set the start address of the luminance signal.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SA[31:16]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SA[15:3]													–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	SA[31:3]	H'0000 0000	R/W	Display Data Start Address These bits set the start address of the LCD display data in memory. When the data format of display data is YCbCr, these bits set the start address of the luminance signal.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

40.3.13 LCD Display Data Read Start Address Register 2 (MLDSA2R)

MLDSA2R sets the start address of the color difference signal of LCD display data in memory. When the data format of display data is YCbCr, this register is valid.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SA[31:16]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SA[15:3]													–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	SA[31:3]	H'0000 0000	R/W	Display Data Start Address These bits specify the start address of the color difference signal of the LCD display data in memory. When the data format of display data is YCbCr, these bits are valid.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

40.3.14 LCD Display Data Storing Memory Line Size Register (MLDMLSR)

MLDMLSR specifies the amount of one line of LCD display data in memory. A vertical line number is incremented when the specified size of memory is read. When the data format of display data is YCbCr 4:4:4, twice the size set is used in memory.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LS[15:3]													–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 3	LS[15:3]	H'0000	R/W	Line Size These bits set the amount of one line of LCD display data in memory. When the data format of display data is YCbCr 4:4:4, twice the size set is used in memory.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

40.3.15 LCD Write-Back Data Format Register (MLDWBFR)

MLDWBFR specifies the data format of data written back to the LCD. The LCDC handles data with big endian in the default settings.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	AI								WP
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	LS	WS	BS	–	–	–	–	–	WBTYP[2:0]		
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	AI	0	R/W	Address Increment Select Enables or disables incrementing of the start address to

Bit	Bit Name	Initial Value	R/W	Description
				which data is written back. 0: Disables incrementing of the start address. 1: Enables incrementing of the start address.
23 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	WP	0	R/W	Write-Back Data Polarity Select Inverts the polarity of the data to be written back (to support reflective LCD modules). 0: Data is active high. 1: Data is active low.
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	LS	0	R/W	Write-back Longword Swap Select Enables or disables longword swapping on data with the type specified by the WBTYP bits (see figure 38.3). 0: Disables longword swapping. 1: Enables longword swapping.
9	WS	0	R/W	Write-Back Word Swap Select Enables or disables word swapping on data with the type specified by the WBTYP bits (see figure 38.4). 0: Disables word swapping. 1: Enables word swapping.
8	BS	0	R/W	Write-Back Byte Swap Select Enables or disables byte swapping on data with the type specified by the WBTYP bits (see figure 38.5). 0: Disables byte swapping. 1: Enables byte swapping.
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	WBTYP [2:0]	010	R/W	Write-Back Type Select These bits specify the type of display data to be written (32-bit Pack). 000: WB8a (max. RGB888) 001: WB8d (max. RGB565) 010: WB9 (max. RGB666) 011: WB16 (max. RGB565) 100: WB18 (max. RGB666) 101: WB24 (max. RGB888)

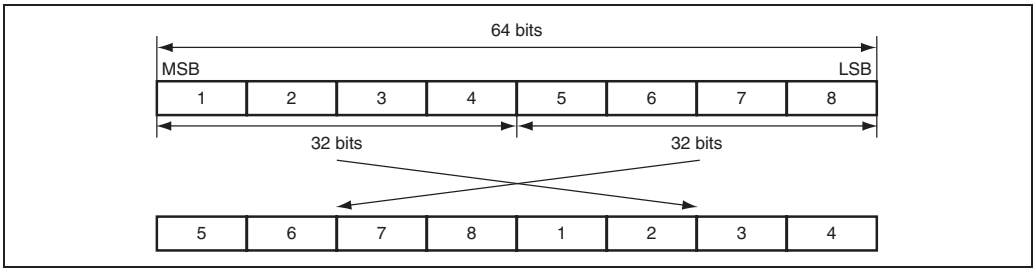

Figure 40.2 Longword Swapping

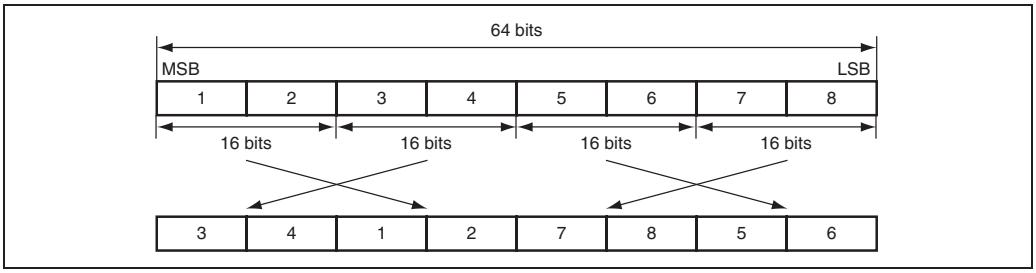

Figure 40.3 Word Swapping

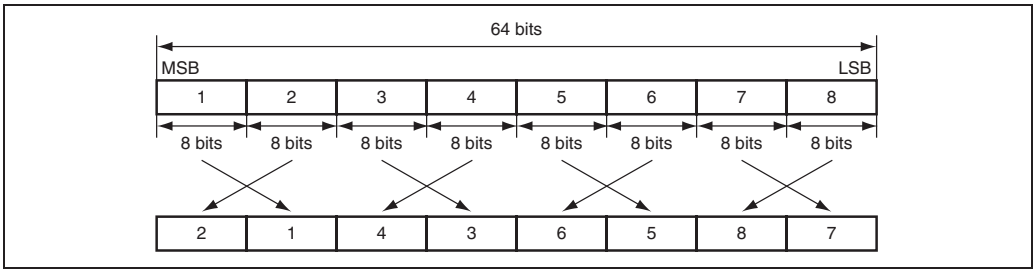

Figure 40.4 Byte Swapping

40.3.16 LCD Write-Back Control Register (MLDWBCNTR)

MLDWBCNTR enables or disables write-back operation to LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	WE
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	WE	0	R/W	Write-Back Enable Enables or disables write-back operation. 0: Disables write-back operation. 1: Enables write-back operation.

40.3.17 LCD Write-Back Start Address Register (MLDWBAR)

MLDWBAR specifies the start address to which display data is written back to the LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WA[31:16]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WA[15:5]											–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	WA[31:5]	H'000 0000	R/W	Write-Back Start Address Specifies the start address to which data is written back.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

40.3.18 LCD Horizontal Character Number Register (MLDHCNR)

MLDHCNR specifies the horizontal size of the LCD and the scan size including the horizontal blanking. This register must be set in units of characters (eight dots).

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	HDCN[7:0]							
nitial :	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	HTCN[8:0]								
nitial :	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	1
R/W :	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	HDCN[7:0]	H'1E	R/W	Horizontal Display Character Count These bits specify the number of horizontal display characters (one character = eight dots). For example, when an LCD module which has 240 pixels horizontally is used, set these bits to H'1E (= 240/8 = 30).
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 0	HTCN[8:0]	H'21	R/W	Horizontal Character Count These bits specify the number of horizontal characters (one characters = eight dots). The horizontal blanking is three characters (24 dots) at a minimum.

Notes: 1. The specified size of horizontal display data has no limitation on the function side, but the limitation on the performance side is caused between refresh rate. Please refer to 40.7 directions for details.

2. Specify the HDCN and HTCN bits so that the following expression is satisfied.
   $HTCN \geq HDCN + 3$

3. When LDDBSLMR.DBM is set to 1, please set HDCN to the display size (The data for the pixel count that adjusts HDCN to 1/2 is acquired, it expands by the twice, and it is output).

40.3.19 LCD Horizontal Sync Signal Register (MLDHSYNR)

MLDHSYNR specifies the timing and size of the horizontal sync signal of the LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	HSYNW[3:0]			
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	HSYNP[8:0]								
nitial :	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	HSYNW [3:0]	H'1	R/W	Horizontal Sync Signal Pulse Width These bits specify the pulse width of the horizontal sync signal in units of characters (one character = eight dots).
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 0	HSYNP[8:0]	H'20	R/W	Horizontal Sync Signal Output Position These bits specify the output position of the horizontal sync signal in units of characters (one character = eight dots).

Note: Specify the HSYNW and HSYNP bits so that the following expressions are satisfied.
HTCN ≥ HSYNP + HSYNW
HSYNP ≥ HDCN + 1

40.3.20 LCD Vertical Line Number Register (MLDVLNR)

MLDVLNR specifies the vertical size excluding or including blanking of LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	VDLN[10:0]										
nitial :	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	VTLN[10:0]										
nitial :	0	0	0	0	0	0	0	1	0	1	0	0	0	0	1	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 16	VDLN[10:0]	H'140	R/W	Vertical Display Line Count These bits specify the number of display lines in the vertical direction in units of lines. For example, when an LCD having 320 vertical lines is used, set these bits to H'140 = 320.
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	VTLN[10:0]	H'142	R/W	Vertical Line Total Count These bits specify the total number of lines in the vertical direction in units of lines. The minimum total number of lines is 3.

Notes: 1. Specify the VTLN and VDLN bits so that the following expression is satisfied.
VTLN ≥ VDLN + 1
2. For VSYNC input mode, the interval of the VSYNC input must be shorter than one frame specified by the VTLN bits. The vertical blanking during which commands can be issued is defined from the completion of display operation to the end of the frame specified by the VTLN bits.
3. When LDDBSLMR.DBM is set to 1, please set HDCN to the display size (The data for the pixel count that adjusts HDCN to 1/2 is acquired, it expands by the twice, and it is output).

40.3.21 LCD Vertical Sync Signal Register (MLDVSYNR)

MLDVSYNR specifies the timing and width of the vertical sync signal of LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	VSYNW[3:0]			
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	VSYNP[10:0]										
nitial :	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	1
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	VSYNW [3:0]	H'1	R/W	Vertical Sync Signal Width These bits specify the pulse width of vertical sync signal assertion in units of lines.
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	VSYNP [10:0]	H'141	R/W	Vertical Sync Signal Output Position These bits specify the output position of the vertical sync signal in units of lines.

Note: Specify the VSYNP bits so that the following expressions is satisfied.
VTLN ≥ VSYNP
VSYNP ≥ VDLN + 1

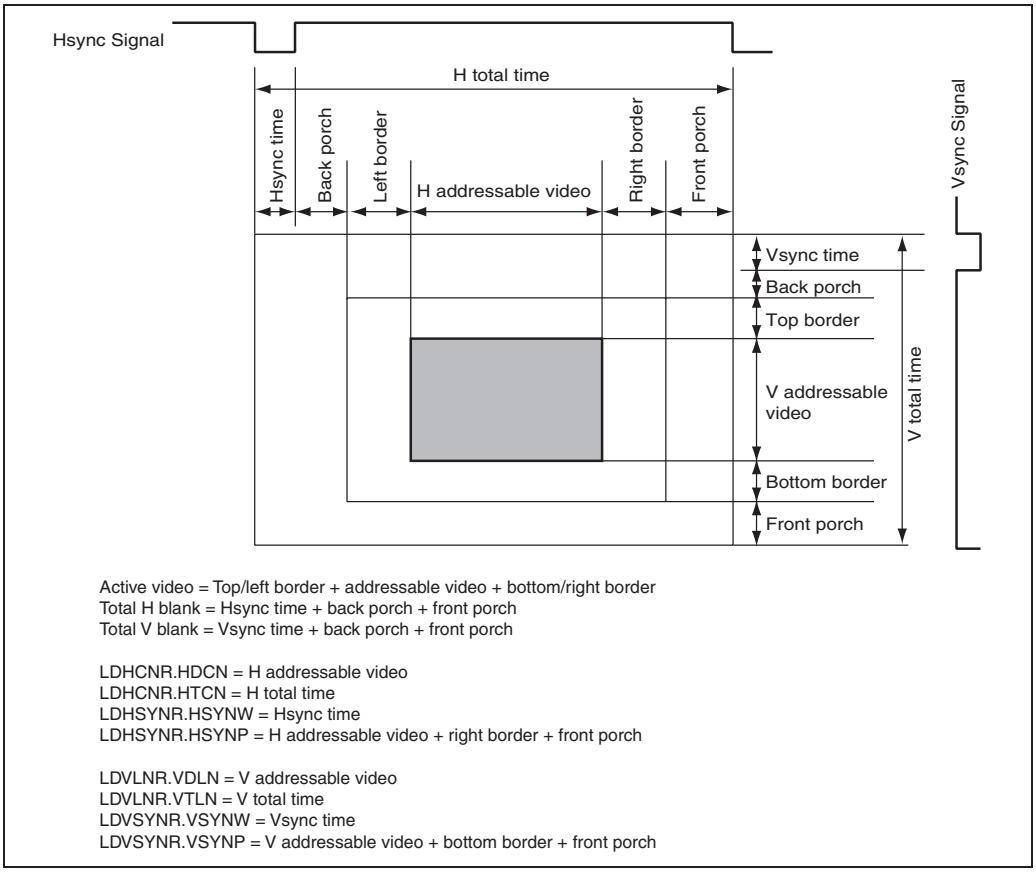

Figure 40.5 Valid Display and Blanking Periods

40.3.22 LCD Horizontal Partial Display Register (MLDHPDR)

MLDHPDR specifies the number of horizontal display characters and the number of offset characters in the LCD partial display mode. For details on settings, see section 40.4.5, Partial Screen Mode.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	HPDCN[7:0]							
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	HPDOCN[7:0]							
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	HPDCN [7:0]	H'00	R/W	Horizontal Partial Display Character Count These bits specify the number of horizontal display characters of the partial display in partial display mode (one character = eight dots).
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	HPDOCN [7:0]	H'00	R/W	Horizontal Partial Display Offset Character Count These bits specify the horizontal offset of the partial display from the display size in partial display mode in units of characters (one character = eight dots).

40.3.23 LCD Vertical Partial Display Register (MLDVPDR)

MLDVPDR specifies the number of vertical display lines and the number of offset lines in the LCD partial display mode.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	VPDLN[10:0]										
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	VPDOLN[10:0]										
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 16	VPDLN [10:0]	H'000	R/W	Vertical Partial Display Line Count These bits specify the number of vertical display lines of the partial display in partial display mode (one character = eight dots).
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	VPDOLN [10:0]	H'000	R/W	Vertical Partial Display Offset Line Count These bits specify the vertical offset of the partial display from the display size in partial display mode in units of lines.

40.3.24 LCD Power Management Register (MLDPMR)

MLDPMR controls power supply circuits for the LCD. For details, see section 40.4.6, Power Management Function. When the LCD module is not used, be sure to clear this register to H'0000 0000.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ONA[3:0]				ONB[3:0]				ONC[3:0]				OFFD[3:0]			
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OFFE[3:0]				OFFF[3:0]				–	VC	VE	DO	–	–	LPS[1:0]	
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	ONA[3:0]	0000	R/W	LCDC Switching-On Sequence Interval A These bits specify the time in units of frames until the display data (LCDD) and timing signals (LCDHSYN, LCDDCK, LCDDISP, LCDVSYN, and $\overline{\text{LCDRD}}$) start to be output after an assertion of the LCDVCPWC signal in the LCDC switching-on sequence. When the VC bit is cleared to 0, clear these bits to H'0.
27 to 24	ONB[3:0]	0000	R/W	LCDC Switching-On Sequence Interval B These bits specify the time in units of frames until the LCDVEPWC signal is asserted after the display data (LCDD) and timing signals (LCDHSYN, LCDDCK, LCDDISP, LCDVSYN, and $\overline{\text{LCDRD}}$) start to be output in the LCDC switching-on sequence. When the VE bit is cleared to 0, clear these bits to H'0.
23 to 20	ONC[3:0]	0000	R/W	LCDC Switching-On Sequence Interval C These bits specify the time in units of frames from assertion of the LCDVEPWC signal to assertion of the LCDDON signal in the LCDC switching-on sequence.
19 to 16	OFFD[3:0]	0000	R/W	LCDC Switching-Off Sequence Interval A These bits specify the time in units of frames from a negation of the LCDDON signal to a negation of the LCDVEPWC signal in the LCDC switching-off sequence. When the VE bit is cleared to 0, clear these bits to H'0.
15 to 12	OFFE[3:0]	0000	R/W	LCDC Switching-Off Sequence Interval B These bits specify the time in units of frames until the display data (LCDD) and timing signals (LCDHSYN, LCDDCK, LCDDISP, LCDVSYN, and $\overline{\text{LCDRD}}$) stop output after a negation of the LCDVEPWC signal in the LCDC switching-off sequence.
11 to 8	OFFF[3:0]	0000	R/W	LCDC Switching-Off Sequence Interval C These bits specify the time in units of frames until the LCDVCPWC signal is negated after the display data (LCDD) and timing signals (LCDHSYN, LCDDCK, LCDDISP, LCDVSYN, and $\overline{\text{LCDRD}}$) stop output in the LCDC switching sequence. When the VC bit is cleared

Bit	Bit Name	Initial Value	R/W	Description
				to 0, clear these bits to H'0.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	VC	0	R/W	LCDVCPWC Signal Enable Enables or disables LCDC switching-on and -off sequences using the LCDVCPWC signal. 0: LCDVCPWC fixed low 1: LCDVCPWC assertion and negation controlled by a given sequence
5	VE	0	R/W	LCDVEPWC Signal Enable Enables or disables LCDC switching-on and -off sequences using the LCDVEPWC signal. 0: LCDVEPWC fixed low 1: LCDVEPWC assertion and negation controlled by a given sequence
4	DO	0	R/W	LCDDON Signal Enable Enables or disables LCDC switching-on and -off sequences using the LCDDON signal. 0: LCDDON fixed low 1: LCDDON assertion and negation controlled by a given sequence
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	LPS[1:0]	00	R	LCD Module Power Supply State These bits indicate the state of the power supply for the LCD module while LCDC switching-on and -off sequences are enabled. 00: Power is not supplied to the LCD module. 11: Power is supplied to the LCD module.

40.3.25 LCDC Palette Control Register (LDPALCR)

LDPALCR specifies the access mode to the palette memory. For details on the color palette specification and settings, see section 40.4.2, Color Palette Specifications.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	MM
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	PE
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	MM	0	R/W	LCD Palette Mode Enables the LCD to use the palette memory. 0: Disables use of the palette memory by the LCD. 1: Enables use of the palette memory (24-bit input and output palette memory) by the LCD.
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PE	0	R/W	Palette Read/Write Enable Specifies the source of access to the palette memory. 0: The LCDC uses the palette memory (display mode). 1: The host (CPU) uses the palette memory (CPU access mode).

40.3.26 LCDC Interrupt Register (LDINTR)

LDINTR specifies the start timing of interrupts and indicates the interrupt status.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	BFS	WRE	CE	UILN[10:0]										
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EE	SE	UE	ME	MHE	FE	VSE	VEE	ES	SS	US	MS	MHS	FS	VSS	VES
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 30	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
29	BFS	0	R/W	Line Buffer Error Status This bit is set to 1 when the data in the line buffer is not supplied to the LCD display block in time (underrun). Write 0 to this bit to clear it.
28	WRE	0	R/W	Write Error Status This bit is set to 1 when data to be written back to the external memory is overwritten before the write operation. Write 0 to this bit to clear it.
27	CE	0	R/W	SYS Error Status This bit is set to 1 when a LCD display operation is triggered during writing or reading the driver. Write 0 to this bit to clear it.
26 to 16	UILN[10:0]	H'000	R/W	User-Specified Interrupt Line Number These bits specify the position to generate a user-specified interrupt. A user-specified interrupt occurs when image data for the specified number of lines has been read from the external memory. The number of lines is specified by this register.
15	EE	0	R/W	Error Interrupt Enable Enables or disables an interrupt to be generated when a BFS, WRE, or CE error occurs. 0: Disables an interrupt. 1: Enables an interrupt.
14	SE	0	R/W	Frame Start Interrupt Enable Enables or disables an interrupt to be generated when the first pixel data of a frame is output to the LCD. This setting is valid only for output frame in one-shot mode. 0: Disables an interrupt when the first pixel data is output to the LCD. 1: Enables an interrupt when the first pixel data is output to the LCD.
13	UE	0	R/W	User-Specified Interrupt Enable Enables or disables an LCDC user-specified interrupt. 0: Disables a user-specified interrupt. 1: Enables a user-specified interrupt.

Bit	Bit Name	Initial Value	R/W	Description
12	ME	0	R/W	Memory Access Interrupt Enable Enables or disables an interrupt to be generated on completion of one frame of data access to external memory. 0: An interrupt is not generated on completion of one-frame data access to external memory. 1: An interrupt is generated on completion of one-frame data access to external memory.
11	MHE	0	R/W	Data Memory Read Interrupt Enable Enables or disables an interrupt to be generated on completion of one line of data access to the external memory. 0: An interrupt is not generated on completion of one-line data access to the external memory. 1: An interrupt is generated on completion of one-line data access to the external memory.
10	FE	0	R/W	Frame End Interrupt Enable Enables or disables an interrupt to be generated when the last pixel of a frame is output to the LCD. 0: Disables an interrupt when the last pixel of a frame is output to the LCD. 1: Enables an interrupt when the last pixel of a frame is output to the LCD.
9	VSE	0	R/W	VSYNC Start Interrupt Enable Enables or disables a VSYNC start interrupt to be generated. 0: A VSYNC start interrupt is not generated. 1: A VSYNC start interrupt is generated.
8	VEE	0	R/W	VSYNC End Interrupt Enable Enables or disables a VSYNC end interrupt to be generated. 0: A VSYNC end interrupt is not generated. 1: A VSYNC end interrupt is generated.
7	ES	0	R/W	Error Interrupt Status This bit is set to 1 when an error interrupt is generated. Write 0 to this bit to clear it.
6	SS	0	R/W	Frame Start Interrupt Status Indicates that a frame start interrupt has been generated. In one-shot mode, an interrupt is generated only for an output frame. Write 0 to this bit to clear it in the frame start interrupt handler. 0: Indicates that a frame start interrupt has not occurred or the interrupt handling has been completed. 1: Indicates that a frame start interrupt has occurred or the interrupt handling has not been completed.

Bit	Bit Name	Initial Value	R/W	Description
5	US	0	R/W	User-Specified Interrupt Status Indicates that a user-specified interrupt has been generated. Write 0 to this bit to clear it in the user-specified interrupt handler. 0: Indicates that a user-specified interrupt has not occurred or the interrupt handling has been completed. 1: Indicates that a user-specified interrupt has occurred or the interrupt handling has not been completed.
4	MS	0	R/W	Memory Access Interrupt Status Indicates that a frame end interrupt has been generated for access to external memory. Write 0 to this bit to clear it in the frame end interrupt handler of the external memory access. 0: Indicates that a frame-end interrupt for external memory access has not been generated or handling of the interrupt has been completed. 1: Indicates that an external memory access has been generated occurred or handling of the interrupt has not been completed.
3	MHS	0	R/W	Data Memory Read Interrupt Status Indicates that a line-end interrupt has been generated for access to external memory. Write 0 to this bit to clear it from in the line-end interrupt handler for the external memory access. 0: Indicates that an external memory access line end interrupt has not occurred or the interrupt handling has been completed. 1: Indicates that an external memory access line end interrupt has occurred or the interrupt handling has not been completed.

Bit	Bit Name	Initial Value	R/W	Description
2	FS	0	R/W	Frame End Interrupt Status Indicates that a frame end interrupt has been generated. In one-shot mode, an interrupt is generated only for an output frame. Write 0 to this bit to clear it in the frame end interrupt handler. 0: Indicates that a frame end interrupt has not occurred or the interrupt handling has been completed. 1: Indicates that a frame end interrupt has occurred or the interrupt handling has not been completed.
1	VSS	0	R/W	VSYNC Start Interrupt Status Indicates that a VSYNC start interrupt has been generated. Write 0 to this bit to clear it in the VSYNC end interrupt handler. 0: Indicates that a VSYNC start interrupt has not occurred or the interrupt handling has been completed. 1: Indicates that a VSYNC start interrupt has occurred or the interrupt handling has not been completed.
0	VES	0	R/W	VSYNC End Interrupt Status Indicates that a VSYNC end interrupt has been generated. Write 0 to this bit to clear it in the VSYNC end interrupt handler. 0: Indicates that a VSYNC end interrupt has not occurred or the interrupt handling has been completed. 1: Indicates that a VSYNC end interrupt has occurred or the interrupt handling has not been completed.

40.3.27 LCDC Status Register (LDSR)

LDSR indicates status related to the LCDC operations.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	MRLS[10:0]										
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	MSS	–	MRS	–	–	–	–	–	–	AS	ST
nitial :	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0.
26 to 16	MRLS[10:0]	H'000	R	Memory Read Line Status These bits indicate the number of lines, which have been read from external memory.
15 to 11	—	All 0	R	Reserved These bits are always read as 0.
10	MSS	1	R	Operating LCD Status Indicates which the LCDC is controlling. This bit is changed when one frame of display data is completed (when a frame end interrupt is generated). 0: LCD is in operation. 1: LCD is not in operation.
9	-	0	R	Reserved These bits are always read as 0.
8	MRS	0	R	LCD Register Set Status Indicates the register set of the LCD used by the LCDC. 0: Set A is used. 1: Set B is used.
7 to 2	—	All 0	R	Reserved These bits are always read as 0.
1	AS	0	R	SYS Interface Access Status Indicates the access status of the SYS interface. When the status indicates bus busy, do not issue the next transaction. Otherwise, operation is not guaranteed. 0: Bus idle 1: Bus busy (read or write access is being executed or is waiting)
0	ST	0	R	Indicates the LCDC operating status. 0: LCDC is idle. 1: LCDC is operating.

40.3.28 LCDC Control Register 1 (LDCNT1R)

LDCN1R specifies whether to output display data to an LCD during LCDC operation.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	DE
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DE	1	R/W	Display Enable Specifies whether to output display data to the LCD during LCDC operation. When only write-back operation is necessary, writing 0 to this bit fixes the data output to the LCD. 0: Does not output display data (fixes output data low or high). 1: Outputs display data.

40.3.29 LCDC Control Register 2 (LDCNT2R)

LDCNT2R specifies a reset and the display operation of the LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	SR	BR	–	–	–	–	–	–	ME	DO
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	SR	0	R/W	Software Reset Setting this bit to 1 initializes all internal circuitry of the LCDC other than registers. Bus transactions in progress at the time are guaranteed. However, when the LCDC is operating with the BEU, handshaking between them is not guaranteed. Even if handshaking is in progress, the LCDC is immediately initialized by a reset. Initialization by a software reset must be performed more than once. Thus, when the BEU and LCDC are operating together, the BEU should be initialized before a software reset is issued. Do not set both the SR bit and the BR bit to 1 at the same time. 0: LCDC is in normal operation. 1: Writing 1 initializes the LCDC.
8	BR	0	R/W	Module Reset Setting this bit to 1 initializes all internal circuitry of the LCDC other than registers. Bus transactions in progress at the time are guaranteed. However, when the LCDC is operating with the BEU, handshaking between them is not guaranteed. Even if handshaking is in progress, the LCDC is immediately initialized by a reset. Thus, when the BEU and LCDC are operating together, the BEU should be initialized before a software reset is issued. Do not set both the BR bit and the SR bit to 1 at the same time. 0: LCDC is in normal operation. 1: Writing 1 initializes the LCDC.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	ME	0	R/W	LCD Enable Enables or disables whether the LCDC operates the LCD while the display is turned on. When the ME bits is set to 1, the LCD is operated by time-division multiplexing. 0: LCDC does not operate the LCD. 1: LCDC operates the LCD.
0	DO	0	R/W	Display On Starts or stops the LCDC display operation. The state of the switching-on process can be read from the LPS bit in MLDPMR. When the DO bit is set to 1, set either ME, or SS bit to 1. 0: Stops the LCDC operation (display-off mode). 1: Starts the LCDC operation (display-on mode).

The display switching-on and switching-off sequences for the LCD are shown below.

- Display switching-on sequence (when changing the DO bit from 0 to 1)
  1. Start the LCDC display operation.
  2. Turn on the LCD power according to the method specified by MLDPMR and LDCNT2R.

  When a change from B'00 to B'11 in the LPS bit is confirmed, the switching-on sequence is completed.

  Do not access the DO bit until the completion of the sequence.

- Display switching-off sequence (when changing the DO bit from 1 to 0)

Note: Do not change the ME bit from 1.

1. Turn off the LCD power according to the method specified by MLDPMR and LDCNT2R.
2. Stop the LCDC display operation.

   When a change from B'11 to B'00 in the LPS bit is confirmed, the switching-off sequence is completed.

   Do not access the DO and ME bits until the completion of the sequence.

40.3.30 LCDC Register Set Change Control Register (LDRCNTR)

LDRCNTR specifies register sets of the LCD.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	MRS	MRC
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	MRS	0	R/W	LCD Register Set Select Selects the LCD register set the LCDC uses. Register sets are changed when display of one frame of data is completed. This bit is valid when the MRC bit is cleared to 0. 0: Set A registers are used for the LCD. 1: Set B registers are used for the LCD.
0	MRC	0	R/W	LCD Register Set Change Enable In synchronization with completion of frame display on the sub-LCD, selects the register set for use by the LCDC with the sub-LCD. If this bit is cleared (0), the register set selected by the SRS bit is used. When this bit is set to 1, the sets are toggled. 0: Register set is selected by the MRS bit. 1: Register set is toggled.

40.3.31 LCDC Input Image Data Swap Register (LDDDSR)

LDDDSR enables or disables byte, word, and longword swap on input image data.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	LS	WS	BS
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/S	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	LS	0	R/W	Input Image Data Longword Swap Select Enables or disables input image data to be swapped in longwords. This setting is valid for LCD. 0: Disables longword swap. 1: Enables longword swap.
1	WS	0	R/W	Input Image Data Word Swap Select Enables or disables input image data to be swapped in words. This setting is valid for LCD. 0: Disables word swap. 1: Enables word swap.
0	BS	0	R/W	Input Image Data Byte Swap Select Enables or disables input image data to be swapped in bytes. This setting is valid for LCD. 0: Disables byte swap. 1: Enables byte swap.

40.3.32 LCDC Register Set Forcible Select Register (LDRCR)

LDRCR immediately selects the register set when changing register sets.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	MR
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	MR	0	R/W	LCD Register Set Select Selects the LCD register set the LCDC uses. 0: Set A registers are used. 1: Set B registers are used.

40.3.33 Tabular Mode Register (LDDBSLMR)

LDDBSLMR specifies tabular mode or slider mode.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	DBM
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	SLM
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	DBM	0	R/W	Tabular Mode Select Tabular mode doubles display images horizontally and vertically. 0: Normal mode 1: Tabular mode Tabular mode cannot be used with slider mode.
15 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SLM	0	R/W	Slider Mode Select Slider mode slides display images horizontally and vertically. The area to be blanked by sliding is displayed in the background color. The amount to slide is specified in LDSLHPNR and LDSLVLNR. The background color is specified in LDSLRGBR. 0: Normal mode 1: Slider mode Slider mode cannot be used with tabular mode.

Note: Tabular mode and slider mode are intended to resize still images to smaller sizes.

40.3.34 Horizontal Slide Number Register (LDSLHPNR)

LDSLHPNR specifies the horizontal number of characters to slide in slider mode.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	HC2[7:0]							
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–							HC1[7:0]							
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	HC2	0	R/W	The area behind the number of characters set in HC2 is displayed in the background color after sliding images horizontally in slider mode.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	HC1	0	R/W	The area behind the number of characters set in HC1 is displayed in the background color after sliding images horizontally in slider mode. Normal images are displayed adjacent horizontally to the area.

Note: When specifying the numbers of characters (MLDHCNR.HDCN and SLDHCNR.HDCN), the values must include background-colored areas.

40.3.35 Vertical Slide Number Register (LDSLVLNR)

LDSLHPNR specifies the vertical number of lines to slide in slider mode.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	VL2[10:0]										
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–				VL1[10:0]										
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 16	VL2	0	R/W	The area behind the number of lines set in VL2 is displayed in the background color after sliding images vertically in slider mode.
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	VL1	0	R/W	The area behind the number of characters set in VL1 is displayed in the background color after sliding images vertically in slider mode. Normal images are displayed adjacent vertically to the area.

Note: When specifying the numbers of lines (MLDVLNR.VDLN and SLDVLNR.VDLN), the values must include background-colored areas.

40.3.36 Slide Data Register (LDSLRGBR)

LDSLRGBR specifies the background color in slider mode.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	RGB[23:16]							
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RGB[15:0]															
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	RGB	0	R/W	Specifies the background color in RGB888 format.

Note: 1. The overall background color is displayed when setting it to HC1==HC2 and VL1==VL2.
2. Please set the value in order of CrYCb when the output data form is YCbCr form.

40.3.37 LCD Horizontal Sync Signal Adjust Register (MLDHAJR)

MLDHAJR is a register for adjusting in 1-pixel unit the total horizontal width, the horizontal sync signal width, and the horizontal sync signal output point, which are usually specified in 8-pixel unit.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	HDCN_ADPIX[2:0]			–	–	–	–	–	HTCNAJ[2:0]		
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	HSYNWAJ[2:0]			–	–	–	–	–	HSYNPAJ[2:0]		
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 24	HDCN_ADPIX[2:0]	H'0	R/W	Specifies the display horizontal adjusting size. The display horizontal size is large only in this setting.
23 to 19	—	All 0	R/W	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
18 to 16	HTCNAJ [2:0]	H'0	R/W	Specifies the total horizontal adjusting size. The total horizontal size is large only in this setting.
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	HSYNWAJ [2:0]	H'0	R/W	Specifies the adjusting width horizontal sync signal. The total horizontal sync signal width is large only in this setting.
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	HSYNPAJ [2:0]	H'0	R/W	Specifies the adjusting size of the sync signal output point. The horizontal sync signal output point is delayed.

40.3.38 LCD Vertical Sync Signal Adjustment Register (MLDIVSNR

MLDIVSYNR is a register for setting the VSYNC output delay. This register is enabled when the VSSM bit in MLDMT1R register is 1.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	VSYNC_SLD[13:0]													
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VSYNC_SLD [13:0]	H'0000	R/W	Specifies the VSYNC output lagged

40.3.39 LCDC Color Palette Expander Control Register (LDPALECR)

LDPALECR is a register for controlling the color palette expander. This register is FIFO structure on current side/program side. Writing on a current side is reflected at once, please write it only for the period when LCD has stopped. When the UPD bit on the program side is 1, a set value on the program side is reflected in a current side according to the register reflection timing (display completion of one screen). For details of the settings, see section 40.4.2 Color Palette.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	UPD	UPF	AE	ASWP	–	–	–	–	–	–	–	–	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	AB	–	–	–	CB	–	–	–	–	–	–	–	MB
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R/W	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	UPD	0	R/W	Update permission bit Program side When one is set, a set value on the program side of the LDPALECR register and the LPPALADR register is reflected in a current side according to the register reflection timing. This bit is cleared by the set value reflection on a current side. It is cleared by writing 0. Current side It is always read as 0.
30	UPF	0	R/W	Update completion flag Program side When the register value is reflected in current side, 1 is set. It is cleared by writing 1. Even if 0 is written, the value is not changed. Current side It is always read as 0.
29	AE	0	R/W	Palette data automatic acquisition function operate Palette data is acquired from the address by setting LDPALADR, and stored in the bank by AB. Current side The automatic acquisition function starts at once when 1 is written (LDPALADR on a current side is used). When the acquisition of data is completed, it is cleared to 0. Program side The value of LDPALADR on the program side is copied onto a current side when UPD=1 and AE=1 are set, and the register reflection timing comes, AE bit on the current side is set, and the automatic acquisition function starts. The AE bit on the program side is cleared by the reflection on a current side. Note: Please judge timing that actual data acquisition is completed by AE bit on a current side though AE bit on the program side is cleared by the reflection on a current side.

Bit	Bit Name	Initial Value	R/W	Description
28	ASWP	0	R/W	Palette data swap 1: When the palette data is acquired automatically, data is swapped in each long word. 0: disables long word swapping
27～13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	AB	0	R/W	Palette bank that sets palette data automatically 0: The value is set to bank 0 by the automatic acquisition function. 1: The value is set to bank 1 by the automatic acquisition function.
11～9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CB	0	R/W	Palette bank that write to CPU and read from CPU 0: bank 0 1: bank 1
7～1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	MB	0	R/W	Palette bank to which LCD refers 0: bank 0 1: bank 1

40.3.40 LCDC Color Palette Address Register (LDPALADR)

LDPALADR specifies the address of color palette data. This register is FIFO structure on current side/program side. Writing on a current side is reflected at once, please write it only for the period when LCD has stopped. When the LDPALECR.UPD bit on the program side is 1, a set value on the program side is reflected in a current side according to the register reflection timing (display completion of one screen). For details of the settings, see section 40.4.2 Color Palette.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PALADR[31:16]															
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PALADR[15:0]															
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PALADR	H'0	R/W	Palette data start address

40.3.41 LCDC Driver Write Data Registers 0 to F (LDDWD0R to LDDWDFR)

LDDWDnR specifies the write data and the register select signal (LCDRS) polarity for the LCD driver.

For details on write data stored in the DWD bits such as bits used as a valid instruction, refer to the specifications for the LCD driver used.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	WDACT	–	–	–	RSW	–	–	–	–	–	–	DWD[17:16]	
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R/W	R	R	R	R/W	R	R	R	R	R	R	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DWD[15:0]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	WDACT	0	R/W	Data Write Select Selects whether write data set in the DWD bits is output when the SYS interface is used. 0: Write data in DWD is not output to the LCD driver. 1: Write data in DWD is output to the LCD driver.
27 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	RSW	0	R/W	Write Register Select Polarity Selects the polarity of the register select signal (LCDRS) when data is written to via the SYS interface by the CPU. 0: Register select signal is active low. 1: Register select signal is active high.
23 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17 to 0	DWD[17:0]	H'0	R/W	Write data These bits store data to be written to the LCD driver via the SYS interface.

40.3.42 LCDC Driver Read Data Register (LDDRDR)

LDDRDR specifies the read data and the register select signal (LCDRS) polarity for the LCD driver.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	RSR	–	–	–	–	–	–	DRD[17:16]	
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DRD[15:0]															
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	RSR	0	R/W	Read Register Select Polarity Selects the polarity of the register select signal (LCDRS) when data is read by the CPU via the SYS interface. 0: Register select signal is at the low level. 1: Register select signal is at the high level.
23 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17 to 0	DRD[17:0]	H'0 0000	R	Read Data These bits store data to be read from the LCD via the SYS interface.

40.3.43 LCDC Driver Write Access Register (LDDWAR)

The LCDC issues a write transaction to an LCD when the WA bit is set to 1. Data stored in the DWD bits in LDDWDnR in which the WDACT bit is set to 1 is used. The data is written to in the following order: LDDWD0R, LDDWD1R, LDDWD2R, when the WDACT bit is read as 0, the write access is stopped. If all the WDACT bits are read as 1, the write access is stopped when a write transaction of LDDWDFR is issued. Before a write transaction is issued, set the WDACT bit in LDDWD0R to 1. After the write transaction is issued, the WA bit is automatically cleared to 0.

Notes: 1. To issue a write transaction to an LCD via the SYS interface during display operation, the vertical blanking time must be equal to two lines or more.

2. To issue a write transaction, specify the vertical blanking time so that access to the LCD can be completed. If a write access is not completed within the vertical blanking time, the CA bit in LDINTR is set to 1.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	WA
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	WA	0	R/W	Write Transaction Issue Issues a write transaction. 0: — 1: A write transaction issued

40.3.44 LCDC Driver Read Access Register (LDDRAR)

The LCDC issues a read transaction to an LCD when the RA bit is set to 1. When this register is accessed, read data is stored in the DRD bits in LDDRDR.

Notes: 1. To issue a read transaction to an LCD via the SYS interface during display operation, the vertical blanking time must be equal to two lines or more.
2. To issue a read transaction, specify the vertical blanking time so that access to the LCD driver can be completed. If a write access is not completed within the vertical blanking time, the CA bit in LDINTR is set to 1.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	RA
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	RA	0	R/W	Read Transaction Issue Issues a read transaction. 0: — 1: A read transaction issued

40.3.45 LCDC RGB Coefficient Register for Color Management Matrix R (LDCMRKRGBR)

LDCMRKRGBR specifies the coefficient RGBCMY of color management matrix R.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	CMRKR[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMPKG[6:0]							–	CMRKB[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMRKR[6:0]	H'0	R/W	Coefficient R for color management RGBCMY matrix R These bits specify the R signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMRKG[6:0]	H'0	R/W	Coefficient G for color management RGBCMY matrix R These bits specify the G signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMRKB[6:0]	H'0	R/W	Coefficient B for color management RGBCMY matrix R These bits specify the B signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63

40.3.46 LCDC CMY Coefficient Register for Color Management Matrix R (LDCMRKCMYR)

LDCMRKCMYR specifies the coefficient RGBCMY of color management matrix R.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	CMRKC[6:0]							–	CMRKM[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMPKY[6:0]							–	CMRKW[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
30 to 24	CMRKC[6:0]	H'0	R/W	Coefficient C for color management RGBCMY matrix R These bits specify the C signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMRKM[6:0]	H'0	R/W	Coefficient M for color management RGBCMY matrix R These bits specify the M signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMRKY[6:0]	H'0	R/W	Coefficient Y for color management RGBCMY matrix R These bits specify the Y signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMRKW[6:0]	H'0	R/W	Coefficient W for color management RGBCMY matrix R These bits specify the W signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63

40.3.47 LCDC Coefficient of Hue Circle Register 1 for Color Management Matrix R (LDCMRK1R)

LDCMRK1R specifies the coefficient of hue circle for color management matrix R.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	CMRK0[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMRK1[6:0]							–	CMRK2[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMRK0[6:0]	H'0	R/W	Coefficient 0 for color management hue circle matrix R These bits specify the R signal correction value for displaying the color included in hue circle region 0. The MSB indicates the sign (0: positive ; 1: negative). Hue region 0 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMRK1[6:0]	H'0	R/W	Coefficient 1 for color management hue circle matrix R These bits specify the R signal correction value for displaying the color included in hue circle region 1. The MSB indicates the sign (0: positive ; 1: negative). Hue region 1 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMRK2[6:0]	H'0	R/W	Coefficient 2 for color management hue circle matrix R These bits specify the R signal correction value for displaying the color included in hue circle region 2. The MSB indicates the sign (0: positive ; 1: negative). Hue region 2 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63

40.3.48 LCDC Coefficient of Hue Circle Register 2 for Color Management Matrix R (LDCMRK2R)

LDCMRK2R specifies the coefficient of hue circle for color management matrix R.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	CMRK3[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMRK4[6:0]							–	CMRK5[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMRK3[6:0]	H'0	R/W	Coefficient 3 for color management hue circle matrix R These bits specify the R signal correction value for displaying the color included in hue circle region 3. The MSB indicates the sign (0: positive ; 1: negative). Hue region 3 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMRK4[6:0]	H'0	R/W	Coefficient 4 for color management hue circle matrix R These bits specify the R signal correction value for displaying the color included in hue circle region 4. The MSB indicates the sign (0: positive ; 1: negative). Hue region 4 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMRK5[6:0]	H'0	R/W	Coefficient 5 for color management hue circle matrix R These bits specify the R signal correction value for displaying the color included in hue circle region 5. The MSB indicates the sign (0: positive ; 1: negative). Hue region 5 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63

40.3.49 LCDC RGB Coefficient Register for Color Management Matrix G (LDCMGKRGBR)

LDCMGKRGBR specifies the coefficient RGBCMY of color management matrix G.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	CMGKR[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMGKG[6:0]							–	CMGKB[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMGKR[6:0]	H'0	R/W	Coefficient R for color management RGBCMY matrix G These bits specify the R signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMGKG[6:0]	H'0	R/W	Coefficient G for color management RGBCMY matrix G These bits specify the G signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMGKB[6:0]	H'0	R/W	Coefficient B for color management RGBCMY matrix G These bits specify the B signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63

40.3.50 LCDC CMY Coefficient Register for Color Management Matrix G (LDCMGKCMYR)

LDCMGKCMYR specifies the coefficient RGBCMY of color management matrix G.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	CMGKC[6:0]							–	CMGKM[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMGKY[6:0]							–	CMGKW[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
30 to 24	CMGKC[6:0]	H'0	R/W	Coefficient C for color management RGBCMY matrix G These bits specify the C signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMGKM[6:0]	H'0	R/W	Coefficient M for color management RGBCMY matrix G These bits specify the M signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMGKY[6:0]	H'0	R/W	Coefficient Y for color management RGBCMY matrix G These bits specify the Y signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMGKW[6:0]	H'0	R/W	Coefficient W for color management RGBCMY matrix G These bits specify the W signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63

40.3.51 LCDC Coefficient of Hue Circle Register 1 for Color Management Matrix G (LDCMGK1R)

LDCMGK1R specifies the coefficient for color management hue circle matrix G.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	CMGK0[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMGK1[6:0]							–	CMGK2[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMGK0[6:0]	H'0	R/W	Coefficient 0 for color management hue circle matrix G These bits specify the G signal correction value for displaying the color included in hue circle region 0. The MSB indicates the sign (0: positive ; 1: negative). Hue region 0 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMGK1[6:0]	H'0	R/W	Coefficient 1 for color management hue circle matrix G These bits specify the G signal correction value for displaying the color included in hue circle region 1. The MSB indicates the sign (0: positive ; 1: negative). Hue region 1 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMGK2[6:0]	H'0	R/W	Coefficient 2 for color management hue circle matrix G These bits specify the G signal correction value for displaying the color included in hue circle region 2. The MSB indicates the sign (0: positive ; 1: negative). Hue region 2 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63

40.3.52 LCDC Coefficient of Hue Circle Register 2 for Color Management Matrix G (LDCMGK2R)

LDCMGK2R specifies the coefficient for color management hue circle matrix G.

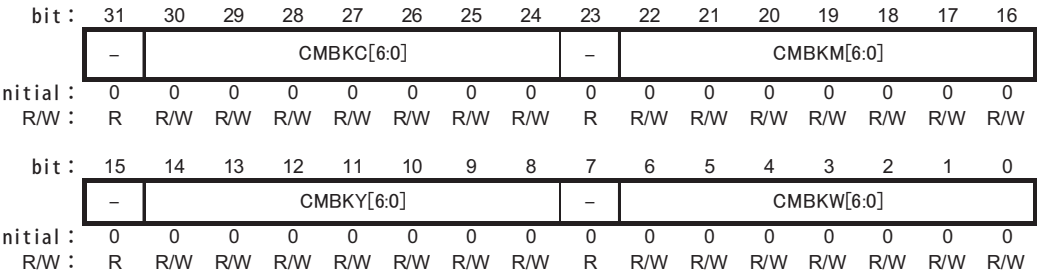
bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	CMGK3[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMGK4[6:0]							–	CMGK5[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMGK3[6:0]	H'0	R/W	Coefficient 3 for color management hue circle matrix G These bits specify the G signal correction value for displaying the color included in hue circle region 3. The MSB indicates the sign (0: positive ; 1: negative). Hue region 3 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMGK4[6:0]	H'0	R/W	Coefficient 4 for color management hue circle matrix G These bits specify the G signal correction value for displaying the color included in hue circle region 4. The MSB indicates the sign (0: positive ; 1: negative). Hue region 4 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMGK5[6:0]	H'0	R/W	Coefficient 5 for color management hue circle matrix G These bits specify the G signal correction value for displaying the color included in hue circle region 5. The MSB indicates the sign (0: positive ; 1: negative). Hue region 5 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63

40.3.53 LCDC RGB Coefficient Register for Color Management Matrix B (LDCMBKRGBR)

LDCMBKRGBR specifies the coefficient RGBCMY of color management matrix B.



bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	CMBKR[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMBKG[6:0]							–	CMBKB[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMBKR[6:0]	H'0	R/W	Coefficient R for color management RGBCMY matrix G These bits specify the R signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMBKG[6:0]	H'0	R/W	Coefficient G for color management RGBCMY matrix B These bits specify the G signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMBKB[6:0]	H'0	R/W	Coefficient B for color management RGBCMY matrix B These bits specify the B signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63

40.3.54 LCDC CMY Coefficient Register for Color Management Matrix B (LDCMBKCMYR)

LDCMRKCMYR specifies the coefficient RGBCMY of color management matrix B.

Bit	Bit Name	Initial Value	R/W	Description
31	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
30 to 24	CMBKC[6:0]	H'0	R/W	Coefficient C for color management RGBCMY matrix B These bits specify the C signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMBKM[6:0]	H'0	R/W	Coefficient M for color management RGBCMY matrix B These bits specify the M signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMBKY[6:0]	H'0	R/W	Coefficient Y for color management RGBCMY matrix B These bits specify the Y signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMBKW[6:0]	H'0	R/W	Coefficient W for color management RGBCMY matrix B These bits specify the W signal correction value for displaying red. The MSB indicates the sign (0: positive ; 1: negative). Specifiable value: -63 to +63

40.3.55 LCDC Coefficient of Hue Circle Register 1 for Color Management Matrix B (LDCMBK1R)

LDCMBK1R specifies the coefficient of hue circle for color management matrix B.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	CMBK0[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMBK1[6:0]							–	CMBK2[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMBK0[6:0]	H'0	R/W	Coefficient 0 for color management hue circle matrix B These bits specify the B signal correction value for displaying the color included in hue circle region 0. The MSB indicates the sign (0: positive ; 1: negative). Hue region 0 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMBK1[6:0]	H'0	R/W	Coefficient 1 for color management hue circle matrix B These bits specify the B signal correction value for displaying the color included in hue circle region 1. The MSB indicates the sign (0: positive ; 1: negative). Hue region 1 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMBK2[6:0]	H'0	R/W	Coefficient 2 for color management hue circle matrix B These bits specify the B signal correction value for displaying the color included in hue circle region 2. The MSB indicates the sign (0: positive ; 1: negative). Hue region 2 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63

40.3.56 LCDC Coefficient of Hue Circle Register 2 for Color Management Matrix B (LDCMBK2R)

LDCMBK2R specifies the coefficient for color management hue circle matrix B.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	CMBK3[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	CMBK4[6:0]							–	CMBK5[6:0]						
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	CMBK3[6:0]	H'0	R/W	Coefficient 3 for color management hue circle matrix B These bits specify the B signal correction value for displaying the color included in hue circle region 3. The MSB indicates the sign (0: positive ; 1: negative). Hue region 3 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 8	CMBK4[6:0]	H'0	R/W	Coefficient 4 for color management hue circle matrix B These bits specify the B signal correction value for displaying the color included in hue circle region 4. The MSB indicates the sign (0: positive ; 1: negative). Hue region 4 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	CMBK5[6:0]	H'0	R/W	Coefficient 5 for color management hue circle matrix B These bits specify the B signal correction value for displaying the color included in hue circle region 5. The MSB indicates the sign (0: positive ; 1: negative). Hue region 5 is a region between two of the six hues(red, yellow, green, cyan, blue, and magenta) and is selected bye the CMSEL bit setting in LDCMSELR. Specifiable value: -63 to +63

40.3.57 LCDC Hue Circle Peak Correction Coefficient Register 1 for Color Management (LDCMHKPR)

LDCMHKPR specifies the hue peak correction coefficients.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	CMHKP0[3:0]				CMHKP1[3:0]				CMHKP2[3:0]			
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	CMHKP3[3:0]				CMHKP4[3:0]				CMHKP5[3:0]			
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 24	CMHKP0[3:0]	H'0	R/W	Hue peak correction coefficient 0 for color management These bits in combination with the CMHKQ0 bits in LDCMHKQR specify the color that produces best correction results in hue region 0. hue region 0 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.
23 to 20	CMHKP1[3:0]	0	R/W	Hue peak correction coefficient 1 for color management These bits in combination with the CMHKQ1 bits in LDCMHKQR specify the color that produces best correction results in hue region 1. Hue region 1 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.
19 to 16	CMHKP2[3:0]	H'0	R/W	Hue peak correction coefficient 2 for color management These bits in combination with the CMHKQ2 bits in LDCMHKQR specify the color that produces best correction results in hue region 2. Hue region 2 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	CMHKP3[3:0]	H'0	R/W	Hue peak correction coefficient 3 for color management These bits in combination with the CMHKQ3 bits in LDCMHKQR specify the color that produces best correction results in hue region 3. Hue region 3 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	CMHKP4[3:0]	H'0	R/W	Hue peak correction coefficient 4 for color management These bits in combination with the CMHKQ4 bits in LDCMHKQR specify the color that produces best correction results in hue region 4. Hue region 4 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.
3 to 0	CMHKP5[3:0]	H'0	R/W	Hue peak correction coefficient 5 for color management These bits in combination with the CMHKQ5 bits in LDCMHKQR specify the color that produces best correction results in hue region 5. Hue region 5 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.

40.3.58 LCDC Hue Circle Peak Correction Coefficient Register 2 for Color Management (LDCMHKQR)

LDCMHKQR specifies the hue peak correction coefficients.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	CMHKQ0[3:0]				CMHKQ1[3:0]				CMHKQ2[3:0]			
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	CMHKQ3[3:0]				CMHKQ4[3:0]				CMHKQ5[3:0]			
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 24	CMHKQ0[3:0]	H'0	R/W	Hue peak correction coefficient 6 for color management These bits in combination with the CMHKQ0 bits in LDCMHKQR specify the color that produces best correction results in hue region 0. hue region 0 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.
23 to 20	CMHKQ1[3:0]	0	R/W	Hue peak correction coefficient 7 for color management These bits in combination with the CMHKQ1 bits in LDCMHKQR specify the color that produces best correction results in hue region 1. Hue region 1 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.
19 to 6	CMHKQ2[3:0]	H'0	R/W	Hue peak correction coefficient 8 for color management These bits in combination with the CMHKQ2 bits in LDCMHKQR specify the color that produces best correction results in hue region 2. Hue region 2 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	CMHKQ3[3:0]	H'0	R/W	Hue peak correction coefficient 9 for color management These bits in combination with the CMHKQ3 bits in LDCMHKQR specify the color that produces best correction results in hue region 3. Hue region 3 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.
7 to 4	CMHKP4[3:0]	H'0	R/W	Hue peak correction coefficient 10 for color management These bits in combination with the CMHKQ4 bits in LDCMHKQR specify the color that produces best correction results in hue region 4. Hue region 4 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.
3 to 0	CMHKP5[3:0]	H'0	R/W	Hue peak correction coefficient 11 for color management These bits in combination with the CMHKQ5 bits in LDCMHKQR specify the color that produces best correction results in hue region 5. Hue region 5 is a region between two of the six hues (red, yellow, green, cyan, blue, and magenta) and is selected by the CMSEL bit setting in LDCMSELR.

40.3.59 LCDC Multiplication Coefficient Select Register for Color Management (LDCMSELR)

LDCMSELR selects multiplication coefficients.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	CMSEL0[2:0]			–	CMSEL1[2:0]			–	CMSEL2[2:0]		
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	CMSEL3[2:0]			–	CMSEL4[2:0]			–	CMSEL5[2:0]		
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 24	CMSEL0 [2:0]	H'0	R/W	Coefficient select 0 for color management These bits select the color for hue region 0 among the six hues (red, yellow, green, cyan, blue, and magenta). CMxK0, CMHKP0, and CMHKQ0 are enabled in hue region 0.
23	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 20	CMSEL1 [2:0]	H'0	R/W	Coefficient select 1 for color management These bits select the color for hue region 1 among the six hues (red, yellow, green, cyan, blue, and magenta). CMxK1, CMHKP1, and CMHKQ1 are enabled in hue region 1.
19	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
18 to 16	CMSEL2 [2:0]	H'0	R/W	Coefficient select 2 for color management These bits select the color for hue region 2 among the six hues (red, yellow, green, cyan, blue, and magenta). CMxK2, CMHKP2, and CMHKQ2 are enabled in hue region 2.
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	CMSEL3 [2:0]	H'0	R/W	Coefficient select 3 for color management These bits select the color for hue region 3 among the six hues (red, yellow, green, cyan, blue, and magenta). CMxK3, CMHKP3, and CMHKQ3 are enabled in hue region 3.

Bit	Bit Name	Initial Value	R/W	Description
7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 4	CMSEL4 [2:0]	H'0	R/W	Coefficient select 4 for color management These bits select the color for hue region 4 among the six hues (red, yellow, green, cyan, blue, and magenta). CMxK4, CMHKP4, and CMHKQ4 are enabled in hue region 4.
3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	CMSEL5 [2:0]	H'0	R/W	Coefficient select 5 for color management These bits select the color for hue region 5 among the six hues (red, yellow, green, cyan, blue, and magenta). CMxK5, CMHKP5, and CMHKQ5 are enabled in hue region 5.

40.3.60 LCDC Color Saturation Improvement Register for Color Management (LDCMTVR)

LDCMTVR specifies color saturation improvement processing and pixel property.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	CMINC1[5:0]						–	–	CMINC2[5:0]					
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMTH1[3:0]				CMTH2[3:0]				–	–	–	–	–	–	CMYSEL[1:0]	
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 24	CMINC1[5:0]	H'0	R/W	Dark part inclination for color saturation improvement in color management These bits specify the dark part inclination for color saturation improvement in color management. Upper 3 bits specify the integral part and lower 3 bits specify the decimal part.
23 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
21 to 16	CMINC2[5:0]	H'0	R/W	Light part inclination for color saturation improvement in color management These bits specify the light part inclination for color saturation improvement in color management. Upper 3 bits specify the integral part and lower 3 bits specify the decimal part.
15 to 12	CMTH1[3:0]	H'0	R/W	Dark section threshold for color saturation improvement in color management These bits specify the dark section threshold parameter for color saturation improvement in color management.
11 to 8	CMTH2[3:0]	H'0	R/W	Light section threshold for color saturation improvement in color management These bits specify the light section threshold parameter for color saturation improvement in color management.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1 to 0	CMYSEL[1:0]	H'0	R/W	Pixel property select for color saturation improvement in color management These bits select the pixel property for color saturation improvement in color management 00: largest value among R, G, and B 01: largest value - smallest value among R, G, and B 10: largest value - smallest value/2 among R, G and B 11: largest value - smallest value/2 among R, G and B

40.3.61 LCDC Color Saturation Improvement Select Register for Color Management (LDCMTVSELR)

LDCMTVSELR enables or disables color saturation improvement.

Bit	Bit Name	Initial Value	R/W	Description
31	UPD	0	R/W	Register set (CM) related to the color management does the FIFO structure on a current side and the program side. When the UPD bit on the program side is 1, a set value on the program side is reflected in a current side according to the register reflection timing. Program side When 1 is set in this bit, the reflection on a current side from the program side is permitted. It is cleared automatically by the reflection on a current side. When 0 is set, permission is withdrawn. Current side The value of the UPD bit on the program side at the register reflection timing is reflected and displayed. There is no influence in operation.
30 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CMTHRU	0	R/W	Color management through mode Enables or disables color management 0: disables color management (through output) 1: enables color management

40.4 Operation

40.4.1 LCDC Display Features

- Supported LCD Module
  TFT panel. The RGB interface and 80-Series CPU bus interface (SYS interface) are supported as the module interface.
- Display Colors
  16,777,215 colors max. (24-bit colors)
- Display Color Control
  Each of RGB, it is corresponding to 8-bit data input and 8-bit output the built-in palette memory (two banks).
  The 256-entry palette memory supports 24-bit input and 24-bit output.
- Data Polarity Inversion
  The polarity of the RGB interface signals can be inverted. Display data can also be inverted.

40.4.2 Color Palette Specifications

The LCDC has a color palette function that it is possible to define 8-bit input/output data each of RGB. The palette memory is built into two banks, and the definition of two sets can be retained.

The bank to which LCD refers is set by the LDPALECR.MB bit.

The color palette can be set with CPU and the external memory.

The method of doing with CPU

The color palette must be specified while the LCDC is not operated.

1. set LDPALCR.PE to 1 : the color palette set mode is entered.
2. set LDPALECR.CB to 0, and set bank 0
3. access LDPRnn (nn = H'00~H'FF), and set the data to PALDnn
4. set LDPALECR.CB to 1, and set bank 1
5. access LDPRnn (nn = H'00~H'FF), and set the data to PALDnn
6. set LDPALCR.PE to 0 : the normal display mode is returned.

Figure 40.6 shows a data format of the color palette.

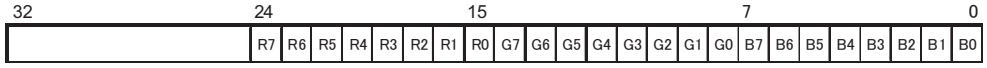

Figure 40.6 Data Format of Color Palette

For PALDnn bits in LDPRnn, bits 23 to 16 correspond to R data, bits 15 to 8 correspond to G data, and bits 7 to 0 correspond to B data. Bits 31 to 24 are reserved.

The setting data from the external memory (the automatic acquisition function)

Please arrange the data which has 256 entries continuously according to Figure 40.6 color palette data format on the external memory. Please make data on the memory as an array of data every 4-bytes, set LDPALECR.ASWP to 1 for the little endian.

Set start address register LDPALADR, and set the bank register LDPALECR.AB, the automatic acquisition function starts at once when 1 is written to LDPALECR.AE. When the acquisition of data is completed, LDPALECR.AE is cleared to 0. Set another bank or another set value is acquired from the same bank, please do it after confirming the AE bit is cleared.

The method of used two side register

LDPALECR and LDPALADR have a two-structure on current side/program side. Please set the value for the period when LCD has stopped on current side. Set the value to the program side when LCD operates, and set 1 to LDPALECR.UPD(program side). The value is reflected in a current side according to the register reflection timing (one screen display is completed).

LDPALECR.AE on program side is cleared when the reflection on current side is done. Actually the acquisition of the palette data is completed when the following display is completed and the AE on current side is cleared according to this timing.

40.4.3 Display Timing Control

The display timing control is specified by the horizontal character number registers (MLDHCNR and SLDHCNR), horizontal sync signal registers (MLDHSYNR and SLDHSYNR), vertical line number registers (MLDVLNR and SLDVLNR), and vertical sync signal registers (MLDVSYNR and SLDVSYNR).

The LCDC dot clock register (LDDCKR) specifies the division ratio. The frame rate of an LCD module is determined by the following factors: the display size and blanking period for a screen, the clock frequency used, and the division ratio.

The LCDC can generate an interrupt when the last pixel data of a frame is output after one frame of data has been read from memory. An interrupt can also be generated at intervals of user-specified lines. The LCDC interrupt register (LDINTR) specifies these settings.

40.4.4 One-Shot Mode

The LCDC supports the one-shot mode in which display data is read depending on the frame rate of the display image.

Examples and notes for use are shown in below.

- Usage example 1
  1. Clear the OS bit in MLDSM1R to 0: continuous mode (initial value) is selected.
  2. Set to the OS bit to 1: a transition to the one-shot mode is made.
  3. Set the OSTRG bit in MLDSM2R to 1 when the image should be displayed: one frame of display data is read.
  4. Repeat step 3.
  5. Clear the OS bit to 0: the continuous mode is returned.

- Usage example 2: When continuously reading display data in one-shot mode
  1. Clear the OS bit in MLDSM1R to 0: continuous mode (initial value) is selected.
  2. Set to the OS bit to 1: a transition to the one-shot mode is made.
  3. Read the frame end interrupt status bit (FS) in LDINTR.
  4. When the FS bit is read as 1, set the OSTRG bit in MLDSM2R to 1: one frame of display data is read.
  5. Clear the FS bit to 0: the frame end interrupt status is cleared.
  6. Repeat steps 3 to 5.
  7. Clear the OS bit to 0: continuous mode is returned.

Note: When an offset (other than a value of H'F) is specified in the ONA, ONB, or ONC bits in MLDPMR, the trigger must be output first. The image data corresponding to the frame is not output.

40.4.5 Partial Screen Mode

The LCDC supports the partial screen mode in which display data only for an area to be updated is read.

Examples and notes for use are shown below.

1. Specify the size of the partial screen through MLDHPDR and MLDVPDR.
2. Clear the PRD bit in MLDSM1R to 0 and set the OS bit to 1: full screen size in one-shot mode.
3. Set the DO bit in LDCNT2R to 1: the LCDC is started.
4. Display data for the full screen size is read in one-shot mode.
5. To use the partial screen mode, set both the PRD and OS bits to 1 while display data is not being read: partial screen in one-shot mode.
6. Set the OSTRG bit in MLDSM2R to 1: display data for the partial screen size is read.
7. Repeat step 6.
8. Clear the PRD bit to 0 and set the OS bit to 1: the full screen size in one-shot mode.

Notes: 1. The screen size obtained from the partial screen size + offset specified in MLDHPDR and MLDVPDR must not exceed the full screen size.
2. Screen size change (a transition between full screen size and partial screen size modes or change of the partial screen sizes) cannot be used in the continuous mode. Read screen sizes can be changed only while the LCDC is stopped (the LPS bits in MLDPMR are cleared to B'00) or while display data is not being read in the one-shot mode.

40.4.6 Power Management Function

The power management function for the LCD is shown below.

Most LCD modules require particular sequences to turn the power on and off. In the LCDC, the LCD power management register (MLDPMMR), LCDC control register 1 (LDCNT1R), and LCDC control register 2 (LDCNT2R) can be specified to control the LCD power supply control pins (LCDVCPWC, LCDVEPWC, and LCDDON) and execute various power control sequences using these pins. Figure 40.7 shows an example of a timing chart for switching-on and switching-off sequences.

The power management function can be used only when the LCDC is in stand-alone operation. The setting of the power management function for the LCD currently not used must be off (MLDPMR = 0 or SLDPMR = 0).

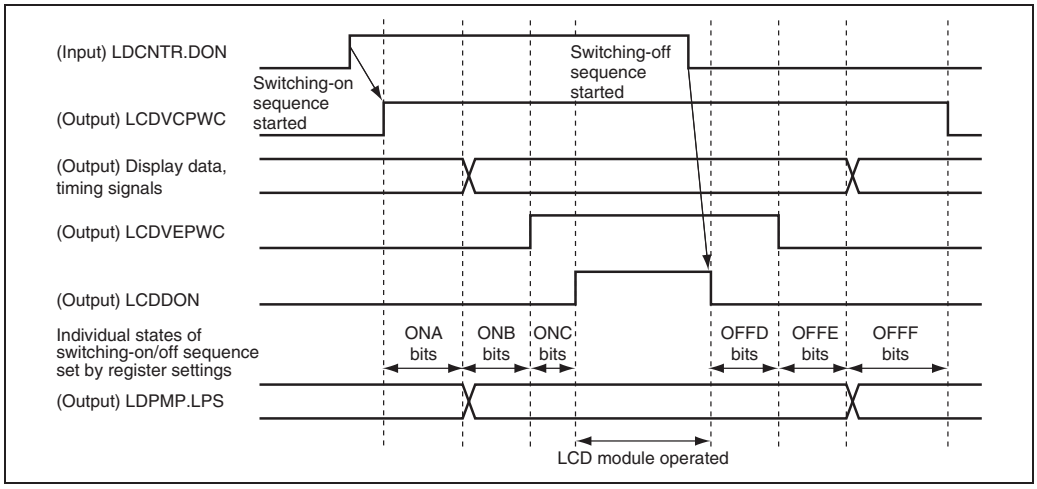

Figure 40.7 Switching-On and -Off Sequences and the LCD Module Operating State

40.4.7 Dot Clock Settings

Setting the dot clock is described. Figure 40.8 shows an example of a dot clock pattern to make the refresh rate 55 MHz. In this example, registers are set to a 33-MHz source clock, 304 dots in the horizontal direction (the HTCN bits in MLDHCNR), and 330 lines in the total vertical direction (the VTLN bit in MLDVLNR). When two or three times transfer mode is used, specify the registers so that the dot clock is two or three times the refresh rate.

The registers to set the dot clock (LDDCKR, MLDDCKPAT1R, and MLDDCKPAT2R) must be accessed while the LCDC stops the operation. Otherwise, the operation is not guaranteed.

33 MHz ÷ (304 × 330 × 55 MHz) = 5.98 ≈ 6 → Specify the division ratio to 10/60.

The MDCDR bits in LDDCKR = H'3C

The DCKPAT1 bits in MLDDCKPAT1R = H'1C71C71

The DCKPAT1 bits in MLDDCKPAT2R = H'C71C71C7

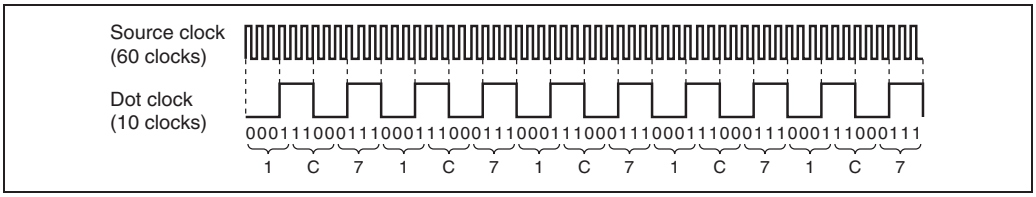

Figure 40.8 Example of Dot Clock Pattern

Note: For the source clock of the dot clock, the bus clock, the peripheral clock, or LRCKR setting clock can be selected. When selecting a clock other than the bus clock, select it so that its frequency is lower than that of the bus clock. (Setting the clock ratio to 1:1 is prohibited.)

40.4.8 Color Management

The LCDC includes a color management unit that supports the functions listed below and enables non-linear color conversions well-suited to the characteristics of the LCD module.

- Enhanced color reproducibility
- Capability for adjusting a hue of interest without affecting other hue.
- Improved color saturation in high-chroma spots

(1) Register setting

The registers of color management have a register set on current side and program side. It is reflected at once when the value on current side is updated, don’t change the value on current side when LCD operates. Please set 1 to LDCMCNTR.UPD after setting the value to program side. The setting on program side is reflected in current side according to the next register reflection timing.

LDCMCNTR.UPD on program side is cleared by 0 automatically when the value is reflected in current side. It clears to 0 by writing 0. After UPD is set to 1, change set value on program side before it reflects, clear it to 0.

UPD on program side is copied and the UPD on current side is expressed as register reflection timing.

(2) Color adjustment functional block

The color adjustment functional block, which enables the adjusting of a hue of interest without affecting any other hues, can flexibly reproduce a wide variety of color conversion characteristics. In addition, computations using data on regions between six hues permit the execution of color transform processing without the risk of a narrowed color reproducibility range.

Matrix computations are performed using the following equation:

$$\begin{bmatrix} Ro \\ Go \\ Bo \end{bmatrix} = \begin{bmatrix} Ri \\ Gi \\ Bi \end{bmatrix} + \begin{bmatrix} cmrkr & cmrkg & cmrkb & cmrkc & cmrkm & cmrky & cmrk\ 0 & \cdots & cmrk\ 5 & cmrkw \\ cmgkr & cmgkg & cmgkb & cmgkc & cmgkm & cmgky & cmgk\ 0 & \cdots & cmgk\ 5 & cmgkw \\ cmbkr & cmbkg & cmbkb & cmbkc & cmbkm & cmbky & cmbk\ 0 & \cdots & cmbk\ 5 & cmbkw \end{bmatrix} \begin{bmatrix} \Delta r \\ \Delta g \\ \Delta b \\ \Delta c \\ \Delta m \\ \Delta y \\ \Delta ih\ 0 \\ \Delta ih\ 1 \\ \Delta ih\ 2 \\ \Delta ih\ 3 \\ \Delta ih\ 4 \\ \Delta ih\ 5 \\ wh \end{bmatrix}$$

Ri, Gi, Bi: input data

Ro, Go, Bo: output data

△r, △g, △b, △c, △m, △y: hue region data valid for red, green, blue, cyan, magenta and yellow respectively

△ih0, △ih1, △ih2, △ih3, △ih4, △ih5: hue region data valid for any of 6 hue regions: red-yellow, yellow-green, green-cyan, cyan-blue, blue-magenta and magenta-red

wh: achromatic color component

(a) Selection of Hue coefficients

Depending on the values assigned to CMSEL0 to CMSEL5 (LDCMSELR), hue regions 0 to 5 are configured as shown in figure 40.9.

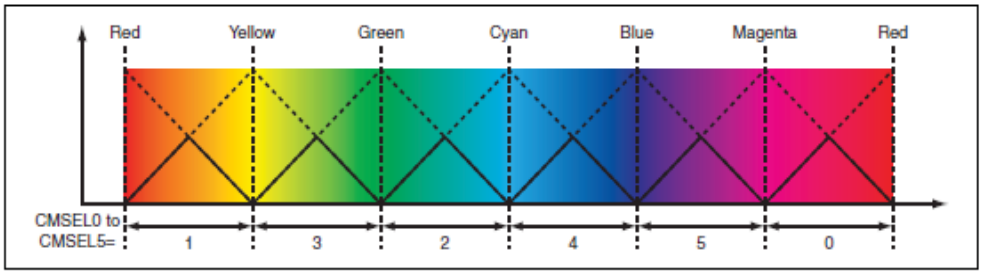

Figure 40.9 Relationship between Values Assigned to CMSEL0 to CMSEL5 (LDCMSELR) and Six Hue Regions that are selected

Select matrix coefficients (for using between hues LDCMxK1R, CDCMxK2R(x=R, G, B)) and hue peak correction coefficients (LDCMHKPR, LDCMHKQR) to be used in matrix computations according to the values of CMSEL0 to CMSEL5 (LDCMSELR), as shown in tables 40.10 and 40.11.

Table 40.10 selecting a hue coefficient and hue peak correction coefficient (1)

	CMSEL0～2（LDCMSELR）							
	1	3	2	4	5	0	6	7
CMxK0～2（LDCMxK1R LDCMxK2R）	coefficient of R-Y(RY)	coefficient of G-Y (GY)	coefficient of G-C(GC)	coefficient of B-C(BC)	coefficient of B-M(BM)	coefficient of R～M(RM)	0	0

CMHKQ0～2（LDCMHKQR）	shift the peak value of R-Y toward R (RYR1)	shift the peak value of G-Y toward G (GYG1)	shift the peak value of G-C toward G (GCG1)	shift the peak value of B-C toward B (BCB1)	shift the peak value of B-M toward B (BMB1)	shift the peak value of R-M toward R (RMR1)	don't care	don't care

Note: x = R, G, B

Table 40.11 selection hue coefficient and hue peak correction coefficient (2)

	CMSEL3～5（LDCMSELR）							
	1	3	2	4	5	0	6	7
CMxK3～5（LDCMxK1R、LDCMxK2R）	coefficient of R-Y(RY)	coefficient of G-Y (GY)	coefficient of G-C(GC)	coefficient of B-C(BC)	coefficient of B-M(BM)	coefficient of R～M(RM)	0	0
CMHKP3～5（LDCMHKPR）	shift the peak value of R-Y toward Y (RYY2)	shift the peak value of G-Y toward Y (GYY2)	shift the peak value of G-C toward C (GCC2)	shift the peak value of B-C toward C (BCC2)	shift the peak value of B-M toward M (BMM2)	shift the peak value of R-M toward M (RMM2)	don't care	don't care
CMHKQ3～5（LDCMHKQR）	shift the peak value of R-Y toward R (RYR2)	shift the peak value of G-Y toward G (GYG2)	shift the peak value of G-C toward G (GCG2)	shift the peak value of B-C toward B (BCB2)	shift the peak value of B-M toward B (BMB2)	shift the peak value of R-M toward R (RMR2)	don't care	don't care

Notes: 1. x= R, G, B

2. The corresponding values of CMSEL0 to CMSEL2 should be distinct from those of CMSEL3 to CMSEL5.

3. The maximum number of coefficients that can be assigned to hue region is two (one each from CMSEL0 to CMSEL2 and CMSEL3 to CMSEL5).

(b) Hue region data

The six hue region data items, △r, △g, △b, △c, △m, and △y are valid only for red, green, blue, cyan, magenta, and yellow hue regions, respectively.

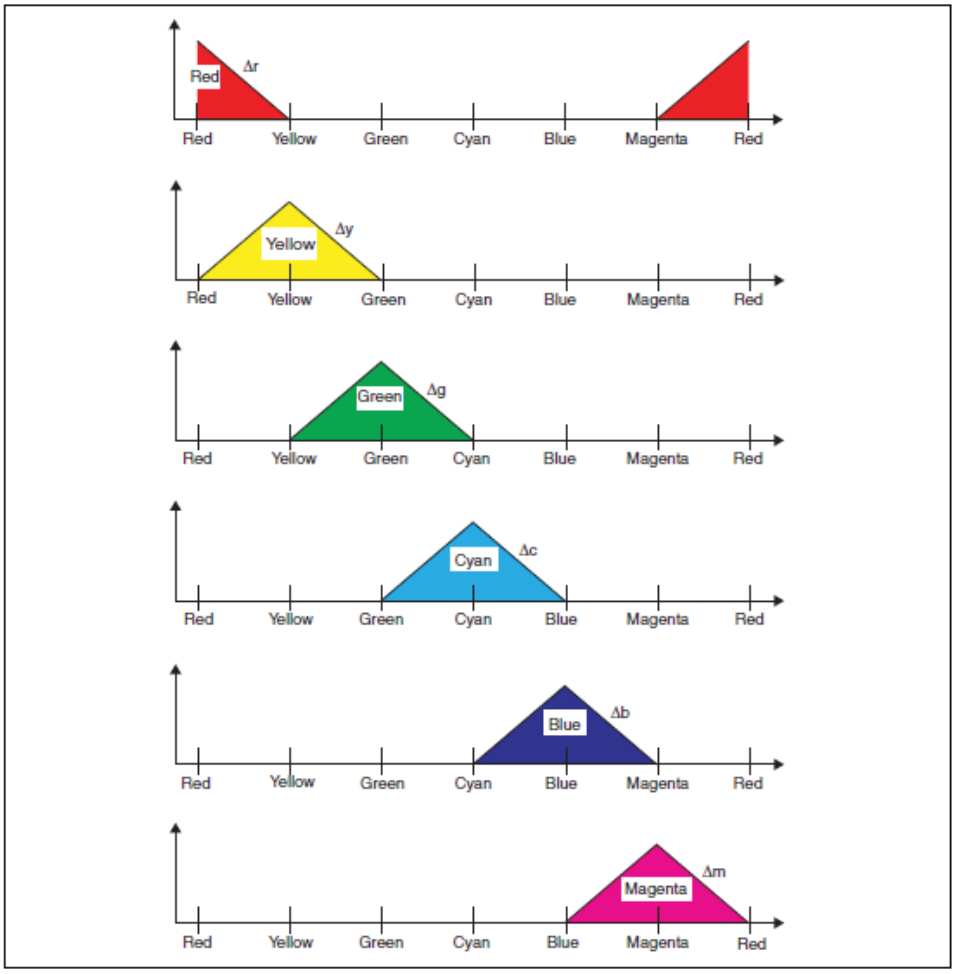

Figure 40.10 The relationship between the six hues and △r, △g, △b, △c, △m, and △y

(c) Hue region data

The six hue region data items △ry, △gy, △gc, △bc, △bm, and △rm are valid only in the six regions that are between two adjacent hues each.

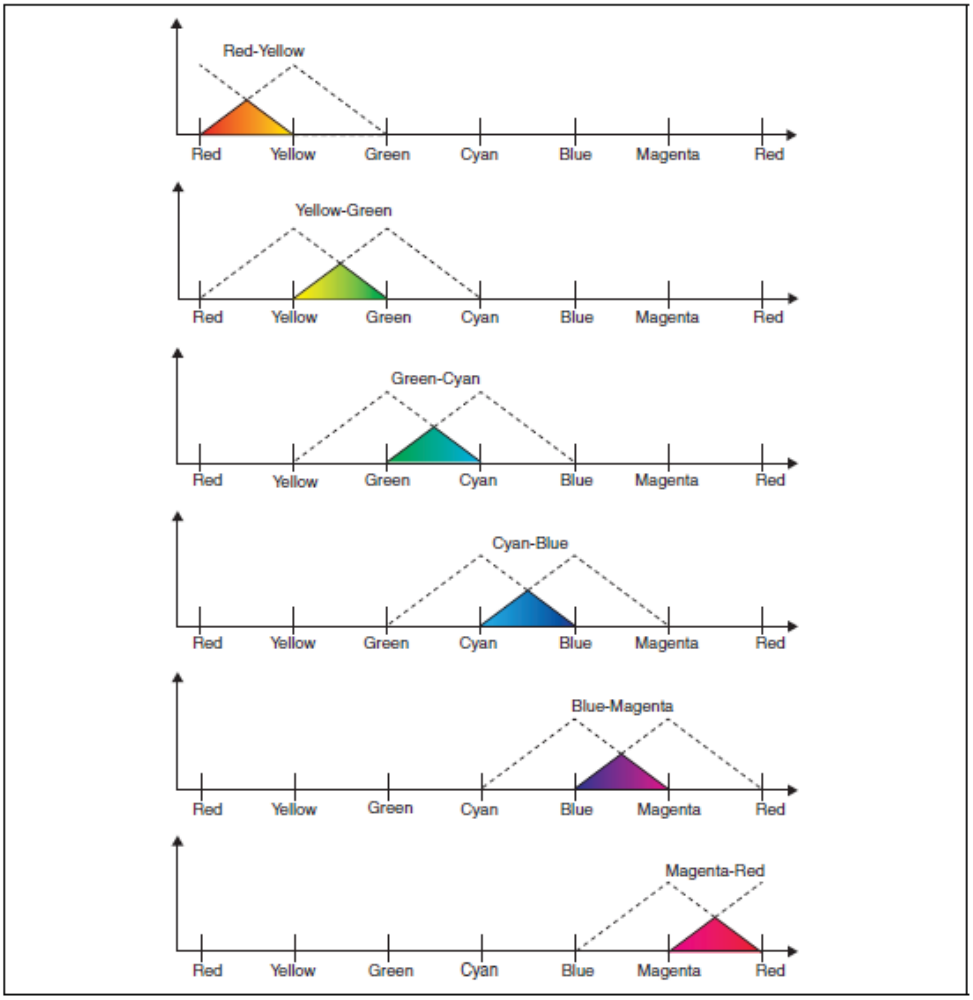

Figure 40.11 The relationship between six hues and △ry,△gy,△gc,△bc,△bm, and △rm

(3) Function of color saturation improvement

The problem of color saturation in high-chroma spots can be improved upon by the extraction of feature information from each pixel and by the control of the amount of correction applied. The color conversion processing with the color saturation improvement function can be expressed by the following formula:

$$\begin{bmatrix} Ro \\ Go \\ Bo \end{bmatrix} = \begin{bmatrix} Ri \\ Gi \\ Bi \end{bmatrix} + f(CA) \begin{bmatrix} \Delta r \\ \Delta g \\ \Delta b \end{bmatrix}$$

CA: feature information (saturation, brightness)

F(CA): correction amount control coefficient

△r, △g,△b: standard correction amount

This processing is designed to control the amount of correction applied by multiplying the correction amount control coefficient determined by feature information CA by a standard correction amount. Figure40.12 shows an example of the relationship between the correction amount control coefficient f(CA) and the feature information CA.

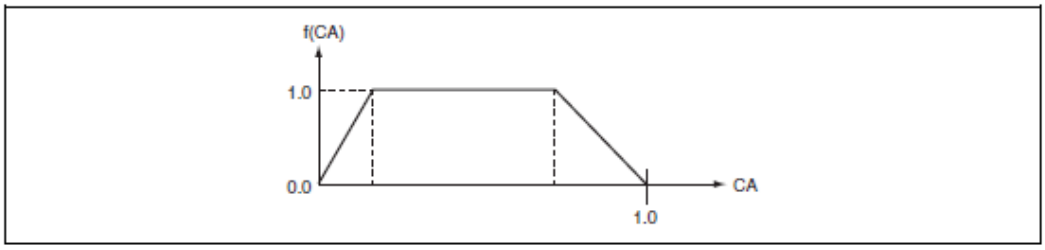

Figure 40.12 example of the relationship between the correction amount control coefficient and the feature information

As a method for calculating a correction amount control coefficient, this circuit uses a polygonal line approximation method with four parameters: a dark part threshold value (LDCMTVR.CMTH1), a dark part slop (LDCMTVR.CMINC1), a bright part threshold value (LDCMTVR.CMTH2), and bright part slope (LDCTVR.CMINC2). If CA is less than the dark part threshold value, then f(CA)=0, and if CA becomes greater than the dark part threshold value, then f(CA) is a slope that is set in terms of a dark-part slope, and it increases up to f(CA)=1 as CA increases. If CA is greater than the bright part threshold value, then f(CA)=0, and when CA declines below the bright part threshold value, f(CA) increases up to f(CA)=1 with a slope that is set in terms of the bright part slope, as CA decreases.

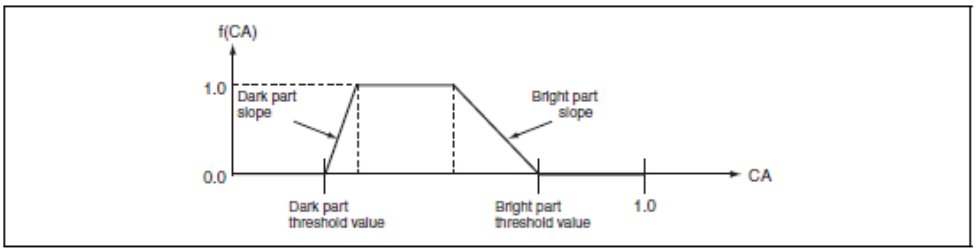

Figure 40.13 parameters for the calculation of a correction amount control coefficient

(4) Dither processing unit

This unit performs dithering processing on the lower 2 bits of the color-converted data.

- Conversion from 8 to 6 bits
- There are two choices to perform this processing: changes the value to be added on a pixel-by-pixel basis, and changes the value to be added for each frame + pixel.
  Pixel-by pixel addition: for LDCMDTHR.DTHA0 = 0, DTHA1 = 1, DTHA2 = 2, DTHA3 = 3.

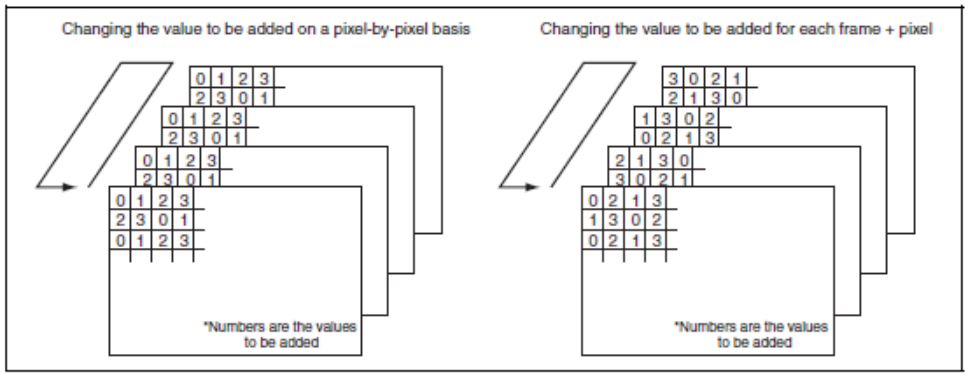

Figure 40.15 dither processing method and example

40.5 Blend Function

This LCDC has a blend function. The image of 4 channels can be operated α-blend or ROP3, and be arranged for the display image of LCD. The blend image of four channels can be overlay mutually, and the LCD display image is processed as an undermost layer in the following order in which to overlay:

LCD display image < channel 1 image < channel 2 image < channel 3 image < channel 4 image

(However, there is a limitation in the amount of overlay between the blend images. Please refer to the note.)

The α-blend or ROP3 operation function can be used in channel-1 and channel-2. In channel-3 or channel-4, all penetration and the display selection function or ROP3 operation functions can be used by the penetration color specification.

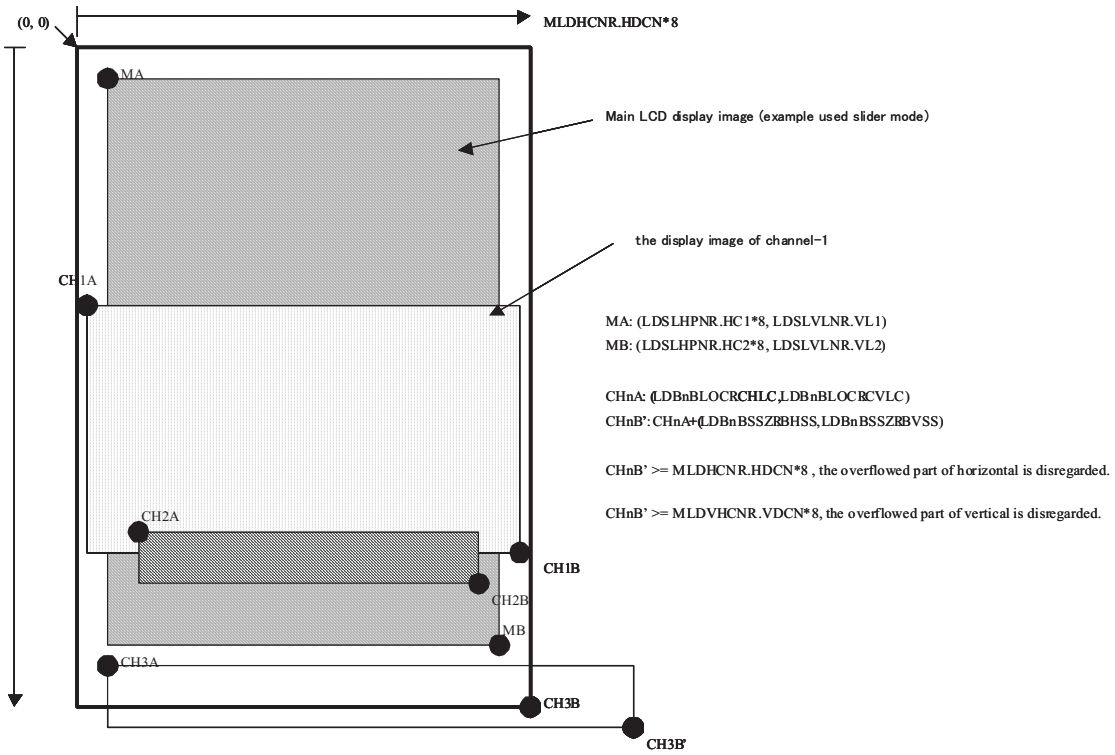

Figure 40.15 LCDC (blend function) Specification

The input image format of 4 channels must all be RGB format or YCbCr format. The input format of LCD can select RGB format or YCbCr format, it is processed according to the input format on blend side attended with the conversion of RGB/YCbCr format as follows.

LCD input format	blend side input format	LCD panel output format	the method processing		
			input conversion	blend processing	output conversion
RGB	Invalidity	RGB	None	RGB format (thought)	None
	RGB		None	RGB format	None
	YCbCr		RGB→YCbCr	YCbCr format	YCbCr→RGB (before palette)
YCbCr	Invalidity		YCbCr→RGB	RGB format (through)	None
	RGB		YCbCr→RGB	RGB format	None
	YCbCr		None	YCbCr format	YCbCr→RGB (before palette)
RGB	Invalidity	YCbCr	None	RGB format	RGB→YCbCr

			(through)	(after NCM)
	RGB	None	RGB format	RGB→YCbCr (after NCM)
	YCbCr	RGB→YCbCr	YCbCr format	None
YCbCr	Invalidity	None	YCbCr format	None
	RGB	YCbCr→RGB	RGB format	RGB→YCbCr (after NCM)
	YCbCr	None	YCbCr format	None

The input format of blend side: be judged the smallest number of the effective channel.

40.6 Blend Register Descriptions

40.6.1 Register Read/Write

The blend register divides into 4-sets (be called BC1~BC4) in each blend side n(n=1~4), and is FIFO structure on current side/program side. The register on current side is shown the setting processing and cannot be written. The register setting does to program side, controls the reflection on current side by LDBCR register.

In the LDBCR register corresponding to register set BC1~4, there is update permission bit (UPDn), update completion flag (UPFn), and update permission cancellation bit (UPCn).

- Update permission bit (UPDn): It is set that 1 is written. It is not cleared even if 0 is written, and the last value is retained. UPDn is set to 1 and the register switch timing is caused, the value on program side of register set BCn is reflected in current side. The UPDn bit is cleared automatically when reflected. Please update register set BCn when UPDn is set 0.
- Update completion flag (UPFn): UPDn is set to 1 and the register switch timing is caused, the value on program side of register set BCn is reflected in current side, it is set 1 automatically. It is cleared by writing 1. It is not cleared even if 0 is written, and the last value is retained.
- Update permission cancellation bit (UPCn): When 1 is written, the corresponding UPDn is cleared. It is usesd to update the value of the register set before the next register switch timing is generated after UPDn is set.

Example: change the setting of blend side 1

The update permission is canceled by UPC1. Write 0 to UPF1.

LDCBR ← 32’h0001_0000

Refer to the UPF1 flat when the distinction whether the last set value was reflected is necessary.

```
If (LDBBCR.UPF1){
  Set the value-1 to LDB1BLOCR
} else {
  Set the value-2 to LDB1BLOCR
}
```

After register set BC1 setting is completed, the UPD1 flag is set. At the same time, UPF1 flag clears and uses it to judge in next time.

LDBCR ← 32’h0000_0101

40.6.2 Blend control register （LDBCR）

LDBCR controls that the value on program side of register set BCn is reflected in current side. For details, see section 40.6.1, Register Read/Write.

bit：	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W :	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	EN	0	R/W	Enable bit 1: enable CHn 0: disable CHn
30	-	0	R	Reserved
29	VS	0	R/W	Virtual screen setting 1: virtual screen mode 0: normal In the virtual screen mode, the value of foreground color1(fg1) is used in LDBnBSAYR register. The value of foreground color 2(fg2) is used in LDBnBSACR register. Data is not fetched from the extrinsic memory, and the CHn screen is generated with the pixel with the value of fg1 and fg2. When the pixel is arranged to be (x,y) that is assumed the parents screen coordinates value, pixel value of each coordinates is set as follows X[0]^y[0] == 0 : fg1 X[0]^y[0] == 1 : fg2 ([0] is shown the LSB of coordinates value)
28	BRSEL	0	R/W	Select blend or ROP3 operation 1: ROP3 operation 0: Blend operation When the blend operation is selected with CH3 or CH4, it is processed as complete penetration when α value is 0, except when α value is 0, it is processed as complete non-penetration.
27 to 26	MX MY	0	R/W	Specify twice expansion with the direction of x and Y 1: twice expansion 0: normal Specify the size after it expands for LDBnBSSZR(source size specification register) by the even number. Specify LDBnBLOCR(blend of offset register) by the even number when expansion mode.
25 to 24	CV[1:0]	00	R/W	Penetration color control 00 : normal 01 : the penetration color specification with CHnBPCR is effective 11 : the penetration color specification with CHnBPCR and CHnBSARA is effective (it is effective only at AL[1] = 0) 10 : it is replaced with CHnBPCCR2 when the data match CHnBPCCR (it is effective only at AL[1] = 0)

Bit	Bit Name	Initial Value	R/W	Description
23 to 16	LAY[7:0]	8'b0	R/W	Set layer α-value or specify ROP3 operator
	ROP3[7:0]			Set layer α-value
				Set the value of 8-bits defined as follows to ROP3 operator.
				Pixel α-value P[7:0]
				Each pixel value S[7:0]
				Each background pixel value D[7:0]
				Pixel value [n] = ROP3 operator [{P[n], S[n], D[n]}] (n=0~7)
15 to 14	AL[1:0]	000	R/W	Specify the each pixel α-value
				00 : set 1 to α-value only 1 bit
				01 : enable the α-value of αRGB format. Accuracy depends on the format(1/4/5/6/8 bit accuracy). α-value is set 1 of the 1-bit accuracy with none α-value format of RGB or YCbCr.
				10 : plane 1 bit-α is read, and it is assumed pixel α-value of 1 bit accuracy.
				11 : plane 8 bit-α is read, and it is assumed pixel α-value of 8 bit accuracy.
				When pixel obtained α is compared with the layer α, and pixel α is larger than the layer α, it is clipped by layer α.(It is effective only at BRSEL = 0)
13 to 11	-	000	R	Reserved
10 to 8	SWP[2:0]	000	R/W	Specify the swap parameter of RGB/Y, C plane.
				The α plane is used 000 at SWP[2:0] = 000, and 111 at SWP[2:0] !=000.
				[2] = 1 : data is swapped by long word
				[1] = 1 : data is swapped by word
				[0] = 1 : data is swapped by byte
7	RY	0	R/W	Specify the input format
				0: YCbCr format
				1: RGB format
6~5	-	00	R	Reserved
4～0	RPKF[4:0]	00000	R/W	The input format is RGB:
	or			RPKF[4:0] specifies the input data of RGB back.
	000,			For details, see figure 40.7
	CHRR[1:0]			
				The input format is YCbCr:
				CHRR[1:0] specifies the input data of YCbCr back.
				00: YCbCr 4:4:4
				01: YCbCr 4:2:2
				10: YCbCr 4:2:0
				Note:
				1: when the input format is YCbCr, MLDDFR.CF1 and MLDDFR.CF0 specify ITU-R BT.601/ITU-R BT.709 and full-range YCbCr/compressed-range YCbCr.
				2: CHRR[1:0] is different with MLDDFR.YF[1:0].

40.6.4 CHn Source Size Register （LDBnBSSZR）

LDBnBSSZR specifies the input size of image (n=1~4).

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	BVSS[11:0]											
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	BHSS[11:0]											
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved
27 to 16	BVSS[11:0]	H'000	R/W	Set the number of vertical pixels read. These bits set the number of vertical read pixels of the source image. When input n is YCbCr 4:2:0, these bits can be set in 2-pixel units. For other formats, these bits can be set in 1-pixel units.
15 to 12	-	All 0	R	Reserved
11 to 0	BHSS[11:0]	H'000	R/W	Set the number of horizontal pixels read These bits set the number of horizontal read pixels of the source image. When input n is YCbCr 4:2:2 or YCbCr 4:2:0, these bits can be set in 2-pixel units. For other formats these bits can be set in 1-pixel units.

40.6.5 CHn Blend Location Register （LDBnBLOCR）

LDBnBLOCR specifies the location for input n(n=1~4).

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	CVLC[11:0]											
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CHLC[11:0]											
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved
27 to 16	CVLC[11:0]	H'000	R/W	Specify the number of pixels for the vertical offset from the base point as the blending start location of input n (1-pixel units).
15 to 12	-	All 0	R	Reserved
11 to 0	CHLC[11:0]	H'000	R/W	Specify the number of pixels for the horizontal offset from the base point as the blending start location of input n (1-pixel units).

40.6.6 CHn Source Memory Width Register LDBnBSMWR）

LDBnBSMWR set the memory width of the source memory areas of input n(n=1~4).

bit：	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BSMWA[15:0]															
initial：	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W：	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit：	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSMW[15:0]															
initial：	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W：	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	BSMWA [15:0]	H'0000	R/W	Set the α source memory area width by long word units.
15 to 0	BSMW [15:0]	H'0000	R/W	Set the source memory area width by long word units. These bits set the horizontal width of the source memory area where the source image is located. For YCbCr 4:4:4 format, the setting is doubled because the data size of C plane is twice as large as Y plane.

40.6.7 CHn Source Address Y Register （LDBnBSAYR）

This register function changes by LDBnBSIFR.VS.

- LDBnBSIFR.VS = 0

Set the start address for the Y/RGB plane of the images read.

bit：	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BSAY[31:16]															
initial：	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W：	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit：	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	FG1A[7:0]	H'00	R/W	Set the α value of foreground color fg1
23 to 16	FG1R[7:0]	H'00	R/W	Set the R/Cr value of foreground color fg1
15 to 8	FG1G[7:0]	H'00	R/W	Set the G/Y value of foreground color fg1
7 to 0	FG1B[7:0]	H'00	R/W	Set the B/Cb value of foreground color fg1

40.6.8 CHn Source Address C Register (LDBnBSACR)

This register changes by LDBnBSIFR.VS.

- LDBnBSIFR.VS = 0

Set the start address of C plane.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BSAC[31:16]															
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSAC[15:0]															
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BSAC[31:0]	H'00	R/W	Set the start address of C plane. This register is not used when the input format is RGB.

- LDBnBSIFR.VS = 1

Set the pixel value of foreground color fg2.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FG2A[7:0]								FG2R[7:0]

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	FG2A[7:0]	H'00	R/W	Set the α value of foreground color fg2
23 to 16	FG2R[7:0]	H'00	R/W	Set the R/Cr value of foreground color fg2

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	FG2G[7:0]	H'00	R/W	Set the G/Y value of foreground color fg2
7 to 0	FG2B[7:0]	H'00	R/W	Set the B/Cb value of foreground color fg2

40.6.9 CHn Source address α/CHn Penetration Color Control register 2 (LDBnBSAAR/LDBnBPCCR2)

This register changes by LDBnBSIFR.AL[1].

- LDBnBSIFR.AL[1] = 1

Set the start address of α plane.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BSAA[31:16]

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	AP[7:0]	H'00	R/W	Set the α-value used at a data comparison match
23 to 16	R[7:0]	H'00	R/W	Compare data R(RGB)
15 to 8	GY[7:0]	H'00	R/W	Compare data G(RGB) or Y(YCbCr)
7 to 0	B[7:0]	H'00	R/W	Compare data B(RGB)

Note : n = 1~4

Figure 40.16 the number of input pixels and start address

40.6.10 CHn Transparent Color Control Register（LDBnBPCCR）

LDBnBPCCR set the compare data used in transparent color comparison and the alpha value.

When the input format is RGB, the input data is compared with LDnBPCCR.R, GY, and B, the alpha value is replaced with LDBnBPCCR.AP that matched. It is compared between the setting of LDBnBPCCR and the value that enhances of input data to 8 bit when the packing form of less than 8 bit. This enhancing is done by the form that supplements the MSB bit. For example, the input data that RGB565 packing form is r[7:3], g[7:3], b[7:0], as follows:

r[7:0] = {r[7:3], r[7], r[7], r[7]}

g[7:0] = {g[7:3], g[7], g[7], g[7]}

b[7:0] = {b[7:3], b[7], b[7], b[7]}

Note that only the Y component is to be compared in case of YCbCr format. The alpha value is replaced with LDBnBPPCCR.AP at Y data comparison match LDBnBPCCR.GY.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
23 to 16	R[7:0]	H'00	R/W	Compare data R(RGB)
15 to 8	GY[7:0]	H'00	R/W	Compare data G(RGB) or Y(YCbCr)
7 to 0	B[7:0]	H'00	R/W	Compare data B(RGB)

40.6.11 CHn Background Color Register （LDBnBBGCL）

LDBnBBGCL specifies the pixel value outside the image range of input. The area specified by this register is all the areas outside the image area, and is blended. The initial alpha value of background color (BGA[7:0]) is 0, and it doesn't contribute to the generation of the display image.

bit：	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	BGB[7:0]	H'00	R/W	B/Cb value of the outside area

40.6.12 Other Register Settings

(a) Frame Buffer Settings (for Setting to the LCD)

If the data format for frame data is YCbCr, you need to set both MLDSA1R and MLDSA2R. For the data format is RGB, set only MLDSA1R.

The horizontal size of image data on the frame buffer should be set in MLDLSR. The setting value should have a size that enables one line of data to be saved.

- Data format: YCbCr422, extension-type RGB conversion
  Y data head address: H'4000 0000
  CbCr data head address: H'4000 1000
  Horizontal image size: 480
  MLDDFR = H'0001 0100
  MLDSA1R = H'4000 0000
  MLDSA2R = H'4000 1000
  MLDLSR = H'0000 01E0[*1]
- Data format: RGB packform = 0 (32bpp)

Data address: H'E558 0000
Horizontal image size: 240
MLDDFR = H'0000 0000
MLDSA1R = H'E558 0000
MLDLSR = H'0000 03C0*2

Note: 1. The data size per pixel in the YCbCr data format is Ydata 1byte, Cdata 1byte (2 bytes in the 4:4:4 format). Set a value larger than "1 byte x horizontal size" in MLDMLSR, taking the Ydata size into consideration.
1 byte × 480 pixels = 480 = 1E0h
2. The data size per pixel in the RGB data format is as follows:
When MLDDFR.PKF[4:0]= 5'b00000, 5'b00001, 5'b00111, 5'b01100, or 5'b01101: 4 bytes
When MLDDFR.PKF[4:0]= 5'b00010, 5'b01001, 5'b01010, or 5'b01011 : 3 bytes
When MLDDFR.PKF[4:0]= 5'b00011, 5'b00101, 5'b00110, or 5'b01000 : 2 bytes
When MLDDFR.PKF[4:0]= 5'b00100 :1 byte
Set a value larger than the value multiplied by the horizontal size above.
In this case (RGB packform = 00000), it should be 4 bytes x 240 pixels = 960 = 3C0h.

40.6.13 Two-Set Register Switching

The LCDC has two sets of LCD registers.

Register sets are changed when the LCD completes its display of one frame of data and a frame end interrupt occurs.

Figure 40.17 shows an example of the timing when register sets are changed and frame end interrupts occur. Specify a register set for the next frame every time a frame end interrupt occurs.

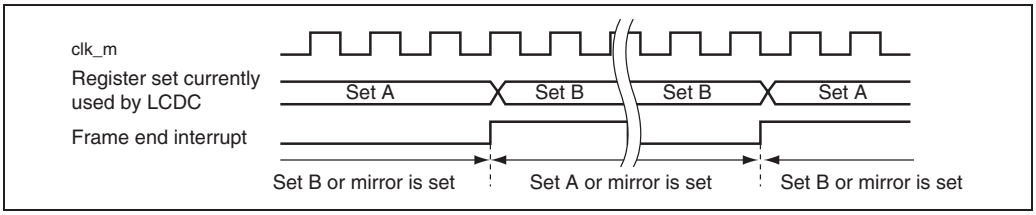

Figure 40.17 Timing of Interrupts and Register Settings

40.6.14 Autonomous Clock Stop

The LCDC stops supplying a clock to the blocks that do not need clock in standby mode and autonomously restarts supplying a clock to them when the LCDC is activated.

40.6.15 Examples of Clock and LCD Data Signals

Figure 40.22 shows the data format when the display data is written back.

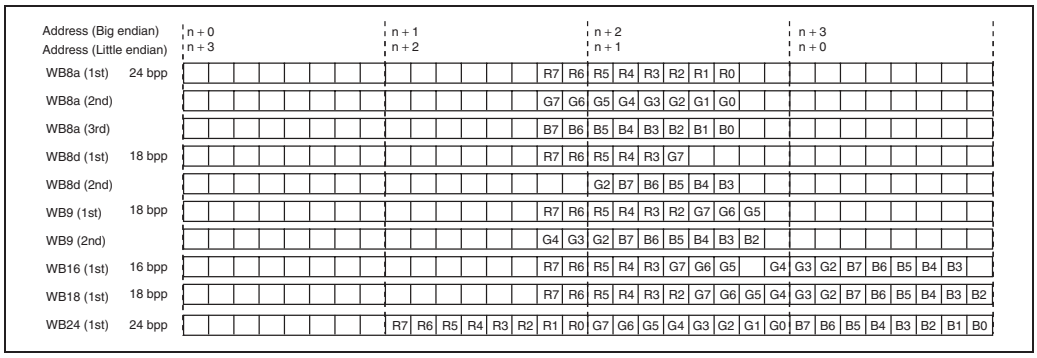

Figure 40.22 Write-Back Data Format

40.7 Usage Note

LCDC acquires all data of the LCD display every on horizontal line and the data of CHn on this line from extrinsic memory. The dot clock is high-speed, and the underflow might be caused when there is a lot of maximum data on one line.

LCD display and the blend CHn image is used by MERAM function (read flied buffer/ frame buffer cash), the MERAM direct access or LCD refresh function. LCDC must be used on the condition that the acquisition data gross weight of one line (the maximum value of the entire image, include the LCD display data) divides by 1HD period is less than 800MB/s.

Section 41 Camera Serial Interface (CSI2)

The Camera Serial Interface (CSI2) receives image data from an external camera compliant with the MIPI (Mobile Industry Processor Interface)-CSI2 standard via a high-speed differential serial interface.

41.1 Features

The CSI2 has the following major features:

This LSI mounts two CSI2 module. It is CSI2C and CSI2I.

- Performs serial-to-parallel conversion of data from a camera . And CSI2C passes parallel data to CEU2 (Camera Engine Unit) . CSI2I passes parallel data to ISP(Image Signal Processor) .
- Compliant with the MIPI-CSI2 standard
- Up to 850 Mbps (HS) transfer rate per channel
  Frequency of the serial clock is 850-200MHz.
- CSI2C is supported up to 2 lanes. CSI2I is supported up to 4 lanes.
- CSI2C mounts ECC function and CRC function. CSI2I doesn't mount them.
- Format that can receive CSI2C is YUV422,YUV420,Embedded 8bit Data, and UserDefine 8bit Data. Format that can receive CSI2I is RAW8,RAW10, and RAW12.

Connection diagram of the CSI2 is shown in figure 41.1.

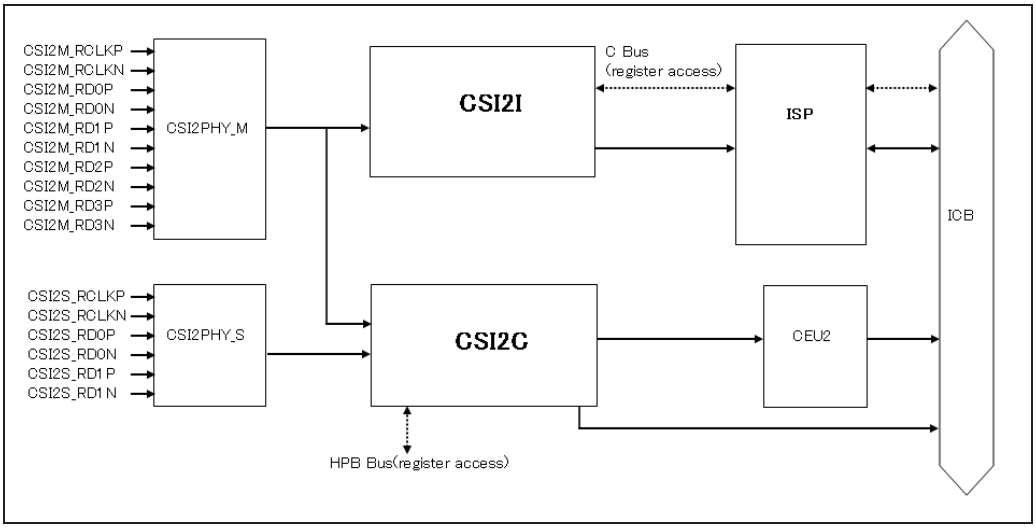

Figure 41.1 CSI2 Connection Diagram

41.2 Pin Configuration

Table 41.1 shows the CSI2 pin configuration.

Table 41.1 Pin Configuration

Pin Name	Function	I/O Type	Description
CSI2M_RCLKP CSI2S_RCLKP	CSI2 CLK differential pin (Plus)	Input	The differential signal pin (Plus) of clock input.
CSI2M_RCLKN CSI2S_RCLKN	CSI2 CLK differential pin (Minus)	Input	The differential signal pin (Minus) of clock input.
CSI2M_RD0P CSI2M_RD1P CSI2M_RD2P CSI2M_RD3P CSI2S_RD0P CSI2S_RD1P	CSI2 DATA differential pin (Plus)	Input	The differential signal pin (Plus) of data input.
CSI2M_RD0N CSI2M_RD1N CSI2M_RD2N CSI2M_RD3N CSI2S_RD0N CSI2S_RD1N	CSI2 DATA differential pin (Minus)	Input	The differential signal pin (Minus) of data input.

41.3 CSI2C Register Description

Table 41.2 shows the CSI2C register configuration. Table 41.3 shows the register states in each operating mode.

41.3.1 Control Timing Select Register (CSI2_TREF)

CSI2_TREF selects the reflection timing for the CSI2 registers.

It covers the following registers:

- Channel data type select register (CSI2_VCDT)
- Embedded Data capture control register (CSI2_CAP)
- Field detect control register (CSI2_FLD)
- Monitor control register (CSI2_MONCNT)
- Output control register (CSI2_OUT)

The setting of this register is effective immediately after it is configured (immediately reflected).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TREF	0	R/W	Register Reflection Timing Select Bit 0: Upon completion of frame processing 1: Immediately

"Upon completion of frame processing" refers to when the CSI-2 completes outputting frames (the falling edge of CSIR_VD). The hardware has a double-buffer structure consisting of HPB access register and CSI2 control register.

The sequence to set the TREF bit is as follows:

1. Set the adequate registers during initialization (the TREF bit should remain B'1).
2. Then, set the TREF bit to B'0.

This sequence allows the register setting to be changed even during data processing (while the CSI-2 is operating).

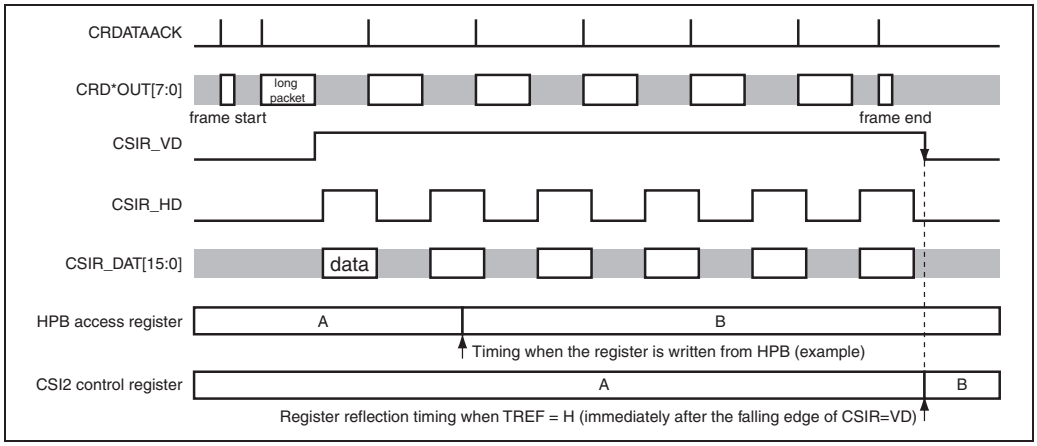

Figure 41.2 Reflection Timing on Registers

41.3.2 Software Reset Register (CSI2_SRST)

CSI2_SRST resets the CSI2C block control circuit. Note that the CSI2C register settings are not initialized by a software reset.

The setting of this register is effective immediately after it is configured (immediately reflected).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

0	SRST	0	R/W	Software Reset Control Bit Set to B'1 to reset. Make sure to re-set to B'0 to clear the reset. 0: Normal operation 1: Reset

41.3.3 PHY Operation Control Register (CSI2_PHYCNT)

CSI2_PHYCNT controls the operation of the PHY.

The setting of this register is effective immediately after it is configured (immediately reflected). The setting should be configured while data input is stopped (the sensor is stopped). Changing the register setting during operating is prohibited.

	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

Bit	Bit Name	Initial Value	R/W	Description
1	CRD1ENH	0	R/W	Data Lane 2 Operation Enable Bit This bit turns on/off the PHY of data lane 2. Set to B'1 to enable operation. Operation should be enabled when two lanes are used. The clock lane and data lane 1 should also be enabled via the CRCLKENH and CRD0ENH bits respectively. 0: Operation disabled 1: Operation enabled
0	CRD0ENH	0	R/W	Data Lane 1 Operation Enable Bit This bit turns on/off the PHY of data lane 1. Set to B'1 to enable operation. In this case, the clock lane should also be enabled via the CRCLKENH bit. 0: Operation disabled 1: Operation enabled

41.3.4 Checksum Control Register (CSI2_CHKSUM)

CSI2_CHKSUM controls checksum processing.

The setting of this register is effective immediately after it is configured (immediately reflected). The setting should be configured while data input is stopped (the sensor is stopped). Changing the register setting during operating is prohibited.

	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	ECC_EN	1	R/W	ECC Processing Control Bit This bit controls ECC processing of packet headers in Low Level Protocol (LLP). Set to B'1 to enable ECC. When this bit is set to B'0, packet headers are always considered to have no error and no error correction is made. 0: OFF 1: ON
0	CRC_EN	1	R/W	CRC Processing Control Bit This bit controls checksum processing of long packet data in Low Level Protocol (LLP). Set to B'1 to enable CRC checksum. When this bit is set to B'0, long packet data are always considered to have no error. 0: OFF 1: ON

41.3.5 Channel Data Type Select Register (CSI2_VCDT)

CSI2_VCDT selects a channel on which data are captured and the data type.

The reflection timing of this register can be set in the CSI2_TREF register (double-buffer scheme).

	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	SEL_VC[1:0]		–	–	SEL_DT[5:0]					
initial value :	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0
R/W :	R	R	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	SEL_VC[1:0]	00	R/W	Channel Select Bit These bit specify a channel (Virtual Channel) on which data are captured. Four channels from B'00 to B'11 are available for selection.
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	SEL_DT[5:0]	H'1E	R/W	Data Type Select Bit These bits specify the data type of data to be captured. There are limitations on data types (refer to table 41.4). Available data types are YUV4:2:2, YUV4:2:0 (excluding Legacy), and User-Defined 8-bit Data.

Table 41.4 Summary of Data Types and Their Availabilities

Data Type	Function/Data Format	Availability	Remarks
H'00 to H'0F	Short Packet (data and no packet footers)		
H'10	Null		
H'11	Blanking Data		
H'12	Embedded 8-bit non Image Data	√	*
H'13 to H'17	Reserved		
H'18	YUV420 8-bit	√	
H'19	YUV420 10-bit		
H'1A	Legacy YUV420 8-bit		
H'1B	Reserved		
H'1C	YUV420 8-bit (Chroma Shifted Pixel Sampling)	√	
H'1D	YUV420 10-bit (Chroma Shifted Pixel Sampling)		
H'1E	YUV422 8-bit	√	
H'1F	YUV422 10-bit		
H'20	RGB444		
H'21	RGB555		
H'22	RGB565		
H'23	RGB666		
H'24	RGB888		
H'25 to H'27	Reserved		
H'28	RAW6		
H'29	RAW7		
H'2A	RAW8		
H'2B	RAW10		
H'2C	RAW12		
H'2D	RAW14		
H'2E to H'2F	Reserved		
H'30	User Defined 8-bit Data Type 1	√	Such as JPEG
H'31	User Defined 8-bit Data Type 2	√	Such as JPEG
H'32	User Defined 8-bit Data Type 3	√	Such as JPEG
H'33	User Defined 8-bit Data Type 4	√	Such as JPEG

Data Type	Function/Data Format	Availability	Remarks
H'34 to H'37	Reserved		
H'38 to H'3F	Reserved		

Note: * A separate setting is required for capturing.

41.3.6 Embedded Data Capture Control Register (CSI2_CAP)

CSI2_CAP controls capturing of Embedded Data.

The reflection timing of this register can be set in the CSI2_TREF register (double-buffer scheme).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	CAP_EBD
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CAP_EBD	1	R/W	Embedded Data Capture Control Bit This bit controls capturing of Embedded Data. Embedded Data appear before (as the first part) or after (as the last part) a valid line during a frame period. Set this bit to B'1 to enable capturing. Embedded Data are transferred to dedicated SRAM (8 kbytes) and can be monitored from HPB. Embedded Data more than 8 kbytes per channel cannot be stored. 0: Capturing disabled 1: Capturing enabled

41.3.7 Field Detect Control Register (CSI2_FLD)

CSI2_FLD controls detection of the first field in an interlaced image.

The reflection timing of this register can be set in the CSI2_TREF register (double-buffer scheme).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FLD_NUM[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FLD_EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	FLD_NUM[15:0]	H'0000	R/W	First Field Number Set Bit The setting is used to detect the first field in an interlaced image. To detect it, the WC value (16 bits) in a Frame Start packet is referenced. If the WC value matches the setting, it is detected as the first field. The CSIR_FLD signal is driven High during the corresponding frame period. Set a value within a range from 0 to 3. Otherwise, normal operation is not guaranteed.
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	FLD_EN	0	R/W	First Field Detect Control Bit This bit is used to turn on/off detection of the first field. Set to B'1 to turn on detection. 0: Detection of the first field is turned off. 1: Detection of the first field is turned on.

41.3.8 Monitor Control Register (CSI2_MONCNT)

CSI2_MONCNT controls monitoring of Embedded Data.

The setting of this register is effective immediately after it is configured (immediately reflected).

The CAP_EBD bit in the CSI2_CAP register should be set to B'1 before monitoring is enabled. Enable monitoring after one frame of Embedded Data is captured.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EBD_MON_EN	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R

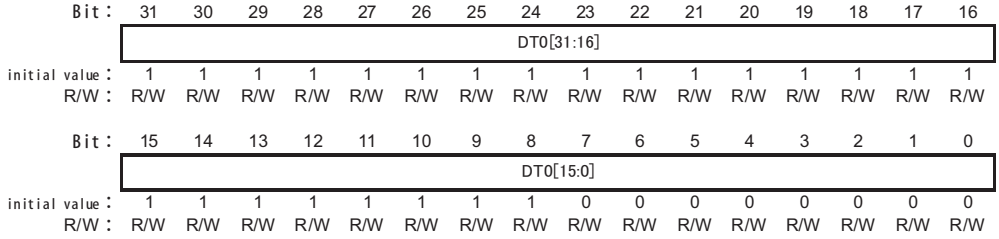
Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	EBD_MON_EN	0	R/W	Embedded Data Monitor Enable Bit This bit enables monitoring of Embedded Data. Disable monitoring (set to B'0) while Embedded Data are being captured. Enable it (set to B'0) when they are read. Embedded Data cannot be read with monitoring disabled. 0: Monitoring is disabled (normal setting). 1: Monitoring is enabled.
0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

41.3.9 Output Control Register (CSI2_OUT)

CSI2_OUT sets the CSI2 output horizontal blanking period and enables/disables the CSI2 output.

The reflection timing of this register can be set in the CSI2_TREF register (double-buffer scheme).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OUT_BLANK[15:0]															
initial value:	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



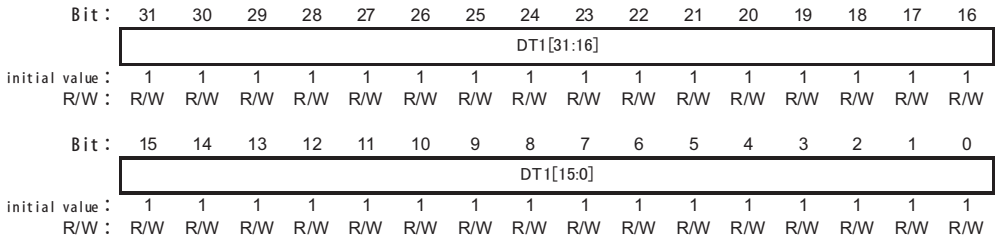
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	OUT_STOP
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	OUT_BLANK [15:0]	H'0080	R/W	Output Horizontal Blanking Period Control Bit These bits set the CSI2C output horizontal blanking period (minimum value) in YUV420 mode. This setting is invalid for other data formats. The period is specified in CLKCSI clock cycles. The specified period is calculated as a half of the CSI output clock CSIR_CLK with the fraction rounded up. A value of 0 cannot be specified. Specifying a value larger than needed causes an overflow during YUV420 conversion, resulting in incorrect data.
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	OUT_STOP	0	R/W	Output Disable Control Bit This bit disables/enables the CSI2C output. When it is disabled, To CEU2 signal's are fixed to Low. 0: Output enabled 1: Output disabled

41.3.10 Long DataType setting register0 (CSI2LNGDT0)

Long/short packet of each data type (0x1f – 0x00) is set.

The initial value conforms to the standard of CSI2.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DT0 [31:0]	H'FFFF_ FF00	R/W	Setting Long or Short. DT0[31] corresponds to "0x1F" of the DataType. DT0[0] corresponds to "0x00" of the DataType. 0 : short packet 1 : long packet

41.3.11 Long DataType setting register1 (CSI2LNGDT1)

Long/short packet of each data type (0x3f – 0x20) is set.

The initial value conforms to the standard of CSI2.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DT1 [31:0]	H'FFFF_ FFFF	R/W	Setting Long or Short. DT1[31] corresponds to "0x3F" of the DataType. DT1[0] corresponds to "0x20" of the DataType. 0 : short packet 1 : long packet

41.3.12 Interrupt Enable Register (INT_EN)

INT_EN controls interrupts.

Interrupts (INT31 to INT00) can be enabled or disabled individually. If enabled, they can output to the INT_CSI port. INT_CSI is a signal in which INT31 to INT00 are tied together as one bit and is meaningful when it is Low. The source of each interrupt can be checked in the interrupt status register.

The setting of this register is effective immediately after it is configured (immediately reflected).

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INT31	INT30	–	–	–	INT26	INT25	INT24	–	–	–	–	–	–	INT17	INT16
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	INT15	INT14	–	INT12	INT11	INT10	INT9	INT8	–	INT6	–	INT4	–	–	INT1	INT0
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	INT31	0	R/W	Interrupt 31 (INT_RELOAD1_AB) Enable Bit When setting it as CSI2DDRLD1.E_AB=1, It is showing interrupt as for changing the output address to CSI2DESTADR1B from CSI2DESTADR1A. 0: Interrupt disabled 1: Interrupt enabled
30	INT30	0	R/W	Interrupt 31 (INT_RELOAD1_BA) Enable Bit When setting it as CSI2DDRLD1.E_BA=1, It is showing interrupt as for changing the output address to CSI2DESTADR1A from CSI2DESTADR1B. 0: Interrupt disabled 1: Interrupt enabled
29 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
26	INT26	0	R/W	Interrupt 26 (INT_VD_START) Enable Bit VD output start (start of frame) interrupt from the CSI2. This interrupt is issued synchronously with the rising edge of the CSIR_VD signal. 0: Interrupt disabled 1: Interrupt enabled
25	INT25	0	R/W	Interrupt 25 (INT_VD_END) Enable Bit VD output end (end of frame) interrupt from the CSI2. This interrupt is issued synchronously with the falling edge of the CSIR_VD signal. 0: Interrupt disabled 1: Interrupt enabled
24	INT24	0	R/W	Interrupt 24 (INT_EBD_WR_END) Enable Bit Embedded Data write end interrupt. This interrupt is issued on the basis of frame. 0: Interrupt disabled 1: Interrupt enabled
23 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	INT17	0	R/W	Interrupt 17 (INT_SHP_STB) Enable Bit Short packet receive interrupt. This interrupt is issued when a short packet such as Frame Start and Frame End is received. 0: Interrupt disabled 1: Interrupt enabled
16	INT16	0	R/W	Interrupt 16 (INT_LNP_STB) Enable Bit Long packet receive interrupt . This interrupt is issued when a long packet such as YUV data and Embedded Data is received. 0: Interrupt disabled 1: Interrupt enabled

Bit	Bit Name	Initial Value	R/W	Description
15	INT15	0	R/W	Interrupt 15 (INT_BUF_ERR) Enable Bit Buffer error interrupt. This interrupt is issued when an overflow occurs during converting from YUV420 to YUV422. The causes of overflow include short blanking period between packets or inadequate (too large) OUT_BLANK value. 0: Interrupt disabled 1: Interrupt enabled
14	INT14	0	R/W	Interrupt 14 (INT_CRC_ERR) Enable Bit CRC error interrupt. This interrupt is issued when there is a data error in long packets. To enable CRC check, set the CRC_EN bit in the CSI2_CHKSUM register to B'1. 0: Interrupt disabled 1: Interrupt enabled
13	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	INT12	0	R/W	Interrupt 12 (INT_HD_WC_ZERO) Enable Bit WC zero interrupt. This interrupt is issued when the WC (Word Count) value in the packet header of a long packet is 0. 0: Interrupt disabled 1: Interrupt enabled
11	INT11	0	R/W	Interrupt 11 (INT_FRM_SEQ_ERR1) Enable Bit Frame sequence error 1 interrupt. This interrupt is issued when an invalid Frame End packet is received. 0: Interrupt disabled 1: Interrupt enabled The sequence error may be caused in the following cases, in which it is assumed that the same channel is used: A Frame End packet is received without receiving a Frame Start packet. More than one Frame End packets are received serially.

Bit	Bit Name	Initial Value	R/W	Description
10	INT10	0	R/W	Interrupt 10 (INT_FRM_SEQ_ERR0) Enable Bit Frame sequence error 0 interrupt. This interrupt is issued when an invalid Frame Start packet is received. 0: Interrupt disabled 1: Interrupt enabled The sequence error may be caused in the following case, in which it is assumed that the same channel is used: More than one Frame Start packets are received serially.
9	INT09	0	R/W	Interrupt 09 (INT_ECC_ERR) Enable Bit ECC error interrupt. This interrupt is issued when there are more than one bit of error in a packet header detected during ECC processing or when there is an error in the ECC code. To enable ECC processing, set the ECC_EN bit in the CSI2_CHKSUM register to B'1. 0: Interrupt disabled 1: Interrupt enabled
8	INT08	0	R/W	Interrupt 08 (INT_ECC_CRCT_ERR) Enable Bit ECC1 bit correction interrupt. This interrupt is issued when a single bit error is corrected during ECC processing. To enable ECC processing, set the ECC_EN bit in the CSI2_CHKSUM register to B'1. 0: Interrupt disabled 1: Interrupt enabled
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	INT06	0	R/W	Interrupt 06 (INT_DERR1B_SYNC) Enable Bit SYNC code 1 bit error interrupt. This interrupt is issued when the CRDATAERR1B input becomes High. 0: Interrupt disabled 1: Interrupt enabled

Bit	Bit Name	Initial Value	R/W	Description
5	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
4	INT04	0	R/W	Interrupt 04 (INT_LP11ERR_PSCK) Enable Bit Clock lane PHY state error interrupt. This interrupt is issued when LP-11 is input in an incorrect sequence during maintaining PHY states. 0: Interrupt disabled 1: Interrupt enabled
3, 2	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
1	INT01	0	R/W	Interrupt 01 (INT_LP11ERR_PSDT1) Enable Bit Data lane 2 PHY state error interrupt. This interrupt is issued when LP-11 is input in an incorrect sequence during maintaining PHY states. 0: Interrupt disabled 1: Interrupt enabled
0	INT00	0	R/W	Interrupt 00 (INT_LP11ERR_PSDT0) Enable Bit Data lane 1 PHY state error interrupt. This interrupt is issued when LP-11 is input in an incorrect sequence during maintaining PHY states. 0: Interrupt disabled 1: Interrupt enabled

41.3.13 Interrupt Status Monitor Register (INT_STATE)

INT_STATE is used to monitor interrupt sources.

INT_STATE holds B'1 when an interrupt occurs and is cleared by a write to clear (writing B'1) from CPU.

The interrupt sources are held regardless of the interrupt enable (INT_EN) settings.

The setting of this register is effective immediately after it is configured (immediately reflected).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IST31	IST30	–	–	–	IST26	IST25	IST24	–	–	–	–	–	–	IST17	IST16
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	IST31	0	R/W	Interrupt 31 (IST_RELOAD1_AB) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor in READ access: 0: Operating normally 1: Interrupt has occurred.
30	IST30	0	R/W	Interrupt 30 (IST_RELOAD1_BA) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor in READ access: 0: Operating normally 1: Interrupt has occurred.
29 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
26	IST26	0	R/W	Interrupt 26 (IST_VD_START) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor in READ access: 0: Operating normally 1: Interrupt has occurred.
25	IST25	0	R/W	Interrupt 25 (IST_VD_END) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor in READ access: 0: Operating normally 1: Interrupt has occurred.
24	IST24	0	R/W	Interrupt 24 (IST_EBD_WR_END) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor in READ access: 0: Operating normally 1: Interrupt has occurred.
23 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	IST17	0	R/W	Interrupt 17 (IST_SHP_STB) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor in READ access: 0: Operating normally 1: Interrupt has occurred.

Bit	Bit Name	Initial Value	R/W	Description
16	IST16	0	R/W	Interrupt 16 (IST_LNP_STB) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor in READ access: 0: Operating normally 1: Interrupt has occurred.
15	IST15	0	R/W	Interrupt 15 (IST_BUF_ERR) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor in READ access: 0: Operating normally 1: Interrupt has occurred.
14	IST14	0	R/W	Interrupt 14 (IST_CRC_ERR) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.
13	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
12	IST12	0	R/W	Interrupt 12 (IST_HD_WC_ZERO) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.
11	IST11	0	R/W	Interrupt 11 (IST_FRM_SEQ_ERR1) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.

Bit	Bit Name	Initial Value	R/W	Description
10	IST10	0	R/W	Interrupt 10 (IST_FRM_SEQ_ERR0) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.
9	IST09	0	R/W	Interrupt 09 (IST_ECC_ERR) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.
8	IST08	0	R/W	Interrupt 08 (IST_ECC_CRCT_ERR) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	IST06	0	R/W	Interrupt 06 (IST_DERR1B_SYNC) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.
5	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	IST04	0	R/W	Interrupt 04 (IST_LP11ERR_PSCK) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.
3, 2	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
1	IST01	0	R/W	Interrupt 01 (IST_LP11ERR_PSDT1) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.
0	IST00	0	R/W	Interrupt 00 (IST_LP11ERR_PSDT0) Monitor Bit Cleared by WRITE access: 1: Interrupt is cleared. Functions as a status monitor for READ access: 0: Operating normally 1: Interrupt has occurred.

41.3.14 Short packet data register (CSI2SHPDAT)

The received short packet is stored. FrameStart, FrameEnd and EOT(DataType=0x08) is excepted. It is FIFO structure, and it stores it up to 9. Whenever leading, the following data is displayed.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECC[7:0]								WC[15:8]							
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WC[7:0]								VC[1:0]		DT[5:0]					
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

41.3.15 Short packet count register (CSI2SHPCNT)

The number of short packet stored in FIFO of CSI2SHPDAT is shown.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	OVF
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	NUM[3:0]			
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	OVF	H'0	R	It is shown that FIFO becomes full, and there is an annulled packet.
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	NUM[3:0]	H'0	R	Number of short packets stored in FIFO . The maximum is 9.

41.3.16 Direct dump control register 1 (CSI2DDCNT1)

The function to output data is provided directly without CEU2.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CONTI	–	–	–	–	–	ST_EN1	I_EN1	–	ST_AB1	CH_AB1	DR_AB1	–	SWAP1[2:0]		
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	CONTI	H'0	R/W	In the standard of CSI2, only one HS-packet can be received for the HS period of one time. The continuous reception of HS-packet becomes possible by making this bit "1". However, there is a limitation. (1)The data length of Long-packet is every 4 bytes. (2)The maximum packet size is 8kbyte. (3) It is not possible to use it together with the output function to CEU2. (4) It is necessary to add the EOT packet(DT='h08) at the end of the packet group. (5)CSI2DDCNT1.ST_EN1 = 0
14 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	ST_EN1	H'0	R/W	Output address computational method 0: Continuous mode All the packet data is output to a consecutive address. 1: Stride mode The data of each packet is output to the address where the value of CSI2DESTWDT1 was added every one packet.
8	I_EN1	H'0	R/W	Direct output function enable 0: disable 1: enable
7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	ST_AB1	H'0	R	Use side of destination base address 0: CSI2DESTADR1A 1: CSI2DESTADR1B
5	CH_AB1	H'0	R/W	Auto change output base address 0: Not change 1: Changes at each reception completion of the frame.
4	DR_AB1	H'0	R/W	Select Start base address 0: CSI2DESTADR1A 1: CSI2DESTADR1B
3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	SWAP1[2:0]	H'0	R/W	Output data swap setting Bit2 : long word swap Bit1: word swap Bit0: byte swap

41.3.17 Destination address register 1A (CSI2DESTADR1A)

The base address to which the packet data is output is set. It is side A in two address settings.

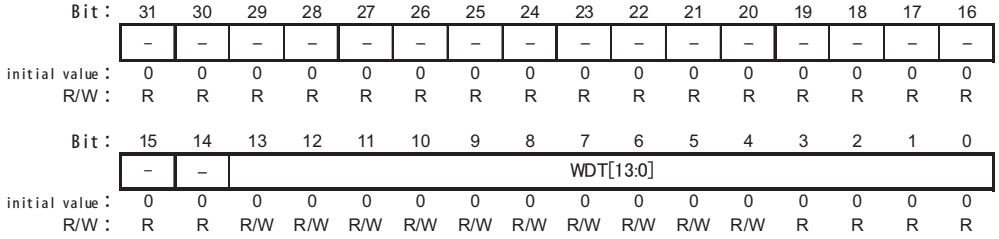
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADR[31:16]															
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADR[15:0]															
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	ADR[31:4]	H'0000000	R/W	Destination address A side
	ADR[3:0]	H'0	R	

41.3.18 Destination address register 1B (CSI2DESTADR1B)

The base address to which the packet data is output is set. It is side B in two address settings.



Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADR[31:16]															
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADR[15:0]															
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	ADR[31:4]	H'0000000	R/W	Destination address B side
	ADR[3:0]	H'0	R	

41.3.19 Destination space width register (CSI2DESTWDT1)

The width of the storage space of about one packet is set.

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	WDT[13:4]	H'000	R/W	Width of storage space
	WDT[3:0]	H'0	R	

41.3.20 Direct dump reload register1 (CSI2DDRLD1)

The upper limit of storage space is set.

When it reaches limit, Change of address and reload, or stop is set.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RL_EN	–	E_AB	E_BA	–	–	–	–	LIMIT[23:16]							
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LIMIT[15:0]															
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	RL_EN	0	R/W	Reload enable 0 : Limit setting of storage space is invalid. 1 : Limit setting of storage space is effective.
30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29	E_AB	0	R/W	When it reached limit, If the address use side is CSI2DESTADR1A, 0 : Stop store 1 : address change(-> CSI2DESTADR1B) and restart.
28	E_BA	0	R/W	When it reached limit, If the address use side is CSI2DESTADR1B, 0 : Stop store 1 : address change(-> CSI2DESTADR1A) and restart.
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23to 0	LIMIT [23:4]	H'00000	R/W	Limit of storage space.
	LIMIT[3:0]	H'0	R	

41.3.21 Embedded Data Receive Byte Count Register (EBD_BCUNT)

EBD_BCUNT monitors the number of received Embedded Data bytes.

Though the maximum value of the byte counter is H'FFFF FFFF, an overflow occurs when the byte count exceeds H'0000 2000 because the Embedded Data monitor register is 8 Kbytes (8192 bytes) in size. If the value exceeds the maximum counter value, it is clipped at H'FFFF FFFF.

EBD_BCUNT is refreshed when writing of Embedded Data is complete.

Bytes are counted on the basis of frame. After a frame is written, the byte count for the next frame starts.

To receive Embedded Data, set the CAP_EBD bit in the CSI2_CAP register to B'1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EBD_BCUNT[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EBD_BCUNT[31:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	EBD_BCUNT [31:0]	H'0000 0000	R	Embedded Data Received Byte Count These bits are used to monitor the number of received Embedded Data bytes on the basis of frame.

41.3.22 Embedded Data Monitor Register (EBD_MONn)

EBD_MONn is an 8-Kbyte (8192-byte) register that is used to monitor Embedded Data.

To capture Embedded Data, set up the registers as follows:

1. Set the CAP_EBD bit in the CSI2_CAP register to B'1.
2. Set the EBD_MON_EN bit in the MON_CNT register to B'0.

After these setting, a data stream (in one byte units) is written from the MSB side. With these setting, data cannot be read out. Data are held on the basis of frame. When a frame is refreshed, data are overwritten from address H'A4D0 2000.

Once the amount of data written exceeds 8 Kbytes, writing of the 8193th and following bytes s is stopped.

To read the data, set the EBD_MON_EN bit in the MON_CNT register to B'1. With this setting, no Embedded Data is written.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EBD_MON (4n+3)								EBD_MON (4n+2)							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EBD_MON (4n+1)								EBD_MON (4n)							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	EBD_MON (4n+3)	H'00	R	Embedded Data Monitor Bit
23 to 16	EBD_MON (4n+2)	H'00	R	Embedded Data Monitor Bit
15 to 8	EBD_MON (4n+1)	H'00	R	Embedded Data Monitor Bit
7 to 0	EBD_MON (4n)	H'00	R	Embedded Data Monitor Bit

Note: n: History number (0 to 2047)

41.4 CSI2C control procedure

41.4.1 Control procedure of starting

There is a possibility of doing the incorrect data in capture when a differential terminal starts CSI2 in the indetermination. Therefore, please start CSI2 after fixing all differential pins.

41.4.2 Direct dump function

The following notes exist for the direct dump function(used CSI2DDCNT1).

(1) The received data packet is stored without converting format.

(2) Y and C cannot be separated by the data of YUVformat. It is stored in the same area.

(3) The FrameStart packet is necessary ahead of the data packet.
The FrameEnd packet is necessary behind the data packet.

(4) When using it with Continuous mode(CSI2DDCNT1.ST_EN1 = 0), All receive data might not be output at once. The stay data is the maximum and is 24 bytes.
This stay data is output by pushing it out by the following receive data. Or, it is output by receiving the FrameEnd packet.

It is similar for reload mode(CSI2DDRLD1.RN_EN1=1).
For example,
It is assumed that it is set as CSI2DDRLD1.LIMIT[23:0] == 00_0190h(400byte), and received the packet in 400 bytes. At this time, 384 bytes are output, and 16 bytes stay. Moreover, interrupt(INT_STATE.IST31,IST30) not occur.

The following packet is received, interrupt occurs when 400 bytes in total are output.

41.5 CSI2C Limitations

41.5.1 Set limitation of CEU2

There is a limitation in the setting of the register of CEU2 when using it by CSI2 and synchronization. And, a special setting is necessary.

- CEU2.CAMCR.VDPOL=0 :
  The polarity of the VD signal is assumed to be a positive polarity.
- CEU2.CAMCR.HDPOL=0 :
  The polarity of the HD signal is assumed to be a positive polarity.
- CEU2.CAMOR.HOFST[12:0], CEU2.CAPWR.HWDTH[13:0]:
  Special setting is necessary. Please refer to the manual of CEU2 for details.

41.5.2 Data size limitations

There is a limitation in the data size at each data format.

- YUV422/ YUV420

  Maximum horizontal size is 8188 pixels(Maximum packet size is 16376 bytes). The pixel count should be an even number. The pixel count should be constant for one frame period.

- User Define 8-bit Data

  Maximum date size is 9900 byte. The pixel count should be constant for one frame period.

- Embedded Data

  It is 8192 bytes or less one frame

.

41.6 CSI2I Register Description

Table 41.5 shows the CSI2I register configuration. Table 41.6 shows the register states in each operating mode.

Table 41.5 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
Control timing select register	CSI2I_TREF	R/W	H'FE8F 7000	32
Software reset register	CSI2I_SRST	R/W	H'FE8F 7004	32
PHY operation control register1	CSI2I_PHYCNT1	R/W	H'FE8F 7008	32
Control register1	CSI2I_CNT1	R/W	H'FE8F 7020	32
Pixel size register	CSI2I_SIZE	R/W	H'FE8F 7024	32
Control register2	CSI2I_CNT2	R/W	H'FE8F 7060	32
Field detect control register	CSI2I_FLD	R/W	H'FE8F 7064	32
Interrupt clear register	CSI2I_INTCLR	R/W	H'FE8F 7070	32
Interrupt enable register	CSI2I_INTEN	R/W	H'FE8F 7074	32
Interrupt monitor register	CSI2I_INTMON	R/W	H'FE8F 707C	32

Table 41.3 Register States in Each Operating Mode

Register Abbreviation	Reset *	Module Standby

CSI2I_INTMON	Initialized	Retained

* For details, refer to section 1-D Overview of reset.

41.6.1 Control Timing Select Register (CSI2I_TREF)

CSI2I_TREF selects the reflection timing for the CSI2I registers.

It covers the following registers:

- CSI2I_SIZE
- CSI2I_CNT1
- CSI2I_CNT2
- CSI2I_FLD

The setting of this register is effective immediately after it is configured (immediately reflected).

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CLKENH	0	R/W	Clock Lane Operation Enable Bit 0: Operation disabled 1: Operation enabled
3	D3ENH	0	R/W	Data Lane 3 Operation Enable Bit 0: Operation disabled 1: Operation enabled
2	D2ENH	0	R/W	Data Lane 2 Operation Enable Bit 0: Operation disabled 1: Operation enabled
1	D1ENH	0	R/W	Data Lane 1 Operation Enable Bit 0: Operation disabled 1: Operation enabled
0	D0ENH	0	R/W	Data Lane 0 Operation Enable Bit 0: Operation disabled 1: Operation enabled

The setting of CSI2I_PHYCNT is decided by CSI2I_CNT1.CHLN[1:0].

- Case of CSI2I_CNT1.CHLN[1:0]=2'b00 :
  CSI2I_PHYCNT.{CLKENH,D3ENH,D2ENH,D1ENH,D0ENH} = 5'b10001
- Case of CSI2I_CNT1.CHLN[1:0]=2'b01 :
  CSI2I_PHYCNT.{CLKENH,D3ENH,D2ENH,D1ENH,D0ENH} = 5'b10011
- Case of CSI2I_CNT1.CHLN[1:0]=2'b10 :
  CSI2I_PHYCNT.{CLKENH,D3ENH,D2ENH,D1ENH,D0ENH} = 5'b10111
- Case of CSI2I_CNT1.CHLN[1:0]=2'b11:
  CSI2I_PHYCNT.{CLKENH,D3ENH,D2ENH,D1ENH,D0ENH} = 5'b11111

Other combinations are set prohibitions.

41.6.4 Control register1 (CSI2I_CNT1)

It is CSI2I control register.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	PEGM	–	–	–	PSEL	–	–	CHNL[1:0]

R/W :	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	PEGM	0	R/W	Pixel Enable generate Bit Generating PE during horizontal blanking. 0: Generate (Setting prohibited) 1: Not Generate

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	PSEL	1	R/W	Protocol Select Bit 0: Setting prohibited 1: CSI2 select
19,18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17,16	CHLN[1:0]	0	R/W	Channel Lane Number Bit 2’b00: 1lane 2’b01: 2lane 2’b10: 3lane 2’b11: 4lane
15,14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 8	DT[5:0]	6’h2C	R/W	Data Type Bit DT of the CSI2 standard is set. 6’h2A : 8bit Raw 6’h2B : 10bit Raw 6’h2C : 12bit Raw
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	IPEN	0	R/W	CSI2I Operation Enable Bit 0: Operation disabled 1: Operation enabled

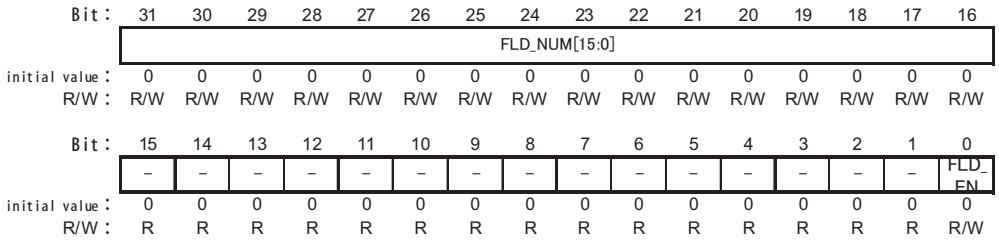
41.6.5 Picture size register (CSI2I_SIZE)

It is picture size register.

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 16	SIZEH[12:0]	13'h0280	R/W	Horizontal picture size Set
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	SIZEV[12:0]	13'h01E0	R/W	Vertical picture size Set

41.6.6 Control register2 (CSI2I_CNT2)

It is CSI2I control register.



Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	VC[1:0]		–	–	–	–
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5,4	VC[1:0]	2'b00	R/W	Virtual channel Set
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

41.6.7 Field detect control register (CSI2I_FLD)

It is CSI2I control register.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	FLD_NUM [15:0]	H'0000	R/W	First Field Number Set Bit The setting is used to detect the first field in an interlaced image. To detect it, the WC value (16 bits) in a Frame Start packet is referenced. If the WC value matches the setting, it is detected as the first field. The CSIR_FLD signal is driven High during the corresponding frame period. Set a value within a range from 0 to 3. Otherwise, normal operation is not guaranteed.
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	FLD_EN	0	R/W	First Field Detect Control Bit This bit is used to turn on/off detection of the first field. Set to B'1 to turn on detection. 0: Detection of the first field is turned off. 1: Detection of the first field is turned on.

41.6.8 Interrupt clear register (CSI2I_INTCLR)

It is CSI2I interrupt clear register.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	MON	CLR
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	MON	’b0	R	Interrupt monitor bit 0: There is no interrupt. 1: There is interrupt.
0	CLR	‘b0	R/W	Interrupt clear bit When this bit is made "1", all causes of interrupts are cleared. This bit is not cleared by the automatic operation. Please clear by software.

41.6.9 Interrupt enable register (CSI2I_INTEN)

It is CSI2I interrupt enable setup register.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INT31	INT30	–	–	–	–	–	–	–	INT22	–	INT20	–	–	–	–
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R	R	R	R	R	R	R	R/W	R	R/W	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	INT31	‘b0	R/W	VD start interrupt enable It is asserted by the VD output beginning(frame start) from CSI2I. 0: disable 1: enable
30	INT30	’b0	R/W	VD end interrupt enable It is asserted by the VD output end(frame end) from CSI2I. 0: disable 1: enable
29 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22	INT22	‘b0	R/W	Horizontal size error interrupt enable When the reception packet contradicts the setting of CSI2I_SIZE.HSIZE, it is asserted. 0: disable 1: enable

Bit	Bit Name	Initial Value	R/W	Description
21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	INT20	'b0	R/W	Vertical size error interrupt enable When the reception packet contradicts the setting of CSI2I_SIZE.VSIZE, it is asserted. 0: disable 1: enable
19 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

41.6.10 Interrupt monitor register (CSI2I_INTMON)

It is CSI2I interrupt monitor register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INS31	INS30	–	–	–	–	–	–	–	INS22	–	INS20	–	–	–	–
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	INS31	‘b0	R	VD start interrupt 0: Operating normally 1: Interrupt has occurred.
30	INS30	’b0	R	VD end interrupt 0: Operating normally 1: Interrupt has occurred.
29 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22	INS22	‘b0	R	Horizontal size error interrupt 0: Operating normally 1: Interrupt has occurred.
21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	INS20	‘b0	R	Vertical size error interrupt 0: Operating normally 1: Interrupt has occurred.
19 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

41.7 CSI2I control procedure

41.7.1 Control procedure of starting

There is a possibility of doing the incorrect data in capture when a differential terminal starts CSI2 in the indetermination. Therefore, please start CSI2 after fixing all differential pins.

41.7.2 CSIR_CLK setup

The clock set by the FRQCRA.CSIRFC[3:0] register of CPG is named CSIR_CLK.
CSI2I uses CSIR_CLK for the state(LowPower or HighSpeed) transition.
The frequency of CSIR_CLK is decided according to the frequency of receive clock as follows.

Receive clock	CSIR_CLK	FRQCRA.CSIFRC[3:0]
850-500MHz	37.5MHz	4'b1001
500-320MHz	16.6MHz	4'b1101
320-200MHz	12.5MHz	4'b1110

41.8 CSI2I Limitations .

41.8.1 Data size limitations

- Horizontal pixel count restriction

  It should be an even number for RAW12.

  It should be a multiple of four for RAW10.

- Maximum picture size : 4800x3600

Section 42 Display Serial Interface(DSI-Tx)

The DSI-Tx is a module that performs serial communications with LCD panels, which is compliant with the MIPI (Mobile Industry Processor Interface) Display Serial Interface specification.

42.1 Features

- Compliant with MIPI Alliance Standard for Display Serial Interface Draft Version 1.01.00 Release 09
- Compliant with the MIPI Alliance Specification for D-PHY v0.90.00
  - Functions as a DSI host processor (Tx) device.
  - Support for 4/3/2/1 lanes (HS mode)
  - Transfer mode:
    - High-speed (HS) unidirectional communication
    - Low power (LP) bidirectional communication
  - Support for video mode:
    - Non-burst mode with sync pulses
    - Non-burst mode with sync events
    - Burst mode
  - Support for command mode:
    - Command packet generation registers Long packets; 4 channels, short packets; 1 channel
    - Tearing effect (TE) trigger receive
  - Support for ultra low power mode
  - Data integrity mechanism
    - ECC/CRC code generation/addition to transmit packets
    - ECC/CRC check on receive packets
  - Virtual channel
    - 4 virtual channel supported
- Function outside DSI-Tx regulations
  - YUV422/YUV420 format transmission in the video mode
  - Data0/Data1 switching function while transmitting VsyncStart packets

Figure 42.1 shows the block diagram of DSITx0.

DSITX0 receives data from LCDC0 at the video mode, and outputs data with 4lane.

DSITX1 receives data from LCDC1 at the video mode, and outputs data with 2lane.Data .

An internal composition of DSITX1 is the same as DSITX0.

LPCLK and DSIPCLK of the figure below are about 80MHz, and from 10MHz to 50MHz respectively. Please set the rate of dividing frequency of PLL in CPG.

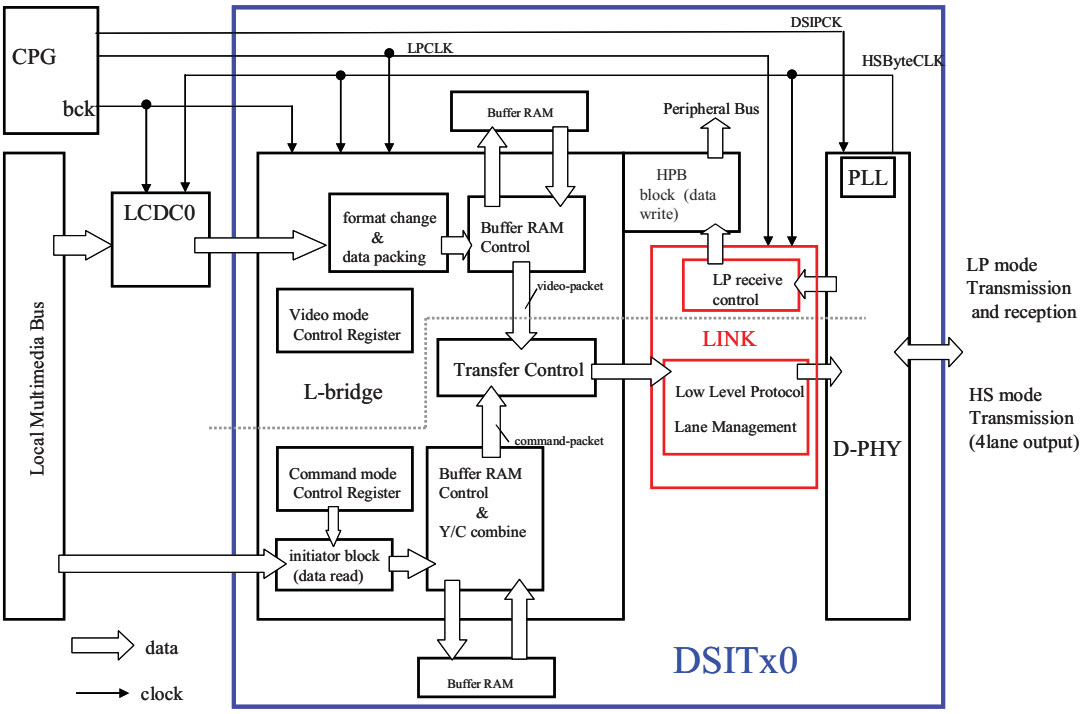


Figure 42.1 Block Diagram of DSITx0

42.1.1. block composition

The DSI-TX consists of the three major blocks:

1) D-PHY block that has Differential terminal and PLL
2) LINK block that has a direct connection with the D-PHY
3) L-bridge block that performs overall data processing

As these are practically separated modules, they may be noted individually in the description.

42.1.2. Terminology

In this document, many terms in the MIPI specification are used. For details on them, see the specification. Local terms other than those are defined as follows:

- HS byte clock: Clock that is eight dividing the high-speed serial communications clock.
  It is generated in D-PHY as follows.
  DSIPφ(DSIPCLK) (MIPI DSI PHY, 10MHz～50MHz)
  ↓
  Multiply by D-PHY(×12～×30) (PHYCTRL.PLLDS[3:0])
  ↓ ← High-speed serial communications clock(120～850Mbps)
  eight dividing
  ↓
  HS byte clock
- LP PHY clock: It is a clock that works in PHY of the LP control, and a frequency of 1/4 of LPCLK. It is generated with “AND” of LPCLK and internal enable signal.
- BLLP1: Indicates the BLLP period of VSA, VBP, and VFP lines excluding BLLP3.
- BLLP2: Indicates the BLLP period of VACT lines in the burst mode.
- BLLP3: Indicates the BLLP period immediately before the LPM of VFP lines.

42.2 Terminal composition

Table 42.1 shows the terminal composition of DSITx0.

Table 42.2 shows the terminal composition of DSITx1.

Table 42.1 DSITx0 Pin Configuration

Name	Function	I/O	Description
DSIM_TCLKP,DSIM_TCLKN	Differential clock	Output	Differential clock output
DSIM_TD0P,DSIM_TD0N	lane0 data	InOut	High-speed differential data output, LP data input/output.
DSIM_TD1P,DSIM_TD1N	lane1 data	Output	High-speed differential data output.
DSIM_TD2P,DSIM_TD2N	lane2 data	Output	High-speed differential data output.
DSIM_TD3P,DSIM_TD3N	lane3 data	Output	High-speed differential data output.

Table 42. 2 DSITx1 Pin Configuration

Name	Function	I/O	Description
DSIS_TCLKP,DSIS_TCLKN	Differential clock	Output	Differential clock output
DSIS_TD0P,DSIS_TD0N	lane0 data	InOut	High-speed differential data output, LP data input/output.
DSIS_TD1P,DSIS_TD1N	lane1 data	Output	High-speed differential data output.

42.3 Register Descriptions

Table 42.3 shows the resistor configuration of DSITx0. The resistor configuration of DSITx1 is similar to DSITx0 , though the address becomes H 'FFC7 *.

Table 42.3 Register Configuration

Register name	Abbreviation	R/W	DSI-Tx Address	Access Size
System Control Register	SYSCTRL	R/W	H'FFC60000	32

42.3.1. System Control Register (SYSCTRL)

It is a register that resets the Link block.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	SWRST
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial value	R/W	Description
31 to 1	-	All 0	R	Reserved
0	SWRST	0	R/W	Resets the LINK block. After a reset by writing 1, write 0 to clear the reset. This bit should be set for the Clock 100 cycle with the lowest frequency among the bus clock, HS byte clock, and LP clock . “1” is read for the SWRST set period. After SWRST is cleared, “0” is read. 0: Clears the LINK block reset (initial value). 1: Resets the LINK block.

42.3.2. System Configuration Register (SYSCONF)

It is a register concerning the transmission data and receive data that variously sets it.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	L123ULPSE	CONEN	CLSTPM	EOTEN	CRCCEN	ECCCEN	–	–	–	–	LANEEN[3:0]			
nitial :	0	0	1	1	0	1	1	1	0	0	0	0	0	0	0	0
R/W :	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial value	R/W	Description

Bit	Bit Name	Initial value	R/W	Description
31 to 14	-	H'00000	R	Reserved
13	L123ULPSEN	1	R/W	The ULPS transition outputs of lanes 1, 2, and 3 are set , disabling or enable. When this is enable, the ULPS transition is output . When this is disable, the LP-11 is output. Please set this bit only by initialization. 0: ULPS of lanes 1, 2, and 3 is disabled. 1: ULPS of lanes 1, 2, and 3 is enabled. (initial value)
12	CONEN	1	R/W	Enables and disables contention detection. Please set this bit only by initialization. 0: Contention detection disabled 1: Contention detection enabled (initial value)
11	CLSTPM	0	R/W	Used in the LP mode to output the HS clock (clock lane software control mode) or stop it (clock lane hardware control mode). Please set this bit only by initialization. 0: Clock lane hardware control mode (initial value) 1: Clock lane software control mode
10	EOTEN	1	R/W	Enable and disables EoT packet transmission in HS transmission. Please set this bit only by initialization. 0: EoT packet transmission disabled 1: EoT packet transmission enabled (initial value)
9	CRCCEN	1	R/W	Enables and disables CRC check in LP reception. Please set this bit only by initialization. 0: CRC check disabled 1: CRC check enabled (initial value)

Bit	Bit Name	Initial value	R/W	Description
8	ECCCEN	1	R/W	Enables and disables ECC check in LP reception. Please set this bit only by initialization. 0: ECC check disabled 1: ECC check enabled (initial value)
7 to 4	-	0000	R	Reserved
3 to 0	LANEEN[3:0]	0000	R/W	Enables and disables individual lanes. Bit[0], bit[1], bit[2], and bit[3] correspond to lane1, lane2, lane3, and lane 4 respectively. Do not set any values other than 4'b0001, 4'b0011, 4'b0111, and 4'b1111. Please set this bit only by initialization. 0000: All lanes are disabled (Initial value) 0001: Lane1 0011: Lane 2 0111: Lane 3 1111: Lane 4

42.3.3. Transition Timing Parameter Setting Register (TIMSET)

It is a register that sets the transition timing provided for by the MIPI D-PHY standard.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	WKUPVL[14:0]														
nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HSTRVL[3:0]				–	HSPPVL[2:0]			CKTRVL[3:0]				–	CKPPVL[2:0]		
nitial :	1	0	0	1	0	0	0	0	1	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial value	R/W	Description

31	-	0	R	Reserved
30 to 16	WKUPVL[14:0]	All 0	R/W	Set a value for T_{WAKEUP}. This value * the LP clock period * 4 is used as the T_{WAKEUP} value. Set a value so that this value is equal to or greater than 1 ms. The operation guarantee when other values are set cannot be done. Please set this bit only by initialization.
15 to 12	HSTRVL[3:0]	1001	R/W	Set a value for $T_{HS-TRAIL}$. (This value -2.5) * the HS byte clock period is used as the $T_{HS-TRAIL}$ value. Set a value so that (this value-2.5) * the HS byte clock period fills $T_{HS-TRAIL}$ and T_{EOT}. The operation guarantee when other values are set cannot be done. Please set this bit only by initialization.
11	-	0	R	Reserved
10 to 8	HSPPVL[2:0]	000	R/W	Set a value for $T_{HS-PREPARE}$. This value multiplied by the HS byte clock period is used as the $T_{HS-PREPARE}$ value. Set a value so that this value multiplied by the HS byte clock period is between 40 ns + 4 UI and 85 ns + 6 UI. The operation guarantee when other values are set cannot be done. Please set this bit only by initialization. UI indicates one-cycle period of the high-speed serial communications clock. It becomes a unit defined in written standards of MIPI D-PHY.

7 to 4	CKTRVL[3:0]	1000	R/W	Set a value for T_{CLK_TRAIL} . This value multiplied by the HS byte clock period is used as the T_{CLK_TRAIL} value. Set a value so that this value multiplied by the HS byte clock period fills $T_{CLK\text{-}TRAIL}$ and T_{EOT}. The operation guarantee when other values are set cannot be done. Please set this bit only by initialization.
3	-	0	R	Reserved
2 to 0	CKPPVL[2:0]	000	R/W	Set a value for $T_{CLK\text{-}PREPARE}$. This value multiplied by the HS byte clock period is used as the $T_{CLK\text{-}PREPARE}$ value. Set a value so that this value multiplied by the HS byte clock period is between 38 ns and 95 ns. The operation guarantee when other values are set cannot be done. Please set this bit only by initialization.

42.3.4. Transmission Packet Type Setting Register 0 (PTYPESET0)

It is a register that sets the packet type (long packet / short packet)
of each Data Type (from 00 0000 to 01 1111) of the transmission packet.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PTS[31:16]															
nitial :	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

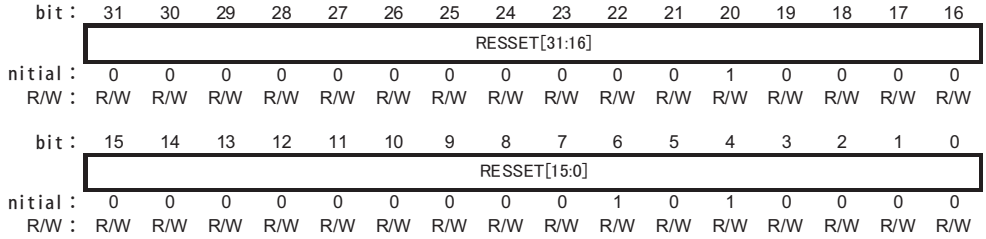
bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PTS[15:0]															
nitial :	1	1	1	1	1	1	1	0	1	0	0	0	0	0	0	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PTS[31:0]	H'FFC1_FE81	R/W	Sets the packet type (short or long packet) of each data type. It is a set prohibition to the bit 8 excluding 0. Bit 0 corresponds to the data type 00 0000 and bit 31 to 01 1111. Please set this bit only by initialization. 0: The corresponding data type is short packet. 1: The corresponding data type is long packet.

42.3.5. Transmission Packet Type Setting Register 1 (PTYPSET1)

It is a register that sets the packet type (long packet / short packet) of each Data Type (from 10 0000 to 11 1111) of the transmission packet.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PTS[31:16]															
nitial :	1	1	1	1	1	1	1	1	0	1	1	1	1	0	0	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

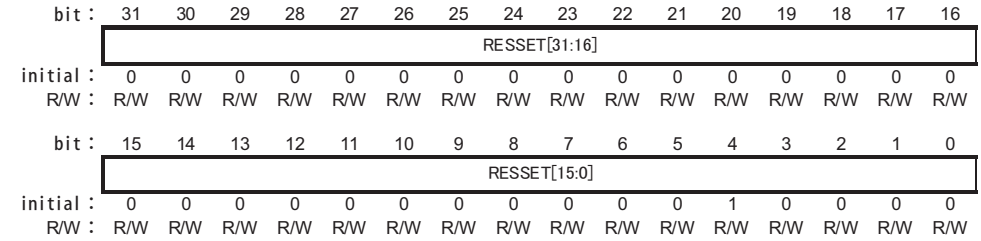


bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PTS[15:0]															
nitial :	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PTS[31:0]	H'FF79_FFE1	R/W	Sets the packet type (short or long packet) of each data type. Bit 0 corresponds to the data type 10 0000 and bit 31 to 11 1111. Please set this bit only by initialization. 0: The corresponding data type is short packet. 1: The corresponding data type is long packet.

42.3.6. Response Request Setting Register 0 (RESREQSET0)



It is a register that sets the response demand of the packet of Data Type(from 00 0000 to 01 1111).

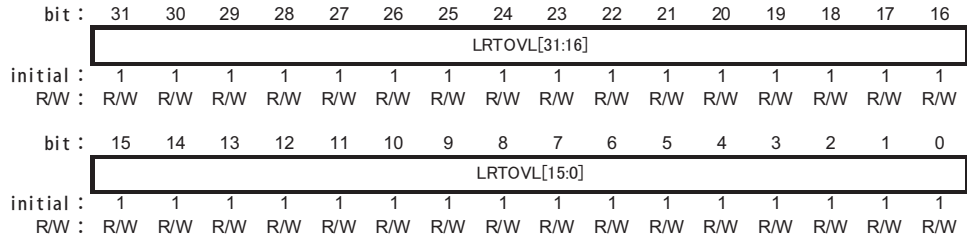
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RESSET[31:0]	H'0010_0050	R/W	Specifies whether or not packets of the specified data type request response. Bit 0 corresponds to the data type 00 0000 and bit 31 to 01 1111. Please set this bit only by initialization. 0: The packet with corresponding data type does not request a response. 1: The packet with corresponding data type requests a response.

42.3.7. Response Request Setting Register 1 (RESREQSET1)

It is a register that sets the response demand of the packet of Data Type(from 10 0000 to 11 1111).

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RESSET[31:0]	H'0000_0010	R/W	Specifies whether or not packets of the specified data type request response. Bit 0 corresponds to the data type 10 0000 and bit 31 to 11 1111. Please set this bit only by initialization. 0: The packet with corresponding data type does not request a response. 1: The packet with corresponding data type requests a response.

42.3.8. HS Transmission Time-out Setting Register (HSTTOVSET)

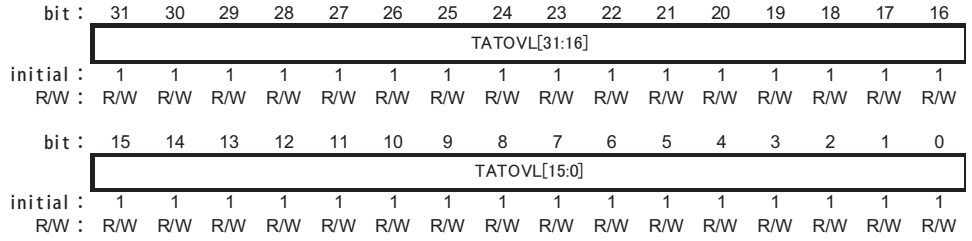


It is a register that sets the HS transmission time-out value.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	HTTOVL[31:16]															
initial :	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HTTOVL[15:0]															
initial :	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	HTTOVL[31:0]	All 1	R/W	Sets the HS transmit timeout value. This value multiplied by the HS byte clock period is used as the HS transmit timeout value. From bit31 to bit8 are recordable. From bit7 to bit0 are 1 fixed. Therefore, the minimum value that can be set becomes 255(h'FF).

42.3.9. LP Reception Time-out Setting Register (LPRTOVSET)



It is a register that sets the LP reception time-out value.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	LRTOVL[31:0]	All 1	R/W	Sets the LP reception timeout value. This value * LP clock period * 4 is used as the LP reception timeout value. Please set this bit only by initialization.

42.3.10. Turn Around Time-out Value Setting Register (TATOVSET)

It is a register that sets the turnaround time out value.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TATOVL[31:0]	All 1	R/W	Sets the turn around timeout value. This value * LP clock period * 4 is used as the turn around timeout value. Please set this bit only by initialization.

42.3.11. Peripheral Reset Time-out Value Setting Register (PRTOVSET)

It is a register that sets the peripheral reset time-out value.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PRTOVL[31:16]															
initial :	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PRTOVL[15:0]															
initial :	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PRTOVL[31:0]	All 1	R/W	Sets the peripheral reset timeout value. This value multiplied by the LP PHY clock period is used as the turn around timeout value. Please set this bit only by initialization.

42.3.12. DSI-LINK Control Register (DSICTRL)

It is a set register to control the Link block.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	PRTOS RQ	TATOE N	LPRTO EN	HSTTO EN	—	HTTOR C	—	RSTRR Q	—	ULENR Q	—	CLHER Q
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R	R/W	R	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	−	All 0	R	Reserved
11	PRTOSRQ	0	R/W	Requests to start counting of the peripheral reset timeout timer. Only 1 can be written. When this bit is 1, the start of counting is being requested, and no write access to it is allowed.
10	TATOEN	0	R/W	TA timeout timer count enable. This bit should be set only during initial setting. Please set it after setting TATOVSET.TATOVL. 0: Disables TA timeout timer counting (initial value). 1: Enables TA timeout timer counting.
9	LPRTOEN	0	R/W	LP reception timeout timer count enable. This bit should be set only during initial setting. Please set it after setting LPRTOVSET.LRTOVL. 0: Disables LP reception timeout timer counting (initial value). 1: Enables LP reception timeout timer counting.
8	HSTTOEN	0	R/W	HS transmission timeout timer count enable. This bit should be set only during initial setting. Please set it after setting HSTTOVSET.HTTOVL. 0: Disables HS transmission timeout timer counting (initial value). 1: Enables HS transmission timeout timer counting.
7	-	0	R	Reserved
6	HTTORC	0	R/W	When a HS transmit timeout occurs, the HS byte clock block is reset. Use this bit to clear the reset. Only 1 can be written. When this bit is 1, no write access is allowed. 1 is writable only that DSIINT.HSTXTOINTS=1 or DSIS.HTTORS=1. 0: Writing 1 access enabled 1: Clears the HS transmission timeout reset (writing 1 access disabled)
5	-	0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
4	RSTRRQ	0	R/W	Requests a reset trigger transmission. Only 1 can be written. When this bit is 1, no write access is allowed. 0: Writing 1 access enabled 1: Reset trigger transmission requested (writing 1 access disabled)
3	-	0	R	Reserved
2	ULENRQ	0	R/W	Requests a transition to and from ULPS. Writing 1 requests a transition to ULPS and writing 0 requests a transition from ULPS. 0: Transmission request from ULPS 1: Transmission request to ULPS
1	-	0	R	Reserved
0	CLHERQ	0	R/W	Requests the clock lanes transmission to HS mode. Writing 1 requests a transition to HS mode and writing 0 requests a transition from HS mode. 1 is writable only at DSIS.CLHENS=0. 0 is writable only at DSIS.CLHENS=1 0: Clock lane transmission from HS mode requested 1: Clock lane transmission to HS mode requested

42.3.13. Reception packet type setting register0 (RPTYPESET0)

It is a register that sets each packet type (long packet / short packet).
of each Data Type (from 00 0000 to 01 1111) of the reception packet.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RPTS[31:16]															
initial :	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RPTS[15:0]															
initial :	1	1	1	1	1	1	1	0	1	1	1	1	1	0	1	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RPTS[31:0]	H'FFF9_FEFB	R/W	The packet type (long packet / short packet) of each Data Type of the reception packet set. It is a set prohibition to the eighth bit excluding 0. The 0th bit corresponds in Data Type 000000 and the 31st bit corresponds to 011111. Please set this bit only by initialization. 0: Corresponding Data Type is a short packet. 1: Corresponding Data Type is a long packet.

42.3.14. Reception packet type setting register1 (RPTYPESET1)

It is a register that sets each packet type (long packet / short packet).
of each Data Type (from 10 0000 to 11 1111) of the reception packet.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RPTS[31:16]															
initial :	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RPTS[15:0]															
initial :	1	1	1	1	1	1	1	0	1	1	1	1	1	0	0	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RPTS[31:0]	H'FFFF_FEF9	R/W	The packet type (long packet / short packet) of each Data Type of the reception packet set. The 0th bit corresponds in Data Type 100000 and the 31st bit corresponds to 111111. Please set this bit only by initialization. 0: Corresponding Data Type is a short packet. 1: Corresponding Data Type is a long packet.

42.3.15. DSI-LINK Status Register (DSIS)

It is a status register of the Link block.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	TXMODE	HTTORS	STOPS	—	—	ULPSNS	—	CLHENS
initial :	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved
7	TRMODE	0	R	Indicates whether the direction of lane 0 is Tx or Rx. 0: Lane 0 is set as Tx (initial value). 1: Lane 0 is set as Rx.
6	HTTORS	0	R	Indicates the status of the reset caused by a HS transmit timeout. 0: The HS transmit timeout reset is being cleared (initial value). 1: The HS transmit timeout reset is in progress.
5	STOPS	1	R	Indicates that the valid lanes have transitioned to Stop State (LP-11). 0: The valid lanes are not in Stop State. 1: The valid lanes are in Stop State (initial value).
4 , 3	-	00	R	Reserved
2	ULPSENS	0	R	Indicates that both clock and data lanes have transitioned to ULPS. 0: Neither of clock and data lanes are not in the ULPS state or either of the data or clock lanes are not in the ULPS state (initial value). 1: Both clock and data lanes have transitioned to the ULPS state.
1	-	0	R	Reserved
0	CLHENS	0	R	Indicates that clock lanes have transitioned to HS mode. This status bit should be referenced only when the CLSTPM bit in the SYSCONF register is 1. 0: Clock lanes have not transitioned to HS mode (initial value). 1: Clock lanes have transitioned to HS mode.

42.3.16. DSI-LINK Interrupt Status Register (DSIINT)

It is a status register of the Link block. OR of each bit of this register is assumed to be an interrupt signal. It is allocated in DSITX1 as an interrupt factor in INTC.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	DPHYC INTS	ULPSC INTS	RSTTR INTS	RSHOR TINTS	CRCCE RINTS	ECCME RINTS	ECCSE RINTS	ULPT1INT	LDSYE RINTS	PLCTE RINTS	EMENE RINTS
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	HCOTE ERINT	LCOTE ERINT	TATOT NTS	TATOT NTS	LPRXT OINTS	HSTXT OINTS	—	—	—	—	ULPSE XINTS	ULPSE NINTS	CLHEX INTS	CLHEN INTS
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	-	All 0	R	Reserved
26	DPHYCINTS	0	R/W	Indicates that the D-PHY defined code of any of the command pattern "10011111" (Undefine-1), "11011110" (Undefine-2), or "10100000" (Unknown-5) has been received. To clear this bit, write 0 to it. 0: The D-PHY defined code has not been received (initial value). 1: The D-PHY defined code has been received.
25	ULPSCINTS	0	R/W	Indicates that a command of the command pattern "00011110" (ULPS) has been received. To clear this bit, write 0 to it. 0: ULPS command has not been received (initial value). 1: ULPS command has been received.
24	RSTTRINTS	0	R/W	Indicates that a trigger of the command pattern "01100010" (Reset) has been received. To clear this bit, write 0 to it. 0: Reset trigger has not been received (initial value). 1: Reset trigger has been received.
23	RSHORTINTS	0	R/W	It is shown to have received LP11 of the reception end without receiving the reception packet to the last minute. To clear this bit, write 0 to it. 0: Reception packet byte shortage error has not been detected.(initial value) 1: Reception packet byte shortage error is detected.
22	CRCCERINTS	0	R/W	Indicates that a CRC error has been detected in the receive packet. To clear this bit, write 0 to it. 0: CRC error has not been detected (initial value). 1: CRC error has been detected.
21	ECCMERINTS	0	R/W	Indicates that ECC multi-bit error has been detected in the receive packet. To clear this bit, write 0 to it. 0: ECC multi-bit error has not been detected (initial value).

Bit	Bit Name	Initial Value	R/W	Description
				1: ECC multi-bit error has been detected.
20	ECCSERINTS	0	R/W	Indicates that a single-bit ECC error has been detected in the receive packet. To clear this bit, write 0 to it. 0: Single-bit ECC error has not been detected (initial value). 1:Single-bit ECC error has been detected.
19	UELP11INTS	0	R/W	Indicates that unexpected LP11 has been detected during reception. To clear this bit, write 0 to it. 0: Unexpected LP11 has not been detected (initial value). 1: Unexpected LP11 has been detected.
18	LDSYERINTS	0	R/W	Indicates that a protocol error (LPDT sync error) has been detected in the receive packet. To clear this bit, write 0 to it. 0: LPDT sync error has not been detected (initial value). 1: LPDT sync error has been detected.
17	FLCTERINTS	0	R/W	Indicates that a protocol error (false control error) has been detected in the receive packet. To clear this bit, write 0 to it. 0: False control error has not been detected (initial value). 1: False control error has been detected.
16	EMENERINTS	0	R/W	Indicates that a protocol error (escape mode entry error) has been detected in the receive packet. To clear this bit, write 0 to it. 0: Escape mode entry error has not been detected (initial value). 1: Escape mode entry error has been detected.
15, 14	-	00	R	Reseved
13	HCOTEERRINTS	0	R/W	Indicates that a LP High fault contention error has been detected. To clear this bit, write 0 to it. 0: LP High fault contention error has not been detected (initial value). 1:LP High fault contention error has been detected.

Bit	Bit Name	Initial Value	R/W	Description
12	LCOTEERRINTS	0	R/W	Indicates that a LP Low fault contention error has been detected. To clear this bit, write 0 to it. 0: LP Low fault contention error has not been detected (initial value). 1:LP Low fault contention error has been detected.
11	PRTOINTS	0	R/W	Indicates that a peripheral reset timer timeout has been detected. To clear this bit, write 0 to it. 0: Peripheral reset timer timeout has not been detected (initial value). 1: Peripheral reset timer timeout has been detected.
10	TATOINTS	0	R/W	Indicates that a turn around timeout has been detected. To clear this bit, write 0 to it. 0: Turn around timeout has not been detected (initial value). 1: Turn around timeout has been detected.
9	LPRXTOINTS	0	R/W	Indicates that a LP reception timeout has been detected. To clear this bit, write 0 to it. 0: LP reception timeout has not been detected (initial value). 1: LP reception timeout has been detected.
8	HSTXTOINTS	0	R/W	Indicates that a HS transmission timeout has been detected. To clear this bit, write 0 to it. 0: HS transmission timeout has not been detected (initial value). 1: HS transmission timeout has been detected.
7 to 4	-	0000	R	Reserved
3	ULPSEXINTS	0	R/W	Indicates that both clock and data lanes are detected to have transitioned from ULPS. To clear this bit, write 0 to it. 0: Both clock and data lanes are not detected to have transitioned from ULPS or either of them is not detected to have transitioned from ULPS. 1: Both clock and data lanes are detected to have transitioned from ULPS.
2	ULPSENINTS	0	R/W	Indicates that both clock and data lanes are detected to have transitioned to ULPS. To clear

Bit	Bit Name	Initial Value	R/W	Description
				this bit, write 0 to it. 0: Both clock and data lanes are not detected to have transitioned to ULPS or either of them is not detected to have transitioned to ULPS. 1: Both clock and data lanes are detected to have transitioned to ULPS.
1	CLHSEXINTS	0	R/W	Indicates that clock lanes are detected to have transitioned from HS mode. Refer this status bit only when SYSCONF.CLSTPM = 1. To clear this bit, write 0 to it. 0: Clock lanes are not detected to have transitioned from HS mode (initial value). 1: Clock lanes are detected to have transitioned from HS mode.
0	CLHSENINTS	0	R/W	Indicates that clock lanes are detected to have transitioned to HS mode. Refer this status bit only when SYSCONF.CLSTPM = 1. To clear this bit, write 0 to it. 0: Clock lanes are not detected to have transitioned to HS mode (initial value). 1: Clock lanes are detected to have transitioned to HS mode.

42.3.17. DSI-LINK Interrupt Enable Register (DSIINTE)

It is a register that sets an enable interruption of each bit of the DSIINT register.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	DPHYC INTEN	ULPSC INTEN	RSTTR INTEN	RSHOR TINTE	CRCCE RINTE	ECCME RINTE	ECCSE RINTE	ULPT1 INTE	LDSTE RINTE	FLCTE RINTE	EMENE RINTE
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	HCOTE ERINT	LCOTE ERINT	PRTOT NTEN	TATOT NTEN	LPRXT OINTE	HSTXT OINTE	—	—	—	—	ULPSE XINTE	ULPSE NINTE	CLHEX INTEN	CLHEN INTEN
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	-	ALL 0	R	Reserved
26	DPHYCINTEN	0	R/W	Enables the D-PHY defined code reception interrupt. 0: D-PHY standard code reception interrupt disabled (initial value) 1: D-PHY standard code reception interrupt enabled
25	ULPSCINTEN	0	R/W	Enables the ULPS command reception interrupt. 0: ULPS command reception interrupt disabled (initial value) 1: ULPS command reception interrupt enabled
24	RSTTRINTEN	0	R/W	Enables the reset trigger reception interrupt. 0: Reset trigger reception interrupt disabled (initial value) 1: Reset trigger reception interrupt enabled
23	RSHORTINTEN	0	R/W	Reception byte shortage error reception interrupt is done enable. 0: Reception byte shortage error reception interrupt is disabled (initial value). 1: Reception byte shortage error reception interrupt is enable.
22	CRCCERINTEN	0	R/W	Enables the CRC error reception interrupt. 0: CRC error reception interrupt disabled (initial value) 1:CRC error reception interrupt enabled
21	ECCMERINTEN	0	R/W	Enables the ECC multi-bit error reception interrupt. 0: ECC multi-bit error reception interrupt disabled (initial value) 1: ECC multi bit error reception interrupt enabled
20	ECCSERINTEN	0	R/W	Enables the ECC single-bit reception interrupt. 0: ECC single-bit error reception interrupt disabled (initial value)

Bit	Bit Name	Initial Value	R/W	Description
				1: ECC single bit error reception interrupt enabled
19	UELP11INTEN	0	R/W	Enables the Unexpected LP11 reception interrupt 0: Unexpected LP11 reception interrupt disabled (initial value) 1: Unexpected LP11 reception interrupt enabled
18	LDSYERINTEN	0	R/W	Enables the LPDT sync error interrupt 0: LPDT sync error interrupt disabled (initial value) 1: LPDT sync error interrupt enabled
17	FLCTERINTEN	0	R/W	Enables the `false` control error interrupt 0: false control error interrupt disabled (initial value) 1: false control error interrupt enabled
16	EMENERINTEN	0	R/W	Enables the escape mode entry error interrupt 0: Escape mode entry error interrupt disabled (initial value) 1: escape mode entry error interrupt enabled
15, 14	-	00	R	Reserved
13	HCOTEERINTEN	0	R/W	Enables the LP high fault contention error interrupt 0: LP high fault contention error interrupt disabled (initial value) 1: LP high fault contention error interrupt enabled
12	LCOTEERINTEN	0	R/W	Enables the LP low fault contention error interrupt 0: LP low fault contention error interrupt disabled (initial value) 1: LP low fault contention error interrupt enabled
11	PRTOINTEN	0	R/W	Enables the peripheral reset timeout interrupt 0: Peripheral reset timeout interrupt

Bit	Bit Name	Initial Value	R/W	Description
				disabled (initial value) 1: Peripheral reset timeout interrupt enabled
10	TATOINTEN	0	R/W	Enables the turn around timeout interrupt 0: Turn around timeout interrupt disabled (initial value) 1: Turn around timeout interrupt enabled
9	LPRXTOINTEN	0	R/W	Enables the LP reception timeout interrupt 0: LP reception timeout interrupt disabled (initial value) 1:LP reception timeout interrupt enabled
8	HSTXTOINTEN	0	R/W	Enables the HS transmission timeout interrupt 0: HS transmission timeout interrupt disabled (initial value) 1: HS transmission timeout interrupt enabled
7 to 4	-	0000	R	Reserved
3	ULPSEXINTEN	0	R/W	Enables the ULPS exit interrupt 0: ULPS exit interrupt disabled (initial value) 1:ULPS exit interrupt enabled
2	ULPSENINTEN	0	R/W	Enables the ULPS entry interrupt 0: ULPS entry interrupt disabled (initial value) 1: ULPS entry interrupt enabled
1	CLHSEXINTEN	0	R/W	Enables the clock lane HS exit interrupt 0: Clock lane HS exit interrupt disabled (initial value) 1: Clock lane HS exit interrupt enabled
0	CLHSENINTEN	0	R/W	Enables the clock lane HS entry interrupt 0: Clock lane HS entry interrupt disabled (initial value) 1: clock lane HS entry interrupt enabled

42.3.18. PHY Control Register (PHYCTRL)

It is a set register that controls D-PHY.
First of all, bit0:BIPDWN is set.
Please open the period afterwards more than after 100us, and set other bits.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	CLKPDWN	PSRST	—	—	—	—	—	PLLRST	PLLPDWN	PLLBYPS
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	PLLDS[3:0]				–	–	–	–	–	–	–	BIPDWN
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	ALL 0	R	Reserved
25	CKPDWN	0	R/W	Puts the clock lane into the power-down state. This bit is not reset by software reset, and maintained. 0: Clock lane is reset (initial value) 1: Clock lane reset is canceled
24	PSRST	0	R/W	Resets the parallel/serial circuit. This bit is not reset by software reset, and maintained. 0: Parallel/serial circuit is reset (initial value). 1: Parallel/serial circuit reset is cleared.
23 to 19	-	ALL 0	R	Reserved
18	PLLRST	0	R/W	Resets the PLL. This bit is not reset by software reset, and maintained. 0: PLL is reset (initial value) 1: PLL reset is cleared.
17	PLLPDWN	0	R/W	Puts the PLL into the power-down state. This bit is not reset by software reset, and maintained. Please set “1” to this bit when you transmit HS. 0: PLL is in the power down state (initial value) 1: PLL Is power on
16	PLLBYPS	0	R/W	On/off in the bypass circuit of PLL is set. 0: The reference clock is output. (initial value) 1: Multiplication clock is output
15 to 12	-	0000	R	Reserved
11 to 8	PLLDS[3:0]	0000	R/W	Set the PLL multiplication ratio(The setting of less than six is prohibited.) This bit is not reset by software reset, and maintained. From 13 Multiplication to 31 Multiplication(Only the odd number) setting is possible. It becomes like the following expressions. Multiplication = 2 * PLLDS[3:0] + 1
7 to 1	-	ALL 0	R	Reserved
0	BIPDWN	0	R/W	Puts the bias circuit in the DSI-Tx block into the power-down state. 0: Bias circuit in the DSI-Tx block is in the power-down

Bit	Bit Name	Initial Value	R/W	Description
				state.
				1: Bias circuit in the DSI-Tx block is power-on.

42.3.19. DSI-L-Bridge Control Register (DTCTR)

It is a control register of L-Bridge block.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	STRST	–	MTEN	FLEN	VMEN
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved
4	STRST	0	R/W	The transmission control state machine is reset when setting it to 1. Please write 0 to release the reset state.
3	—	0	R	Reserved
2	MTEN	0	R/W	Enables the all packets transmission function. Please set 1 when you transmit the command. 0: Transmission disabled 1:Transmission enabled
1	FLEN	0	R/W	Specifies whether or not to transit to LPS every time HS packet transmission is completed. 0: Not to transit to LPS every at HS packet transmission completion. 1: Transit to LPS every at HS transmission completion.
0	VMEN	0	R/W	Enables video_mode. 0: Data input via LCDC prohibited. This enables the consecutive command transmission. 1: Data input via LCDC enable. This prohibits the consecutive command transmission.

42.3.20. DSI-L-Bridge Status Register (DTST)

It is an interrupt status register of L-Bridge.

OR of each bit of this register is assumed to be an interrupt signal. It is allocated in DSITX0 as an interrupt factor in INTC.

[31]DBSY and [15:8]HSCD are the monitor signals of the debugging usage, and interrupt cannot be generated.

When [28]CTPE and [23:20]DTE * are 1, the completion of the L-bridge block is shown.

In addition, after [28]CTPE and [23:20]DTE * is becoming 1, completion in the LINK block requires the next cycle number (HS byte clock conversion).

1lane output:27cycles 2lane output:15cycles

3lane output:11cycles 4lane output:10cycles

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DBSY	–	–	CTPE	–	–	–	–	DTE0	DTE1	DTE2	DTE3	FHEX	LPTAK	LPAK	FDEX
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HSCD[7:0]								HFOV	LFOV	ERPT	IRVE	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31	DBSY	0	R	It becomes 1 while DSITX's being transmitting data or receiving it.
30 to 29	—	00	R	Reserved
28	CTPE	0	R	This bit is set to 1 when command transmission of one packet is completed. It becomes active only at DTCTR.VMEN=0. Please write 1 in DTSTCL. CTPEC to return this bit to 0 from 1
27 to 24	—	0000	R	Reserved
23	DTE0	0	R	This bit is set to 1 when all packets for Long packet transmission [CH0] have been transmitted. It becomes active only at CMTLNGCTR0.TXSEL=1 and DTCTR.VMEN=0. Please write 1 in DTSTCL. DTE0C to return this bit to 0 from 1.
22	DTE1	0	R	This bit is set to 1 when all packets for Long packet transmission [CH1] have been transmitted. It becomes active only at CMTLNGCTR0.TXSEL=1 and DTCTR.VMEN=0. Please write 1 in DTSTCL. DTE1C to return this bit to 0 from 1.
21	DTE2	0	R	This bit is set to 1 when all packets for Long packet transmission [CH2] have been transmitted. It becomes active only at CMTLNGCTR0.TXSEL=1 and DTCTR.VMEN=0. Please write 1 in DTSTCL. DTE2C to return this bit to 0 from 1.
20	DTE3	0	R	This bit is set to 1 when all packets for Long packet transmission [CH3] have been transmitted. It becomes active only at CMTLNGCTR0.TXSEL=1 and DTCTR.VMEN=0. Please write 1 in DTSTCL. DTE3C to return this bit to 0 from 1.
19	FHEX	0	R	This bit is set to 1 when there is data in the header information FIFO for command reception (LP). Please write 1 in DTSTCL. FHEXC to return this bit to 0 from 1.

Bit	Bit Name	Initial Value	R/W	Description
18	LPTAK	0	R	This bit is set to 1 when a tearing effect trigger is received. Please write 1 in DTSTCL. LPTAKC to return this bit to 0 from 1.
17	LPAK	0	R	This bit is set to 1 when the Acknowledge is received. Please write 1 in DTSTCL. LPAKC to return this bit to 0 from 1.
16	FDEX	0	R	This bit is set to 1 when there is data in the data FIFO for command reception (LP). Please write 1 in DTSTCL. FDEXC to return this bit to 0 from 1.
15 to 8	HSCD[7:0]	0	R	It is a value of { VCID[1:0] ,DataType [5:0]} when HS output from L-Bridge is transmitted.
7	HFOV	0	R	HS transmission data count mismatch error Please write 1 in DTSTCL. HFOVC to return this bit to 0 from 1
6	LFOV	0	R	LP transmission data count mismatch error Please write one in DTSTCL. LFOVC to return this bit to 0 from one.
5	ERPT	0	R	Acknowledge with Error Report is received at command reception (LP). Please write one in DTSTCL. ERPTC to return this bit to 0 from one.
4	IRVE	0	R	Video mode command transmission error (error of interleave function) Please write one in DTSTCL. IRVEC to return this bit to 0 from one.
3 to 0	—	0000	R	Reserved

42.3.21. DSI−L−Bridge Status Clear Register (DTSTCL)

It is a register that clears the interrupt status of the DTST register.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	CTPEC	–	–	–	–	DTE0C	DTE1C	DTE2C	DTE3C	FHEXC	LPTAKC	LPAKC	FDEXC
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	HFOVC	LFOVC	ERPTC	IRVEC	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	000	R	Reserved
28	CTPEC	0	R/W	DTST.CTPE is cleared when written to 1. After one cycle, it becomes 0.
27 to 24	—	0000	R	Reserved
23	DTE0C	0	R/W	DTST.DTE0 is cleared when written to 1. After one cycle, it becomes 0.
22	DTE1C	0	R/W	DTST.DTE1 is cleared when written to 1. After one cycle, it becomes 0.
21	DTE2C	0	R/W	DTST.DTE2 is cleared when written to 1. After one cycle, it becomes 0.
20	DTE3C	0	R/W	DTST.DTE3 is cleared when written to 1. After one cycle, it becomes 0.
19	FHEXC	0	R/W	DTST.FHEX is cleared when written to 1. After one cycle, it becomes 0.
18	LPTAKC	0	R/W	DTST.LPTAK is cleared when written to 1. After one cycle, it becomes 0.
17	LPAKC	0	R/W	DTST.LPAK is cleared when written to 1. After one cycle, it becomes 0.
16	FDEXC	0	R/W	DTST.FDEX is cleared when written to 1. After one cycle, it becomes 0.
15 to 8	—	ALL 0	R	Reserved
7	HFOVC	0	R/W	DTST.HFOV is cleared when written to 1. 0 is always read.
6	LFOVC	0	R/W	DTST.LFOV is cleared when written to 1. After one cycle, it becomes 0.
5	ERPTC	0	R/W	DTST.ERPT is cleared when written to 1. After one cycle, it becomes 0.
4	IRVEC	0	R/W	DTST.IRVE is cleared when written to 1. After one cycle, it becomes 0.
3 to 0	—	0000	R	Reserved

42.3.22. DSI-L-Bridge Interrupt Enable Register (DTIRQEN)

It is an interrupt enable register of the DTST register.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	CTPEIE	–	–	–	–	DTE0IE	DTE1IE	DTE2IE	DTE3IE	FHEXIE	LPTAKIE	LPAKIE	FDEXIE
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	HFOVIE	LFOVIE	ERPTIE	IRVEIE	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	000	R	Reserved
28	CTPEIE	0	R/W	Asserts an interrupt when the condition DTST.CTPE= 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
27 to 24	—	0000	R	Reserved
23	DTE0IE	0	R/W	Asserts an interrupt when the condition DTST.DTE0= 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
22	DTE1IE	0	R/W	Asserts an interrupt when the condition DTST.DTE1= 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
21	DTE2IE	0	R/W	Asserts an interrupt when the condition DTST.DTE2= 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
20	DTE3IE	0	R/W	Asserts an interrupt when the condition DTST.DTE3= 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
19	FHEXIE	0	R/W	Asserts an interrupt when the condition DTST.FHEX = 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
18	LPTAKIE	0	R/W	Asserts an interrupt when the condition DTST.LPTAK = 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
17	LPAKIE	0	R/W	Asserts an interrupt when the condition DTST.LPAK = 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
16	FDEXIE	0	R/W	Asserts an interrupt when the condition

Bit	Bit Name	Initial Value	R/W	Description
				DTST.FDEX = 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
15 to 8	—	ALL 0	R	Reserved
7	HFOVIE	0	R/W	Asserts an interrupt when the condition DTST.HFOV = 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
6	LFOVIE	0	R/W	Asserts an interrupt when the condition DTST.LFOV = 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
5	ERPTIE	0	R/W	Asserts an interrupt when the condition DTST.ERPT is satisfied. 0: Interrupt disabled 1: Interrupt enabled
4	IRVEIE	0	R/W	Asserts an interrupt when the condition DTST.IRVE = 1 is satisfied. 0: Interrupt disabled 1: Interrupt enabled
3 to 0	—	0000	R	Reserved

42.3.23. Video Mode Control Register 1 (VMCTR1)

This register is used for video mode control. It is mainly used to configure transmission packets.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	FSS	VSYNW[3:0]				BKM
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PCTYPE[3:0]				–	–	–	–	VCID[1:0]		DT[5:0]					
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	ALL 0	R	Reserved
21	FSS	0	R/W	Selects the source of the signal from which an Odd/Even field is determined. 0: DSI-Tx 1: LCDC Refer to the descriptions for VMCTR1 for details.
20 to 17	VSYNW[3:0]	0000	R/W	Vertical Sync Signal Width. (unit of line) Please set it when you set VMCTR2.BL1BM=1 and VMCTR2.VSEE=1. Set the same value as in MLDVSYNR.VSYNW[3:0] of LCDC.
16	BKM	0	R/W	LCD Data Reception Clock Selection 0: HS byte clock 1: bck When the HS byte clock is selected, the LCDC dot clock should be set to the HS byte clock. Please set 0 to this bit when as much as one Blanking Packet is selected in VMCTR2[5:0]. note: Please set the clock selection of this bit earlier than DTCTR.VMEN.
15 to 12	PCTYPE[3:0]	0000	R/W	The LCDC supplies RBG888 (24 bits) or YUV422 (16 bits) data. Select the packet format into which this data is converted. Conversion from RGB888: 4'b0000: Not converting (RGB888) 4'b0001: RGB565 4'b0010: RGB666 (loosely packed) 4'b0011: RGB666 4'b1000: BGR888 4'b1001: BGR565 4'b1010: BGR666 (loosely packed) 4'b1011: BGR666 Conversion from YUV422: 4'b0100: YUV422 (Y1, U1, Y2, V1, ……)

Bit	Bit Name	Initial Value	R/W	Description
				4'b0101: YUV422 (U1, Y1, V1, Y2, ……) 4'b0110: YUV420 legacy*[1] 4'b0111: YUV420*[2] Note: *1 U and V uses the data of odd-line and even-line respectively. Note: *2 U and V use the even-line data.
11 to 8	—	0000	R	Reserved
7, 6	VCID[1:0]	00	R/W	Set the virtual channel for the video mode output.
5 to 0	DT[5:0]	ALL 0	R/W	Set the data type for the video mode output.

42.3.24. Video Mode Control Register 2 (VMCTR2)

This register is used for video mode control.

It specifies whether sync event packets are transmitted or HSA or BLLP periods are allowed depending on Non-Burst Mode with Sync Pulses, Non-Burst Mode with Sync Events, or Burst mode.

It also allows or disallows command transmission during the BLLP period.

In addition, it specifies whether to transition to LPS or to hold HS transmission (transmit blanking packets) during the HSA, HBP, HFP, and BLLP periods.

When you set one even by one at 5:0 of this registers, please assume VMCTR1.BKM=0, and give the dot clock to me as HS byte clock.

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	ALL 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23	VSEE	0	R/W	Sets the VSE output 0: VSE is not output. 1: VSE is output.
22	HSEE	0	R/W	Sets the HSE output 0: HSE is not output. 1: HSE is output.
21	HSAE	0	R/W	HSA period 0: HSA period is not allowed. 1: HSA period is allowed.
20 to 18	—	000	R	Reserved
17	BL2E	0	R/W	BLLP2 period 0: BLLP2 is not allowed. 1: BLLP2 is allowed.
16 to 11	—	ALL 0	R	Reserved
10	BL1IEN	0	R/W	Command transmission during BLLP1 period 0: Disabled 1: Enabled Note: When set 1 in this bit, the BL1BM bit need to be set to 0.
9	BL2IEN	0	R/W	Command transmission during BLLP2 period 0: Disabled 1: Enabled Note: When set 1 in this bit, the BL2BM bit need to be set to 0.
8	BL3IEN	0	R/W	Command transmission during BLLP3 period 0: Disabled 1: Enabled Note: When set 1 in this bit, the BL3BM bit need to be set

Bit	Bit Name	Initial Value	R/W	Description
				to 0.
7,6	—	00	R	Reserved
5	HSABM	0	R/W	State setting during HSA period. Please usually set 0, and set 1 only when it is not possible to change to LPS. 0: LPS 1: Blanking packet transmission
4	HBPBM	0	R/W	State setting during HBP period. Please usually set 0, and set 1 only when it is not possible to change to LPS. 0: LPS 1: Blanking packet transmission
3	HFPBM	0	R/W	State setting during HFP period. Please usually set 0, and set 1 only when it is not possible to change to LPS. 0: LPS 1: Blanking packet transmission
2	BL1BM	0	R/W	State setting during BLLP1 period. Please usually set 0, and set 1 only when it is not possible to change to LPS. 0: LPS 1: Blanking packet transmission
1	BL2BM	0	R/W	State setting during BLLP2 period. Please usually set 0, and set 1 only when it is not possible to change to LPS. 0: LPS 1: Blanking packet transmission
0	BL3BM	0	R/W	State setting during BLLP3 period. Please usually set 0, and set 1 only when it is not possible to change to LPS. 0: LPS 1: Blanking packet transmission

Lists the settings at the each mode as follows:

- Non-burst mode with sync pulses: VSEE = 1, HSEE = 1, HSAE = 1, BL2E = 0
- Non-burst mode with sync events: VSEE = 0, HSEE = 0, HSAE = 0, BL2E = 0
- Burst mode: VSEE = 0, HSEE = 0, HSAE = 0, BL2E = 1

42.3.25. Video Mode Data Length Register 1 (VMLEN1)

This register is used for video mode control.

The volume of data at image data and HSA period (Blanking) is set.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RGBLEN[15:0]															
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	BL3LEN[15:0]	H'0001	R/W	Set volume of data (byte) of Blanking Packet at the bllp3 period. It becomes effective only at VMCTR2. BL3BM=1.
15 to 0	—	ALL 0	R	Reserved

42.3.29. Video Mode Short Packet Data Register 1 (VMSDAT1)

This register sets values for the data portion (Data0,Data1) of VsyncStart packets.
The values can be set for states A and B individually.
States A and B can be switched via the FSS bit in the VMCTR1 register.

- When the FSS bit in VMCTR1 register is 0:
  States A and B are switched every time one frame is transmitted.
  This register is initialized to state A when the VMEN bit in the DTCTR register is set to 0.

・When the FSS bit in the VMCTR1 register is 1:
The state depends on the LCDC plane to be used (A or B).

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VSSAD[15:0]															
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VSSBD[15:0]															
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	VSSAD[15:0]	ALL 0	R/W	These bits set the VsyncStart data value in state A.
15 to 0	VSSBD[15:0]	ALL 0	R/W	These bits set the VsyncStart data value in state B.

42.3.30. Video Mode Short Packet Data Register 2 (VMSDAT2)

The data value of VSyncEnd, HSyncStart, and HSyncEnd is set.

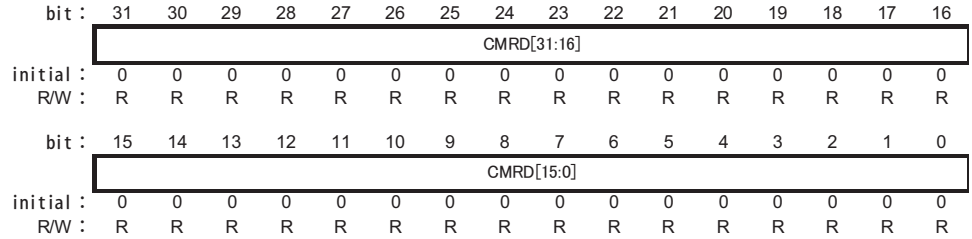
bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VMSRTD[15:0]															
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	ALL 0	R	Reserved
15 to 0	VMSRTD[15:0]	ALL 0	R/W	These bits set the data value for VsyncEnd, HsyncStart, and HsyncEnd.

42.3.31. Command Mode Reception Control Register (CMRCTR)

This register sets the overall LP reception operation.

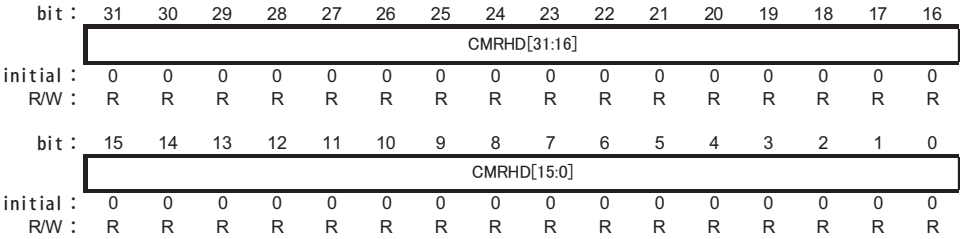


bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	FRST	–	–	–	–	–	CRXEN	DMAEN	FIFOS
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	FHNM[2:0]			FDNM[3:0]			
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	ALL 0	R	Reserved
24	FRST	0	R/W	When 1 setting , Data in reception FIFO for the data and Data in reception FIFO for the header is deleted. Please use it to delete the unnecessary data that has been stored in FIFO when ECC multi-bit error happens. This function cannot be used while receiving data. After 1 cycle with the bus clock , this bit returns to 0 .
23 to 19	—	ALL 0	R	Reserved
18	CRXEN	0	R/W	Reception enable 0: Disables LP reception. Transmitted data is discarded. 1: Enables LP reception.
17	DMAEN	0	R/W	Setting of method of reading data that exists in reception FIFO for data 0: Received data is read by the CPU (software operation). 1: Received data is read by the DMA.
16	FIFOS	0	R/W	Whether PH information is stored in reception FIFO for data is selected. 0: PH information is stored only in reception FIFO for the header. 1: PH information is stored in reception FIFO for the header and reception FIFO for data.
15 to 7	—	0	R	Reserved
6 to 4	FHNM[2:0]	000	R	Indicates the number of data (up to 7) in the receive FIFO for headers. Every time the CPU read CMRHEAD register, this bit value is decremented by 1.
3 to 0	FDNM[3:0]	0000	R	Indicates the number of data (up to 15) in the receive FIFO for datas. Every time the CPU or DMA read CMRDAT register, this bit value is decremented by 1.

42.3.32. Command Mode Reception Data Register (CMRDAT)



This register indicates the data value received during LP reception.
It has a 15-stage FIFO configuration.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMRD[31:0]	ALL 0	R	Show the received data value. When read by the CPU or DMA, the value in the next-stage FIFO is shown in the next cycle.

42.3.33. Command Mode Reception Header Register (CMRHEAD)

This register indicates the PH value received during LP reception.
It has a 7-stage FIFO configuration.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMRHD[31:0]	ALL 0	R	Show the received PH(packet header) value. When read by the CPU, the value in the next-stage FIFO is shown in the next cycle.

42.3.34. Tearing Effect Request Register (CMRTEREQ)

The tearing effect request is set.

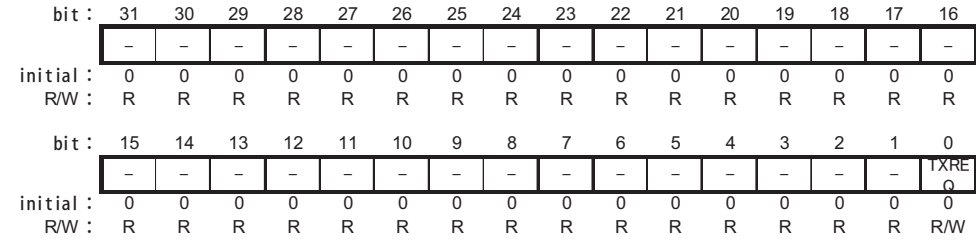
bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	TEREQ
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	ALL 0	R	Reserved
0	TEREQ	0	R/W	Requests the tearing effect for a peripheral (LCD panel). After setting 1 , when the clock putting changing into LPCLK is completed, it becomes 0.

42.3.35. Command Mode Transmission Long Packet Request CH0 Register (CMTLNGREQ0)

This is a command packet generation register. It sets the transmission request for CH0.
There are four channels of registers that are related to generating long command packets. All of them have the same function, so only CH0 will be described.



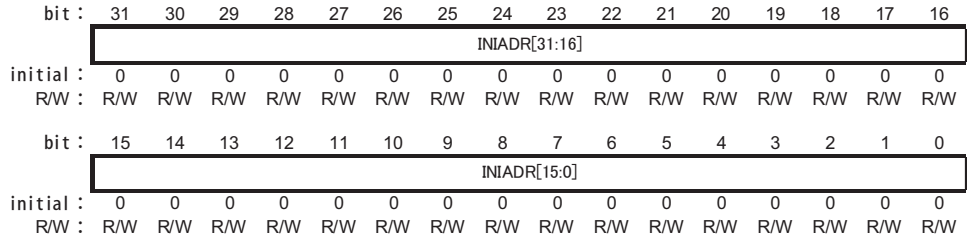
bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	TXWAIT	TXREQ
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	ALL0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	TXWAIT	0	R/W	Transmit stop setting Set TXWAIT to 1 to stop the packet transmission temporarily when TXRERQ is 1. The transmission is stopped after the current packet transmission is completed. When tx_wait is set to 0, the transmission is resumed.
0	TXREQ	0	R/W	Transmission request setting When written to 1, a transmission request is issued and command-packet transmission is started according to the settings of CMTIADR0, CMTITTL0, CMTIADRI0, CMTIRN0, CMTLNGCTR0, and CMTLNGDT0. When all packets are transmitted, this bit changes to 0. Writing 0 to this bit while transmission is in progress (it is 1) cancels the transmission. If there are packets being transmitted, this bit is 0 after the packets are transmitted. If there is no packet being transmitted (packets for other channels are being transmitted), this bit changes to 0 immediately. The values of other registers (CMTIADR0, CMTITTL0, CMTIADRI0, CMTIRN0, CMTLNGCTR0, CMTLNGDT0) related to command-packet transmission must be changed only when this bit is 0. Please go after confirming this bit is 0 when the following command is transmitted.

42.3.36. Command Mode Transmision Short Packet Request Register (CMTSRTREQ)

This register is related to command-packet transmission.
It sets up the transmission request for short packets



Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TXREQ	0	R/W	Transmission request setting When 1 is written to this bit, a transmission request is issued and command-packet transmission is started according to the CMTSRTCTR setting. When the packet transmission is completed, this bit changes to 0. Please go after confirming this bit is 0 when the following command is transmitted.

42.3.37. Command Mode Transmission Initiator Address CH0 Register (CMTIADR0)

This is a command packet generation register. It sets the source address of transmit data for CH0.

Only CH0 is described.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	INIADR[31:0]	ALL 0	R/W	Source address setting These bits function as an address register when CMTLNGCTR0. TXSEL is 1.In this case, the lower 3 bits should be fixed to 0. When CMTLNGCTR0. TXSEL is 0, all bits are used because they function as a data storage register.

42.3.38. Command Mode Transmission Initiator Total Data CH0 Register (CMTITTL0)

This is a command packet generation register.
The volume of data of 1 line is set. Only CH0 is described.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INITTAL[31:16]

Bit	Bit Name	Initial Value	R/W	Description
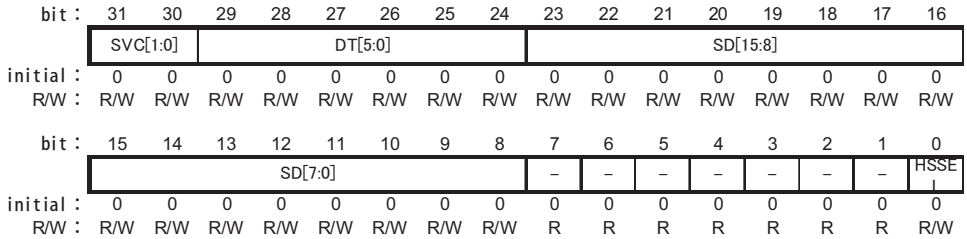
31 to 0	INIRPTNUM[31:0]	ALL 0	R/W	Line size setting When CMTLNGCTR0. TXSEL is 1, set the number of lines. When data to be transmitted is not image data such as JPEG code, set to 1. When CMTLNGCTR0. TXSEL is 0, these bits function as a data storage register.

42.3.41. Command Mode Transmission Long Packet Control CH0 Register (CMTLNGCTR0)

This is a command packet generation register. This register provides transmission control for CH0. Only CH0 is described.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VCID[1:0]		DT[5:0]						–	–	–	–	LENG[11:8]			
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LENG[7:0]								–	–	–	–	–	–	TXSE	HSSE
initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W



Bit	Bit Name	Initial Value	R/W	Description
31, 30	VCID[1:0]	00	R/W	Set the VC of command-packet.
29 to 24	DT[5:0]	ALL 0	R/W	Set the data type of command-packet.
23 to 20	—	0000	R	Reserved
19 to 8	LENG[11:0]	ALL 0	R/W	Set the payload size of command-packet in these bits. The lower 3 bits should be fixed to 0 when the TXSEL bit is 1. The maximum payload size is 2 Kbytes.*
7 to 2	—	ALL 0	0	Reserved
1	TXSEL	0	R/W	Data select 0: Transmits the data stored in the 4 data registers. 1: Transmits the data read from the memory.
0	HSSEL	0	R/W	Transmission speed select 0: Low power (LP) transmission 1: High speed (HS) transmission

Note:*

If a format conversion is to be performed by setting CMTLNGDT0.RGBCNV and YUVCNV , WordCount of transmit packets is processed. For RGB666, the packet length is 3/4 of the original data. The size is limited to 2 Kbytes before processing.

42.3.42. Command Mode Transmission Short Packet Control Register (CMTSRTCTR)

This register is related to command-packet transmission. It sets up short packet data to be transmitted.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	SVC[1:0]	00	R/W	Set the VC of command-packet.
29 to 24	DT[5:0]	All 0	R/W	Set the data type of command-packet. 0x08 is a set prohibition.
23 to 8	SD[15:0]	All 0	R/W	Set the Data0 and Data1 of short packet.
7 to 1	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	HSSEL	0	R/W	Transmission speed select 0: Low power (LP) transmission 1: High speed (HP) transmission

42.3.43. Command Mode Transmission Long Packet Data Type CH0 Register (CMTLNGDT0)

This is a command packet generation register. It sets up special control for CH0.
Only CH0 is described.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	RGBCNV[2:0]			YUVCNV[3:0]				–	COMTLS	COMTWS	COMTBS	–	–	AFSFE	MULDTEN

nitial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved
30 to 28	RGBCNV[2:0]	000	R/W	Selects the packet format into which RGB data is converted. 3'b000: Not converting (RGB888) 3'b001: RGB565 3'b010: RGB666 (loosely packed) 3'b011: RGB666 3'b100: BGR888 3'b101: BGR565 3'b111: BGR666 For RGB888 and BGR888, the original data must be RGB888 (3 bytes/pixel). For RGB666 (LP), RGB666, and BGR666, the original data must be RGB888 and RGB666 (3 bytes/pixel for both of them). For RGB565 and BGR565, the original data must be RGB565 (2 bytes/pixel).
27 to 24	YUVCNV[3:0]	0000	R/W	When data in the YUV format is transmitted, Y data and UV data stored in separate area can be transmitted by combining them. Bit 3: Combining setting 0: Not be combined 1: Combined Bit2: Source data setting 0: YUV420 1: YUV422 Bit1, 0: Transmission format setting 2'b0: Setting prohibited 2'b01: YUV422 (U1, Y1, V1, Y2) 2'b10: YUV420 (legacy) 2'b11: YUV420 Note: This function uses two channels of command packet generation registers. These include channel the CH0 and CH1 pair and the CH2 and CH3 pair.

Bit	Bit Name	Initial Value	R/W	Description
				Y data is specified by CH0 and CH2. UV data is specified by CH1 and CH3.
23	—	0	R	Reserved
22	COMTLS	0	R/W	When this bit is set to 1, the command data is swapped in longword units.
21	COMTWS	0	R/W	When this bit is set to 1, the command data is swapped in word units.
20	COMTBS	0	R/W	When this bit is set to 1, the command data is swapped in byte units.
19 to 18	—	00	R	Reserved
17	AFSFE	0	R/W	Appends FrameStart and FrameEnd short packets before and after the original transmit data automatically .
16	MULDTEN	0	R/W	Makes DTs for the start, intermediate, and end packets configurable when a group of data is to be divided into packets for transmission. 0: Uses the CMTLNGCTR0.DT[5:0] value as DT regardless of whether it is for the start, intermediate, or end packet. 1: Uses the CMTLNGCTR0.DT[5:0], CMTLNGDT0.MDT[5:0], and CMTLNGDT0.FDT[5:0] values for the start, intermediate, and end packets respectively.
15, 14	—	00	R	Reserved
13 to 8	MDT[5:0]	ALL 0	R/W	These bits specify DT for the intermediate packet.
7, 6	—	00	R	Reserved
5 to 0	FDT[5:0]	ALL 0	R/W	These bits specify DT for the end packet.

42.4 Operating Mode

The L-bridge has two operating modes as internal status: video mode and command mode, which are switched by the VMEN in the DTCTR register.

In the video mode, video-packets (Note 1) take precedence in transmission and transmission of command-packets (Note 2) is restricted.

In the command mode, video-packets cannot be transmitted, but transmission of command-packets is not restricted.

Note1:Packet that is generated by processing the input data from the LCDC in the upper stage in figure 42.1.

Note2:Packet that is generated by processing the data from the register in the lower stage in figure 42.1 or from the external memory

42.4.1. Video Mode

Transmission in the video mode cannot be performed without the cooperation of the LCDC.

Please start in order of DSI-Tx → LCDC.

Please stop in order of DSI-Tx → LCDC.

The start of above-mentioned DSI shows DTCTR.VMEN=1 and the stop of DSI shows DTCTR.VMEN=0.

Figure 42.2 shows the example of the image data output when the number of each lane is set.

(The header and the footer are omitted. Beginning of the output of the data of the LINK block actually requires more cycles number from beginning of the output of the data of the L-bridge block.)

The number of lanes is set by SYSCONF.LANEEN[3:0] register.

The output of the image data of the L-bridge block makes the DISP signal from LCDC a trigger, and outputs the image data from one LCDC of the previous line.

At this time, even if it is the same number of packets, output cycle of image data number is different as shown in Figure 42.2 according to the setting of the number of lanes.

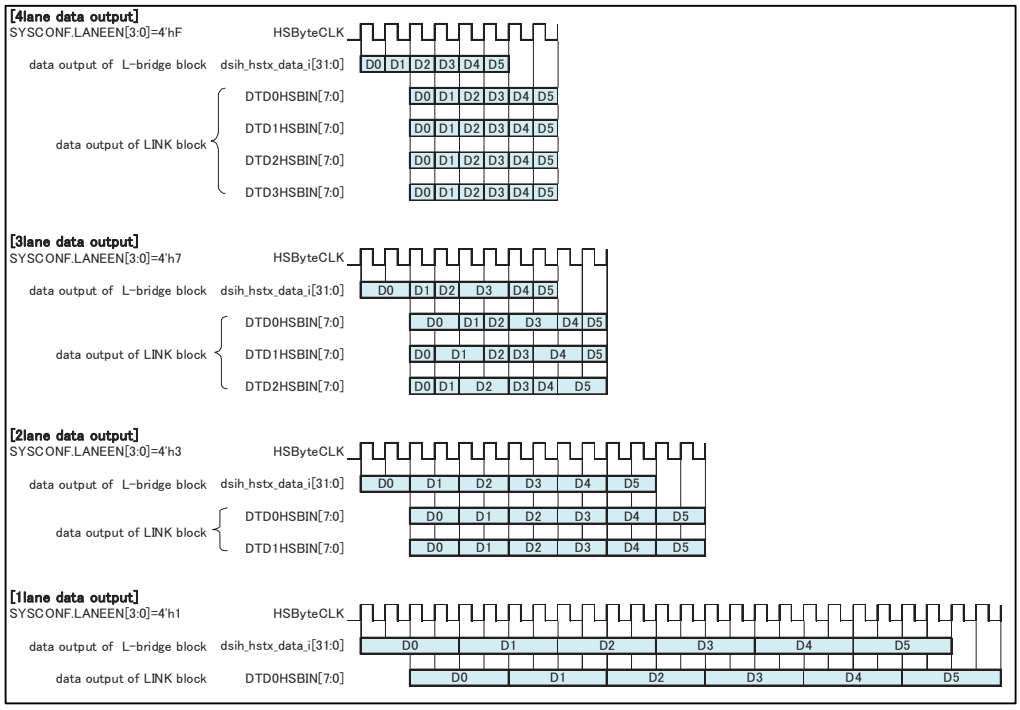

Figure 42.2 Output of data of number of each lane

Please see Figure 42.3.

Before becoming active the following Hsync from LCDC, The image data output, the BLLP2 period, and the HFP period of the L-bridge block must end. Please set LCDC with room enough for that.

It becomes impossible to secure operation because it becomes impossible to output the HSS packet when image data output period + BLLP2 period + HFP period is the following Hsync and comes in succession.

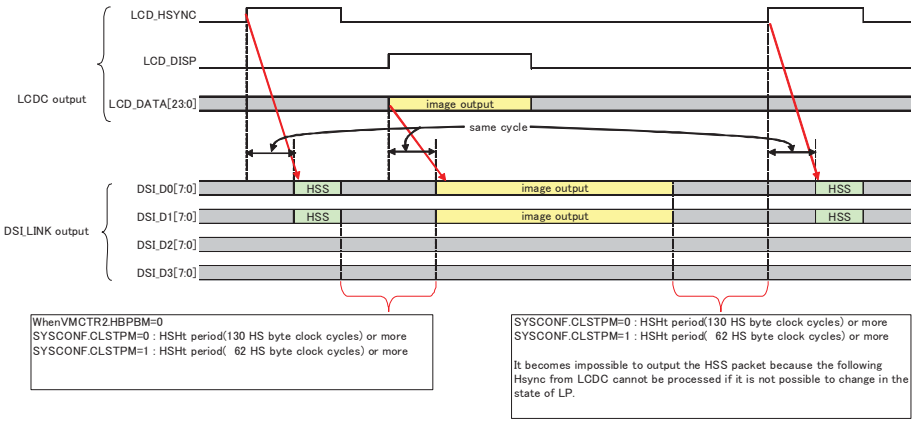

Figure 42.3 Relation between sync signal and output of image

42.4.2. Blanking Packet

It takes a certain time (HSHt) between transitions from HS transmission to LPS to HS transmission.

To transmit HS packets continuously within HSHt in the video mode, the HS transmission state should be maintained by sending a blanking packet because there is not enough time to transition to LPS.

HSHt is 130 HS byte clock cycles (62 cycles if the CLSTPM bit in the SYSCONF register is 1).

The payload of a blanking packet varies depending on the number of lanes and the periods to be inserted (HSA, HBP, HFP, BLLP).

It can be calculated by the following expression:

The following waiting cycle becomes cycle when HS byte clock was converted number for each period of the output signal of LCDC of Figure 42.4.

LPM becomes LP period from the BLLP3 period end to standing up of the following vsync.

Please calculate the waiting cycle from the setting of the register of LCDC value.

If HSA, HBP, BLLP1, and BLLP3 are to be inserted;

Payload(byte) = (Number of lanes × wait cycle) – 10

Figure 42.5 shows the example of calculating the payload length of HSA that uses the above-mentioned type at the BlankingPacket period.

10(byte) subtracted in the above-mentioned type is a value in which HSS(4byte), header (4byte), and footer (2byte) are totaled in Figure 42.5.

If HFP and BLLP2 are to be inserted,

Payload(byte) = (Number of lanes × wait cycle) – 12

Figure 42.6 shows the example of calculating the payload length of HFP that uses the above-mentioned type at the BlankingPacket period.

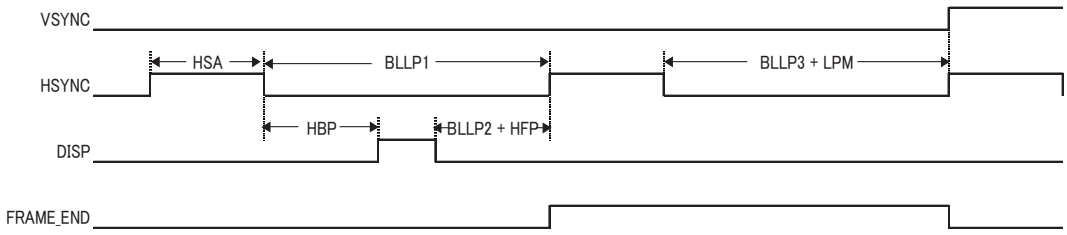
12(byte) subtracted in the above-mentioned type is a value in which header (4byte) of the image data and CheckSum(2byte) of the image data and header (4byte) of HFP and footer (2byte) of HFP is totaled in Figure 42.6.

Note:

Being able to use the above-mentioned type as it is becomes seeing when RGB888, RGB666(loosely packed), BGR888, and BGR666(loosely packed) are selected as image output format in setting VMCTR1. PCTYPE[3:0].

At other image output format., the length of bit of about one pixel of the image data of the DSI output is smaller than the LCDC output.

So it is necessary to add the volume of data of the difference to the above-mentioned type.



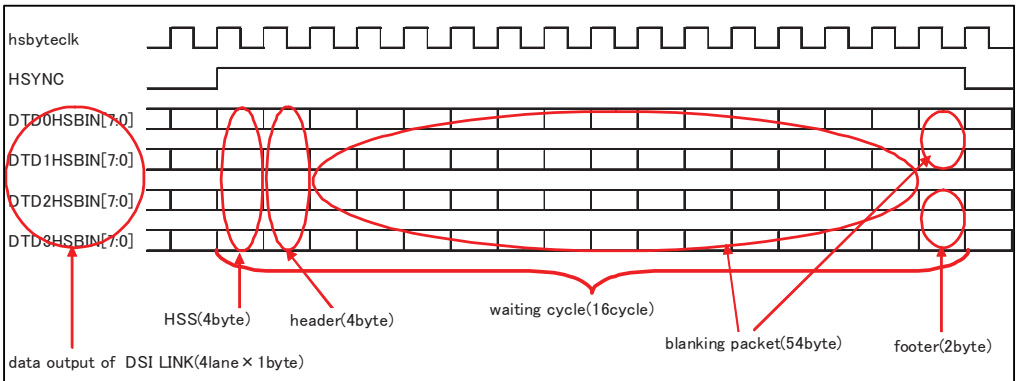


Figure 42.4 Period of waiting cycle

Example of calculating amount of HSA BlankingPacket payload

<Register setting>
LCDC register MLDHSYNR. HSYNW[3:0]= 2 Character(16dot)
SYSCONF.LANEEN[3:0]=4'hF(4lane) => 4byte data output/1cycle

<Calculation of waiting cycle of HSA>
waiting cycle of HSA = LCDC register MLDHSYNR. HSYNW[3:0] × 8 × 1cycle(ns) of dotclock ÷ 1cycle(ns) of HSBYTECLK
Because 1cycle(ns) of dotclock = 1 cycle(ns) of HSBYTECLK , it becomes the following.
(Refer to the explanation for VMCTR1.BKM)
= LCDC register MLDHSYNR. HSYNW[3:0] × 8
= 2 × 8
= 16cycle

<calculating amount of HSA BlankingPacket payload>
amount of HSA BlankingPacket payload = (Number of lanes × waiting cycle of HSA) − 10
= 4 × 16 − 10
= 54byte

Figure 42.5 Example of calculating payload length of HSA at BlankingPacket period

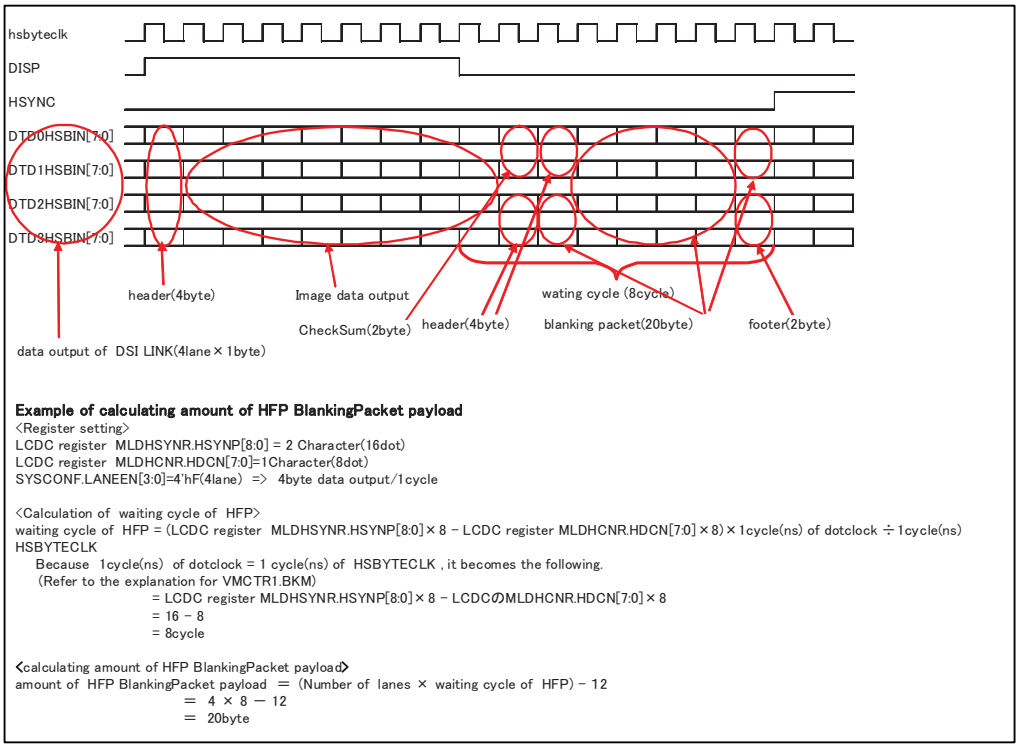

Figure 42.6 Example of calculating payload length of HFP at BlankingPacket period

42.4.3. LCDC Setting

When the DSI-TX is connected with the LCDC, the following limitations are applied to the LCDC setting in order to match the input format of the DIS-TX:

- Use the main LCD setting.
- LDDCKR.MOSEL =1: The divided clock cannot be used.
- MLDMT1R.VPOL = 0, HPOL=0, DIPOL=0: The Vsync, Hsync, and DSIP signals are set to positive.
- MLDMT1R.HSCNT =0: Hsync is kept being output.
- MLDMT1R.IFM=0, MIFTYP[3:0]=4'b1011: Data is output in 24bpp RGB mode.

or

MLDMT1R.YM=1, MLDMT1R.IFM=0, MIFTYP[3:0]=4'b1111: Data is output in the YUV422 format.

- MLDMT2R.VSEL=0: Vsync is set for output mode.
- Set the VSYNP[10:0] in the MLDVSYNR register so that they are one smaller than the actual output to the LCD panel.
  (This is because data is needed one line earlier in order to buffer data within the DSI-Tx.)
- MLDVLNR.VTLN[10:0] – MLDVSYNR.VSYNP[10:0] ≥ 2 :
  (Vertical front-porth periods are needed for proper control.)
- Please set MLDHSYNR.HSYNW[3:0] to two or more at SYSCONF.LANEEN[3:0]=4'h1 (one lane).
  It becomes impossible to set the payload length of BlankingPacket of HSA when one is set.
  Because it comes to transmit ten bytes(ten cycles) of HSS(4byte) + header (4byte) + footer (2byte) in total for the period of HSA (eight cycles).

42.4.4. Transmitting Command-Packets in Video Mode

In the video mode, command-packets are transmitted during BLLP periods between video-packets.

Command-packet transmission is allowed in BLLP1 by using the VMCTR2.BL1IEN.

Command-packet transmission is allowed in BLLP2 by using the VMCTR2.BL2IEN.

Command-packet transmission is allowed in BLLP3 by using the VMCTR2.BL3IEN.

Only one command-packet can be transmitted during a BLLP period. When transmission is completed, a transition to LPS occurs.

Note: Command-packet transmission is prohibited beyond a BLLP period.

Figure 42.7 shows how a command-packet is transmitted during BLLP1.

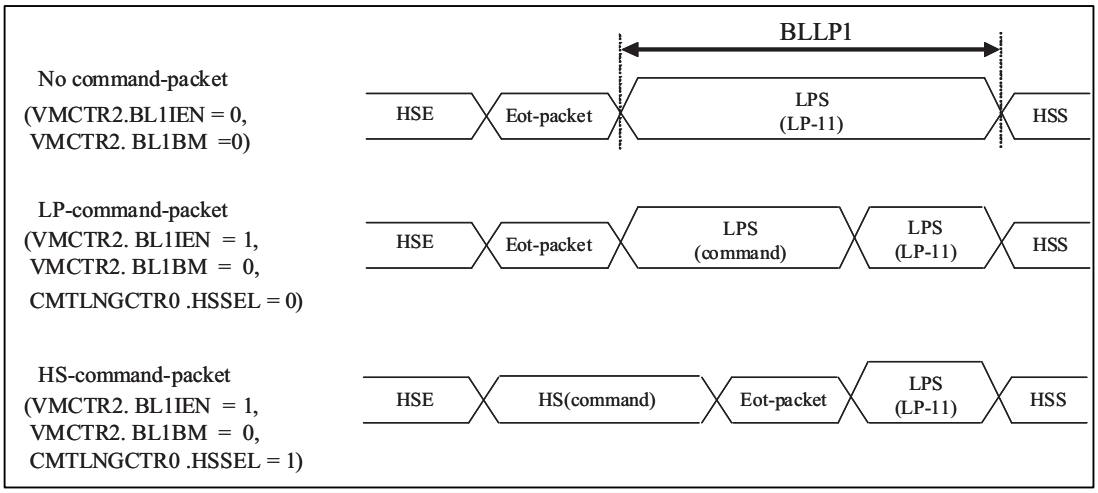

Figure 42.7 Command transmission at Video mode

42.4.5. Command-packet transmission at command mode

When command-packet are transmitted in HighSpeed transmission, the behavior changes depending on the FLEN bit in the DTCTR register.

If the FLEN bit in the DTCTR register is 0, transmission continues as long as there is a command transmission request.

If the FLEN bit in the DTCTR register is 1, a transition to LPS occurs even if there is a command transmission request.

42.4.6. Command-Packet Transmission for Small Data

If the data length to be transmitted is less than 16 bytes, the data can be transmitted from a register.

Data is loaded into CMTIADRx, CMTITTLx, CMTIADRIx, and CMTIRNx in order.

If the TXSEL bit in CMTLNGCTRx register is set to 0 and the TXREQ bit in the CMTLNGREQx register to 1, packets are transmitted in units of the data length specified in the LENG[11:0] bit in CMTLNGCTRx register.

Note: A lowercase "x" in a register name denotes 0 to 3.

Moreover, when it is short packet in two bytes in the transmitted data length, command can transmit by setting the following registers.

- It sets to DTCTR.MTEN=1, and the command mode is enabled.
- According to the CMTSRTCTR register, transmitted virtual channel, Datatype, and short packet data and HS transmission/LP transmission are selected .
- It is assumed CMTSRTREQ. TXREQ=1, and starts the command transmission.

Note:

If you want to do the video mode continuously after this, after becoming CMTSRTREQ. TXREQ=0, and completing the transmission of the command mode, set the register of the video mode and the register of LCDC.

42.4.7. Transmitting Command Packets

Command packet generation registers (4 channels for long packets and 1 channel for short packets) transmit one packet at a time in the order of short, long 0, long 1, long2, long 3, and short packets.

If specific channel data is to take precedence in transmitting, cancel operations for the other channels (set the TXREQ bit in CMTLNGREQx register to 0 or suspend them (set the TXWAIT bit in CMTLNGREQx register to 1).

42.4.8. Dividing Transmit Data

If the value in the INITTAL[31:0] in CMTITTLx register is greater than the one in the LENG[11:0] in CMTLNGCTRx register, transmit data is to be transmitted by dividing into multiple packets.

It is transmitted as packets each of which has the payload length specified in the LENG[11:0] in CMTLNGCTRx register.

Fractional data is transmitted in the last packet.

42.4.9. Example of Command Mode Transmission Setting

An example of the setting when the following data1 and data2 are transmitted in parallel is shown below.

data1:
Image data (1280 for the width × 800 for the height, RGB888 format)
It is stored from address 0x0c000000 at 0x00001000 interval by lines.
The ID information of the transmit packet is set as VC=2, start DT=0Ah, intermediate DT=0Bh, end DT=0C.

data2:
JPEG code (size: 25,001 bytes)
It is stored from address 0x0d000000.
The ID information of the transmit packet is set as VC=0, DT=0Dh.

```
CMTIADR0      = 0x0C000000
CMTITTL0      = 0x00000F00    ← 1280 pixels × 3 bytes/pixel
CMTIADRI0     = 0x00001000
CMTIRN0       = 0x00000320    ← 800 lines
CMTLNGCTR0 = 0x8A080003    ← 1 packet = 2048 bytes, HS transmission
CMTLNGDT0   = 0x00010B0C

CMTIADR1      = 0x0D000000
CMTITTL1      = 0x0003d091    ← 250001 bytes
CMTIADRI1     = 0x00000000
CMTIRN1       = 0x00000001    ← 1 transmission
CMTLNGCTR0  = 0x0D040003    ← 1 packet = 1024 bytes, HS transmission
```

CMTLNGDT0 = 0x00000000

CMTLNGREQ0 = 0x00000001
CMTLNGREQ1 = 0x00000001

The header information of packets to be output with this setting is shown in figure 42.8.

It shows the output order of command packets.

```

Figure 42.8 Example of the order of outputting command packet

42.4.10. Register Settings When Combining YUV

When the command of the YUV mixture is transmitted, the command packet generation register group is used by two channels.

The setting of two channels is as follows.

```
CMTIADR2      = 0x0E000000   ← Y data source address
CMTITTL2      = 0x00000F00   ← Number of the horizontal data
CMTIADRI2     = 0x00001000   ← Stride amount
CMTIRN2       = 0x00000004   ← Number of the line
CMTLNGCTR2    = 0xCA080003   ←1 packet = 2048 bytes, HS transmission
CMTLNGDT2     = 0x0D000000   ←Source data: YUV422, transmission data: YUV422

CMTIADR3      = 0x0E400000   ← C data source address
CMTITTL3      = 0x00000F00   ← Set the same value as in CH2
CMTIADRI3     = 0x00001000   ← Stride amount
CMTIRN3       = 0x00000004   ← Number of the line*
CMTLNGCTR3    = 0x2A080003   ← Set the same value as in CH2
CMTLNGDT3     = 0x0D000000   ←Set the same value as in CH2

CMTLNGREQ3 = 0x00000001      ← These channels can issue requests in either order.
CMTLNGREQ2 = 0x00000001
```

Note: * Set the same value as CH0 if the original data is YUV422. Set 1/2 of CH0 if the original data is YUV420.

42.4.11. DSI control procedure

Figure 42.9 shows the control procedure of DSI.

Showing in the chart becomes a control procedure at the video mode of synchronization with LCDC.

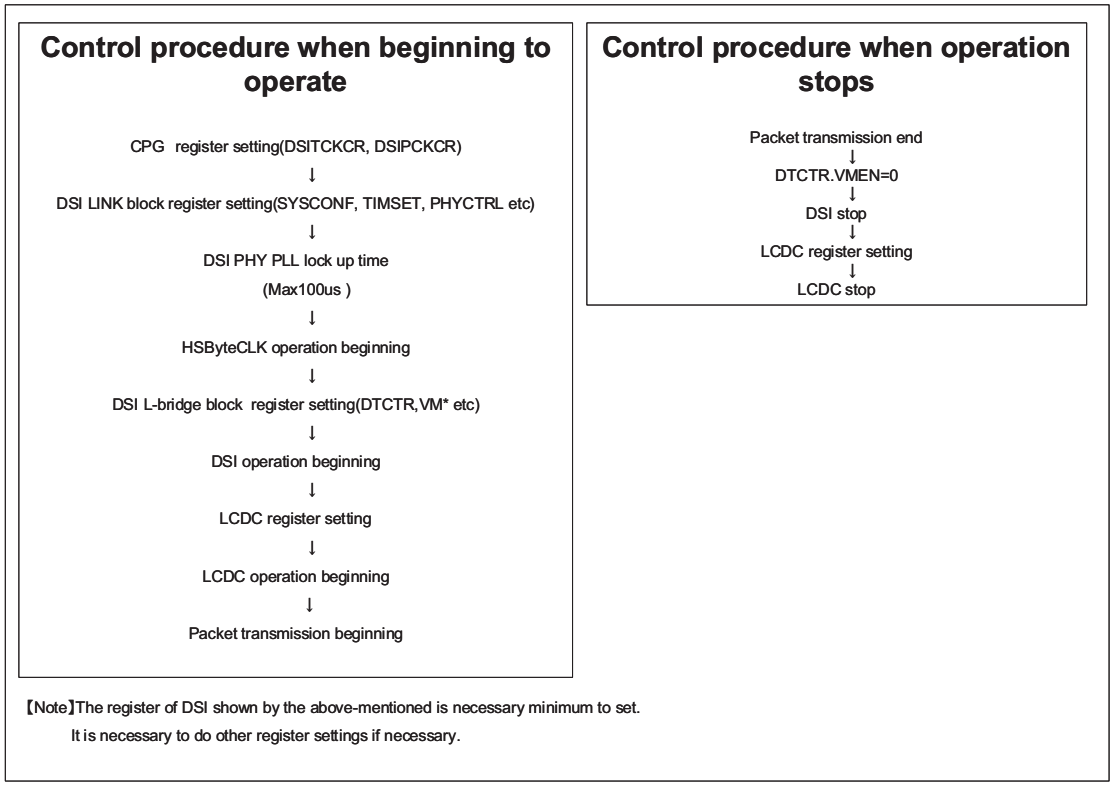

Figure 42.9 DSI control procedure

42.5. Operation sequence

The operation sequences related to the LINK block are described below.

However, 42.5.7 chiefly becomes explanations concerning the L-bridge block.

42.5.1 Power-on Reset Sequence

All FFs in the LINK block are initialized and all lanes transition to LP-11 immediately after reset.

Each register should be set after that.

The lanes disabled by the LANEEN[3:0] bit in the SYSCONF register transition to LP-00.

42.5.2 HS Transmission Sequence (Clock Lane Software Control Mode)

The clock lane software control mode is a mode in which the HS byte clock is kept being output after a transition to LPS. In this case, the clock is turned on/off by software.

The clock lane software control mode is entered by writing 1 to the CLSTPM bit in SYSCONF register and a transition to the HS mode of clock lanes is started by writing 1 to the CLHERQ bit in DSICTRL register. When the CLHERQ bit in DSICTRL register is 1, changing the CLSTPM bit in SYSCONF register is prohibited. Changing the CLSTPM bit in SYSCONF register is also prohibited during transmission within a frame. This is because when a transition from the HS mode to LPS (or vice versa) should occur is changed by turning clock lanes on and off so the output timing of sync event packets (Hsync and Vsync) is changed.

For a clock lane to transition to LPS, the CLHERQ bit in the DSICTRL register should be written to 0.

42.5.3 Reset Trigger Transmission Sequence

The reset trigger transmission sequence is described below.

Write 1 to the RSTRRQ bit in DSICTRL register when there is no transmission request for all video and command modes.

This causes the LINK block to initiate a transition to LPDT and to transmit a reset trigger.

After the transmission is completed, it changes to the LP-11 state.

Then, it waits for peripheral devices to be initialized by using the peripheral reset timer.

Set a timeout value in the PRTOVSET register and write 1 to the PRTOSRQ bit in DSICTRL register to start counting up of the peripheral timer.

When a timeout set in PRTOVSET register occurs, an interrupt is generated if enabled.

42.5.4 ULPS Transition Sequence

The ULPS transition sequence is described below.

Write 1 to the ULENRQ bit in DSICTRL register when there is no transmission request for all video and command modes.

This causes the LINK block to initiate a transition to ULPS.

When the transition to ULPS is completed, in the ULPSENS bit in DSIS register and the ULPSENINTS bit in DSIINT register are asserted to 1 and an interrupt is generated if enabled.

For a transition from ULPS to LP-11 to occur, the ULEXRQ bit in DSICTRL register should be written to 0.

42.5.5 Tearing Effect Sequence

The tearing effect sequence is described below.

When the TEREQ bit in CMRTEREQ register is set to 1, the DSI-Tx transitions to the Rx Stop state (reception wait state).

Then, it waits for a tearing effect trigger from peripheral devices.

When a tearing effect trigger is received, the LPTAK bit in DTST register is set to 1 and an interrupt is generated if enabled.

42.5.6 Recovery Sequence When a Contention is detected

The recovery sequence when a contention is detected is described below.

When a contention is detected, the HCOTEERINTS bit in DSIINT register or the LCOTEERINTS bit in DSIINT register is asserted and an interrupt is generated if enabled.

Then, issue a software reset (set the SWRST bit in SYSCTRL register to 1) or hardware reset. This reset causes a transition to the Tx Stop state (transmission wait state).

42.5.7 Command reception sequence

It explains the sequence when the command is received.

When the command is received at CMRCTR.CRXEN=1, DSI is stored in reception FIFO according to the setting of the CMRCTR register.

When it is a long packet, the part PH (packet header) and the data division are stored in each FIFO.

Moreover, when it is a short packet, the received command is stored in FIFO as a part PH (packet header).

Figure 42.10 shows the storage order to FIFO of receive data.

The received command doesn't store in FIFO and be annulled when FIFO is full.

FIFO1	data 4[7:0]	data 3[7:0]	data 2[7:0]	data 1[7:0]
FIFO2	data 8[7:0]	data 7[7:0]	data 6[7:0]	data 5[7:0]
FIFO3	data12[7:0]	data11[7:0]	data10[7:0]	data 9[7:0]
・	・	・	・	・
・	・	・	・	・
FIFO14	data56[7:0]	data55[7:0]	data54[7:0]	data53[7:0]
FIFO15	data60[7:0]	data59[7:0]	data58[7:0]	data57[7:0]

Figure 42.10 The storage order to FIFO of receive data

- PH (packet header) division

When one or more data is stored in reception FIFO for the header, DTST.FHEX is set ,and the data number in FIFO is displayed to CMRCTR.FHNM [2:0]

Please read data in FIFO from the CMRHEAD register with CPU.

Moreover, when it is CMRCTR.FIFOS=1, the received part PH (packet header) is stored in both reception FIFO for the header and reception FIFO for data..

- Data division

When one or more data is stored in reception FIFO for data , DTST.FDEX is set, and the data number in FIFO is displayed to CMRCTR.FDNM[3:0].

When it is CMRCTR.DMAEN=0, read data in FIFO from the CMRDAT register with CPU

When it is CMRCTR.DMAEN=1, specify the CMRDAT register for the source address of DMAC and read it by DMA forwarding.

When there is one or more data in reception FIFO for data , DREQ is made active from DSI, and the DMA forwarding is done according to the setting of the register of DMAC.

Moreover, when ECC multi-bit error happens to receive data , it doesn't store in FIFO until the packet ends and it is annulled.

When unnecessary data of the packet in which ECC multi-bit error happens remains in FIFO,make FIFO empty by reading with CPU or setting CMRCTR.FRST, and put it into the state that the following receive data can be stored in FIFO.

Section 43 JPEG Processing Unit (JPU)

The JPEG processing unit (JPU) incorporates the JPEG codec with an encoding and decoding function conforming to the JPEG baseline process, so that the JPU can encode image data and decode JPEG data quickly.

For the encoding and decoding processes, frame buffers or line buffers for raster block conversion are necessary in an external buffer space, such as an SDRAM externally connected to the LSI.

43.1 Features

The JPU has the following features.

- Conforming specification: JPEG baseline
- Operating precision: Conforming to JPEG Part 2, ISO-IEC10918-2
- Color format: YCbCr 4:2:2 (H = 2:1:1, V = 1:1:1), YCbCr 4:2:0 (H = 2:1:1, V = 2:1:1)
- Four quantization tables provided
- Four Huffman tables provided (two AC tables, two DC tables)
- Markers supported: Start of image (SOI), start of frame type 0 (SOF0), start of scan (SOS), define quantization tables (DQT), define Huffman tables (DHT), define restart interval (DRI), restart (RSTm), end of image (EOI)
- Image data rate: Maximum 108 Mbytes/s (54 MHz operation)
- The frame buffer size in the RAM area, such as SDRAM, can be reduced by using line buffer mode.

  This mode cannot be used with some pixel clock frequencies of the camera sensor or RAM configuration.
- Image rotation (by 90°, 180°, or 270°) can be performed in the encoding process (only in frame buffer mode).
- In reload mode, address toggling at every transfer of a specified amount of data during stream reading and writing is supported so that the buffer capacity can be reduced.
- Processing unit: 8-byte address boundary, 4-byte data length

  Note that the output data size during encoding is determined by the 16-byte boundary at the end of the address.
- Processable image size: From 16 × 16 to 4092 × 4092 pixels (horizontal × vertical)

  Image is processed in 4-pixel units.

Note: Do not perform unsupported color formatting or encoding or decoding of an image with an unsupported size.

Figure 43.1 shows the connection between the JPU and peripheral modules.

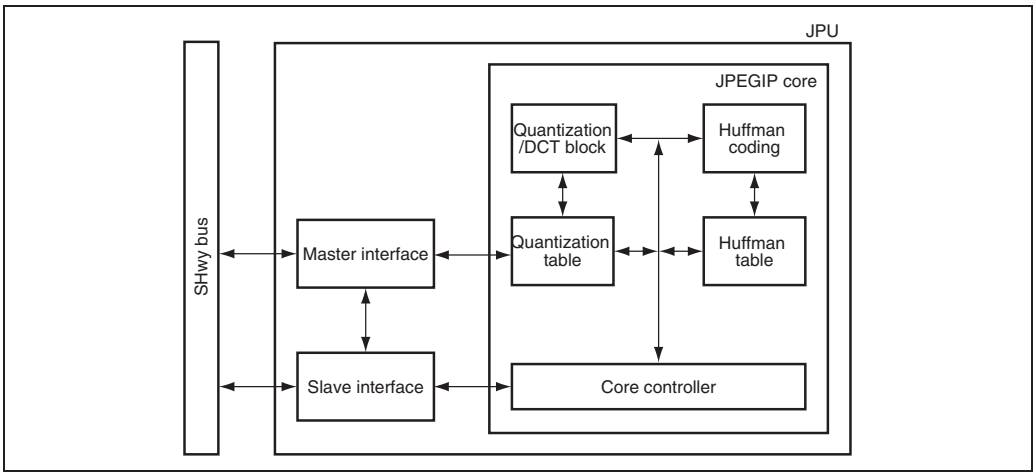

Figure 43.1 Connection between JPU and Peripheral Modules

43.2 Register Descriptions

Table 43.1 shows the JPU registers. Table 43.2 shows the register state in each processing mode.

These registers are 32-bit access registers. When modifying the reserved bits or read-only bits, write 0 to the bits. However, when clearing the bits in the JPEG interrupt status register (JINTS), write 0 only to the bits to be cleared and write 1 to the other bits. If register access which is not specified is performed, operation cannot be guaranteed.

Table 43.1 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size

43.2.1 JPEG Code Mode Register (JCMOD)

JCMOD sets the operating mode before the JPU starts operation.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SOIC	PCTR	MSKIP[1:0]		CCNT	DSP	REDU[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SOIC	0	R/W	SOI Marker Delete This bit is valid when the MSKIP bit is B'00. In this mode, the amount of coded data indicated by registers JCDTCU, JCDTDM, and JCDTCD includes the SOI (2 bytes). 0: SIO marker exists 1: SOI marker deleted
7	PCTR	0	R/W	Image Data Input Control This bit should be fixed to 1.
6, 5	MSKIP[1:0]	00	R/W	Marker Skip Mode 00: Marker output 01: No marker output Other than above: Setting prohibited
4	CCNT	0	R/W	Code Amount Count Mode (This bit is valid only in decoding.) 0: Code amount count mode disabled 1: Code amount count mode enabled

Bit	Bit Name	Initial Value	R/W	Description
3	DSP	0	R/W	Encoding/Decoding Set 0: Encoding process 1: Decoding process
2 to 0	REDU[2:0]	000	R/W (Encoding) R (Decoding)	Subsampling Set 001: 4:2:2 010: 4:2:0 Other than above: Setting prohibited (in encoding) Error (JPU cannot process normally in decoding.)

43.2.2 JPEG Code Command Register (JCCMD)

JCCMD sets commands. Bits of this register need not be cleared to 0 after setting a command.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	SRST	RWCMD	RRCMD	LCMD1	LCMD2	BRST	—	—	—	—	JEND	JRST	JSRT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R*/W	R*/W	R*/W	R*/W	R*/W	R	R	R	R	R*/W	R*/W	R*/W

Note: * Values read from these bits are undefined.

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
12	SRST	0	R/W	Software Reset Setting this bit to 1 resets the JPU. This bit holds 1 until the transfer between the CPU bus and the JPU is completed; it is cleared to 0 when the transfer is completed. After a software reset is specified, do not specify another software reset or a bus reset before this bit is cleared to 0. For details, refer to section 43.6, Software Reset Processing.
11	RWCMD	0	R*/W	Reload Buffer Write Restart Command This bit is valid during the encoding process in reload mode. The JPU stops writing the data to be coded to a reload buffer after one buffer of data specified by JIFEDRSZ has been transferred. Though the encoding process automatically stops, the first two reload buffers of data are automatically written. However, when JIFEDA1 is equal to JIFEDA2, only one reload buffer operates and the JPU stops writing the data to be coded after the first one buffer of data has been transferred. Restart writing the data to be coded by writing 1 to this bit.
10	RRCMD	0	R*/W	Reload Buffer Read Restart Command This bit is valid during decoding in reload mode. The JPU stops reading the coded data from a reload buffer after one buffer of data specified by JIFDDRSZ has been transferred. Restart reading the coded data by writing 1 to this bit. JPU continues reading coded data as long as the end of the code is not detected.
9	LCMD1	0	R*/W	External Line Buffer Processing Restart Command This bit is valid only for subsampling setting 4:2:0 in line buffer mode. JPU stops transferring the image data after transfer of the lines of data specified by JIFDCNT or JIFECNT is completed. Though the JPU automatically stops processing, the first two lines of data are automatically written. However, when JIFDDYA1 is equal to JIFDDYA2 and JIFDDCA1 is equal to JIFDDCA2, only one line buffer operates and the JPU stops writing the image data after the first one buffer of data has been transferred. Restart transferring by writing 1 to this bit in both the encoding and decoding processes.

Bit	Bit Name	Initial Value	R/W	Description
8	LCMD2	0	R*/W	External Line Buffer Process Restart Command This bit is valid only for subsampling setting 4:2:2 in line buffer mode. JPU stops transferring the mage data after transfer of the lines of data specified by JIFDCNT or JIFECNT is completed. Though the JPU automatically stops processing, the first two lines of data are automatically written. However, when JIFDDYA1 is equal to JIFDDYA2 and JIFDDCA1 is equal to JIFDDCA2, only one line buffer operates and the JPU stops writing the image data after the first one buffer of data has been transferred. Restart transferring by writing 1 to this bit in both the encoding and decoding processes.
7	BRST	0	R*/W	Bus Reset Setting this bit to 1 resets internal circuits. While the JPU is in operation (from JPEG core process start command setting to JINTS data transfer end interrupt occurrence), do not set this bit to 1. For the bus reset processing, see section 43.5, Bus Reset Processing.
6 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	JEND	0	R*/W	Interrupt Signal Clear Command This bit is valid for interrupt sources bits INS6, INS5, and INS3 in the JINTS register. To clear an interrupt signal, set this bit to 1.
1	JRST	0	R*/W	JPEG Core Processing-Stopped Revoke Command To clear the processing-stopped state because of requests to read the image size and subsampling setting (the INT3 bit in the JINTE register), set this bit to 1. (This bit is valid only in decoding.)
0	JSRT	0	R*/W	JPEG Core Process Start Command To start JPEG core processing, set this bit to 1. Do not write this bit to 1 again before the JPU is not completely activated.

Note: * Values read from these bits are undefined.

43.2.3 JPEG Code Status Register (JCSTS)

JCSTS indicates the internal state of the JPU.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0.
0	STS	0	R	Operating State This bit indicates the operating state of the JPEG core in the JPU. If its state is indicated as not in operation, the JPU may not have transferred data completely. To check whether the data has been completely transferred, use the transfer end interrupt through the JINTS register. 0: Not in operation 1: Encoding or decoding

43.2.4 JPEG Code Quantization Table Number Register (JCQTN)

JCQTN sets the quantization table number before encoding is started.

- To use quantization table No. 0 (JCQTBL0) as the first color component, set QT1 to B'00
- To use quantization table No. 1 (JCQTBL1) as the first color component, set QT1 to B'01
- To use quantization table No. 2 (JCQTBL2) as the first color component, set QT1 to B'10
- To use quantization table No. 3 (JCQTBL3) as the first color component, set QT1 to B'11

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	QT3[1:0]		QT2[1:0]		QT1[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	QT3[1:0]	00	R/W	Quantization table number for the third color component
3, 2	QT2[1:0]	00	R/W	Quantization table number for the second color component
1, 0	QT1[1:0]	00	R/W	Quantization table number for the first color component

43.2.5 JPEG Code Huffman Table Number Register (JCHTN)

JCHTN sets the Huffman table number (AC/DC) before encoding is started.

- To use DC/AC Huffman table No. 0 (JCHTBD0 and JCHTBA0) as the first color component, set bits HTA1 and HTD1 to B'0
- To use DC/AC Huffman table No. 1 (JCHTBD1 and JCHTBA1) as the first color component, set bits HTA1 and HTD1 to B'1

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W:	R	R	R	R	R	R	R	R	R	R	R\W	R\W	R\W	R\W	R\W	R\W

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	HTA3	0	R/W	Huffman table number (AC) for the third color component
4	HTD3	0	R/W	Huffman table number (DC) for the third color component
3	HTA2	0	R/W	Huffman table number (AC) for the second color component
2	HTD2	0	R/W	Huffman table number (DC) for the second color component
1	HTA1	0	R/W	Huffman table number (AC) for the first color component
0	HTD1	0	R/W	Huffman table number (DC) for the first color component

43.2.6 JPEG Code DRI Upper Register (JCDRIU)

JCDRIU sets the upper bytes of the minimum coded units (MCUs) preceding an RST marker.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DRIU[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	DRIU[7:0]	H'00	R/W	Upper Bytes of MCUs Preceding RST Marker When both upper and lower bytes are set to H'00, neither a DRI nor an RST marker is placed. (These bits are valid only in encoding.)

43.2.7 JPEG Code DRI Lower Register (JCDRID)

JCDRID sets the lower bytes of MCUs preceding an RST marker.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DRID[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	DRID[7:0]	H'00	R/W	Lower Bytes of MCUs Preceding RST Marker When both upper and lower bytes are set to H'00, neither a DRI nor an RST marker is placed. (These bits are valid only in encoding.)

43.2.8 JPEG Code Vertical Size Upper Register (JCVSZU)

JCVSZU sets the upper bytes of the vertical image size. When rotating the image in encoding, set the size of the rotated image in this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	VSZU[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	VSZU[7:0]	H'00	R/W	Upper Bytes of Vertical Image Size Up to 4092 pixels can be set as the vertical image size. In the decoding process, a downloaded value from the JPEG coded data is set. When the vertical image size exceeds 2048 pixels, it is treated as an error.

43.2.9 JPEG Code Vertical Size Lower Register (JCVSZD)

JCVSZD sets the lower bytes of the vertical image size. When rotating the image in encoding, set the size of the rotated image in this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	VSZD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	VSZD[7:0]	H'00	R/W	Lower Bytes of Vertical Image Size In the decoding process, a downloaded value from the JPEG coded data is set.

43.2.10 JPEG Code Horizontal Size Upper Register (JCHSZU)

JCHSZU sets the upper bytes of the horizontal image size. When rotating the image in encoding, set the size of the rotated image in this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	HSZU[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	HSZU[7:0]	H'00	R/W	Upper Bytes of Horizontal Image Size Up to 4092 pixels can be set as the horizontal image size. In the decoding process, a downloaded value from the JPEG coded data is set. When the horizontal image size exceeds 4092 pixels, it is treated as an error.

43.2.11 JPEG Coded Horizontal Size Lower Register (JCHSZD)

JCHSZD sets the lower bytes of the horizontal image size. When rotating the image in encoding, set the size of the rotated image in this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	HSZD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	HSZD[7:0]	H'00	R/W	Lower Bytes of Horizontal Image Size In the decoding process, a downloaded value from the JPEG coded data is set.

43.2.12 JPEG Code Data Count Upper Register (JCDTCU)

The upper bytes for the counted amount of data to be encoded are set to JCDTCU. This register is valid only in an encoding process. The values of this register are reset before encoding starts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DCU[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	DCU[7:0]	H'00	R	Upper bytes for the counted amount of data to be encoded

43.2.13 JPEG Code Data Count Middle Register (JCDTCM)

The middle bytes for the counted amount of data to be encoded are set to JCDTCM. This register is valid only in an encoding process. The values of this register are reset before encoding starts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DCM[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	DCM[7:0]	H'00	R	Middle bytes for the counted amount of data to be encoded

43.2.14 JPEG Code Data Count Lower Register (JCDTCD)

The lower bytes for the counted amount of data to be encoded are set to JCDTCD. This register is valid only in an encoding process. The values of this register are reset before encoding starts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DCD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	DCD[7:0]	H'00	R	Lower bytes of the counted amount of data to be encoded

43.2.15 JPEG Interrupt Enable Register (JINTE)

JINTE enables interrupts.

When bits INT7 to INT5 are set to B'1, the INS5 bit in JINTS which indicates the error status is set to B'1, and the ERR bit in JCDERR indicates the particular error code.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	INT14	INT13	INT12	INT11	INT10	—	—	INT7	INT6	INT5	—	INT3	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14	INT14	0	R/W	This flag sets whether an interrupt is generated at every address reloading for coded data reading. (This bit is valid only when reload mode is enabled.)
13	INT13	0	R/W	This flag sets whether an interrupt is generated at every address reloading for coded data writing. (This bit is valid only when reload mode is enabled.)
12	INT12	0	R/W	This flag sets whether an interrupt is generated at every transmission completion of Y components in multiples of 16 lines and C components in multiples of 8 lines. (This bit is valid only when line buffer mode is enabled.)
11	INT11	0	R/W	This flag sets whether an interrupt is generated at every transmission completion of Y components in multiples of 8 lines and C components in multiples of 8 lines. (This bit is valid only when line buffer mode is enabled.)
10	INT10	0	R/W	This flag sets whether an interrupt of transfer to the external buffer end is generated.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	INT7	0	R/W	This flag sets whether an interrupt is generated when the number of data in the restart interval of the Huffman-coding segment is not correct. When this flag is not set, an error code is not returned. (This bit is valid only in decoding.)
6	INT6	0	R/W	This flag sets whether an interrupt is generated when the total number of data in the Huffman-coding segment is not correct. When this flag is not set, an error code is not returned. (This bit is valid only in decoding.)
5	INT5	0	R/W	This flag sets whether an interrupt is generated when the last MCU number in the Huffman-coding segment is not correct. When this flag is not set, an error code is not returned. (This bit is valid only in decoding.)
4	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
3	INT3	0	R/W	This flag sets whether an interrupt is generated when it has been determined that the image size and the subsampling setting of the encoded data can be read through analyzing the data.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

43.2.16 JPEG Interrupt Status Register (JINTS)

JINTS identifies the interrupt sources.

The interrupts of bits INS10 to INS14 and INS3 are generated when the corresponding bits in the JINTE register are set to B'1. When the interrupt sources are bits INS14 to INS10, the interrupt signal can be negated by clearing the corresponding interrupt status bits to 0. When the interrupt sources are bits INS6, INS5, or INS3 (JPEG core), the interrupt signal can be negated by clearing the corresponding interrupt status bits to 0 and setting the JCCMD register appropriately.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	INS14	INS13	INS12	INS11	INS10	—	—	—	INS6	INS5	—	INS3	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W*	R/W*	R/W*	R/W*	R/W*	R	R	R	R/W*	R/W*	R	R/W*	R	R	R

Note: * When the bit is read as 1, write 0 to clear it.
When the bit is read as 0, write 1 to it.

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14	INS14	0	R/W*	This bit is set to 1 every time the address is reloaded during stream data reading. (This bit is valid only when reload mode is enabled.)
13	INS13	0	R/W*	This bit is set to 1 every time the address is reloaded during stream data writing. (This bits is valid only when reload mode is enabled.)
12	INS12	0	R/W*	This bit is set to 1 when transfer of Y components in multiples of 16 lines and C components in multiples of 8 lines to the line buffer is completed. (Subsampling setting: 4:2:0, This bit is valid only when line buffer mode is enabled.)

Bit	Bit Name	Initial Value	R/W	Description
11	INS11	0	R/W*	This bit is set to 1 when transfer of Y components in multiples of 8 lines and C components in multiples of 8 lines to the line buffer is completed. (Subsampling setting: 4:2:2, This bit is valid only when line buffer mode is enabled.)
10	INS10	0	R/W*	This bit is set to 1 after all data on the result of JPU encoding and decoding have been completely transferred.
9 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	INS6	0	R/W*	This bit is set to 1 when the JPEG completes the encoding process normally.
5	INS5	0	R/W*	This bit is set to 1 when an encoded data error occurs. (This bit is valid only in decoding.)
4	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
3	INS3	0	R/W*	This bit is set to 1 when the image size and subsampling setting can be read. (This bit is valid only in decoding.) When an interrupt occurs, the JPU stops processing and the state is indicated by the JCRST register. To make the JPU resume processing, set the JPEG core processing-stopped release command (JRST bit in the JCCMD register).
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: * When the bit is read as 1, write 0 to clear it.
When the bit is read as 0, write 1 to it.

43.2.17 JPEG Code Decode Error Register (JCDERR)

Through the error code, JCDERR identifies the type of error which occurred in the encoded data analysis for decoding. The values of this register are reset before the JPU starts decoding.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

31 to 4	—	All 0	R	Reserved These bits are always read as 0.
3 to 0	ERR[3:0]	1010	R/W	Error Code (See tables 43.4 and 43.5.)

43.2.18 JPEG Code Reset Register (JCRST)

JCRST indicates a processing-stopped state due to requests to read the image size and subsampling setting (the INTS3 bit in the JINTE register) (available in decoding). To resume processing, set the JPEG core processing-stopped release command (the JRST bit in the JCCMD register).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 16	PU[11:0]	H'000	R/W	Processing Unit (These bits are valid only in line buffer mode.) [YCbCr 4:2:2 processing] Set the number of lines in vertical Y and C components (in multiples of 8: H'008 units). (Write 0 to the bits PU[2:0].) [YCbCr 4:2:0 processing] Set the number of lines in vertical Y components (in multiples of 16: H'010 units). (Write 0 to the bits PU[3:0].) A value equal to half of the number of lines in vertical Y components is automatically set as the number of lines in vertical C components. Note: The maximum number of settable lines is 2048 and the minimum number is 16. Values outside of this range should not be set.
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
6	RELOAD	0	R/W	Reload Mode 0: Reload mode disabled 1: Reload mode enabled
5, 4	SWAP[1:0]	00	R/W	Byte/Word Swap (see the JIFDCNT register) Data transferred to the JPU is swapped (image data in encoding; coded data in decoding). 00: (1) (2) (3) (4) 01: (2) (1) (4) (3) [Byte swap] 10: (3) (4) (1) (2) [Word swap] 11: (4) (3) (2) (1) [Word - byte swap]
3, 2	ROT[1:0]	00	R/W	Rotated Read Mode (These bits are valid only in frame buffer mode.) 00: 0° 01: 90° 10: 180° 11: 270°
1	BUF	0	R/W	Buffer Mode 0: Frame buffer mode 1: Line buffer mode
0	INFT	0	R	Subsampling Setting 0: YCbCr 4:2:2 1: YCbCr 4:2:0

Note: Bits other than SWAP can be modified only when the DSP bit in JCMOD is 0 (encoding process).

43.2.20 JPEG Interface Encode Source Y Address Register 1 (JIFESYA1)

JIFESYA1 sets the source address of the Y component.

This register should be set in 8-pixel units. When reading of an image rotated by 90°, 180°, or 270° is specified, set the origin address for the rotated image. Note that a rotated image can be read only in frame buffer mode (see section 43.3.1 (7), Rotated Read Mode Setting).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	ESYA1[31:3]	H'0000 0000	R/W	Y Component Source Address (in 8-pixel units)
2 to 0	ESYA1[2:0]		R	The lower three bits should be set to 0.

43.2.21 JPEG Interface Encode Source C Address Register 1 (JIFESCA1)

JIFESCA1 sets the source address of the C component.

This register should be set in 8-pixel units. When reading of an image rotated by 90°, 180°, or 270° is specified, set the origin address for the rotated image. Note that a rotated image can be read only in frame buffer mode (see section 43.3.1 (7), Rotated Read Mode Setting).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ESCA1[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ESCA1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	ESCA1[31:3]	H'0000 0000	R/W	C Component Source Address (in 8-pixel units)
2 to 0	ESCA1[2:0]		R	The lower three bits should be set to 0.

43.2.22 JPEG Interface Encode Source Y Address Register 2 (JIFESYA2)

JIFESYA2 sets the source address of the Y component, and is valid in line buffer mode.

Set the start address in 8-pixel units. The source address of the Y component, which is used by the JPU, changes automatically in specified line buffer units: JIFESYA1 → JIFESYA2 → JIFESYA1 → . . . .

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ESYA2[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ESYA2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	ESYA2[31:3]	H'0000 0000	R/W	Y Component Source Address (These bits are valid in line buffer mode. in 8-pixel units)
2 to 0	ESYA2[2:0]		R	The lower three bits should be set to 0.

43.2.23 JPEG Interface Encode Source C Address Register 2 (JIFESCA2)

JIFESCA2 sets the source address of the C component, and is valid in line buffer mode.

Set the start address in 8-pixel units. The source address of the C component, which is used by the JPU, changes automatically in specified line buffer units: JIFESCA1 → JIFESCA2 → JIFESCA1 → . . . .

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ESCA2[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ESCA2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	ESCA2[31:3]	H'00000 0000	R/W	C Component Source Address (These bits are valid in line buffer mode. in 8-pixel units)
2 to 0	ESCA2[2:0]		R	The lower three bits should be set to 0.

43.2.24 JPEG Interface Encode Source Memory Width Register (JIFESMW)

JIFESMW sets the buffer memory width in which the image data is stored (see section 43.3.3, Storing Image Data). Set this register in 8-pixel units. The maximum settable width is 4092 pixels and the minimum is 16 pixels. Sizes outside of this range should not be set.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 3	ESMW[11:3]	H'000	R/W	Buffer memory width in which image data is stored (in 8-pixel units)
2 to 0	ESMW[2:0]		R	The lower three bits should be set to 0.

43.2.25 JPEG Interface Encode Source Vertical Size Register (JIFESVSZ)

JIFESVSZ sets the vertical size of the image transferred from the external buffer (see section 43.3.3, Storing Image Data). Set the image size in 4-pixel units. The maximum settable width is 4092 pixels and the minimum is 16 pixels. Sizes outside of this range should not be set.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 2	ESVSZ[11:2]	H'000	R/W	Vertical size of the image transferred from the external buffer (in 4-pixel units)
1, 0	ESVSZ[1:0]		R	The lower two bits should be set to 0.

43.2.26 JPEG Interface Encode Source Horizontal Size Register (JIFESHSZ)

JIFESHSZ sets the horizontal size of the image transferred from the external buffer (see section 43.3.3, Storing Image Data). Set the image size in 4-pixel units. The maximum settable width is 4092 pixels and the minimum is 16 pixels. Sizes outside of this range should not be set.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 2	ESHSZ[11:2]	H'000	R/W	Horizontal size of the image transferred from the external buffer (in 4-pixel units).
1, 0	ESHSZ[1:0]		R	The lower two bits should be set to 0.

43.2.27 JPEG Interface Encode Destination Address Register 1 (JIFEDA1)

JIFEDA1 sets the destination address of the coded data. Set the start address in 8-pixel units.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EDA1[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EDA1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	EDA1[31:3]	H'0000 0000	R/W	Coded data destination address (in 8-pixel units)
2 to 0	EDA1[2:0]		R	The lower three bits should be set to 0.

43.2.28 JPEG Interface Encode Destination Address Register 2 (JIFEDA2)

JIFEDA2 sets the destination address of the coded data.

Set the start address in 8-pixel units. The coded data destination address, which is used by the JPU, changes every time the data transfer specified by JIFEDRSZ is completed: JIFEDA1 → JIFEDA2 → JIFEDA1 → . . . . (This register is valid only in auto-reload mode.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EDA2[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EDA2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	EDA2[31:3]	H'0000 0000	R/W	Coded data destination address (in 8-pixel units)
2 to 0	EDA2[2:0]		R	The lower three bits should be set to 0.

43.2.29 JPEG Interface Encode Data Reload Size Register (JIFEDRSZ)

JIFEDRSZ sets the number of data (in 256-byte units) before the target address is switched. This register is valid only in auto-reload mode. This register should be set to H'0000 0000 in code amount count mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	EDRSZ[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EDRSZ[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 8	EDRSZ[23:8]	H'00 0000	R/W	Coded data destination address (in 256-byte units)
7 to 0	EDRSZ[7:0]		R	The lower eight bits should be set to 0.

43.2.30 JPEG Interface Decoding Control Register (JIFDCNT)

JIFDCNT controls the decoding process. Note that the SWAP bit is also used in the encoding process.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	PU[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	RE LOAD	SWAP[1:0]		BMS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 16	PU[11:0]	H'000	R/W	Processing Unit (These bits are valid only in line buffer mode.) [YCbCr 4:2:2 processing] Set the number of lines in vertical Y and C components (in multiples of 8: H'008 units). (Write 0 to the bits PU[2:0].) [YCbCr 4:2:0 processing] Set the number of lines in vertical Y components (in multiples of 16: H'010 units). (Write 0 to the bits PU[3:0].) A value equal to half of the number of lines in vertical Y components is automatically set as the number of lines in vertical C components. Note: The maximum number of settable lines is 2048 and the minimum number is 16. Values outside of this range should not be set.
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	RELOAD	0	R/W	Reload Mode 0: Reload mode disabled 1: Reload mode enabled

Bit	Bit Name	Initial Value	R/W	Description
2, 1	SWAP[1:0]	00	R/W	Byte/Word Swap (see the JIFECNT register) Data transferred from the JPU is swapped (coded data in encoding, image data in decoding). 00: (1) (2) (3) (4) 01: (2) (1) (4) (3) [Byte swap] 10: (3) (4) (1) (2) [Word swap] 11: (4) (3) (2) (1) [Byte - word swap]
0	BMS	0	R/W	Buffer Mode 0: Frame buffer mode 1: Line buffer mode

Note: Bits other than SWAP can be modified only when the DSP bit in JCMOD is 1 (decoding process).

43.2.31 JPEG Interface Decode Source Address Register 1 (JIFDSA1)

JIFDSA1 sets the source address of the coded data. Set the start address of the coded data in 8-pixel units.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DSA1[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	DSA1[31:3]	H'0000 0000	R/W	Coded data source address (in 8-pixel units)
2 to 0	DSA1[2:0]		R	The lower three bits should be set to 0.

43.2.32 JPEG Interface Decode Source Address Register 2 (JIFDSA2)

JIFDSA2 sets the source address of the coded data. Set the start address in 8-pixel units. The source address of the coded data, which is used by the JPU, changes automatically every time the data transfer specified by JIFDDRSZ is completed: JIFDSA1 → JIFDSA2 → JIFDSA1 → . . . . (This register is valid only in auto-reload mode.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DSA2[31:16]

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	DSA2[31:3]	H'0000 0000	R/W	Coded data source address (in 8-pixel units)
2 to 0	DSA2[2:0]		R	The lower three bits should be set to 0.

43.2.33 JPEG Interface Decode Data Reload Size Register (JIFDDRSZ)

JIFDDRSZ sets the number of data (256-byte units) transferred before the address is changed (This register is valid only in auto reload mode).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DDRSZ[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDRSZ[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 8	DDRSZ[23:8]	H'00 0000	R/W	Number of data to be transferred before the address is changed (in 256-byte units)
7 to 0	DDRSZ[7:0]		R	The lower eight bits should be set to 0.

43.2.34 JPEG Interface Decode Destination Memory Width Register (JIFDDMW)

JIFDDMW sets the memory width of the data written to the external buffer (see 43.3.3, Storing Image Data).

Set this register in 8-pixel units. The maximum settable size is 4092 pixels and the minimum is 16 pixels. Sizes outside of this range should not be set

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DDMW[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	DDMW[31:3]	H'0000 0000	R/W	Memory width of image data stored in external buffer (in 8-pixel units)
2 to 0	DDMW[2:0]		R	The lower three bits should be set to 0.

43.2.35 JPEG Interface Decode Destination Vertical Size Register (JIFDDVSZ)

JIFDDVSZ indicates the vertical size of the image written to the external buffer.

This register is valid only in decoding. Treat the image size as an error if the size exceeds the processable size.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDVSZ[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	DDVSZ [15:0]	H'0000	R	Vertical size of image written to external buffer After the JPEG coded data is analyzed, the values of JCVSZU and JCVSZD are automatically set to these bits in 4-pixel units.

43.2.36 JPEG Interface Decode Destination Horizontal Size Register (JIFDDHSZ)

JIFDDHSZ indicates the horizontal size of the image written to the external buffer. This register is valid only in decoding. Treat the image size as an error if the size exceeds the processable size.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDHSZ[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	DDHSZ [15:0]	H'0000	R	Horizontal size of image written to external buffer After the JPEG coded data is analyzed, the values of JCHSZU and JCHSZD are automatically set to these bits in 4-pixel units.

43.2.37 JPEG Interface Decode Destination Y Address Register 1 (JIFDDYA1)

JIFDDYA1 sets the destination address of the Y component. Set the address in 8-pixel units.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DDYA1[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDYA1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	DDYA1[31:3]	H'0000 0000	R/W	Y component destination address (in 8-pixel units)
2 to 0	DDYA1[2:0]		R	The lower three bits should be set to 0.

43.2.38 JPEG Interface Decode Destination C Address Register 1 (JIFDDCA1)

JIFDDCA1 sets the destination address of the C component. Set the address in 8-pixel units.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DDCA1[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDCA1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	DDCA1[31:3]	H'0000 0000	R/W	C component destination address (in 8-pixel units)
2 to 0	DDCA1[2:0]		R	The lower three bits should be set to 0.

43.2.39 JPEG Interface Decode Destination Y Address Register 2 (JIFDDYA2)

JIFDDYA2 sets the destination address of the Y component. This register is valid only in line buffer mode.

Set the address in 8-pixel units. The destination address of the Y component, which is used by the JPU, changes automatically every time the data transfer specified by JIFDDRSZ is completed: JIFDDYA1 → JIFDDYA2 → JIFDDYA1 → . . . .

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DDYA2[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDYA2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	DDYA2[31:3]	H'0000 0000	R/W	Y component destination address (in 8-pixel units)
2 to 0	DDYA2[2:0]		R	The lower three bits should be set to 0.

43.2.40 JPEG Interface Decode Destination C Address Register 2 (JIFDDCA2)

JIFDDCA2 sets the destination address of the C component. This register is valid only in line buffer mode.

Set the address in 8-pixel units. The destination address of the C component, which is used by the JPU changes automatically every time the data transfer specified by JIFDDRSZ is completed: JIFDDCA1 → JIFDDCA2 → JIFDDCA1 → . . . .

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DDCA2[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDCA2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	DDCA2[31:3]	H'0000 0000	R/W	C Component Destination Address (in 8-pixel units)
2 to 0	DDCA2[2:0]		R	The lower three bits should be set to 0.

43.3 Operation

43.3.1 Encoding

(1) Overview of Processing

The encoding process flows are described below.

(a) Frame Buffer Mode

1. One frame of image data is transferred to the external buffer.
2. The JPEG core is activated.
   A marker is output. (After a marker is output, image data can be input.)
   Approximately 30000 cycles (necessary for making SOI to SOS markers) in normal mode
   Approximately 300 cycles (necessary for making SOS marker) in marker skip mode
3. Image data is transferred in MCUs from the external buffer to the JPU.
4. Image data is input to the JPEG core.
   The input data is processed in MCUs at any time in the JPEG core, and encoded data is output.
5. An interrupt is generated after frame data is processed completely.
   An interrupt is generated after the specified amount of data is reloaded in reload mode.

(b) Line Buffer Mode

1. The JPEG core is activated.
   A marker is output. (After a marker is output, image data can be input.)
   Approximately 30000 cycles (necessary for making SOI to SOS markers) in normal mode
   Approximately 300 cycles (necessary for making SOS marker) in marker skip mode
2. Y and C components of the image data are transferred to the external line buffer: Y components in multiples of 8 lines and C components in multiples of 8 lines (YCbCr 4:2:2), or Y components in multiples of 16 lines and C components in multiples of 8 lines (YCbCr 4:2:0).
   After transfer has been completed, a transfer end command is issued to the JPU.
   Every time the transfer to the external buffer is completed, a transfer end command is issued to the JPU.
3. Image data is transferred in MCUs from the external buffer to the JPU.
4. Image data is input to the JPEG core.
   The input data is processed in MCUs at any time in the JPEG core, and the encoded data is output.

5. After the JPU has read one external line buffer of the image data, the rest of the image data is transferred to the external line buffer.

   After all of the image data is transferred, a transfer end command is issued to the JPU (go to step 3).
6. After specified frame data processing is completed, an interrupt is generated.

   An interrupt is generated after the specified amount of data is reloaded in reload mode.

(2) Frame Buffer Mode (Encoding)

After the initial settings are completed, input image data in the external buffer and activate the JPU by setting the JSRT bit in JCCMD to B'1. After the JPU has been activated, the JPEG markers (SOI to SOS) are generated and output. It takes approximately 30000 cycles to generate the markers.

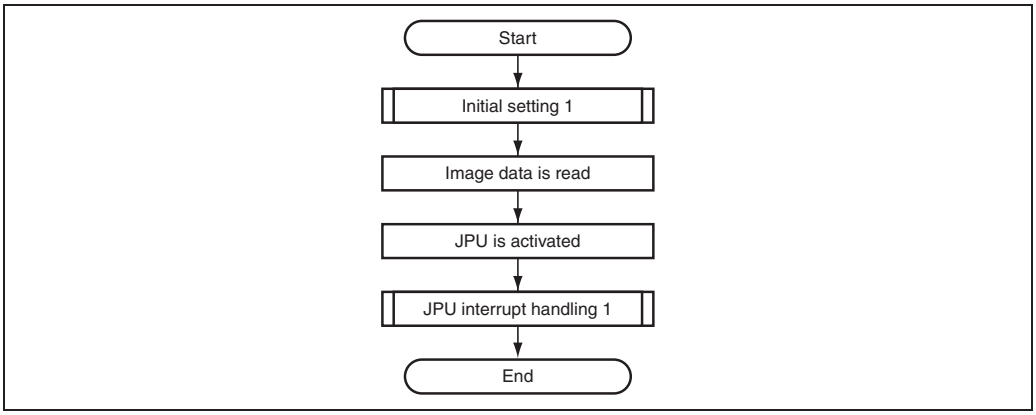

Figure 43.2 Flow of Encoding in Frame Buffer Mode

After a reset, set all necessary registers before the JPU is activated.

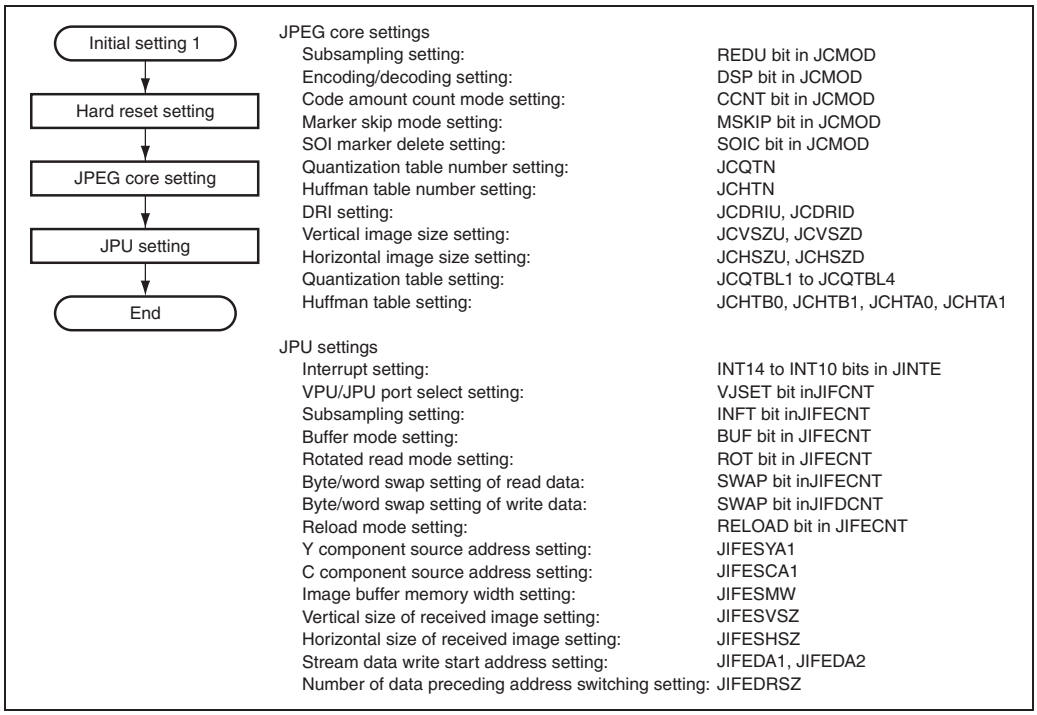

Figure 43.3 Flow of Initial Setting 1

Figure 43.4 shows the interrupt handling flow in frame buffer mode (encoding). When multiple interrupts occur (also when multiple interrupts that are not shown in figure 43.4 occur), process all interrupt sources.

- When the INS6 bit in the interrupt status register JINTS is set to B'1, the JPEG encoding has been completed. Though the JPU continues processing since the coded data to be transferred remains, the INS10 bit will be set to B'1 after the last coded data is transferred. The signal asserted by this interrupt source cannot be negated by clearing the corresponding interrupt status bit to 0. Issue an interrupt signal clear command (set the JEND bit in JCCMD to B'1) to clear the interrupt signal.

- When the INS10 bit in the interrupt status register JINTS is set to B'1, all coded data has been transferred and the JPU has completed encoding; transfer the coded data outside the JPU. When reload mode is set, transfer the rest of the coded data. When the total size of the coded data transferred to the reload buffer matches the number of the coded data set by the JIFEDRSZ, bits INS10 and INS13 are simultaneously set to B'1. This interrupt occurs when the INT10 bit in the interrupt enable register JINTE is set to B'1.
- In encoding with reload mode, when the INS13 bit in the interrupt status register JINTS is set to B'1, it indicates that the number of coded data set by the JIFDDRSZ have been transferred. When the first interrupt occurs, transfer the coded data stored in the reload buffer to the other memory area. When the second and subsequent interrupts occur, transfer the coded data and set a command for restarting transfer to the reload buffer.

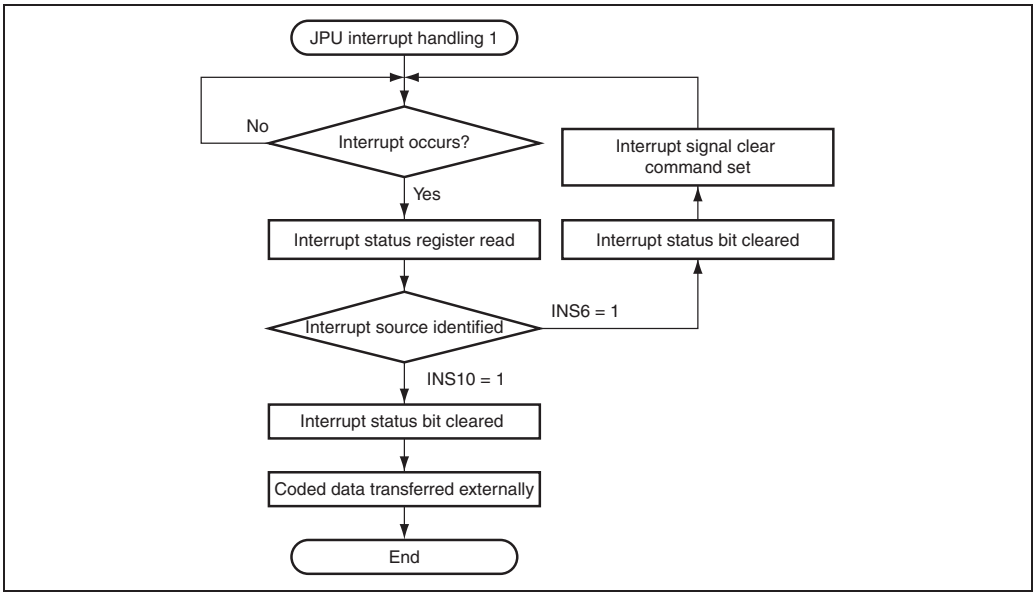

Figure 43.4 Flow of JPU Interrupt Handling 1 in Encoding

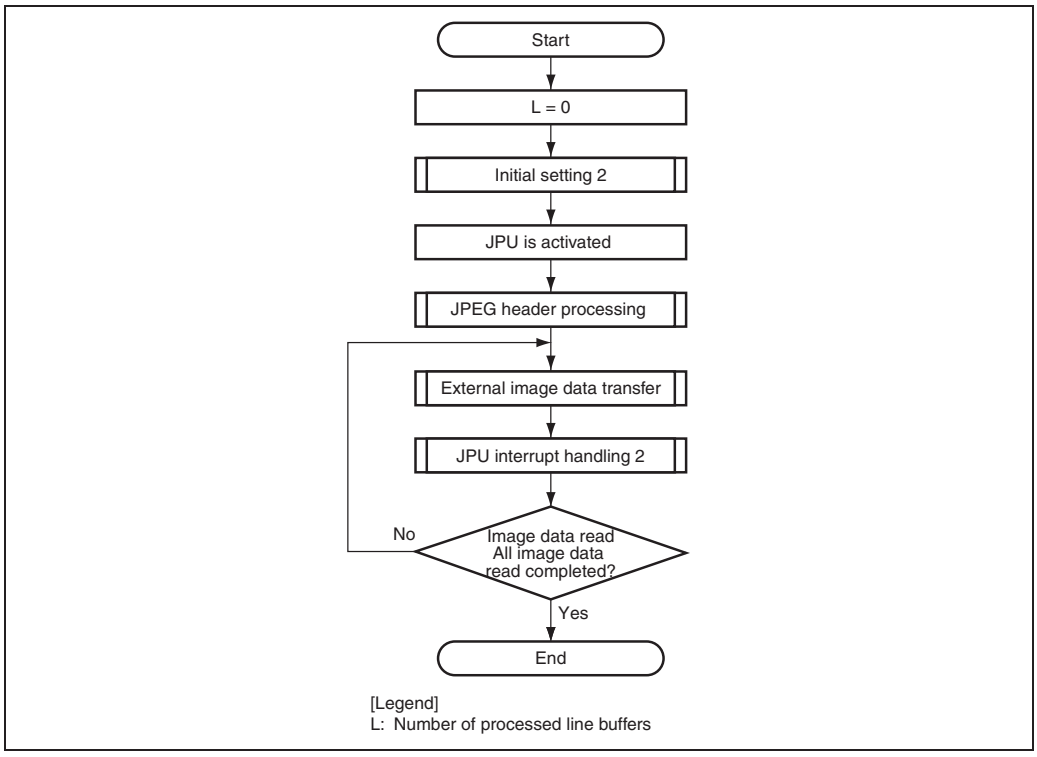
(3) Line Buffer Mode (Encoding)

After the initial settings are completed, activate the JPU by setting the JSRT bit in JCCMD to B'1. After the JPU has been activated, the JPEG markers (SOI to SOS) are generated and output. It takes approximately 30000 cycles to generate the markers. After the image data is stored in the external buffer and a line buffer write end command is issued, the JPU loads the image data from the external buffer and starts encoding it.



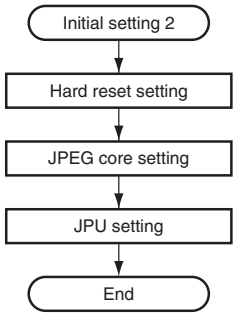


Figure 43.5 Flow of Encoding in Line Buffer Mode

After a reset, set all necessary registers before the JPU is activated.

JPEG core settings

Subsampling setting:	REDU bit in JCMOD
Encoding/decoding setting:	DSP bit in JCMOD
Code amount count mode setting:	CCNT bit in JCMOD
Marker skip mode setting:	MSKIP bit in JCMOD
SOI marker delete setting:	SOIC bit in JCMOD
Quantization table number setting:	JCQTN
Huffman table number setting:	JCHTN
DRI setting:	JCDRIU, JCDRID
Vertical image size setting:	JCVSZU, JCVSZD
Horizontal image size setting:	JCHSZU, JCHSZD
Quantization table setting:	JCQTBL1 to JCQTBL4
Huffman table setting:	JCHTB0, JCHTB1, JCHTA0, JCHTA1

JPU settings

Interrupt setting:	INT14 to INT10 bits in JINTE
VPU/JPU port select setting:	VJSET bit in JIFCNT
Subsampling setting:	INFT bit in JIFECNT
Buffer mode setting:	BUF bit in JIFECNT
Rotated read mode setting:	ROT bit in JIFECNT
Byte/word swap setting of read data:	SWAP bit in JIFECNT
Byte/word swap setting of write data:	SWAP bit in JIFDCNT
Reload mode setting:	RELOAD bit in JIFECNT
Processing unit setting:	PU bit in JIFECNT
Y component source address setting:	JIFESYA1, JIFESYA2
C component source address setting:	JIFESCA1, JIFESYA2
Image buffer memory width setting:	JIFESMW
Vertical size of received image setting:	JIFESVSZ
Horizontal size of received image setting:	JIFESHSZ
Stream data write start address setting:	JIFEDA1, JIFEDA2
Number of data preceding address switching setting:	JIFEDRSZ

Figure 43.6 Flow of Initial Setting 2

In line buffer mode, set the line buffer processing restart command after activating the JPU. Transferring the image data to the line buffer can be done before the JPU is activated. Two line buffers are provided: one for the data to be output to the JPU and the other for the data to be transferred from the external modules. Thus, transfer the image data to the line buffer after confirming that the data stored in the buffer for outputting data to the JPU has been transferred to the JPU through interrupts.

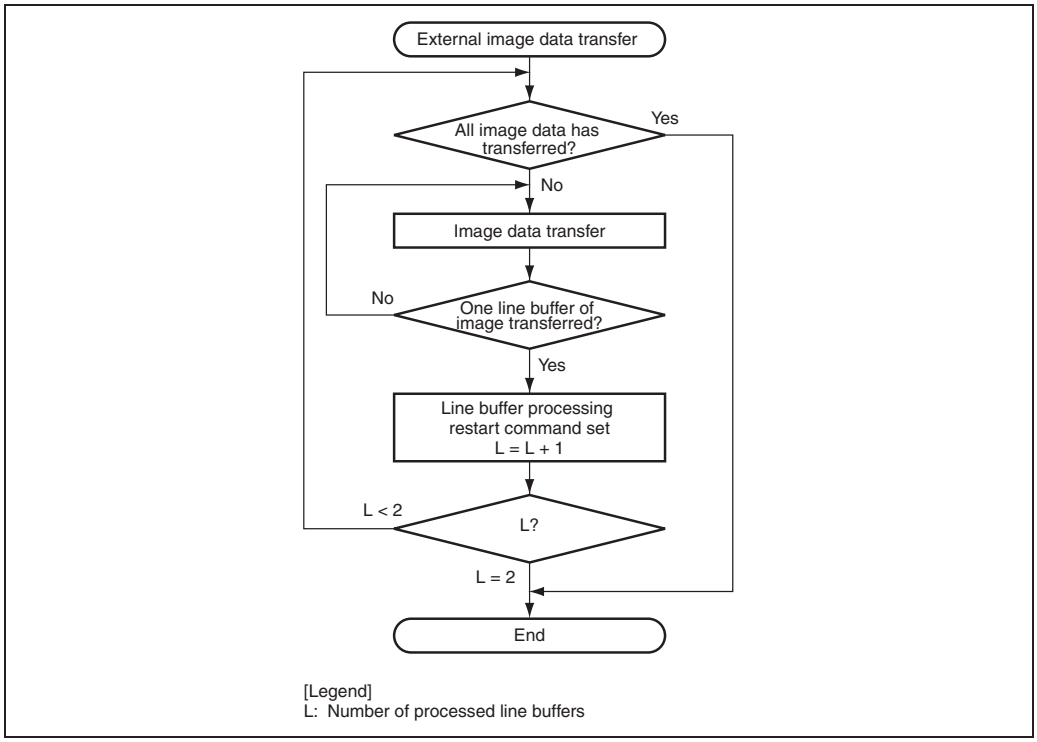

Figure 43.7 Flow of External Image Data Transfer

When multiple interrupts occur (also when multiple interrupts that are not shown in figure 43.8 occur), process all interrupt sources.

- When the INS12 bit or INS11 bit in the interrupt status register JINTS is set to B'1, the transfer of one line buffer of image data has been completed. Thus transfer new data to the line buffer. This interrupt occurs when the INT12 or INT11 bit in the interrupt enable register JINTE is set to B'1.
- When the INS6 bit in the interrupt status register JINTS is set to B'1, the JPEG encoding has been completed. Though the JPU continues processing since coded data to be transferred remains, the INS10 bit will be set to B'1 after the last coded data is transferred. The signal which is asserted by this interrupt source cannot be negated by clearing the corresponding interrupt status bit to 0. Issue an interrupt signal clear command (set the JEND bit in JCCMD to B'1) to negate the interrupt signal.

- When the INS10 bit in the interrupt status register JINTS is set to B'1, all coded data has been transferred and the JPU has completed encoding; transfer the coded data outside the JPU. When reload mode is set, transfer the rest of the coded data. When the total size of the coded data transferred to the reload buffer matches the number of coded data set by JIFEDRSZ, bits INS10 and INS13 are simultaneously set to B'1. This interrupt occurs when the INT10 bit in the interrupt enable register JINTE is set to B'1.
- In encoding with reload mode, when the INS13 bit in the interrupt status register JINTS is set to B'1, it indicates that the number of coded data set by JIFDDRSZ have been transferred. When the first interrupt occurs, transfer the coded data stored in the reload buffer to the other memory area. When the second and subsequent interrupts occur, transfer the coded data and set a command for restarting transfer to the reload buffer.

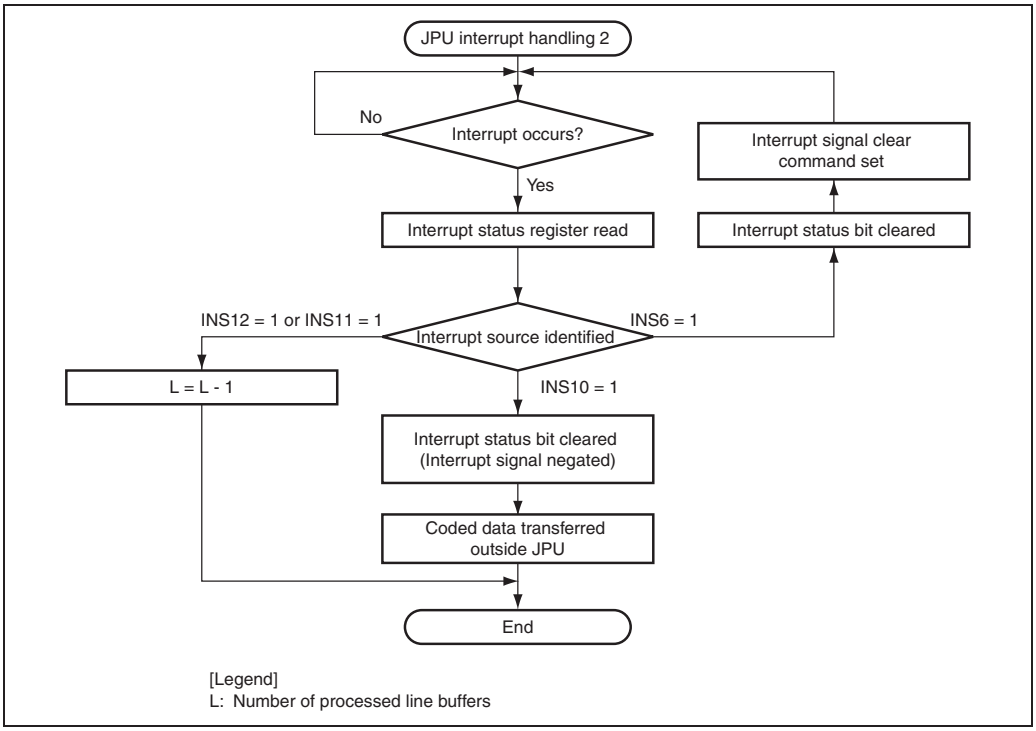

Figure 43.8 Flow of JPU Interrupt Handling 2

(4) JPEG Coded Data Format

Figure 43.9 shows the data output stream in encoding. The amount of coded data from SOI to EOI is indicated by the JCDTCU, JCDTCM, and JCDTCD registers. When the JCDRIU and JCDRID registers are set to H'0000 0000, the following markers are not output.

- DRI marker
- RST marker (in encoded image data)

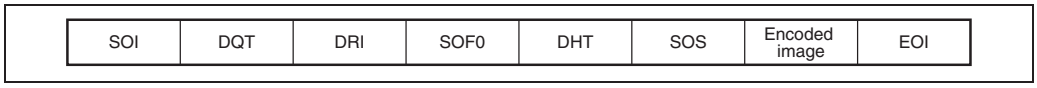

Figure 43.9 JPEG Coded Data Format

DQT: Not output for unused table

DHT: Output in order DC0, AC, DC1, and AC1. Not output for unused table.

SOF0: Component identifiers are C1 = first component, C2 = second component, and C3 = third component

SOS: Scan component selectors are CS1 = first component, CS2 = second component, and CS3 = third component

Header Volume (Reference)

- SOI: 2 bytes (FFD8)
- DQT: 134 bytes when two quantization tables are used, 199 bytes when three quantization tables are used (±65 bytes/table increase or decrease)
- DRI: 6 bytes
- SOF0: 19 bytes (4:2:2)
- DHT: 420 bytes (two tables are used)
- SOS: 14 bytes (4:2:2)
- EOI: 2 bytes (FFD9)

(a) JPEG Coded Data Format when Marker Skip Mode is Set

When MSKIP bits in JCMOD are set to B'01, SOI to DHT markers are not output. The RST marker output depends on the settings of the DRI upper and DRI lower registers. The amount of coded data from SOS to EOI is indicated by the JCDTCU, JCDTCM, and JCDTCD registers.

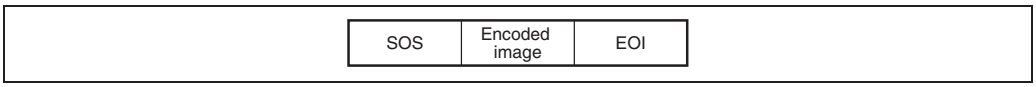

Figure 43.10 JPEG Coded Data Format when Marker Skip Mode is Set

(b) JPEG Coded Data Format when SOI Marker is Deleted

When the SOIC bit in JCMOD is set to B'1, the SOI marker is not output. This setting is valid when marker skip mode is not set. The amount of coded data from DQT to EOI equals the value indicated by JCDTCU, JCDTCM, and JCDTCD – 2.

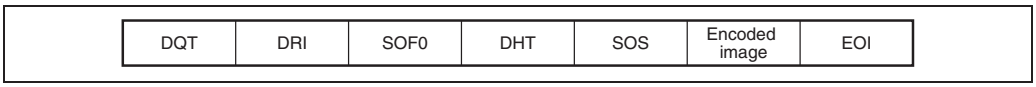

Figure 43.11 JPEG Coded Data Format when SOI Marker is Deleted

(c) Outputting End of JPEG Coded Data

The JPU transfers data as it ends at a 16-byte boundary. When the end of the coded data (the EOI marker) is not placed at the 16-byte boundary, H'FF is inserted into the data and the JPU outputs it. An H'FF byte is not included in the amount of the coded data indicated by the JCDTCU, JCDTCM, and JCDTCD registers.

(5) Code Amount Count Mode

In this mode, only the amount of coded data is counted. In encoding, set the CCNT bit in JCMOD to B'1 and enable reload mode, and set the JIFEDRSZ register (the number of data before the target address is switched) to 0; thus, the JPEG coded data is not output.

(6) Table Setting

(a) Quantization Table Specification

The order of addresses shown in 8 × 8 blocks corresponds to that of the register addresses. Do not access this table while the JPU is in processing.

Table 43.3 Quantization Table

(b) Huffman Table Specification

Examples of the Huffman table specification given in the ITU-T T81 Annex K.3.3 recommended by JPEG are shown below. In encoding, the following settings must be specified for all codes so that Huffman codes can be generated for all group numbers.

- DC Huffman table: The number of codes for each code length is 12 codes.
  The group numbers in order of frequency of occurrence are 12.
- AC Huffman table: The number of codes for each code length is 162 codes.
  The zero run length/the group numbers in order of frequency of occurrence are 162.

Do not access the following tables while the JPU is in processing.

- Table K.3/T81
  JCHTBD0 (H’FE99 0100) = H'0001 0501
  JCHTBD0 (H’FE99 0104) = H'0101 0101
  JCHTBD0 (H’FE99 0108) = H'0100 0000

(7) Rotated Read Mode Setting

In encoding with frame buffer mode, image rotation processing can be performed (set the ROT bit in JIFECNT). When this processing is specified, set the source addresses shown in figure 43.12 in the JIFESYA1 and JIFECYA1 registers.

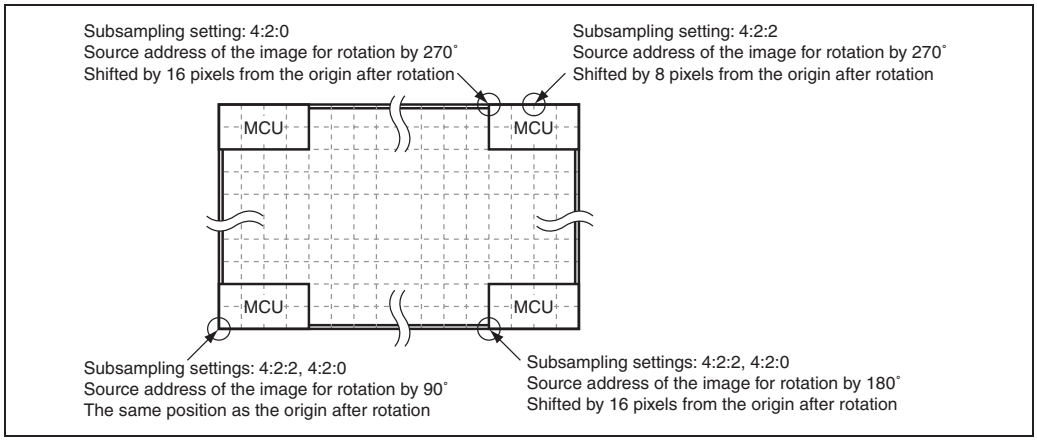

Figure 43.12 Position of Source Addresses for Rotation

43.3.2 Decoding

(1) Overview of Processing

The decoding process flows are described below.

(a) Frame Buffer Mode

1. JPEG core processing (decoding)
   Interrupts are generated every time the specified amount of data has been reloaded in reload mode.
2. Decoding data and transferring
   One frame of data can be processed at anytime and transferred.
3. An interrupt is generated after all of the processing is completed.

(b) Line Buffer Mode

1. JPEG core processing (decoding)
   Interrupts are generated every time the specified amount of data has been reloaded in reload mode.
2. Decoding data and transferring
3. Y and C components of the decoded data are transferred to the external buffer: Y components in multiples of 8 lines and C components in multiples of 8 lines (YCbCr 4:2:2), or Y components in multiples of 16 lines and C components in multiples of 16 lines (YCbCr 4:2:0).
   Every time when the transfer to the external buffer is completed, a transfer end command is issued to the JPU.
4. An interrupt is generated after all of the processing is completed.

(2) Frame Buffer Mode (Decoding)

After the initial setting is completed, activate the JPU by setting the JSRT bit in JCCMD to B'1. After the JPU has been activated, it obtains the coded data from the external buffer and starts decoding it. When multiple interrupts occur (also when multiple interrupts that are not shown in figure 43.13 occur), process all interrupt sources.

- When the INS14 bit in the interrupt status register JINTS is set to B'1, the coded data in the reload buffer has been transferred. This interrupt occurs when the INT14 bit in the interrupt enable register JINTE is set to B'1.

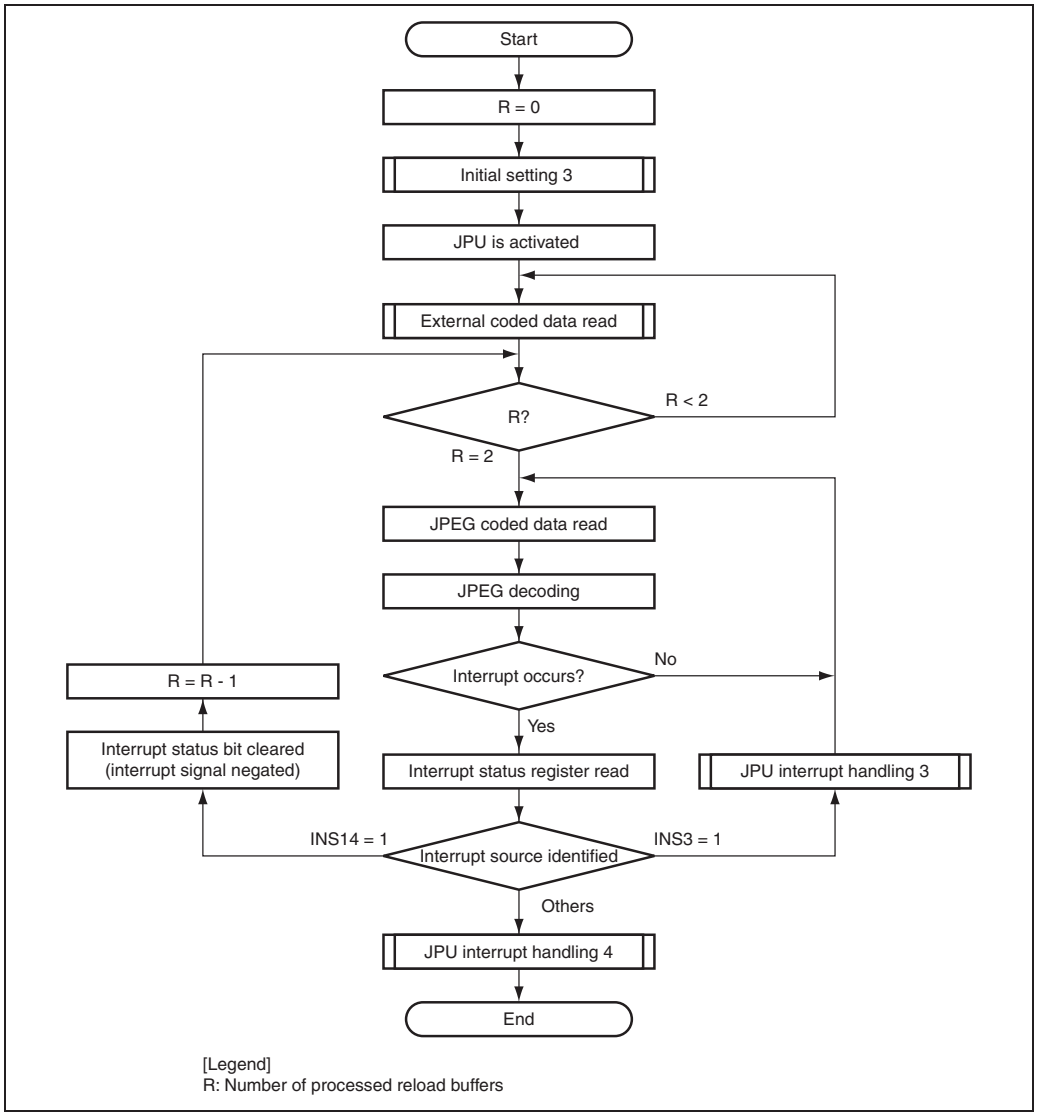

Figure 43.13 Flow of Decoding in Frame Buffer Mode

After a reset, set all necessary registers before the JPU is activated.

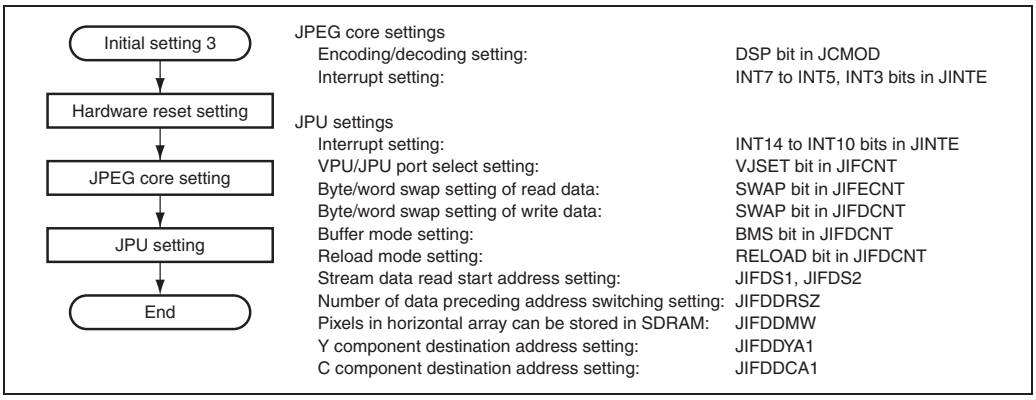

Figure 43.14 Flow of Initial Setting 3

Before the JPU is activated, prepare the coded data since the JPU starts reading the data immediately after being activated when reload mode is not set. If not all of the coded data is prepared, transfer the coded data to the buffer sequentially so that the JPU can read the data smoothly.

When reload mode is set, set a reload transfer write end command after the JPU is activated. The coded data can be transferred to the reload buffer before the JPU is activated. Two reload buffers are provided: one is used for the data to be output to the JPU and the other is for the data to be transferred from the external modules. Thus, transfer the data to the reload buffer after confirming that the data stored in the buffer used to output the data to the JPU has been transferred to the JPU through interrupts.

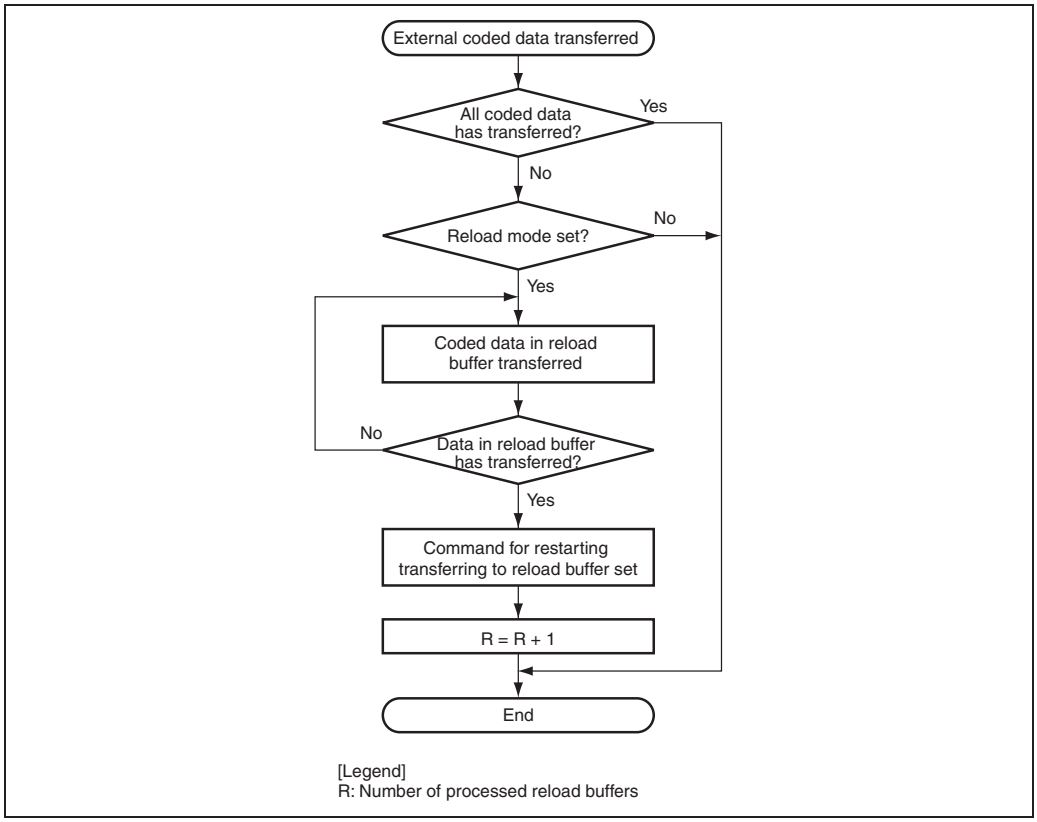

Figure 43.15 Flow of Transferring External Coded Data

When multiple interrupts occur (also when multiple interrupts that are not shown in figure 43.16 occur), process all interrupt sources.

- When the INS3 bit in the interrupt status register JINTS is set to B'1, the JPEG coded data is prepared and its image size and subsampling setting can be read. After reading of all necessary registers, set the command for revoking the processing-stopped state to resume decoding. This interrupt occurs when the INT3 bit in the interrupt enable register JINTE is set to B'1. The interrupt signal which is asserted by this interrupt source cannot be negated through clearing the corresponding interrupt status bit to 0. Issue an interrupt signal clear command (set the JEND bit in JCCMD to B'1) to clear the interrupt signal.

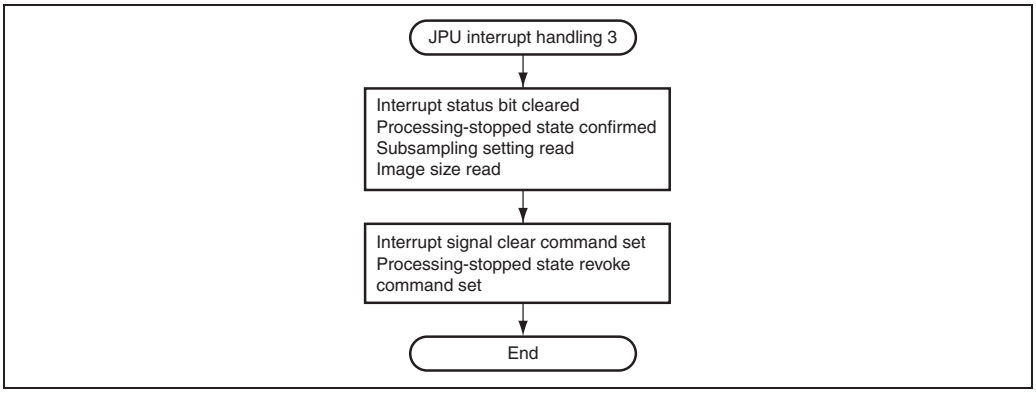

Figure 43.16 Flow of JPU Interrupt Handling 3

Figure 43.17 shows the interrupt handling flow in decoding. When multiple interrupts occur (also when multiple interrupts that are not shown in figure 43.17 occur), process all interrupt sources.

- When the INS5 bit in the interrupt status register JINTS is set to B'1, the input JPEG coded data has an error and the JPU stops the decoding process. Read ERR bits in JCDERR and identify its error source. The interrupt signal which is asserted by this interrupt source cannot be negated by clearing the corresponding interrupt status bit. Issue an interrupt signal clear command (set the JEND bit in JCCMD to B'1) to clear the interrupt signal.
- When the INS6 bit in the interrupt status register JINTS is set to B'1, the JPEG decoding process is completed. When the INS10 bit is set to B'1, all of the image data is transferred and JPU completes decoding. The interrupt signal which is asserted by this interrupt source cannot be negated by clearing the corresponding interrupt status bit. Issue an interrupt signal clear command (set the JEND bit in JCCMD to B'1) to clear the interrupt signal.

- When the INS10 bit in the interrupt status register JINTS is set to B'1, all of the image data has been transferred and the JPU has completed decoding; transfer the image data outside the JPU. This interrupt occurs when the INT10 bit in the interrupt enable register JINTE is set to B'1.

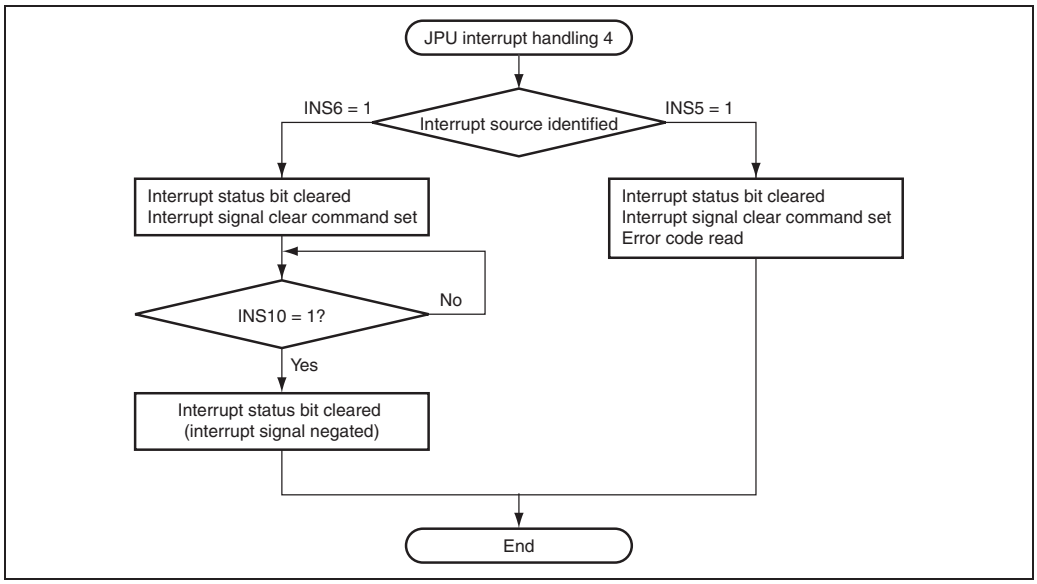

Figure 43.17 Flow of JPU Interrupt Handling 4

(3) Line Buffer Mode (Decoding)

After the initial settings are completed, activate the JPU by setting the JSRT bit in JCCMD to B'1. After the JPU has been activated, transfer the coded data to the external buffer. After the coded data has been stored in the external buffer, the JPU reads the data from the external buffer and starts decoding it.

When multiple interrupts occur (also when multiple interrupts that are not shown in figure 43.18 occur), process all interrupt sources.

- When the INS14 bit in the interrupt status register JINTS is set to B'1, the coded data in the reload buffer has been transferred. This interrupt occurs when the INT14 bit in the interrupt enable register JINTE is set to B'1.

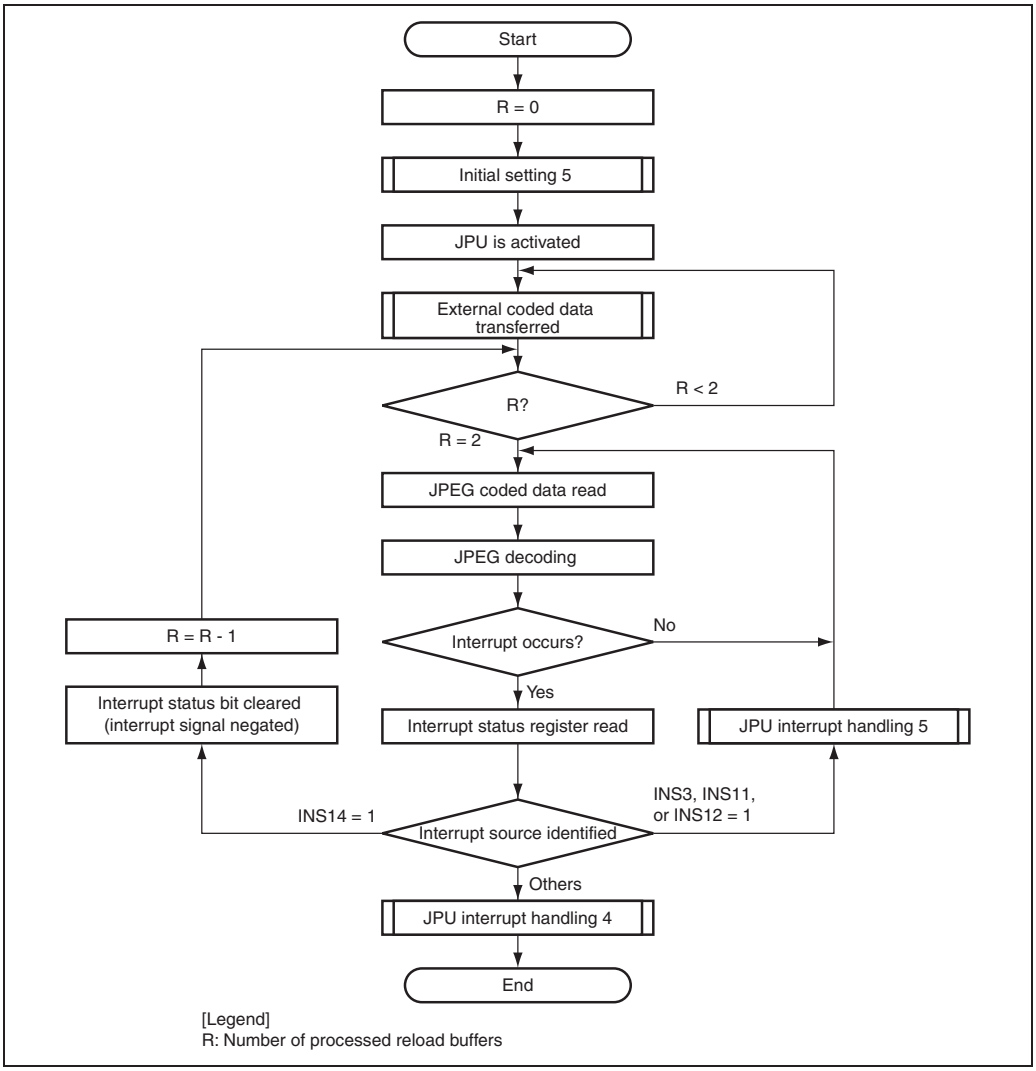

Figure 43.18 Flow of Decoding Process in Line Buffer Mode

After a reset, set all necessary registers before the JPU is activated.

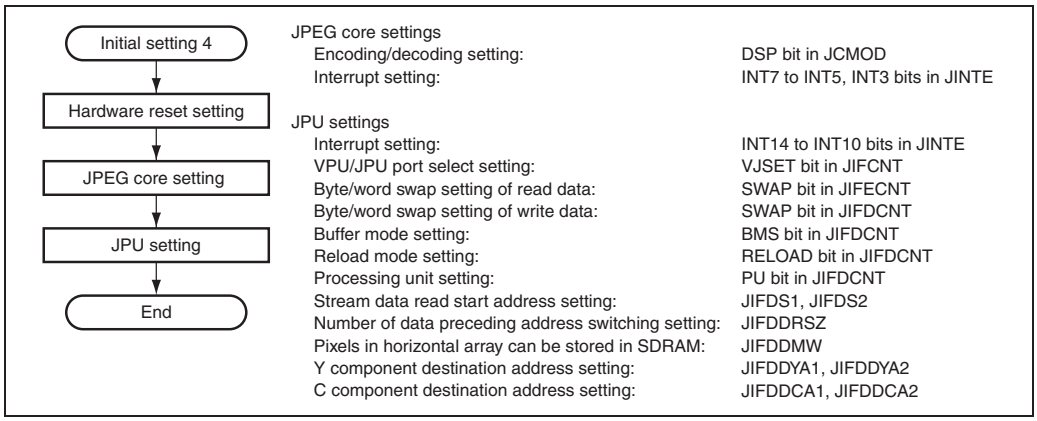

Figure 43.19 Flow of Initial Setting 4

When multiple interrupts occur (also when multiple interrupts that are not shown in figure 43.20 occur), process all interrupt sources.

- When the INS3 bit in the interrupt status register JINTS is set to B'1, the JPEG coded data is prepared and its image size and subsampling setting can be read. After reading all necessary registers, set the command for revoking the processing-stopped state to resume decoding. This interrupt occurs when the INT3 bit in the interrupt enable register JINTE is set to B'1. The interrupt signal which is asserted by this interrupt source cannot be negated by clearing the corresponding interrupt status bit to 0. Issue an interrupt signal clear command (set the JEND bit in JCCMD to B'1) to clear the interrupt signal.
- When the INS11 or INS12 bit in the interrupt status register JINTS is set to B'1, one line buffer of image data has been transferred. When the first interrupt occurs, transfer the image data stored in the line buffer to the other memory area. When the second and subsequent interrupts occur, transfer the image data and set a command for restarting transfer to the line buffer. This interrupt occurs when the INT11 or INT12 bit in the interrupt enable register JINTE is set to B'1.

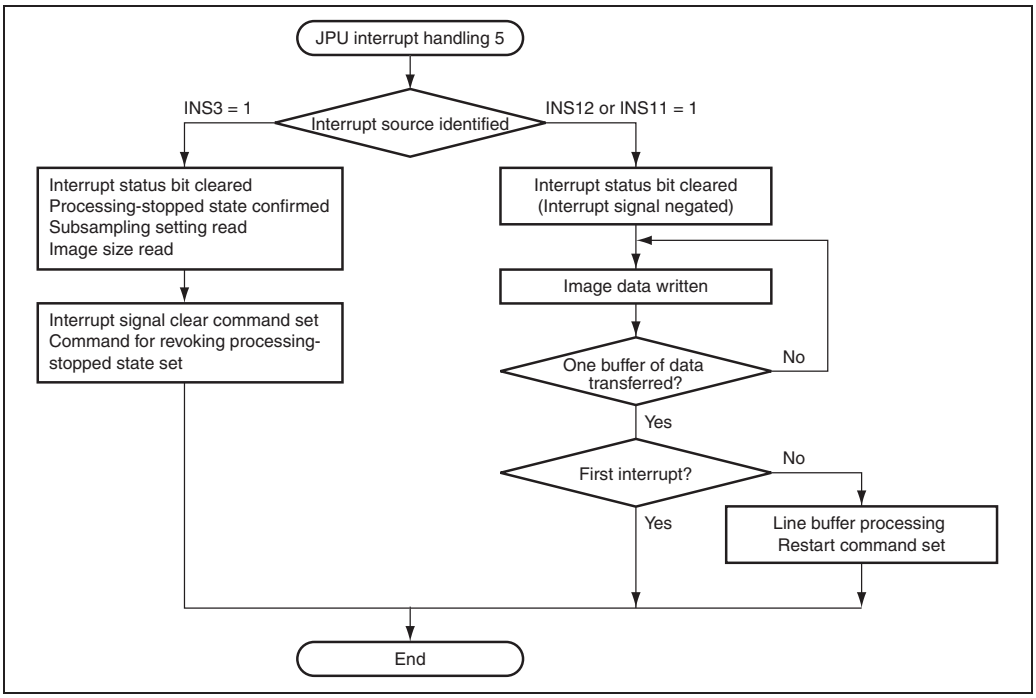

Figure 43.20 Flow of JPU Interrupt Handling 5

(4) Input JPEG Coded Data

Markers to be processed in decoding are SOS, SOF0, SOS, DQT, DHT, DRI, RSTm, and EOI. Other markers except for the error markers shown below are ignored even if they are read.

(5) JPEG Decoding Errors

(a) Error Marker

If an error marker is found while analyzing encoded data for decoding, identify the error type by the code and set the code (shown in table 43.4) to ERR bits in JCDERR. When an error is detected, the JPU generates an interrupt signal and stops decoding. The stored code is 1010 (default value) at the start of processing for the next frame or after a bus reset.

Table 43.4 Decoding Error Codes

Code	Description
0000	Normal
0001	SIO not detected: SIO not detected until EOI detected
0010	SOF1 to SOFF detected
0011	Subsampling setting other than YCbCr 4:4:4 (H = 1:1:1, V = 1:1:1)/YCbCr 4:2:2 (H = 2:1:1, V = 1:1:1)/YCbCr 4:1:1 (H = 4:1:1, V = 1:1:1)/YCbCr 4:2:0 (H = 2:1:1, V = 2:1:1) detected
0100	SOF accuracy error: Other than 8 detected
0101	DQT accuracy error: Other than 0 detected
0110	Component error 1: The number of SOF0 header components detected is other than 1, 3, or 4
0111	Component error 2: The number of components differs between SOF0 header and SOS
1000	SOF0, DQT, and DHT not detected when SOS detected
1001	SOS not detected: SOS not detected until EOI detected
1010	EOI not detected (default)
1011	Restart interval data number error detected
1100	Image size error detected
1101	Last MCU data number error detected
1110	Block data number error detected

(b) Huffman Coded Segment Error

In decoding, if it is determined that the increase or decrease in the number of data to be decoded is caused by an error such as bit inversion or a lack of data in the Huffman coded segment through analysis of the encoded data, the error type is identified and the error code is set in ERR bits in JCDFRR. When a necessary bit among INT7 to INT5 in JINTE is set to B'1, the error code is set and decoding is terminated by an interrupt signal generation. The code to be stored is 1010 (default value) at the start of processing for the next frame or after a bus reset.

In this error detection, an increase or decrease in the number of data to be decoded is detected; an error is not detected even when any other error occurs in the Huffman coded segment and the error does not cause an increase or decrease in the number of data to be decoded.

[Example]

The number of data in a Huffman coded segment with subsampling setting 4:2:2, DRI = 2, X = 80 pixels, and Y = 8 pixels

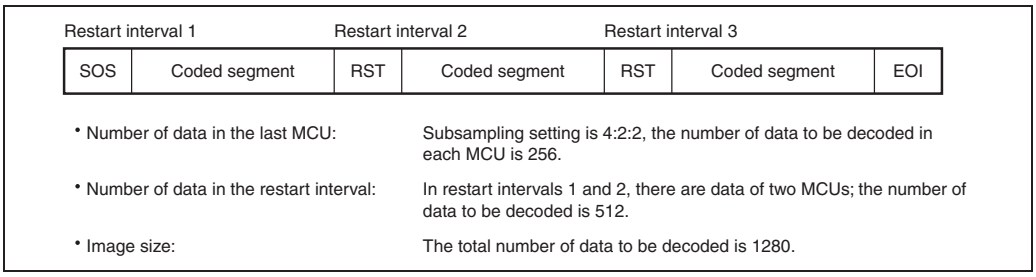

Figure 43.21 Huffman Coded Segment

Table 43.5 Segment Error Codes

Code	Description
0000	Normal
1011	Restart interval data number error: The number of data in each interval is compared with the number of data specified by the DRI marker. If an interval has more or less data that is specified by the DRI marker, the decoding error code (1011) is set. The last interval which is shorter than the restart interval is not compared. If the DRI marker segment is not placed or the specified number is 00, an error is not detected even if the RSTm marker is placed. Also an m which indicates the order of RSTm marker modulo 8 (m = 0 to 7) is exempt from the error detection analysis. When the INT7 bit in JINTE is set to B'0, this error is not detected.
1100	Image size error: The data number of an image which is calculated from the number of lines specified by the frame parameter and the number of samples per line is compared with the total number of data from SOS to EOI (in pixel units). If the numbers of data do not match, the decoding error code (1100) is set. When the INT6 bit in JINTE is set to B'0, this error is not detected. The data number of an image is shown in MCU units. Thus the number of lines and the number of samples per line need to be shown in MCU units.
1101	Last MCU data number error: Whether the number of data in the MCUs at the EOI detection is shown in MCU units is checked and fractions are detected. If error (1100) occurs simultaneously, error (1100) has priority. When the INT5 bit in JINTE is set to B'0, this error is not detected.
1110	Block data number error: Whether a block is an 8×8 array is checked; the check is performed for fractions. When bits INT7 to INT5 in JINTE are set to B'0, this error is not detected.

43.3.3 Storing Image Data

Storing the image data in the buffer and transferring the data to or from the JPU are described below.

(1) Frame Buffer Mode
(VGA: 640 × 480, Image data area ⇔ QVGA: Transferring image data 320 × 240)

- Example of register settings

	VGA → VGA
JIFESMW/JIFDDMW: H'0000 0280 (640)	H'0000 0280
JIFESYAI/JIFDDYAI: H'0001 2CA0 (76960)	H'0000 0000
JIFESHSZ/JIFDDHSZ: H'0000 0140 (320)	H'0000 0280
JIFESVSZ/JIFDDVSZ: H'0000 00F0 (240)	H'0000 01E0
JIFESCAI/JIFDDCA1: H'0005 DCA0 (384160)	H'0004 B000

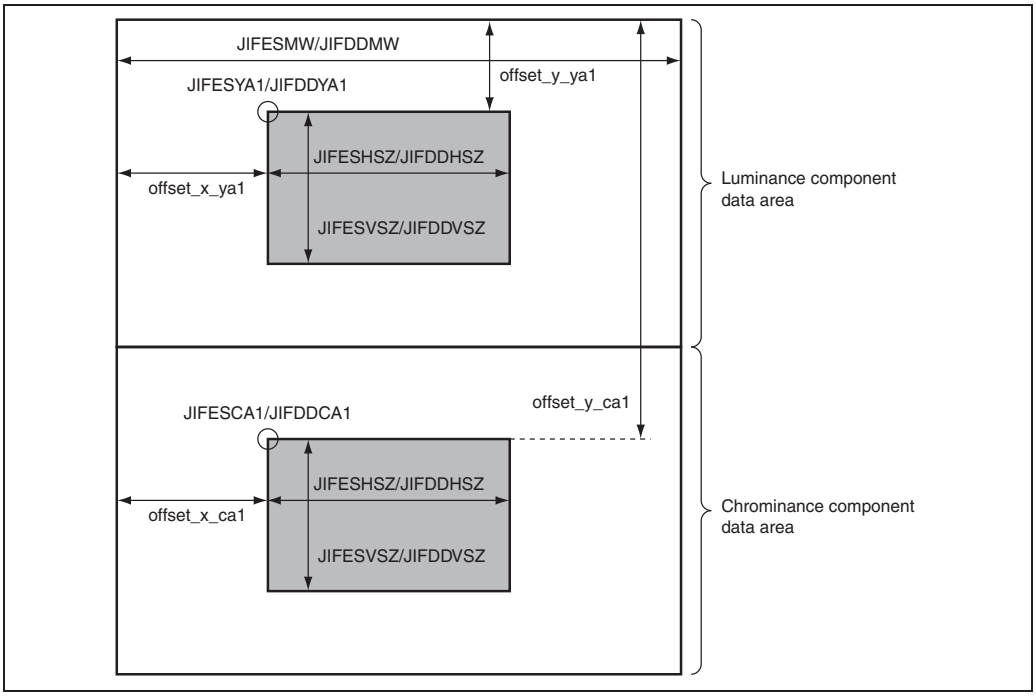

Figure 43.22 Data Allocation Image in Frame Buffer

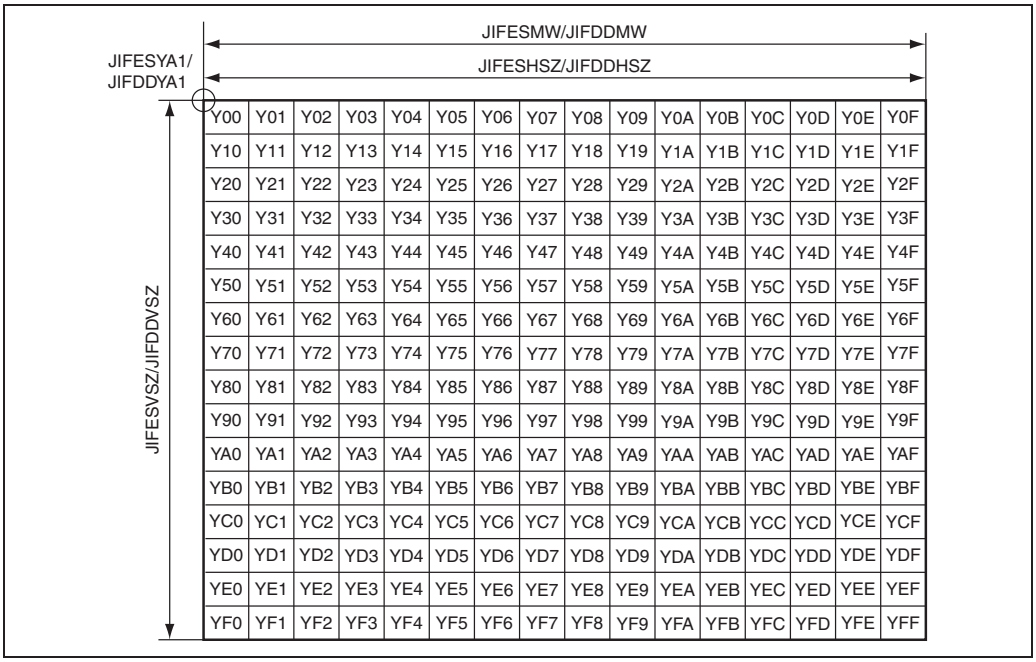
(2) Storing Image Data



(a) Luminance component data

Specify JIFESYA1/JIFDDYA1 (JIFESYA2/JIFDDYA2) as the origin of the image. Transfer the data in the area specified by JIFESHSZ/JIFDDHSZ and JIFESVSZ/JIFDDVSZ.

- Register setting value:
  JIFESMW/JIFDDMW: H'0000 0010 (16)
  JIFESYA1/JIFDDYA1: H'0000 0000 (0)
  JIFESHSZ/JIFDDHSZ: H'0000 0010 (16)
  JIFESVSZ/JIFDDVSZ: H'0000 0010 (16)

- Data stored in buffer:
  H'0000 0000 = Y00, Y01, Y02, Y03
  H'0000 0004 = Y04, Y05, Y06, Y07
  H'0000 0008 = Y08, Y09, Y0A, Y0B
  H'0000 000C = Y0C, Y0D, Y0E, Y0F
  :
  H'0000 00F0 = YF0, YF1, YF2, YF3
  H'0000 00F4 = YF4, YF5, YF6, YF7
  H'0000 00F8 = YF8, YF9, YFA, YFB
  H'0000 00FC = YFC, YFD, YFE, YFF

- Transferring data to the JPU:
  Burst transfer is performed in 1-MCU units in the line direction. One line is 16 bytes.

Y00	Y01	Y02	Y03	Y04	Y05	Y06	Y07	Y08	Y09	Y0A	Y0B	Y0C	Y0D	Y0E	Y0F

43.3.4 Storing Coded Data

Storing the coded data in the buffer and transferring the coded data to or from the JPU are described below.

(1) Coded Data Sample: Coded length (SOI to EOI) is 592 bytes

Table 43.6 Coded Data Sample

(2) Transferring Data at the End of Coded Data

[Encoding]

Insert H'FF up to a 16-byte address boundary.

CC: Coded data, FF-D9: EOI markers

- CC-CC-FF-D9 Insert H'FF up to a 16-byte boundary
- CC-FF-D9-FF Insert H'FF up to a 16-byte boundary
- FF-D9-FF-FF Insert H'FF up to a 16-byte boundary

[Decoding]

- The JPU continues reading until the JPU core detects the EOI marker. The JPU may read other data in addition to coded data.

(3) Reload Mode Disabled

A way of storing the data is shown in table 43.6, Coded Data Sample.

- JIFEDA1/JIFDSA1: H'0000 0000

  As shown in table 43.6, Coded Data Sample, the address of coded data is incremented from the start and then stored.

- JIFEDA1/JIFDSA1: H'0000 0004

43.3.5 Fractional Data Processing

The JPU can encode or decode the image in 4-pixel units, and sometimes it is needed to process the image that partially fills MCU (fractional data processing).

When the size of the image for coding by the JPU leaves one or more MCUs only partially filled, those MCUs are completed by filling the areas at the right and bottom relative to the origin of the image with black data (Y: H'00, CbCr: H'80). The image thus completed is then coded. When rotation is selected, MCUs are completed by filling the right and bottom areas relative to the post-rotation origin of the image with black data.

In decoding, if the image size information (parameter in the SOF0 marker) in the JPEG coded data leaves one or more MCUs only partially filled, the JPU only transfers the portions that contain actual data to the external buffer, e.g. in SDRAM. Thus, when the JPU decodes JPEG coded data that has been produced by the JPU coding data which did not completely fill all MCUs, the black data in the right and bottom areas of the incompletely filled MCUs are not transferred.

43.4 Interrupt Handling Flow

Interrupts for the JPU can be classified into interrupts for encoding/decoding and interrupts for transferring data. The way to clear an interrupt signal differs according to the interrupt sources.

43.4.1 Interrupts for Encoding and Decoding

Bits INS6, INS5, and INS3 in the interrupt status register JINTS are the interrupt sources for the JPEG core incorporated in the JPU. The interrupt signals which are asserted by these interrupt sources cannot be negated by clearing the corresponding interrupt status bits. Issue an interrupt signal clear command (set the JEND bit in JCCMD to B'1) to clear the interrupt signal.

(1) Encoding

- JPEG encoding process end
  When the INS6 bit in the interrupt status register JINTS is set to B'1, the JPEG encoding process is completed. After all of the coded data is transferred, the JPU ends the encoding process.

(2) Decoding

- JPEG decoding process end
  When the INS6 bit in the interrupt status register JINTS is set to B'1, the JPEG decoding process is completed. After all of the image data is transferred, JPU completes decoding.
- JPEG decoding error occurrence
  When the INS5 bit in the interrupt status register JINTS is set to B'1, the input JPEG coded data has an error and the JPU stops the decoding process. Read the error code (ERR bits in JCDERR) and identify the error source.
- Request for reading the image size and subsampling setting
  When the INS3 bit in the interrupt status register JINTS is set to B'1, JPEG coded data is input and information regarding its size and subsampling can be read. Since the JPEG decoding process is suspended, start the JPEG decoding process by setting the command to revoke the processing-stopped state after accessing the necessary registers. This interrupt occurs when the INT3 bit in the interrupt enable register JINTE is set to B'1.

43.4.2 Interrupts for Transferring Data

Bits INS14 to INS10 in the interrupt status register JINTS are the interrupt sources for transferring the image data and coded data. The interrupt signals asserted by these interrupt sources can be negated by clearing the corresponding interrupt status bits to 0.

(1) Encoding

- Occurs after data of one line buffer has been transferred (in line buffer mode)

  When the INS12 or INS11 bit in the interrupt status register JINTS is set to B'1, one line buffer of image data has been transferred; transfer the rest of the image data to the line buffer and resume transferring the data from the line buffer. This interrupt occurs when the INT12 or INT11 bit in the interrupt enable register JINTE is set to B'1.
- Occurs after the specified number of data have been reloaded

  When the INS13 bit in the interrupt status register JINTS is set to B'1, the coded data specified by JIFEDRSZ has been transferred. When the first interrupt occurs, transfer the coded data stored in the reload buffer to the other memory area. When the transfer is completed and the next reload interrupt occurs, transfer the coded data and set a command to restart the transfer to the reload buffer. The data is transferred to the first two reload buffers automatically and interrupts occur. These interrupts occur when the INT13 bit in the interrupt enable register JINTE is set to B'1.
- Occurs after all processes are completed

  When the INS10 bit in the interrupt status register JINTS is set to B'1, all of the coded data has been transferred and the JPU has completed encoding; transfer the coded data outside the JPU. When reload mode is set, transfer the rest of the coded data. When the total size of the coded data transferred to the reload buffer matches the number of coded data set by the JIFEDRSZ, bits INS10 and INS13 in JINTS are simultaneously set to B'1. This interrupt occurs when the INT10 bit in the interrupt enable register JINTE is set to B'1.

(2) Decoding

- Occurs after data of one line buffer has been transferred (in line buffer mode)

  When the INS12 or INS11 bit in the interrupt status register JINTS is set to B'1, one line buffer of image data has been transferred. When the first interrupt occurs, transfer the image data stored in the line buffer to the other memory area. When the transfer is completed and the next reload buffer interrupt occurs, transfer the image data and set a command to restart the transfer to the line buffer. The data is transferred to the first two reload buffers automatically and interrupts occur. These interrupts occur when the INT12 or INT11 bit in the interrupt enable register JINTE is set to B'1.

- Occurs after the specified number of data have been reloaded
  When the INS14 bit in the interrupt status register JINTS is set to B'1, the coded data in the reload buffer has been transferred; transfer the rest of the coded data to the reload buffer and set a command to resume transferring the data from the reload buffer. This interrupt occurs when the INT14 bit in the interrupt enable register JINTE is set to B'1.
- Occurs after all processes are completed
  When the INS10 bit in the interrupt status register JINTS is set to B'1, all of the image data has been transferred and the JPU has completed decoding; transfer the image data outside the JPU. This interrupt occurs when the INT10 bit in the interrupt enable register JINTE is set to B'1.

43.5 Bus Reset Processing

Issuing the bus reset command (setting the BRST bit in JCCMD to 1) causes a bus reset.

When the JPU is in operation, the bus reset command should not be issued. Registers other than below are initialized by a bus reset.

- JPEG code mode register (JCMOD)
- JPEG code command register (JCCMD)
- JPEG code quantization table number register (JCQTN)
- JPEG code Huffman table number register (JCHTN)
- JPEG code DRI upper register (JCDRIU)
- JPEG code DRI lower register (JCDRID)
- JPEG code vertical size upper register (JCVSZU)
- JPEG code vertical size lower register (JCVSZD)
- JPEG code horizontal size upper register (JCHSZU)
- JPEG code horizontal size lower register (JCHSZD)
- JPEG interrupt enable register (JINTE)
- JPEG interface control register (JIFCNT)

43.6 Software Reset Processing

Issuing the software reset command (setting the SRST bit in JCCMD to 1) causes a software reset.

After a software reset is specified, the SRST bit in JCCMD holds 1 until the current transfer in the JPU is completed. After the software reset processing, the following registers are initialized.

- JPEG code status register (JCSTS)
- JPEG code data count upper register (JCDTCU)
- JPEG code data count middle register (JCDTCM)
- JPEG code data count lower register (JCDTCD)
- JPEG interrupt status register (JINTS)
- JPEG code decode error register (JCDERR)
- JPEG code restart register (JCRST)
- JPEG interface control register (JIFCNT)

Section 44 3D Graphics Accelerator (3DG)

This LSI has a 3D graphics accelerator, the PowerVR™* Series SGX540; Imagination Technologies' 3D graphics core.

44.1 Features

- Universal Scalable Shader Engine (USSE) ™*
- Programmable architecture
- Latency tolerant architecture
- Internal True Colour ™*
- Video processing for multi-standard video decode and encode
- API support: Open GL ES 1.1/2.0, OpenVG, Direct3D Mobile

Note: * PowerVR™, Universal Scalable Shader Engine (USSE) ™ and Internal True Colour ™ are trademarks or registered trademark of Imagination Technologies Limited, U.K.

44.2 Block Diagram

Figure 42.1 shows a block diagram of the SGX540.

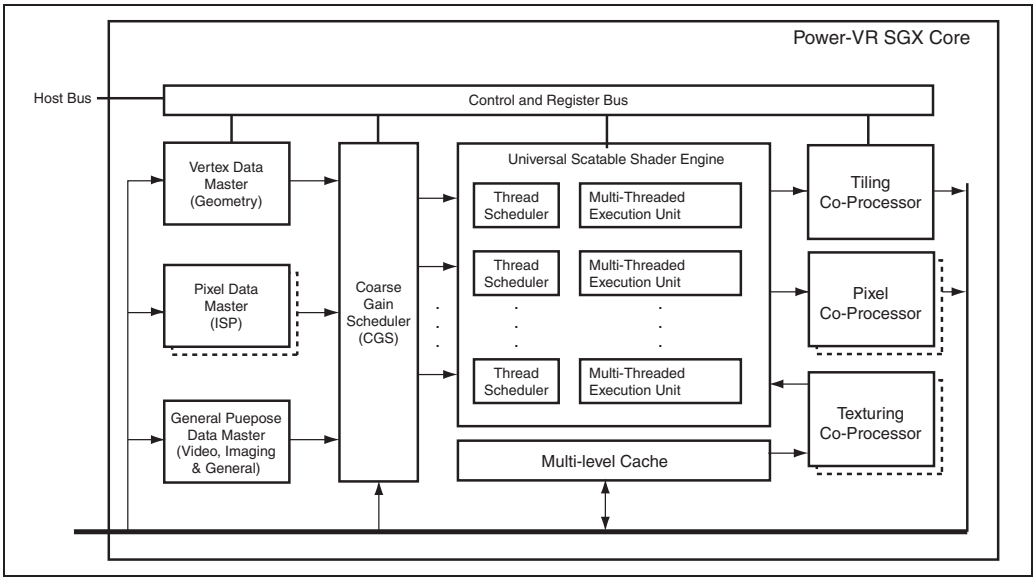

Figure 44.1 Block Diagram

Section 46 Camera ISP

46.1 Features

The image signal processor (ISP) handles processing to turn the output from a camera sensor into image signals. The external camera sensor module is connected to the pins for the MIPI-CSI2 physical layer interface (MIPI-CSI2 PHY module). The MIPI-CSI2 link layer interface (MIPI-CSI2 LINK module: CSI2I) that is connected to the MIPI-CSI2 PHY module handles conversion of the data received from the sensor module into the required raw image format. The ISP applies various processing to this raw image data and then finally stores the result as image data in SDRAM.

The ISP has the following functionality.

- Handles up to 16-Mpixel sensors
- Various kinds of processing to adjust for defective sensor elements
- Processing for various kinds of optical adjustment, including adjustment for shading and adjustment for distortion
- Processing for various kinds of filtering, including noise reduction
- Processing of a wide dynamic range to enhance gradations in images
- Three-A (automatic focus, automatic exposure, and automatic white balance) processing
- Handles HD moving images

46.1.1 ISP Signal Processing System Outline

The ISP's peripheral blocks are shown in figure 46.1 and the outline of the functional blocks in table 46.1.

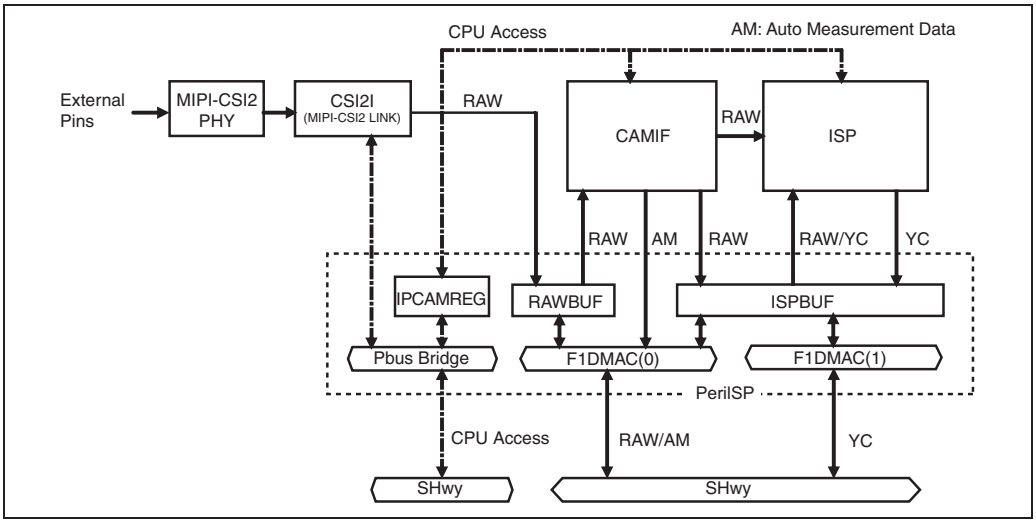

Figure 46.1 ISP Peripheral Block Diagram

Table 46.1 Functional Block Summary

Name	Function	Description
CAMIF	Camera I/F	Contains the sensor I/F, the block that corrects the imaging signal, and the blocks that perform computations necessary for the image correction.
ISP	Image signal processor block	Contains the blocks that performs various types of image processing based on the signal that is corrected by the CAMIF and the results of computations performed in the CAMIF. Note that some references to the ISP in this manual actually refer to all peripheral modules, including the ISP.
IPCAMREG	Signal processing CPUI/F	Serves as the CPU I/F for the CAMIF and ISP. Also contains registers that are common to the CAMIF and ISP.
CSI2I	MIPI-CSI2 LINK layer	A MIPI-CSI2 LINK module. The CSI2I converts the data output from the MIPI-CSI2's physical layer (PHY) block into the raw data format.
RAWBUF	Raw data buffer	Feeds raw data from the CSI2I or SDRAM to the CAMIF. This block is part of the ISP peripheral group module (PeriISP).
ISPBUF	ISP data buffer	Serves as the buffer for the raw data from the CAMIF and the raw/YC data to and from the ISP. This block is part of the PeriISP.
PbusBridge	CPU bus bridge	This is the bus bridge to the CPU. As well as handling CPU access to the IPCAMREG block for CPU access to the CAMIF and ISP blocks, this block also takes care of access to the CPU by CSI2I and the other blocks within the PeriISP (this block is part of the PeriISP).
F1DMAC	Data bus bridge	Arbitrates the data transfers from the CAMIF and ISP and transfers the data to the higher-level bus. The F1DMAC also has various DMA related functions. This block is part of the PeriISP.

46.1.2 CAMIF and ISP Internal Configuration Overview

(1) CAMIF internal configuration overview

The CAMIF consists of the block that corrects the imaging signal and the blocks that perform computations necessary for the image correction. It achieves these types of processing while interfacing with the sensor module and other peripheral circuits. The outline of the CAMIF configuration is shown in figure 46.2.

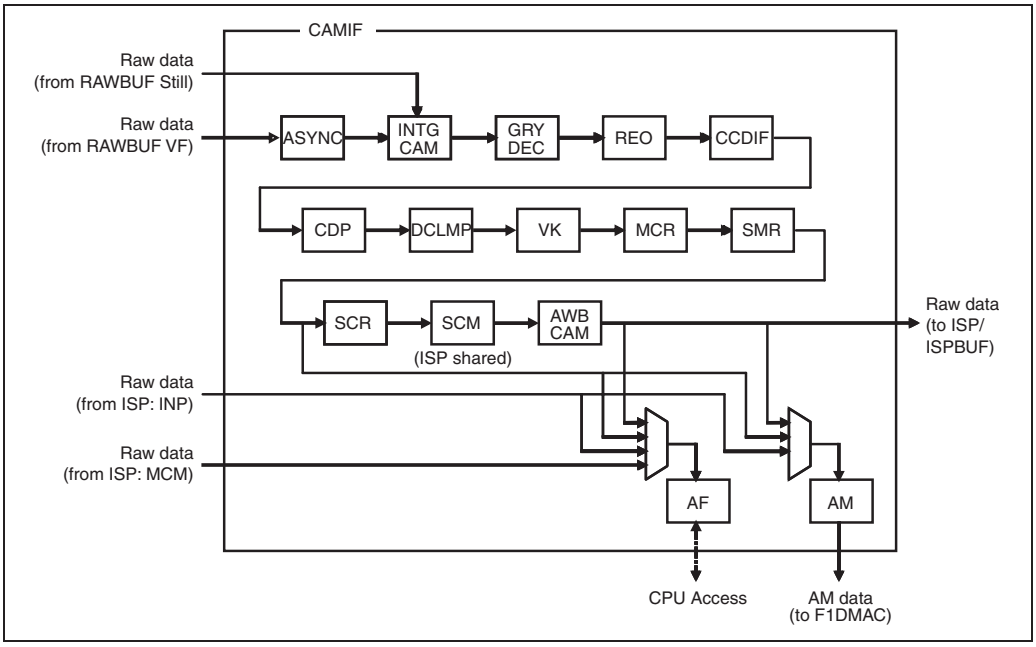

Figure 46.2 CAMIF Internal Configuration

The major functional blocks of the CAMIF are given below.

(Function 1) INTGCAM (CAMIF internal timing generator)

- CAMIF output: Supports 12-bit raw data.
- ISPBUF output: Supports 16-bit YCbCr (4:2:2/4:2:0) and 12-bit raw data.

(Function 2) GRYDEC (Graycode decoder) * Not available in this product.

- Converts the camera head clock to the system clock.
- Handles 12- or 10-bit input.

(Function 3) REO (Pixel array reordering)

- 12-bit input, 12-bit output

(Function 4) CCDIF (CCD interface) * Not available in this product.

- Handles up to 15 fields.
- Sets up the SMR area.

(Function 5) CDP (Defective pixel correction)

- 12-bit input, 12-bit output
- Defective pixel position (horizontal/vertical coordinates) setting register (510 maximum definable pixels)
- Correction method: Horizontal linear interpolation

(Function 6) DCLMP (Digital clamping)

- 12-bit input, 12-bit output
- Clamping method: Horizontal clamping (vertical OB reflection)
- OB accumulation method: Weighted average

(Function 7) VK (Correction processing for a line of defective pixels in the vertical direction)

- 12-bit input, 12-bit output
- Detects integral values for pixels in 64 areas.
- 32 definable defects (horizontal and vertical coordinates)

(Function 8) MCR (Sensor mixed color correction)

- 12-bit input, 12-bit output
- Corrects mixed colors of Gr/Gb pixels using peripheral R/B pixels.

(Function 9) SMR (Smear correction)

- 12-bit input, 12-bit output
- Detects smears in the OB areas and performs smear correction.
- Smear detection mode selectable as upper OB or lower OB.
- Smear detection processing corresponds to processing for horizontal OB averaging and vertical OB averaging.
- Can perform smear correction independently on the 4 color components (R/Gr/Gb/B).

(Function 10) SCR (Shading correction)

- 12-bit input, 12-bit output
- Calculates the optical shading correction coefficients according to the distance from the optical center (arbitrarily definable).
- Corrects each pixel using the optical shading correction coefficients.
- Can correct axial shadings simultaneously and independently.

(Function 11) SCM (Mesh shading correction)

- 12-bit input, 12-bit output
- Correction coefficients are arranged in a 36 (horizontal) × 36 (vertical) mesh configuration.
- Can perform correction on the AWBIP output in the ISP block (mutually exclusively performed in the CAMIF and ISP).

(Function 12) AWBCAM (CAMIF Automatic White Balance)

- WB gain correction calculation (12-bit input, 12-bit output)
  Independent WB gain coefficients for each color: 12 bits (unsigned, integral part: 3 bits, fractional part: 9 bits)
- Gain correction calculation (12-bit input, 12-bit output)
  Gain coefficients common to all colors: 12 bits (unsigned, integral part: 4 bits, fractional part: 8 bits)

(Function 13) AF (Automatic Focus)

- Input: 12-bit raw data * 8-bit raw or 8-bit Y signal depending on the measurement path
- References the upper 8 bits of the input signal.
- Number of windows: 16 floating windows or 32 (horizontal) × 1 (vertical) split windows
- Detection system: Horizontal detection (2-stage filter configuration possible in 32 (horizontal) × 1 (vertical) split window mode)

- Number of bands: 1 band per 8 windows × 2 * 1 band in 32 (horizontal) × 1 (vertical) split window mode

(Function 14) AM (Automatic Measurement)

- Calculates color signals independently (AE, AWB).
- 12-bit input *8-bit raw depending on the measurement path
- References the upper 8 bits of the input signal.
- Calculation targets: R, Gr, Gb, B (signal accumulation processing, threshold accumulation processing, accumulated threshold value counting processing, maximum/minimum measurement)
- Number of split windows: 32 horizontal × 1 vertical
  (Same number of pixels in all windows. Line count specified repeatedly in vertical direction)
- Full-screen measurement
- Detects flickers in the screen (16 lines accumulated independently).
- Accumulation performed on a field basis only.
- The split window accumulated values can be output to SDRAM by DMA transfer.

(2) ISP internal configuration overview

The ISP consists of blocks for displaying images and other blocks that perform various types of image processing based on the signal that is corrected by the CAMIF and the results of computations performed in the CAMIF. The block configuration of the ISP is shown in figure 46.3.

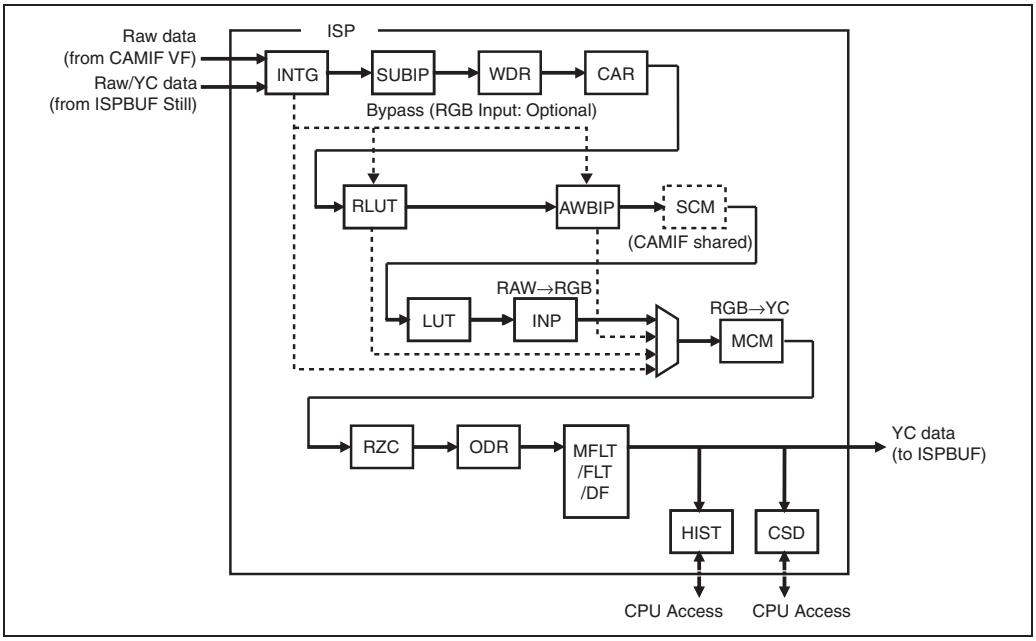

Figure 46.3 ISP Internal Configuration

The major functional blocks of the ISP are given below.

(Function 1) INTG (Internal timing generator)

- CAMIF output: Supports 12-bit raw data.
- ISPBUF output: Supports 16-bit YCbCr (4:2:2) and 12-bit raw data.

(Function 2) SUBIP (ISP block horizontal shrinking)

- CAMIF output: Supports 12-bit raw data.
- 12-bit input, 12-bit output

- Raw data horizontal shrinking processing
  (Shrinking ratio M/N where M and N are integers, $1 \leqq M \leqq 15$, $2 \leqq N \leqq 16$, $M < N$)

(Function 3) WDR (Wide dynamic range processing)

- ISPBUF output: Supports 12-bit raw data (2 images).
- 12-bit input, 12-bit output (input need be an image to which the WB coefficients have been applied.)
- Synthesizes two images at a precision equal to the synthesis ratio (0.0 to 1.0, 10-bit fractional part).
- Performs correction processing on the 2 input images according to the exposure time (12-bit input — 18-bit output, implemented using a 16-line approximation LUT)
- Performs gradation compression processing the synthesized image (19-bit input — 12-bit output, implemented using a 16-line approximation LUT)

(Function 4) CAR (Chromatic aberration correction processing)

- 12-bit input, 12-bit output
- Corrects chromatic aberrations caused by lens aberrations.

(Function 5) RLUT (Raw/RGB gradation correction processing)

- 12-bit input/output LUT (linear approximation curve (32-line approximation))
- 24-bit RGB input/output LUT (linear approximation curve (32-line approximation), mutually exclusive with the other functions of the ISP block)

(Function 6) AWBIP (Image processing block, Automatic White Balance)

- Gain correction calculation (12-bit input, 12-bit output)
  Gain coefficient: 12 bits (unsigned, integral part: 3 bits, fractional part: 9 bits)

(Function 7) LUT (Gradation correction: Look Up Table)

- 12-bit input, 8-bit output
- Linear approximation curve (32-line approximation)
  Y-axis only set up independently for R, G, and B; X-axis set up commonly for the 3 colors.

(Function 8) INP (Color interpolation: Interpolation)

- 8-bit input, 24-bit output (8 bits for each of R, G, and B)
- False color suppression
- Edge smoothing
- Luminance isolated point elimination
- Pixel mixture

(Function 9) MCM (Color correction)

- 24-bit input (8 bits for each of RGB), 24-bit output (8 bits for each of YCbCr)
- Controls hue, chroma, and luminance independently of one another.
- Number of hues: 24 (24 hues selected out of 256 hues), adjustable
- Specific color correction (controls chroma and luminance for each hue.)
- Chroma balance adjustment

(Function 10) RZC (Resolution conversion)

- 24-bit input , 24-bit output
  Can convert the resolution conversion factor from 1% up to 1000%.
  (The resolution conversion factor is specified in the format of numerator/denominator.)
  Supports horizontal reversion (mirror mode).

(Function 11) ODR (Optical distortion correction)

- 24-bit input (YCbCr = 4:4:4), 16-bit output (YCbCr = 4:2:2)
- Corrects optical distortions caused by lens aberrations.

* Enabled only in still image processing modes.

(Function 12) FLT (Filter: edge correction/noise rejection/digital focus/matrix filter)

- 16-bit input, 16-bit output(YCbCr = 4:2:2)
- Noise reduction (luminance/color difference)
- Luminance signal
  - Multiband processing (3 bands set)
    HPF (High Pass Filter), BPF (Band Pass Filter), LPF (Low Pass Filter)
  - BNC (Base level Noise Clip), HC (High level Clip)
  - Peripheral resolution correction
- Color difference signal
  LPF (Low Pass Filter)
- Digital focus processing

(Function 13) HIST (Histogram)

- 8-bit input, 128-grayscale output
- Data to be measured: ISP block output data (after subjected to ring pixel cutoff)

(Function 14) CSD (Camera shake detection processing)

- Input Y: 8 bits
- Maximum number of measured windows: 256
- Maximum window size: 128 × 128 pixels
- Generates horizontal and vertical displacements and detection accuracy index for each window.

46.1.3 Image Processing Data Flows

This section explains the typical image processing flows for the ISP.

(1) View finder processing and moving image shooting flow

The processing flow diagram for view finder processing (VF) and moving image shooting are shown in figure 46.4. The image data output from the sensor is input to the CAMIF via the RAWBUF. The raw data are subjected to various types of correction processes in the CAMIF and passed directly to the ISP. The raw data input in the ISP is subjected to RGB interpolation, YC conversion, and other correction and filtering processes, after which it is stored in SDRAM via the ISPBUF and F1DMAC.

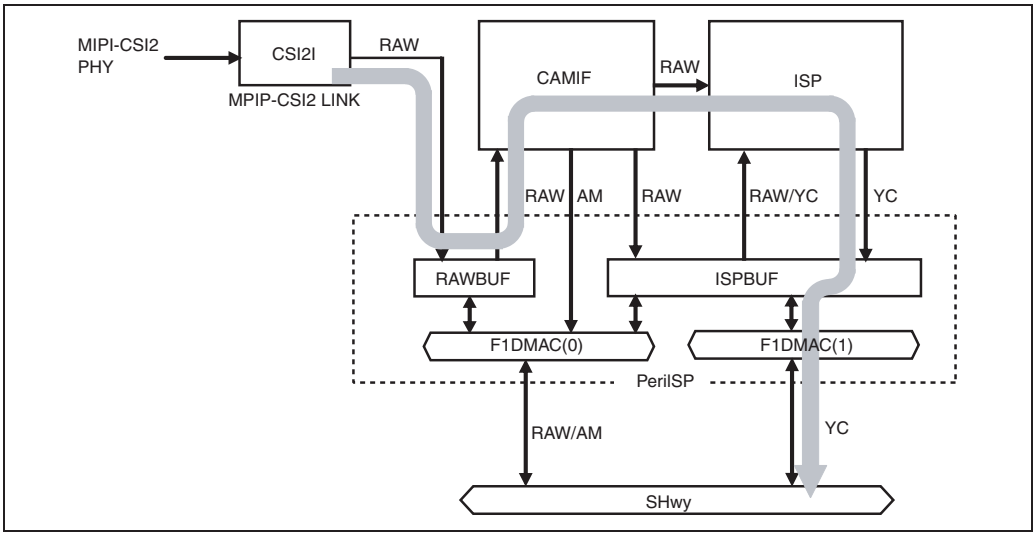

Figure 46.4 Moving Image Shooting Processing Flow

(2) Still image shooting processing flow

The processing flow diagram for still image processing is shown in figure 46.5. The still image shooting processing is divided into three processing passes.

Path (1): Capture processing

The data from the MIPI-CSI2 LINK block is temporarily stored in SDRAM via the RAWBUF and F1DMAC. Although the data could be sent directly to the CAMIF in this case as in moving image shooting processing, is simply transferred to SDRAM for the reasons (1) The size of image to be shot is great and (2) as high as possible an imaging rate need be established to prevent shakes.

Path (2): Raw preprocessing

The raw data which is stored during capture processing is read into the CAMIF and subjected to optical, defective pixel, and other correction processing as well as various measurement processing for AE, AF, and AWB in the CAMIF. The raw data which is preprocessed in this way is stored in SDRAM again.

Pass (3): YC strip processing

The preprocessed raw data are reread and subjected by the ISP to RGB interpolation, YC conversion, and various types filtering and correction processes. In this case, since the ISP is subject to restrictions as to the horizontal size, it is necessary to split the preprocessed raw data for any image with a large image size in the vertical direction into two or more strips of data and process them sequentially. When all of these data strips are processed, they are stored in SDRAM as a single sheet of image.

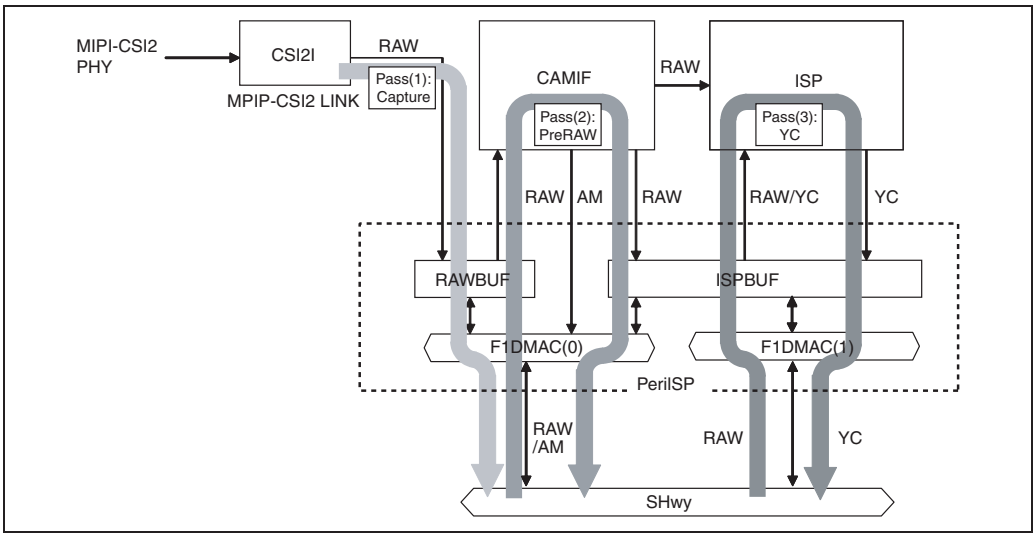

Figure 46.5 Still Image Shooting Processing Flow

46.2 ISP Image Processing Buffer (ISPBUF)

The ISP image processing buffer (ISPBUF) is a module that interfaces between the ISP/CAMIF and F1DMAC and places image data on the bus. The ISPBUF temporarily holds data from the ISP/CAMIF and transfers data through the F1 bus I/F. It also controls the active/inactive state of the other ISP peripheral modules as well as exercises INT control.

Features

The ISPBUF has the following functions:

- Image data transfer of sizes from 1 to 128 64-bit data sizes
- Raw noise reduction (NR) using two blocks of raw data
- Active/inactive state control of the other ISP peripheral modules
- INT monitoring for the other ISP peripheral modules

46.2.1 ISPBUF Function Summary

Table 46.2 summarizes the functions of the ISPBUF.

Table 46.2 Function Summary

Item	Function Implemented	Description
Input format	12-bit raw YCbCr (4:2:2/4:2:0)	
Output format	12-bit raw YCbCr (4:2:2/4:2:0)	
Data size	64 bits/1 to 128	In each YC format data transfer, data are transferred in the order of Y data followed by C data. The data size is the same for the Y and C data.
ISP peripheral module Active/Inactive control	ISP peripheral module clock control	Provides on/off control of the clocks to the other ISP peripheral modules.
ISP peripheral module INT monitoring	ISP peripheral module INT monitoring	Monitors the interrupts occurring in the other ISP peripheral modules.

46.2.2 ISPBUF Internal Configuration

The internal configuration of the ISPBUF is shown in figure 46.6.

- CIFIBUF: The buffer that takes in the raw data (shot image) from SDRAM and merges it with the data output (black image) from the CAMIF for RAWNR processing.
- CIFOBUF: The buffer used to transfer the raw data output from the CAMIF to SDRAM.
- ISPIBUF: The buffer used to transfer raw or YC data from SDRAM to the ISP.
- ISPOBUF: The buffer used to transfer the YC data output from the ISP to SDRAM.
- RAWBUF/AM: Accesses to the F1DMAC are accomplished via the ISPBUF during RAWBUF (buffer for captured raw data output and CAMIF input) and CAMIF's AM (accumulated values for AE and AWB) data output processing. During these accesses, byte/word swap occurs in the raw or AM data. The RAWBUF contains 3 types of buffers, i.e., RAWIBUF, RAWOBUF, and RAWDIRBUF.
- Data path switching: Data transfers to the bus from the RAWIBUF, CIFOBUF, and CIFIBUF are done normally via the F1DMAC(0). The data may be directed through the F1DMAC(1) by making necessary configuration. This makes it easy to secure the F1DMAC(0)'s band which becomes necessary at capture time.

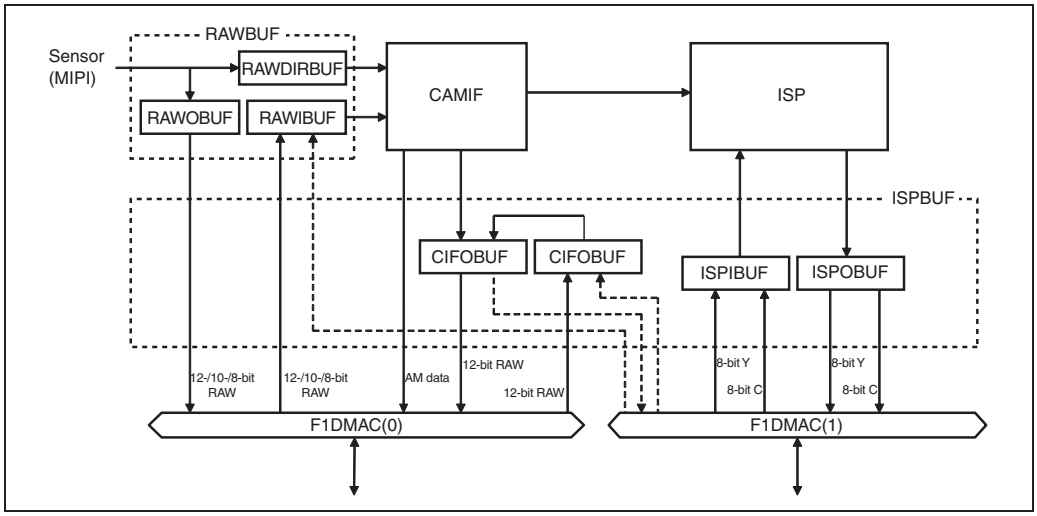

Figure 46.6 ISPBUF Internal Configuration

46.2.3 DMA Source Assignments

The AM outputs from the ISPBUF, RAWBUF, and CAMIF are assigned F1DAMC's input/output data ports with the source numbers listed in the tables given below. The number of the sources to be used must be specified in the DCTG request source select bits of the DMA control registers A: F1DMAC(0/1)_DMCNTAn (n corresponds to channel numbers 0 to 7) in the F1DMAC.

Table 46.3 F1DMAC(0) Source Assignments

F1DMAC(0)	Normal mode	When the path is switched using the data flow select register (ISPBUF_AD_F1SEL)
Source number 1	RAWOBUF	←
Source number 2	CIFOBUF	(Reserved)
Source number 3	CIFIBUF	(Reserved)
Source number 4	RAWIBUF	(Reserved)
Source number 5	AMO	←

Table 46.4 F1DMAC(1) Source Assignments

Source number 7	ISPIBUF(C)	←

46.2.4 Register Description

(1) Register read/write restrictions

Restrictions on register reads and writes are given below. The system operation may fail if the integrity of the following register operations is not guaranteed:

1. Writing 1 into any read-only register bit or reserved area is prohibited. Do not set any value other than the specified values.
2. There are cases in which a nonzero value is read from a read-only bit. Such a value must not be rewritten.
3. Writing into any registers (bits) that are disallowed for writes during operation is prohibited while some operation is in progress (reads are allowed). The operating state of the ISPBUF can be identified by reading the ISPBUF operation register or by identifying the end of the F1DMAC transfer.
4. All of the ISPBUF registers must be allocated to a non-cache area.

(2) Terms and abbreviations used in this document

A term that is used in this document is explained below.

1. "Software reset" refers to a forced reset into the ISPBUF internal circuit. This means that any attempt to effect a module reset while the ISPBUF is running normally might place the ISPBUF peripheral hardware into an inoperative state.

(3) List of Registers

The register configuration of the ISPBUF registers is summarized in table 46.5. The relationship between the processing modes and register states is given in table 46.6.

Table 46.5 ISPBUF Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
ISPBUF buffer operation control register	ISPBUF_AD_BUFSTR	R/W	H'FE8F 6000	32
ISPBUF software reset control register	ISPBUF_AD_SFTRST	R/W	H'FE8F 6004	32
ISPBUF continuous operation control	ISPBUF_AD_CONTI	R/W	H'FE8F 600C	32

46.2.5 ISPBUF Buffer Operation Control Register (ISPBUF_AD_BUFSTR)

ISPBUF_AD_BUFSTR enables or disables FIFO operations in the ISPBUF. It is normally cleared at the end of processing on one frame. It is not cleared, however, if continuous operation is specified by the ISPBUF_AD_CONTI register.

46.2.6 ISPBUF Software Reset Control Register (ISPBUF_AD_SFTRST)

ISPBUF_AD_SFTRST controls the forced reset operation of the ISPBUF's internal circuit. Writing this register during operation is prohibited. Note that any attempt to effect a module reset while the ISPBUF is running normally might place the ISPBUF peripheral modules into an inoperative state.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

46.2.7 ISPBUF Continuous Operation Control Register (ISPBUF_AD_CONTI)

ISPBUF_AD_CONTI controls the termination of the ISPBUF. When this register is enabled, neither the pertinent buffer is stopped nor the ISPBUF_AD_BUFSTR register is cleared. When stopping the buffer operation, disable this register during the processing of the last frame in the continuous processing mode or effect software reset after the F1DMAC transfer is ended.

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
20	bufbusy_cifi	B'0	R	CIFIBUF buffer busy 0: Idle 1: Busy

Bit	Bit Name	Initial Value	R/W	Description
19 to 17	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
16	bufbusy_cifo	B'0	R	CIFOBUF buffer busy 0: Idle 1: Busy
15 to 5	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
4	bufbusy_ispi	B'0	R	ISPIBUF buffer busy 0: Idle 1: Busy
3 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	bufbusy_ispo	B'0	R	ISPOBUF buffer busy 0: Idle 1: Busy

46.2.9 ISPBUF Buffer Full Monitor Register (ISPBUF_AD_BUFFULL)

ISPBUF_AD_BUFFULL is a register that indicates whether the buffers in the ISPBUF are full.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	buffull_cifi	—	—	—	buffull_cifo
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
20	buffull_cifi	B'0	R	CIFIBUF buffer full flag 0: Normal 1: Full
19 to 17	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
16	buffull_cifo	B'0	R	CIFOBUF buffer full flag 0: Normal 1: Full
15 to 13	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
12	buffull_ispi_c	B'0	R	ISPIBUF (C plane) buffer full flag 0: Normal 1: Full
11 to 9	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	buffull_ispi_y	B'0	R	ISPIBUF (Y plane) buffer full flag 0: Normal 1: Full
7 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	buffull_ispo	B'0	R	ISPOBUF buffer full flag 0: Normal 1: Full

46.2.10 ISPBUF Buffer Empty Monitor Register (ISPBUF_AD_BUFEMP)

ISPBUF_AD_BUFEMP is a register that indicates whether the buffers in the ISPBUF are empty.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	bufemp_cifi	—	—	—	bufemp_cifo
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	bufemp_ispi_c	—	—	—	bufemp_ispi_y	—	—	—	—	—	—	—	bufemp_ispo
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
20	bufemp_cifi	B'0	R	CIFIBUF empty flag 0: Normal 1: Empty
19 to 17	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
16	bufemp_cifo	B'0	R	CIFOBUF empty flag 0: Normal 1: Empty
15 to 13	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
12	bufemp_ispi_c	B'0	R	ISPIBUF (C plane) empty flag 0: Normal 1: Empty
11 to 9	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
8	bufemp_ispi_y	B'0	R	ISPIBUF (Y plane) empty flag 0: Normal 1: Empty
7 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	bufemp_ispo	B'0	R	ISPOBUF empty flag 0: Normal 1: Empty

46.2.11 ISPBUF Error Flag Monitor Register (ISPBUF_AD_ERR)

ISPBUF_AD_ERR is a register that indicates the error state of the buffers in the ISPBUF. 1 in a bit in this register indicates that an overflow (or underflow) has occurred in the corresponding buffer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	err_buf_cifi	—	—	—	err_buf_cifo
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	err_buf_ispo
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
20	err_buf_cifi	B'0	R	CIFIBUF error flag 0: Normal 1: Error
19 to 17	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
16	err_buf_cifo	B'0	R	CIFOBUF error flag 0: Normal 1: Error
15 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	err_buf_ispo	B'0	R	ISPOBUF error flag 0: Normal 1: Error

46.2.12 ISPBUF Error Flag Clear Register (ISPBUF_AD_ERRCLR)

ISPBUF_AD_ERRCLR is a register that is used to initialize the ISPBUF error flag monitor register (ISPBUF_AD_ERR).

This register is automatically cleared after the error flags are initialized.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	errclr_cifi	—	—	—	errclr_cifo
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	errclr_ispo
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
20	errclr_cifi	B'0	R/W	CIFIBUF error clear bit 0: NOP 1: Clears the error flag.
19 to 17	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
16	errclr_cifo	B'0	R/W	CIFOBUF error clear bit 0: NOP 1: Clears the error flag.
15 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	errclr_ispo	B'0	R/W	ISPOBUF error clear bit 0: NOP 1: Clears the error flag.

46.2.13 ISPBUF Operand Transfer Data Count Register (ISPBUF_AD_OPESEL)

ISPBUF_AD_OPESEL is a register used to specify the number of blocks (operand size) of data required to complete a single transfer operation. Note that one data block is composed of 8 bytes.

Writing this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	opesel_cifi			—	opesel_cifo

Initial value:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
22 to 20	opesel_cifi [2:0]	H'2	R/W	CIFIBUF operand transfer data count select (data blocks, 1 data block = 8 bytes) 000: 1 001: 2 010: 4 011: 8 100: 16 101: 32 110: 64 111: 128
19	—	B'0	R	Reserved. This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
18 to 16	opesel_cifo [2:0]	H'2	R/W	CIFOBUF operand transfer data count select (data blocks, 1 data block = 8 bytes) 000: 1 001: 2 010: 4 011: 8 100: 16 101: 32 110: 64 111: 128
15 to 7	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
6 to 4	opesel_ispi [2:0]	H'2	R/W	ISPIBUF operand transfer data count select (data blocks, 1 data block = 8 bytes) 000: 1 001: 2 010: 4 011: 8 100: 16 101: 32 110: 64 111: 128
3	—	B'0	R	Reserved. This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2 to 1	opesel_ispo [2:0]	H'2	R/W	ISPOBUF operand transfer data count select (data blocks, 1 data block = 8 bytes) 000: 1 001: 2 010: 4 011: 8 100: 16 101: 32 110: 64 111: 128

46.2.14 ISPBUF Wait Request Control Register (ISPBUF_AD_REQWAITON)

ISPBUF_AD_REQWAITON is a register used to specify whether wait processing is to be performed when the ISPBUF makes a request to the F1DMAC. The interval of waiting is specified using the ISPBUF_AD_WAITCYC_CIF and ISPBUF_AD_WAITCYC_ISP registers.

Writing this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	reqwait_on_cifi	—	—	—	reqwait_on_cifo
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

7 to 5	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
4	reqwait_on_ispo_c	B'0	R/W	ISPOBUF (C plane) wait processing enable 0: Disabled 1: Enabled
3 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	reqwait_on_ispo_y	B'0	R/W	ISPOBUF (Y plane) wait processing enable 0: Disabled 1: Enabled

46.2.15 ISPBUF CIF Wait Cycle Setting Register (ISPBUF_AD_WAITCYC_CIF)

ISPBUF_AD_WAITCYC_CIF is used to specify the interval of waiting when the CIFIBUF or SIFOBUF in the ISPBUF makes a request to the F1DMAC. Counting is started immediately after the request is accepted. The buffers make no request during the specified interval. Values are in the range from 0 to 255 cycles. Whether wait processing is to be performed is controlled using the ISPBUF_AD_REQWAITON register.

Writing this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	waitcyc_cifi

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
23 to 16	waitcyc_cifi [7:0]	H'00	R/W	CIFIBUF wait interval setting 0 to 255 cycles
15 to 8	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
7 to 0	waitcyc_cifo [7:0]	H'00	R/W	CIFOBUF wait interval setting 0 to 255 cycles

46.2.16 ISPBUF ISP Wait Cycle Setting Register (ISPBUF_AD_WAITCYC_ISP)

ISPBUF_AD_WAITCYC_ISP is used to specify the interval of waiting when the ISPIBUF or ISPOBUF in the ISPBUF makes a request to the F1DMAC. Counting is started immediately after the request is accepted. The buffers make no request during the specified interval. Values are in the range from 0 to 255 cycles. Whether wait processing is to be performed is controlled using the ISPBUF_AD_REQWAITON register.

Writing this register during operation is prohibited.

7 to 0	waitcyc_ispo_y [7:0]	H'00	R/W	ISPOBUF (Y plane) wait interval setting 0 to 255 cycles

46.2.17 ISPBUF Raw Data Noise Reduction Control Register (ISPBUF_AD_RAWNR)

ISPBUF_AD_RAWNR sets up the RAWNR function that achieves noise reduction using differential processing on the shot image data that is read by the ISPIBUF from SDRAM and the data image data output from the CAMIF.

Writing this register during operation is prohibited.

The determination algorithm for identifying the output data from the NR circuit is given below. The variables in the expressions are shot image: DataA(x,y), black image: DataB(x,y), output data: DataOut(x,y), and threshold value NLVLK(12 bits, defined in a register).

if (DataA(x,y) < DataB(x,y)) then DataOut(x,y) = DataB(x,y)

else if (first 2 pix's of the line) then DataOut(x,y) = DataA(x,y) - DataB(x,y)

else if (DataB(x,y) > NLVLK) then DataOut(x,y) = DataOut(x - 2,y)

else DataOut(x,y) = DataA(x,y) - DataB(x,y)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

46.2.18 ISPBUF F1DMAC Data Flow Select Register (ISPBUF_AD_F1SEL)

ISPBUF_AD_F1SEL is a register that specifies to which of F1DMAC(0) or F1DMAC(1) data are to be transferred from RAWIBUF, CIFIBUF, or CIFOBUF, or vice versa.

Writing this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15 to 0	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

46.2.19 ISPBUF Raw Data Swap Control Register (ISPBUF_AD_SWP_RAW)

ISPBUF_AD_SWP_RAW is a register that specifies whether data are to be swapped on a longword (32 bits), word (16 bits), or byte (8 bits) basis during RAWBUF data transfer.

Writing this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

46.2.20 ISPBUF CIF Data Swap Control Register (ISPBUF_AD_SWP_CIF)

ISPBUF_AD_SWP_CIF is a register that specifies whether data are to be swapped on a longword (32 bits), word (16 bits), or byte (8 bits) basis during CIFIBUF/CIFOBUF and AM data transfer.

Writing this register during operation is prohibited.

46.2.21 ISPBUF ISP Data Swap Control Register (ISPBUF_AD_SWP_ISP)

ISPBUF_AD_SWP_ISP is a register that specifies whether data are to be swapped on a longword (32 bits), word (16 bits), or byte (8 bits) basis during ISPIBUF/ISPOBUF data transfer.

Writing this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

46.2.22 ISPBUF Buffer Reservation Size Register (ISPBUF_AD_FIFOSLACK)

ISPBUF_AD_FIFOSLACK is a register that controls buffering in the ISPBUF. It generates a data transfer stop signal to the CAMIF or ISP when the size in data block units of the free space in the buffer falls below the specified value. Data overflow conditions may easily be avoided by specifying a larger value.

Writing this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
17 to 16	fifoslack_ cifo[1:0]	H'2	R/W	CIFOBUF buffer size setting Sends a STOP signal to the CAMIF if the free buffer area size is smaller than the value specified in this bit. 0: Setting prohibited 1 to 3: Specifies the threshold free data area size (Transfer size × 1 to 3)
15 to 2	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
1 to 0	fifoslack_ ispo[1:0]	H'2	R/W	ISPOBUF buffer size setting Sends a STOP signal to the CAMIF if the free buffer area size is smaller than the value specified in this bit. 0: Setting prohibited 1 to 3: Specifies the threshold free data area size (Transfer size × 1 to 3)

46.2.23 ISPBUF ISP Peripheral Module Activation Control Register (ISPBUF_AD_MSTP)

ISPBUF_AD_MSTP is a register that activates or deactivates the ISP peripheral modules.

Writing this register during operation is prohibited.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

46.2.24 ISPBUF Interrupt Monitor Register (ISPBUF_AD_INT_ALL)

ISPBUF_AD_INT_ALL is a register that combines the interrupt monitors of the ISP and ISP peripheral modules. It handles the bits that are de-masked by the monitor mask registers (ISPBUF_AD_INT_MASK0/1). Identify the source of the interrupt that is generated with this register and the status registers (ISPBUF_AD_INT_STAT0/1), then access the output source module and reset the interrupt.

46.2.25 ISPBUF Interrupt Status Register 0 (ISPBUF_AD_INT_STAT0)

ISPBUF_AD_INT_STAT0 is the interrupt monitor register for the ISP and ISP peripheral modules. It monitors the interrupts other than those which are excluded by the interrupt monitor mask register (ISPBUF_AD_INT_MASK0).

Each bit is cleared by accessing the output source module and resetting the corresponding interrupt.

1	F1DMINT_ERN_0_stat	B'0	R/W	F1DMAC(0) error interrupt monitor This flag is set by an interrupt occurring in the F1DMAC(0). 0: No interrupt 1: Interrupt present
0	F1DMINTA_N_0_stat	B'0	R/W	F1DMAC(0) common interrupt monitor This flag is set by a common interrupt occurring in the F1DMAC(0). 0: No interrupt 1: Interrupt present

46.2.26 ISPBUF Interrupt Status Register 1 (ISPBUF_AD_INT_STAT1)

ISPBUF_AD_INT_STAT1 is the interrupt monitor register for the ISP and ISP peripheral modules. It monitors the interrupts other than those which are excluded by the interrupt monitor mask register (ISPBUF_AD_INT_MASK1).

Each bit is cleared by accessing the output source module and reset the corresponding interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
23 to 16	F1DMINT_N_1_stat[7:0]	H'00	R/W	F1DMAC(1) interrupt monitor This interrupt is generated when an interrupt occurs in the corresponding F1DMAC(1) channel. (Bit 7 corresponds to channel 0, …, bit 0 corresponds to channel 7.) 0: No interrupt (each channel) 1: Interrupt present (each channel)
15 to 8	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
7 to 0	F1DMINT_N_0_stat[7:0]	H'00	R/W	F1DMAC(0) interrupt monitor This interrupt is generated when an interrupt occurs in the corresponding F1DMAC(0) channel. (Bit 7 corresponds to channel 0, …, bit 0 corresponds to channel 7.) 0: No interrupt (each channel) 1: Interrupt present (each channel)

46.2.27 ISPBUF Interrupt Monitor Mask Register (ISPBUF_AD_INT_MASK0)

ISPBUF_AD_INT_MASK0 specifies the masks for the ISP and ISP peripheral module interrupts to be monitored. The bits that are masked in this register are reflected in ISPBUF_AD_INT_STAT0 and ISPBUF_AD_INT_ALL. Note that there is no mask register for the F1DMAC peripheral module interrupts. The F1DMAC interrupts must be masked by the mask feature of the F1DMAC proper.

Each bit is cleared by accessing the output source module and resetting the corresponding interrupt.

8	intreq_n_cmosif_ msk	B’0	R/W	CSI2I interrupt monitor mask bit 0: Masked 1: Not masked
7 to 0	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

46.2.28 ISPBUF CAMIF Control register (ISPBUF_AD_CAMIF1)

ISPBUF_AD_CAMIF1 is a register that controls the CCD interface in the CAMIF. Enabling this register makes the CCD interface available.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	CK1X_ CAMCLK0EN	H'00	R/W	CAMIF CCDI/F control 0: The CAMIF CCD I/F stopped. 1: The CAMIF CCD I/F operates.

46.2.29 ISPBUF CMOSIF Monitor Register 0 (ISPBUF_AD_CMOSIF0)

ISPBUF_AD_CMOSIF0 is a monitor register for the MIPI-CSI Link module (CSI2I). It monitors the information detected by the CSI2I.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	CMOSIF_SIZEH												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	CMOSIF_SIZEV												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
28 to 16	CMOSIF_ SIZE[12:0]	H'000	R/W	CSI2I horizontal pixel size
15 to 13	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
13 to 0	CMOSIF_ SIZEV[12:0]	H'000	R/W	CSI2I vertical pixel size

46.2.30 ISPBUF CMOSIF Monitor Register 1 (ISPBUF_AD_CMOSIF1)

ISPBUF_AD_CMOSIF1 is a monitor register for the MIPI-CSI Link module (CSI2I). It monitors the information detected by the CSI2I.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CMOSIF_DPCM_stat	—	—	CMOSIF_FORM_stat					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
8	CMOSIF_ DPCM_stat	B'0	R/W	CSI2I completion format control
7 to 6	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
5 to 0	CMOSIF_ FORM_stat[5:0]	H'00	R/W	CSI2I format control

46.2.31 ISPBUF CIFIBUF Byte Count Register (ISPBUF_AD_BC_CIFI)

ISPBUF_AD_BC_CIFI is a register that indicates the byte count of the data that is transferred through the CIFIBUF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BC_CIFI[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BC_CIFI[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BC_CIFI [31:0]	H'0000 0000	R	CIFIBUF byte count

46.2.32 ISPBUF CIFO Byte Count Register (ISPBUF_AD_BC_CIFO)

ISPBUF_AD_BC_CIFO is a register that indicates the byte count of the data that is transferred through the CIFOBUF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BC_CIFO[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BC_CIFO[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BC_CIFO [31:0]	H'0000 0000	R	CIFOBUF byte count

46.2.33 ISPBUF ISPI_Y Byte Count Register (ISPBUF_AD_BC_ISPIY)

ISPBUF_AD_BC_ISPIY is a register that indicates the byte count of the data that is transferred through the ISPIBUF (Y plane).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BC_ISPIY[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BC_ISPIY[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BC_ISPIY [31:0]	H'0000 0000	R	ISPIBUF (Y plane) byte count

46.2.34 ISPBUF ISPI_C Byte Count Register (ISPBUF_AD_BC_ISPIC)

ISPBUF_AD_BC_ISPIC is a register that indicates the byte count of the data that is transferred through the ISPIBUF (C plane).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BC_ISPIC[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BC_ISPIC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BC_ISPIC [31:0]	H'0000 0000	R	ISPIBUF (C plane) byte count

46.2.35 ISPBUF ISPO_Y Byte Count Register (ISPBUF_AD_BC_ISPOY)

ISPBUF_AD_BC_ISPOY is a register that indicates the byte count of the data that is transferred through the ISPOBUF (Y plane).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BC_ISPOY[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BC_ISPOY[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BC_ISPOY [31:0]	H'0000 0000	R	ISPOBUF (Y plane) byte count

46.2.36 ISPBUF ISPO_C Byte Count Register (ISPBUF_AD_BC_ISPOC)

ISPBUF_AD_BC_ISPOC is a register that indicates the byte count of the data that is transferred through the ISPOBUF (C plane).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BC_ISPOC[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BC_ISPOC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	BC_ISPOC [31:0]	H'0000 0000	R	ISPOBUF (C plane) byte count

46.2.37 Usage Note

(1) Restrictions to be applied during operation

Do not attempt to stop any module while the ISP and ISP peripheral modules are running.

46.3 RAWBUF

The raw data buffer (RAWBUF) is a module that takes in the image data (32-bit packed data) from the CSI2I (CMOSIF-Link) and transfers it to the external memory (SDRAM) through the camera head interface block (CAMIF) in the image processing block or the F1 bus based on the starting and ending information of the line/frame. It also takes in the image data from the external memory (SDRAM) through the F1 bus and transfers it to the camera head interface block (CAMIF) in the image processing block.

The formats of data input from the CMOSIF-Link can be 12-bit, 10-bit, or 8-bit parallel.

46.3.1 RAWBUF Function Summary

Table 46.7 summarizes the functions of the RAWBUF and figure 46.10 shows its internal block diagram.

Table 46.7 RAWBUF Function Summary

Item	Function Summary
Frequency	• CMOSIF-Link IF clock (BCLK_INTR): 166 MHz maximum • CAMIF clock (CAMCLK): 200 MHz maximum • System clock (ICLK): 200 MHz maximum These clocks run in an asynchronous mode in which they are free from any mutual phase restrictions.
CMOSIF-Link input data format	One of the following formats must be selected: • 12-bit parallel data: 12 bits/pixel • 10-bit parallel data: 10 bits/pixel • 8-bit parallel data: 8 bits/pixel (with/without compression) • Minimum line size: 4 pixels • Minimum retrace time: 17 cycles (BCLK_INTR)
DMA bus interface	Conforms to the F1 Bus Specification. • Data bus width: 64 bits • Operand size: RAWOBUF 16/32/64 words : RAWIBUF 16/32 words
Control bus interface	Conforms to the C Bus Specification. • Area: 64K bytes • Word (32 bits) access only

Item	Function Summary
Interrupt request source	• DIRBUF overflow interrupt • RAWOBUF overflow interrupt • CMOSIF overflow interrupt
Available buffer configuration	• DIRBUF: For direct path output 32 bits × 4 words × 1 plane • RAWOBUF: For F1 path output (SRAM) 64 bits × 16/32/64 words × 4 × 8 planes • RAWIBUF: For F1 path input 64 bits × 16/32 words × 2 planes

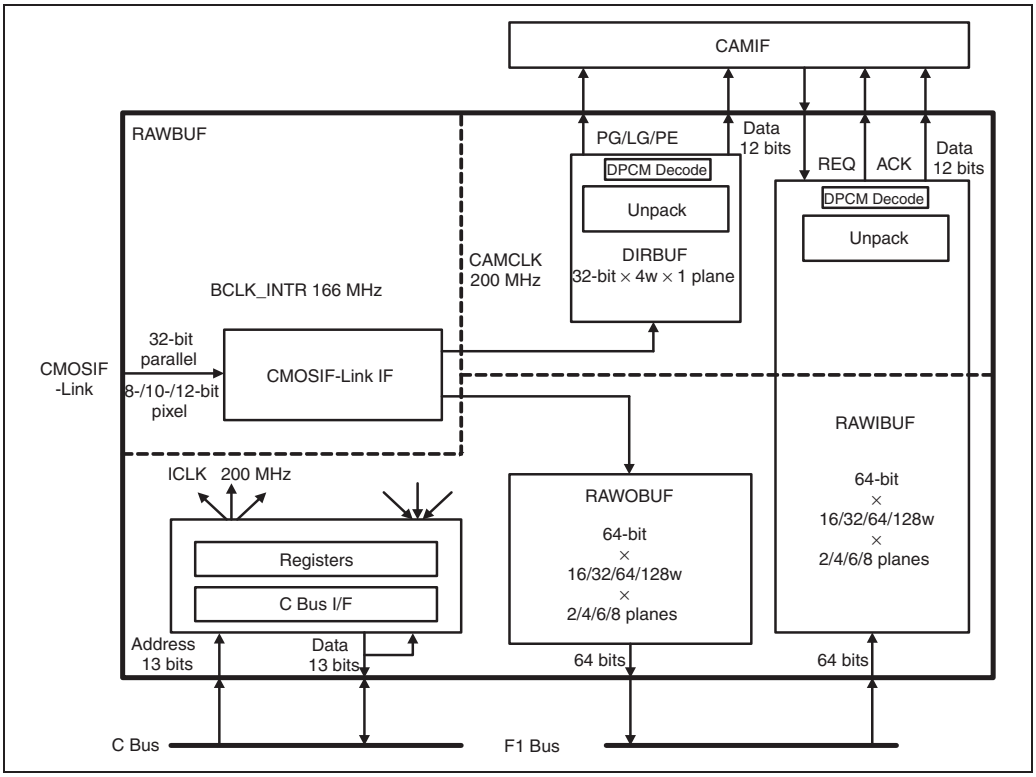

Figure 46.10 RAWBUF Block Diagram

46.3.2 Data Formats

A data format of the input from the CMOSIF-Link is shown in figure 46.11.

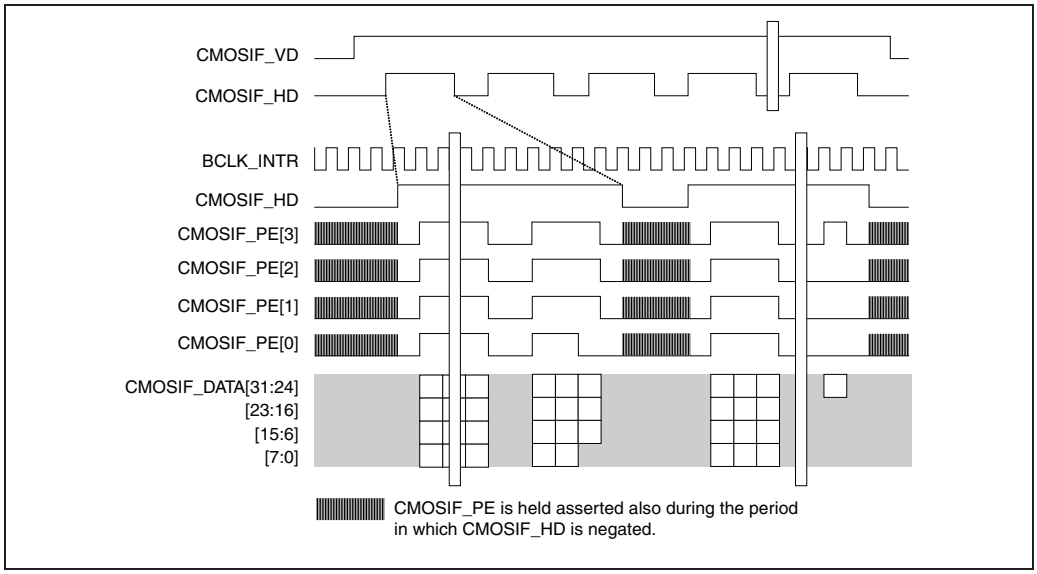

Figure 46.11 Format of the Input from the CMOSIF-Link

(1) 12-bit parallel data

An even number of pixels are always processed, in 8 pixel units with a period of 3 × BCLK_INTR in 12-bit raw packed mode.

Figure 46.12 shows the format (12-bit parallel data) of the data received from the CMOSIF-Link.

The number of pixels is not always a multiple of 8; odd pixels (2/4/6 bytes) can occur. The effective bytes are indicated in CMOSIF_PE.

- Pixels up to pixel 1 are output (CMOSIF_PE[3:1] asserted) when the residue is 2.
- Pixels up to pixel 3 are output (CMOSIF_PE[3:2] asserted) when the residue is 4.
- Pixels up to pixel 5 are output (CMOSIF_PE[3] asserted) when the residue is 6.

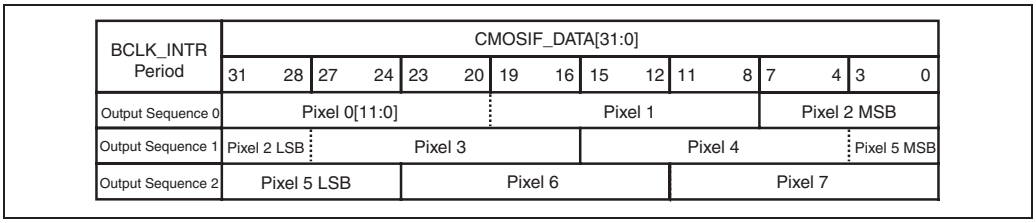

Figure 46.12 Format of Data Received from the CMOSIF-Link (12-Bit Parallel Data)

(2) 10-bit parallel data

A multiple of 4 of pixels are always processed, in 16 pixel units with a period of 5 × BCLK_INTR in 10-bit raw packed mode

Figure 46.13 shows the format (10-bit parallel data) of the data received from the CMOSIF-Link.

The number of pixels is not always a multiple of 16; odd pixels (4/8/12 bytes) can occur. The effective bytes are indicated in CMOSIF_PE.

- Pixels up to pixel 3 are output (CMOSIF_PE[3] asserted) when the residue is 4.
- Pixels up to pixel 7 are output (CMOSIF_PE[3:2] asserted) when the residue is 8.
- Pixels up to pixel 11 are output (CMOSIF_PE[3:1] asserted) when the residue is 12.

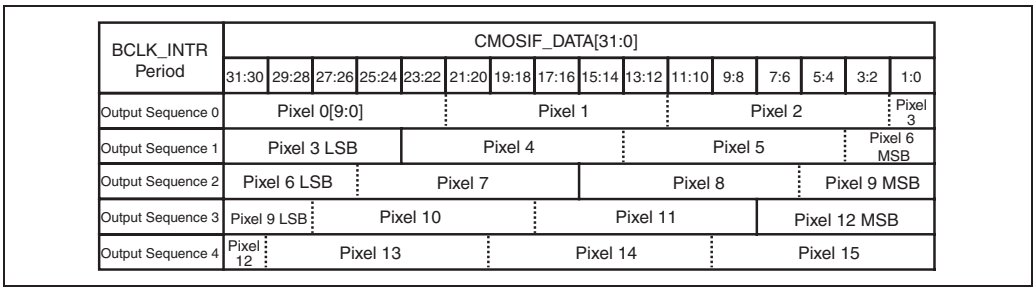

Figure 46.13 Format of Data Received from the CMOSIF-Link (10-Bit Parallel Data)

(3) 8-bit parallel data

In 8-bit packed mode, pixels are processed in 8-bit raw or 10- to 8-bit DPCM/PCM Compression mode, in 4 pixel units with a period of 1 × BCLK_INTR.

Figure 46.14 shows the format (8-bit parallel data) of the data received from the CMOSIF-Link.

The number of pixels is not always a multiple of 4; odd pixels (1/2/3 bytes) can occur. The effective bytes are indicated in CMOSIF_PE.

- Pixels up to pixel 0 are output (CMOSIF_PE[3] asserted) when the residue is 1.
- Pixels up to pixel 1 are output (CMOSIF_PE[3:2] asserted) when the residue is 2.
- Pixels up to pixel 2 are output (CMOSIF_PE[3:1] asserted) when the residue is 3.

BCLK_INTR Period	CMOSIF_DATA[31:0]															
	31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0
Output Sequence 0	Pixel 0[7:0]				Pixel 1				Pixel 2				Pixel 3			

Figure 46.14 Format of Data Received from the CMOSIF-Link (8-Bit Parallel Data)

Register Description

(1) Register read/write restrictions

Restrictions on register reads and writes are given below. The system operation may fail if the integrity of the following register operations is not guaranteed:

1. Writing a 1 into any read-only register bit or reserved area is prohibited. Do not set any value other than the specified values.
2. There are cases in which a nonzero value is read from a read-only bit. Such a value must not be rewritten.
3. Writing into any registers (bits) that are disallowed for writes during operation is prohibited while some operation is in progress (reads are allowed). The operating state of the RAWBUF can be identified by reading the RAWBUF operation register or by identifying the end of the F1DMAC transfer.

(2) Terms and abbreviations used in this document

A term that is used in this document is explained below.

1. "Software reset" refers to a forced reset into the RAWBUF internal circuit. This means that any attempt to effect a module reset while the RAWBUF is running normally might place the ISPBUF peripheral hardware into an inoperative state.

(3) List of Registers

The register configuration of the RAWBUF registers is summarized in table 46.8. The relationship between the processing modes and register states is given in table 46.9, Processing Modes and Register States.

Table 46.8 RAWBUF Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
RAWBUF control register	RAWBUF_RBCR	R/W	H'FE8F 0000	32
RAWBUF initialization register	RAWBUF_RBINITR	R/W	H'FE8F 0004	32
RAWBUF operating mode register	RAWBUF_RBMDR	R/W	H'FE8F 0008	32
RAWBUF RAWOBUF DMA operating mode register	RAWBUF_RBOBFMDR	R/W	H'FE8F 000C	32
RAWBUF RAWIBUF DMA operating mode register	RAWBUF_RBIBFMDR	R/W	H'FE8F 0010	32
RAWBUF Interrupt mask register	RAWBUF_RBINTMSKR	R/W	H'FE8F 0014	32
RAWBUF status register	RAWBUF_RBINTSTSR	R/W	H'FE8F 0018	32
RAWBUF raw format error 1 register	RAWBUF_RBFER1R	R/W	H'FE8F 001C	32
RAWBUF raw format error 2 register	RAWBUF_RBFER2R	R/W	H'FE8F 0020	32
RAWBUF prohibited area*[1]	—	—	H'FE8F 0024 to H'FE8F 0030	—
RAWBUF H/V status register	RAWBUF_RBSESTSR	R	H'FE8F 0034	32
RAWBUF RAWOBUF internal status register 1	RAWBUF_RBOBFSTSR1	R	H'FE8F 0038	32
RAWBUF RAWOBUF internal status register 2	RAWBUF_RBOBFSTSR2	R	H'FE8F 003C	32
RAWBUF RAWIBUF internal status register 1	RAWBUF_RBIBFSTSR1	R	H'FE8F 0040	32
RAWBUF RAWIBUF internal status register 2	RAWBUF_RBIBFSTSR2	R	H'FE8F 0044	32
RAWBUF prohibited area*[1]	—	—	H'FE8F 0048 to H'FE8F 00FC	—
RAWBUF buffer access mode register	RAWBUF_RBACCMDR	R/W	H'FE8F 0100	32

Register Name	Abbreviation	R/W	Address	Access Size
RAWBUF prohibited area*1	—	—	H'FE8F 0104 to H'FE8F 01FC	—
RAWBUF RAWIBUF*2	—	R/W	H'FE8F 2000 to H'FE8F 3FFC	32
RAWBUF RAWOBUF*3	—	R/W	H'FE8F 4000 to H'FE8F 5FFC	32

Notes: 1. Normal operation is not guaranteed if an attempt is made to write into any prohibited area.
Reading from a prohibited area will yield an undefined value.
2. The accessible area is limited by the IBUFASP and IOPSZ bits of the RAWIBUF DMA operating mode register.
3. The accessible area is limited by the OBUFASP and OOPSZ bits of the RAWOBUF DMA operating mode register.

Table 46.9 Processing Modes and Register States

46.3.3 RAWBUF Control Register (RAWBUF_RBCR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	RAWBUFEN	—	—	OBUFEN	IBUFEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
4	RAWBUFEN	B'0	R/W	RAWBUF receive enable 0: Disables raw data receive operation. 1: Enables raw data receive operation.
3, 2	—	B'00	R	Reserved. These bits are always read as 0. The write value should always be 0.
1	OBUFEN	B'0	R/W	RAWOBUF start/stop 0: Stops RAWOBUF operation. 1: Starts RAWOBUF operation.
0	IBUFEN	B'0	R/W	RAWIBUF start/stop 0: Stops RAWIBUF operation. 1: Starts RAWIBUF operation.

(1) RAWBUFEN (RAWBUF receive enable) bit (b4)

This bit enables or disables the operation to receive raw data from the CMOSIF-Link.

Clearing this bit to 0 disables the raw data receive operation.

Setting this bit to 1 enables the raw data receive operation.

(2) OBUFEN (RAWOBUF start/stop) bit (b1)

This bit starts or stops the RAWOBUF operation.

Clearing this bit to 0 stops the RAWOBUF operation.

Setting this bit to 1 starts the RAWOBUF operation.

When the RAWOBUF operation is stopped, the RAWBUF neither writes the data input to the RAWOBUF into the FIFO buffer nor issues a DMA request to the F1 bus.

(3) IBUFEN (RAWIBUF start/stop) bit (b0)

This bit starts or stops the RAWIBUF operation.

Clearing this bit to 0 stops the RAWIBUF operation.

Setting this bit to 1 starts the RAWIBUF operation.

When the RAWIBUF operation is stopped, the RAWBUF neither issues a DMA request to the F1 bus nor responds to any data transfer requests from the CAMIF.

Notes on the sequence of setting up the registers

- When using the DIRBUF
  After setting up the RBMDR register, provide intervals of 4 clocks or longer using BCLK and CAMCLK, respectively, before setting the RAWBUFEN bit of this register.
- When using the RAWOBUF
  After setting up the RBMDR register, provide an interval of 4 clocks or longer using BCLK before setting the OBUFEN bit of this register.
- When using the RAWIBUF
  After setting up the RBMDR and RBIBFMDR registers, provide an interval of 4 clocks or longer using CAMCLK before setting the IBUFEN of this register.

46.3.4 RAWBUF Initialization Register (RAWBUF_RBINITR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RBFRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	RBFRST	B'0	R/W	RAWBUF reset 0: Does not reset the RAWBUF. 1: Resets the RAWBUF.

(1) RBFRST (RAWBUF reset) bit (b0)

This bit resets the RAWBUF.

Clearing this bit to 0 does not reset the RAWBUF.

Any reset attempt made by setting this bit to 1 cannot be canceled even by clearing this bit to 0.

Setting this bit to 1 resets the RAWBUF. This bit is automatically cleared to 0 when the RAWBUF reset sequence is completed.

Be sure to reset the RAWBUF before restarting it after stopping it.

The following registers are not cleared by this rest function:

(1) RAWBUF Control Register (RAWBUF_RBCR)

(2) RAWBUF Operating Mode Register (RAWBUF_RBMDR)

(3) RAWOBUF DMA Operating Mode Register (RAWBUF_RBOBFMDR)

(4) RAWIBUF DMA Operating Mode Register (RAWBUF_RBIBFMDR)

(5) RAWBUF Interrupt Mask Register (RAWBUF_RBINTMSKR)

(6) RAWBUF Buffer Access Mode Register (RAWBUF_RBACCMDR)

The following registers are cleared by this reset function:

(1) RAWBUF Status Register (RAWBUF_RBINTSTSR)
COVF bit, OOVF bit, DOVF bit

(2) RAW Format Error 1 Register (RAWBUF_RBFER1R)
DERRV bit, DERRH bit

(3) RAW Format Error 2 Register (RAWBUF_RBFER2R)
FERRH bit

(4) RAWBUF Receive Size Register (RAWBUF_RBRXSZR)
PIXSZ bit, LINSZ bit

(5) RAWBUF H/V Status Register (RAWBUF_RBSESTSR)
H bit, V bit

(6) RAWOBUF Internal Status Register 1 (RAWBUF_RBOBFSTSR1)
OFUL bit, OEMP bit, ODRQ bit, ODCPLT bit

(7) RAWOBUF Internal Status Register 2 (RAWBUF_RBOBFSTSR2)
OWPTR bit, ORPTR bit

(8) RAWIBUF Internal Status Register 1 (RAWBUF_RBIBFSTSR1)
IFUL bit, IEMP bit, IDRQ bit, IDCPLT bit

(9) RAWIBUF Internal Status Register 2 (RAWBUF_RBIBFSTSR2)
IWPTR bit, IRPTR bit

46.3.5 RAWBUF Operating Mode Register (RAWBUF_RBMDR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RAWPIX[9:8]		—	—	—	—	—	—	—	PTHSEL
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
9, 8	RAWPIX[9:8]	B'01	R/W	Raw data pixel size select 00: Sets the size of the raw data input to 12 bits/pixel. 01: Sets the size of the raw data input to 10 bits/pixel. 10: Sets the size of the raw data input to 8 bits/pixel. 11: Sets the size of the raw data input to 8 bits/pixel (DPCM/PCM).
7 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	PTHSEL	B'1	R/W	Raw data output path select 0: Directs the raw data to the F1 bus. 1: Directs the raw data to the CAMIF (initial value).

(1) RAWPIX (Raw data pixel size select) bits (b9, b8)

These bits define the pixel size of the raw data input to the RAWBUF.

Setting these bits to 00 sets the pixel size of the raw data input to 12 bits/pixel.

Setting these bits to 01 sets the pixel size of the raw data input to 10 bits/pixel (initial value).

Setting these bits to 10 sets the pixel size of the raw data input to 8 bits/pixel.

Setting these bits to 11 sets the pixel size of the raw data input to 8 bits/pixel (DPCM/PCM).

(2) PTHSEL (Raw data output path select) bit (b0)

This bit defines the destination of the raw data output.

Clearing this bit to 0 directs the raw data to the F1 bus and from the F1 bus to the CAMIF (F1 path).

Setting this bit to 1 directs the raw data to the CAMIF. The data are not transferred from the F1 bus to the CAMIF (direct path) (initial value).

46.3.6 RAWBUF RAWOBUF DMA Operating Mode Register (RAWBUF_RBOBFMDR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	OBUFASP[25:24]		—	—	—	ODRQE	—	—	OOPSZ[17:16]	
Initial value:	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R/W	R	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OITVLE	ODRITVL[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
25 to 24	OBUFASP[25:24] (RAWOBUF Buffer Aspect)	B'11	R/W	Buffer plane count select 01: Number of planes to be used is 4 planes. 11: Number of planes to be used is 8 planes. Other than the other values: Reserved.
23 to 21	—	B'000	R	Reserved. These bits are always read as 0. The write value should always be 0.
20	ODRQE	B'0	R/W	DMA request enable 0: Disables DMA requests to be issued. 1: Enables DMA requests to be issued.
19 to 18	—	B'00	R	Reserved. These bits are always read as 0. The write value should always be 0.
17 to 16	OOPSZ[17:16]	B'10	R/W	DMA operand size 00: Sets the operand size to 16 data blocks. 01: Sets the operand size to 32 data blocks. 10: Sets the operand size to 64 data blocks. Other than the other values: Reserved.
15 to 9	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	OITVLE	B'0	R/W	DMA request interval setting enable 0: Disables the DMA request interval setting. 1: Enables the DMA request interval setting.
7 to 0	ODRITVL[7:0]	All 0	R/W	DMA request interval These bits define the minimum number of cycles required from the time the response (Acknowledge) to the last DMA request is recognized till the time the issuance of the next DMA request is enabled. Set value + 1 = Minimum cycle count (1 cycle to 256 cycles)

(1) OBUFASP (buffer plane count select) bits (b25, b24)

These bits define the number of RAWOBUF buffer planes to be used.

4 planes are used when these bits are set to 01.

8 planes are used when these bits are set to 11 (initial value).

(2) ODRQE (DMA request enable) bit (b20)

This bit enables DMA requests to be issued from the RAWOBUF.

When this bit is cleared to 0, no DMA request is issued even when the DMA request issuance conditions are established.

When this bit is set to 1, a DMA request is issued when the DMA request issuance conditions are established.

(3) OOPSZ (DMA operand size) bits (b17, b16)

These bits define the size of the operands (DMA transfer size) for RAWOBUF DMA transfers.

When these bits are set to 00, DMA transfers occur in units of 16 data blocks (64 bits × 16 words).

When these bits are set to 01, DMA transfers occur in units of 32 data blocks (64 bits × 32 words).

When these bits are set to 10, DMA transfers occur in units of 64 data blocks (64 bits × 64 words) (initial value).

(4) OITVLE (DMA request interval setting enable) bit (b8)

This bit enables or disables the DMA request interval setting that is defined in the ODRITVL bits.

Clearing this bit to 0 disables the DMA request interval setting that is defined in the ODRITVL bits.

Setting this bit to 1 enables the DMA request interval setting that is defined in the ODRITVL bits.

When the DMA request interval setting is disabled, a DMA request is issued immediately when the DMA request issuance conditions for the next DMA request are established after the response (Acknowledge) to the last DMA request is recognized.

(5) ODRITVL (DMA request enable setting) bits (b7 to b0)

These bits define the minimum number of cycles required from the time the response (Acknowledge) to the last DMA request is recognized till the time the issuance of the next DMA request is enabled.(1 to 256 cycles).

The issuance of the next DMA request is enabled before the data transfer for the last DMA request is completed. The setting made in these bits is enabled when the OITVLE bit is set to 1.

46.3.7 RAWBUF RAWIBUF DMA Operating Mode Register (RAWBUF_RBIBFMDR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	IBUFASP [25:24]		—	—	—	IDRQE	—	—	IOPSZ[17:16]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R/W	R	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	IITVLE	IDRITVL[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
25 to 24	IBUFASP[25:24] (RAWIBUF Buffer Aspect)	B'00	R/W	Buffer plane count select 00: Number of planes to be used 2 planes Other than the other values: Reserved.
23 to 21	—	B'0000	R	Reserved. These bits are always read as 0. The write value should always be 0.
20	IDRQE	B'0	R/W	DMA request enable 0: Disables DMA requests to be issued. 1: Enables DMA requests to be issued.
19, 18	—	B'00	R	Reserved. These bits are always read as 0. The write value should always be 0.
17, 16	IOPSZ[17:16]	B'01	R/W	DMA operand size 00: Sets the operand size to 16 data blocks. 01: Sets the operand size to 32 data blocks. Others: Reserved.
15 to 9	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	IITVLE	B'0	R/W	DMA request interval setting enable 0: Disables the DMA request interval setting. 1: Enables the DMA request interval setting.
7 to 0	IDRITVL[7:0]	All 0	R/W	DMA request interval These bits define the minimum number of cycles required from the time the response (Acknowledge) to the last DMA request is recognized till the time the issuance of the next DMA request is enabled. Set value + 1 = Minimum cycle count (1 cycle to 256 cycles)

(1) IBUFASP (buffer plane count select) bits (b25, b24)

These bits define the number of RAWIBUF buffer planes to be used.

2 planes are used when these bits are set to 00 (initial value).

(2) IDRQE (DMA request enable) bit (b20)

This bit enables DMA requests to be issued from the RAWIBUF.

When this bit is cleared to 0, no DMA request is issued even when the DMA request issuance conditions are established.

When this bit is set to 1, a DMA request is issued when the DMA request issuance conditions are established.

(3) IOPSZ (DMA operand size) bits (b17, b16)

These bits define the size of the operands (DMA transfer size) for RAWIBUF DMA transfers.

When these bits are set to 00, DMA transfers occur in units of 16 data blocks (64 bits × 16 words).

When these bits are set to 01, DMA transfers occur in units of 32 data blocks (64 bits × 32 words) (initial value).

(4) IITVLE (DMA request interval setting enable) bit (b8)

This bit enables or disables the DMA request interval setting that is defined in the IDRITVL bits.

Clearing this bit to 0 disables the DMA request interval setting that is defined in the IDRITVL bits.

Setting this bit to 1 enables the DMA request interval setting that is defined in the IDRITVL bits.

When the DMA request interval setting is disabled, a DMA request is issued immediately when the DMA request issuance conditions for the next DMA request are established after the response (Acknowledge) to the last DMA request is recognized.

(5) IDRITVL (DMA request enable setting) bits (b7 to b0)

These bits define the minimum number of cycles required from the time the response (Acknowledge) to the last DMA request is recognized till the time the issuance of the next DMA request is enabled.(1 to 256 cycles).

The issuance of the next DMA request is enabled before the data transfer for the last DMA request is completed. The setting made in these bits is enabled when the IITVLE bit is set to 1.

46.3.8 RAWBUF Interrupt Mask Register (RAWBUF_RBINTMSKR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INTMSK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	INTMSK	B'0	R/W	Interrupt request mask 0: Interrupt requests are not masked. 1: Interrupt requests are masked.

(1) INTMSK (interrupt request mask) bit (b0)

This bit masks or de-masks interrupt requests generated by overflow conditions.

When this bit is cleared to 0, interrupt requests caused by overflow errors are enabled.

When this bit is cleared to 1, interrupt requests caused by overflow conditions are masked on.

Overflow errors are detected by the CMOSIF Link IF, DIRBUF, and RAWOBUF. An interrupt request signal is made available for each of the respective interrupt sources. These interrupt sources are masked or de-masked by this bit alone.

46.3.9 RAWBUF Status Register (RAWBUF_RBINTSTSR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	ERRT	—	—	—	—	—	—	DT2FMT	DT1FMT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	COVF	OOVF	DOVF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
24	ERRT	B'0	R/W	Raw data format error test 0: Normal 1: Enables tests on the DT1FMT bit, DT2FMT bit, and the RAWBUF_RBFER1R and RAWBUF_RBFER1R registers.
23 to 18	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
17	DT2FMT	B'0	R/W	F1 path raw data format error 0: Indicates that no format error has occurred in the raw data. 1: Indicates that a format error has occurred in the raw data.
16	DT1FMT	B'0	R/W	Direct path raw data format error 0: Indicates that no format error has occurred in the raw data. 1: Indicates that a format error has occurred in the raw data.
15 to 3	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2	COVF	B'0	R/W	CMOSIF Link I/F buffer overflow error 0: Indicates that no overflow error has occurred in the CMOSIF Link I/F buffer. The interrupt request associated with the overflow error by setting this bit to 0. 1: Indicates that an overflow error has occurred in the CMOSIF Link I/F buffer. An interrupt request can be generated by setting this bit to 1 (for testing).
1	OOVF	B'0	R/W	RAWOBUF overflow error 0: Indicates that no overflow error has occurred in the RAWOBUF. The interrupt request associated with the overflow error by setting this bit to 0. 1: Indicates that an overflow error has occurred in the RAWOBUF. An interrupt request can be generated by setting this bit to 1 (for testing).
0	DOVF	B'0	R/W	DIRBUF overflow error 0: Indicates that no overflow error has occurred in the DIRBUF. The interrupt request associated with the overflow error by setting this bit to 0. 1: Indicates that an overflow error has occurred in the DIRBUF. An interrupt request can be generated by setting this bit to 1 (for testing).

(1) ERRT (Raw data format error test) bit (b24)

This bit is used to enable the display for format tests made on the raw data.

Setting this bit to 0 disables the error tests. No error is then displayed when a 1 is written into the DT2FMT or DT1FMT bit. In addition, any value written into the RAWBUF_RBFER1R or RAWBUF_RBFER2R is not displayed.

Setting this bit to 1 enables the pseudo error tests. An error is signaled by writing a 1 into the DT2FMT or DT1FMT bit. Any value written into RBFER1R or RBFER2R is displayed as is (for testing).

(2) DT2FMT (F1 path raw data format error) bit (b17)

This bit indicates if an F1 path raw data format error has occurred.

0 in this bit indicates that no raw data format error has occurred.

1 in this bit indicates that a raw data format error has occurred.

Clearing this bit to 0 clears the error display.

A time equivalent to CAMCLK × 5 clocks + ICLK × 5 clocks is required until this bit is zero-cleared.

Another interval of CAMCLK × 8 clocks + ICLK × 8 clocks or longer is required to rewrite this bit.

An error display is generated when the ERRT bit (b7) is set to 1 and the DT2FMT bit (b14) to 1 (for testing).

(3) DT1FMT (Direct path raw data format error) bit (b16)

This bit indicates if a direct path raw data format error has occurred.

0 in this bit indicates that no raw data format error has occurred.

1 in this bit indicates that a raw data format error has occurred.

Clearing this bit to 0 clears the error display.

A time equivalent to CAMCLK × 5 clocks + ICLK × 5 clocks is required until this bit is zero-cleared.

Another interval of CAMCLK × 8 clocks + ICLK × 8 clocks or longer is required to rewrite this bit.

An error display is generated when the ERRT bit (b7) is set to 1 and the DT1FMT bit (b15) to 1 (for testing).

(4) COVF (CMOSIF Link I/F buffer overflow error) bit (b2)

This bit indicates if an overflow error has occurred in the CMOSIF Link I/F buffer.

A 0 in this bit indicates that no overflow has occurred in the CMOSIF Link I/F buffer.

A 1 in this bit indicates that an overflow has occurred in the CMOSIF Link I/F buffer, in which case an interrupt request is generated according to the state of the interrupt request mask bit.

Clearing this bit to 0 clears the interrupt request associated with the overflow.

A time equivalent to BCLK × 5 clocks + ICLK × 5 clocks is required until this bit is zero-cleared.

Another interval of BCLK × 6 clocks + ICLK × 6 clocks or longer is required to rewrite this bit.

An interrupt request can be generated according to the state of the interrupt request mask bit by setting this bit to 1 (for testing).

The interrupt request mask is set up by the INTMSK bit of the RAWBUF Interrupt Mask Register (RBINTMSKR).

(5) OOVF (RAWOBUF overflow error) bit (b1)

This bit indicates if an overflow error has occurred in the RAWOBUF.

A 0 in this bit indicates that no overflow has occurred in the RAWOBUF.

A 1 in this bit indicates that an overflow has occurred in the RAWOBUF, in which case an interrupt request is generated according to the state of the interrupt request mask bit.

Clearing this bit to 0 clears the interrupt request associated with the overflow.

An interrupt request can be generated according to the state of the interrupt request mask bit by setting this bit to 1 (for testing).

The interrupt request mask is set up by the INTMSK bit of the RAWBUF Interrupt Mask Register (RBINTMSKR).

(6) DOVF (DIRBUF overflow error) bit (b0)

This bit indicates if an overflow error has occurred in the DIRBUF.

A 0 in this bit indicates that no overflow has occurred in the DIRBUF.

A 1 in this bit indicates that a DIRBUF overflow has been caused by the data input initiated by asserting the CMOSIF_PE signal while the CMOSIF_VD and CMOSIF_HD signals are being asserted. In this case, an interrupt request is generated according to the state of the interrupt request mask bit.

Clearing this bit to 0 clears the interrupt request associated with the overflow.

A time equivalent to CAMCLK × 3 clocks + ICLK × 4 clocks is required until this bit is zero-cleared.

Another interval of CAMCLK × 4 clocks + ICLK × 2 clocks or longer is required to rewrite this bit.

An interrupt request can be generated according to the state of the interrupt request mask bit by setting this bit to 1 (for testing).

The interrupt request mask is set up by the INTMSK bit of the RAWBUF Operating Mode Register (RBFMDR).

46.3.10 RAWBUF Raw Format Error 1 Register (RAWBUF_RBFER1R)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	DERRV[28:16]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	DERRH[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
28 to 16	DERRV [28:16]	All 0	R/W	Direct path 8-bit DPCM/PCM data format error vertical position Indicate the line position within the frame in which a data format error occurred.
15 to 14	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
13 to 0	DERRH [13:0]	All 0	R/W	Direct path 8-bit DPCM/PCM data format error horizontal position Indicates the pixel position within the line in which a data format error occurred.

(1) DERRV (Direct path 8-bit DPCM/PCM data format error vertical position) bits (b28 to 16)

These bits indicate the position of the line within the frame in which a direct path raw data format error occurred.

These bits are normally read-only and cannot be modified but an arbitrary value can be written into these bits by setting the ERRT bit of the RAWBUF_RBINTSTSR register to 1 (for testing).

(2) DERRH (Direct path 8-bit DPCM/PCM data format error horizontal position) bits (b13 to b0)

These bits indicate the position of the pixel within the line in which a direct path raw data form error occurred.

These bits are normally read-only and cannot be modified but an arbitrary value can be written into these bits by setting the ERRT bit of the RAWBUF_RBINTSTSR register to 1 (for testing).

46.3.11 RAWBUF Raw Format Error 2 Register (RAWBUF_RBFER2R)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
13 to 0	FERRH [13:0]	All 0	R/W	F1 path 8-bit DPCM/PCM data format error horizontal position Indicates the pixel position within the line in which a data format error occurred.

(1) DERRH (F1 path 8-bit DPCM/PCM data format error horizontal position) bits (b13 to b0)

These bits indicate the position of the pixel within the line in which an F1 path raw data form error occurred.

These bits are normally read-only and cannot be modified but an arbitrary value can be written into these bits by setting the ERRT bit of the RAWBUF_RBINTSTSR register to 1 (for testing).

46.3.12 RAWBUF H/V Status Register (RAWBUF_RBSESTSR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	H	V	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
2	H	B'0	R	H bit 0: No H signal detected. 1: H signal detected.
1	V	B'0	R	V bit 0: No V signal detected. 1: V signal detected.
0	—	B'0	R	Reserved. This bit is always read as 0. The write value should always be 0.

(1) H (H) bit (b2)

This bit indicates the state of the horizontal sync signal.

A 0 in this bit indicates that the horizontal sync signal is negated.

A 1 in this bit indicates that the horizontal sync signal is asserted.

This is a read-only bit and cannot be modified.

(2) V (V) bit (b1)

This bit indicates the state of the vertical sync signal.

A 0 in this bit indicates that the vertical sync signal is negated.

A 1 in this bit indicates that the vertical sync signal is asserted.

This is a read-only bit and cannot be modified.

46.3.13 RAWBUF RAWOBUF Internal Status Register 1 (RAWBUF_RBOBFSTSR1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	OFUL	OEMP	—	—	ODRQ	ODCPLT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
21	OFUL	B'0	R	Full flag 0: Indicates that the RAWOBUF is not full. 1: Indicates that the RAWOBUF is full.
20	OEMP	B'0	R	Empty flag 0: Indicates that the RAWOBUF is not empty. 1: Indicates that the RAWOBUF is empty.
19 to 18	—	B'00	R	Reserved. These bits are always read as 0. The write value should always be 0.
17	ODRQ	B'0	R	DMA request display 0: Indicates that no DMA request has been issued from the RAWOBUF. 1: Indicates that a DMA request has been issued from the RAWOBUF. This bit is cleared by a response (Acknowledge) to the DMA request.
16	ODCPLT	B'0	R	DMA completion display 0: Indicates that the data transfer in response to a DMA request from the RAWOBUF has been completed. 1: Indicates that there is a response (Acknowledge) to a DMA request from the RAWOBUF but that the data transfer has not yet been completed.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

(1) OFUL (full flag) bit (b21)

This bit indicates if the RAWOBUF is full.

A 0 in this bit indicates that the RAWOBUF is not full.

A 1 in this bit indicates that the RAWOBUF is full.

This is a read-only bit and cannot be modified.

(2) OEMP (empty flag) bit (b20)

This bit indicates if the RAWOBUF is empty.

A 0 in this bit indicates that the RAWOBUF is not empty.

A 1 in this bit indicates that the RAWOBUF is empty.

This is a read-only bit and cannot be modified.

(3) ODRQ (DMA request display) bit (b17)

This bit indicates if there is a DMA request from the RAWOBUF.

A 0 in this bit indicates that no DMA request has been issued from the RAWOBUF.

A 1 in this bit indicates that a DMA request has been issued from the RAWOBUF. In this case, the bit is cleared by a response (Acknowledge) to the DMA request.

This is a read-only bit and cannot be modified.

(4) ODCPLT (DMA completion display) bit (b16)

This bit indicates whether the data transfer initiated in response to a DMA request from the RAWOBUF has been completed.

A 0 in this bit indicates that the data transfer initiated by a DMA request from the RAWOBUF has been completed.

A 1 in this bit indicates that there is a response (Acknowledge) to a DMA request from the RAWOBUF but that the data transfer has not yet been completed. In this case, the bit is cleared when the transfer of 1 operand is completed.

This bit is set to 1 upon recognition of a response (Acknowledge) to a DMA request from the RAWOBUF and set to 0 when the transfer of one operand data are completed.

This is a read-only bit and cannot be modified.

46.3.14 RAWBUF RAWOBUF Internal Status Register 2 (RAWBUF_RBOBFSTSR2)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	OWPTR[25:16]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ORPTR[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
25 to 16	OWPTR [25:16]	All 0	R	Write pointer Indicate the value of the write pointer for the RAWOBUF.
15 to 10	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
9 to 0	ORPTR [9:0]	All 0	R	Read pointer Indicate the value of the read pointer for the RAWOBUF.

(1) OWPTR (write pointer) bits (b25 to b16)

These bits represent the write pointer for the RAWOBUF.

The write pointer holds a 64-bit pointer value.

This is a read-only bit and cannot be modified.

(2) ORPTR (read pointer) bits (b9 to b0)

These bits represent the read pointer for the RAWOBUF.

The read pointer holds a 64-bit pointer value.

This is a read-only bit and cannot be modified.

46.3.15 RAWBUF RAWIBUF Internal Status Register 1 (RAWBUF_RBIBFSTSR1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	IFUL	EEMP	—	—	IDRQ	IDCPLT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
21	IFUL	B'0	R	Full flag 0: Indicates that the RAWIBUF is not full. 1: Indicates that the RAWIBUF is full.
20	IEMP	B'0	R	Empty flag 0: Indicates that the RAWIBUF is not full. 1: Indicates that the RAWIBUF is full.
19 to 18	—	B'00	R	Reserved. These bits are always read as 0. The write value should always be 0.
17	IDRQ	B'0	R	DMA request display 0: Indicates that no DMA request has been issued from the RAWIBUF. 1: Indicates that a DMA request has been issued from the RAWIBUF. This bit is cleared by a response (Acknowledge) to the DMA request.
16	IDCPLT	B'0	R	DMA completion display 0: Indicates that the data transfer in response to a DMA request from the RAWIBUF has been completed. 1: Indicates that there is a response (Acknowledge) to a DMA request from the RAWIBUF but that the data transfer has not yet been completed.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.

(1) IFUL (full flag) bit (b21)

This bit indicates if the RAWIBUF is full.

A 0 in this bit indicates that the RAWIBUF is not full.

A 1 in this bit indicates that the RAWIBUF is full.

This is a read-only bit and cannot be modified.

(2) IEMP (empty flag) bit (b20)

This bit indicates if the RAWIBUF is empty.

A 0 in this bit indicates that the RAWIBUF is not empty.

A 1 in this bit indicates that the RAWIBUF is empty.

This is a read-only bit and cannot be modified.

(3) IDRQ (DMA request display) bit (b17)

This bit indicates if there is a DMA request from the RAWIBUF.

A 0 in this bit indicates that no DMA request has been issued from the RAWIBUF.

A 1 in this bit indicates that a DMA request has been issued from the RAWIBUF. In this case, the bit is cleared by a response (Acknowledge) to the DMA request.

This is a read-only bit and cannot be modified.

(4) IDCPLT (DMA completion display) bit (b16)

This bit indicates whether the data transfer initiated in response to a DMA request from the RAWIBUF has been completed.

A 0 in this bit indicates that the data transfer initiated by a DMA request from the RAWIBUF has been completed.

A 1 in this bit indicates that there is a response (Acknowledge) to a DMA request from the RAWIBUF but that the data transfer has not yet been completed. In this case, the bit is cleared when the transfer of 1 operand is completed.

This bit is set to 1 upon recognition of a response (Acknowledge) to a DMA request from the RAWIBUF and set to 0 when the transfer of one operand data are completed.

This is a read-only bit and cannot be modified.

46.3.16 RAWBUF RAWIBUF Internal Status Register 2 (RAWBUF_RBIBFSTSR2)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	IWPTR[25:16]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	IRPTR[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
25 to 16	IWPTR [25:16]	All 0	R	Write pointer Indicate the value of the write pointer for the RAWIBUF.
15 to 10	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
9 to 0	IRPTR[9:0]	All 0	R	Read pointer Indicate the value of the read pointer for the RAWIBUF.

(1) IWPTR (write pointer) bits (b25 to b16)

These bits represent the write pointer for the RAWIBUF.

The write pointer holds a 64-bit pointer value.

This is a read-only bit and cannot be modified.

(2) IRPTR (read pointer) bits (b9 to b0)

These bits represent the read pointer for the RAWIBUF.

The read pointer holds a 64-bit pointer value.

This is a read-only bit and cannot be modified.

If the read pointer is read while the RAWIBUF is running when the frequency of CAMCLK is higher than that of ICLK, the lower bits will not reflect the correct value according to the ratio of the respective frequencies.

46.3.17 RAWBUF Buffer Access Mode Register (RAWBUF_RBACCMDR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BUFACC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved. These bits are always read as 0. The write value should always be 0.
0	BUFACC	B'0	R/W	Buffer access bus select 0: RAWIBUF and RAWOBUF are accessed over the F1 bus. 1: RAWIBUF and RAWOBUF are accessed over the C bus.

(1) BUFACC (buffer access bus select) bits (b0)

This bit defines the bus over which the RAWIBUF and RAWOBUF are to be accessed.

Clearing this bit to 0 sets the active access bus to the F1 bus.

Setting this bit to 1 sets the active access bus to the C bus.

When the C bus is selected as the active access bus, no raw data can be placed on the F1 bus.

Even when the C bus is selected as the active access bus, no data can be written into the RAWIBUF or RAWOBUF over the C bus. Data can only be read over the C bus.

To access the RAWIBUF and RAWOBUF over the C bus, allocate the RAWIBUF and RAWOBUF to the following memory areas:

RAWIBUF	:H'FE8F 2000	to	H'FE8F 3FFC
RAWOBUF	:H'FE8F 4000	to	H'FE8F 5FFC

When RAWIBUF and RAWOBUF are to be accessed over the C bus, they must be accessed only on a word (32 bits) basis.

Figures 46.15 and 46.16 show the mapping method for the RAWIBUF and RAWOBUF, respectively.

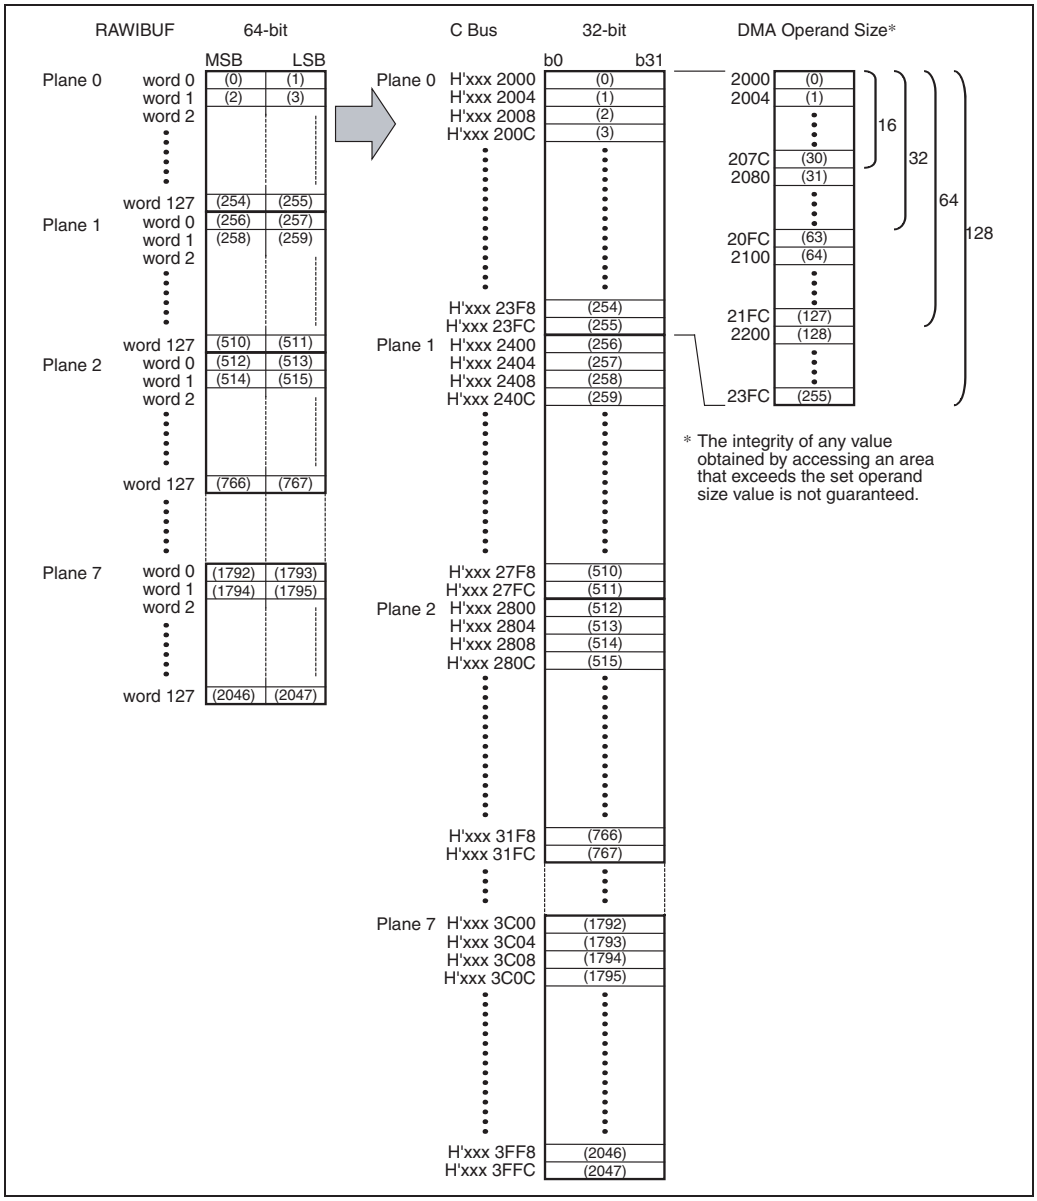

Figure 46.15 RAWIBUF Mapping Method

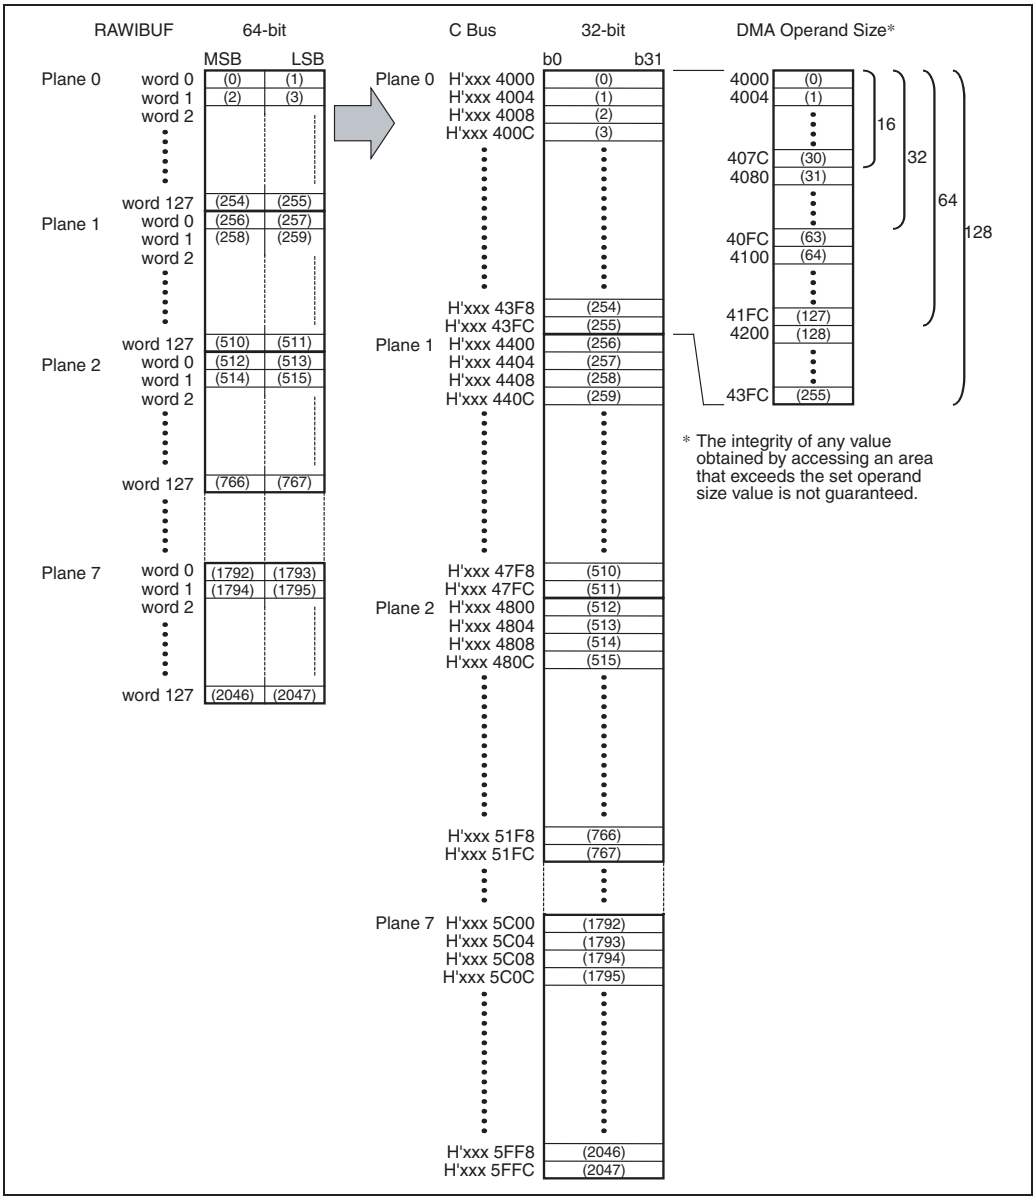

Figure 46.16 RAWOBUF Mapping Method

46.4 F1DMAC

46.4.1 F1DMAC Feature Overview

The DMA controller (F1DMAC) for exclusive use by the ISP is a module that transfers data at high speed bypassing the CPU, as requested by the software or on-chip peripheral I/O device. The ISP contains two of these modules. One is the F1DMAC(0) used mainly for data transfer from the CMAIF or RAWBUF. The other is the F1DMAC(1) responsible for data transfer from the ISP. Table 46.10 shows the F1DMAC features.

Table 46.10 F1DMAC Features

Item	Feature
Number of channels	8
Transfer request	Request from the software trigger or on-chip peripheral I/O device. (There are five factors for the F1DMAC(0) and seven factors for the F1DMAC(1).)
Maximum number of transfer bytes	64 Mbytes
Address space	4 Gbytes
Transfer data size	1-unit transfer: 8, 16, 32, 64 or 128 bits* 1-operand transfer: 1, 2, 4, 8, 16, 32, 64 or 128 data units Non-stop transfer: Performed until the byte count reaches 0.
Transfer mode	Cycle stealing mode (dual-address transfer) Pipeline mode (dual-address transfer) Fly-by mode (single-address transfer)
Maximum transfer rate	Cycle stealing mode: Three or more clock cycles per 1-unit transfer Pipeline mode: One or more clock cycles per 1-unit transfer Fly-by mode: One clock cycle per 1-unit transfer

Item	Feature
Transfer conditions	Single-operand transfer: Several DMA requests are generated, each causing one operand to be transferred. Channel arbitration takes place each time one operand is transferred. Request triggering is required each time one operand is transferred.
	Consecutive-operand transfer: When one DMA request is generated, it causes operands to be transferred one after another until the byte count reaches 0. Channel arbitration takes places each time one operand is transferred. Request triggering is only required at the start of the first transfer.
	Non-stop transfer: Transfer starts upon a DMA request and continues without cessation until the byte count reaches 0. Channel arbitration does not take place during non-stop transfer. Request triggering is only required at the start of this transfer.
Channel priority	Channel 0 > Channel > … > Channel 6 > Channel 7 (fixed priority)
Interrupt requests	When the byte count reaches 0, the following interrupt requests are generated:
	Interrupt request signal for each channel
	Common interrupt request signal shared by the channels
Others	Reload function (for each source address, destination address or byte count)
	Rotate function
	2D addressing
	DMAC suspend/resume/abort function

Note: * Factory fixed at 64 bits for this product.

Notes: The terms used in this document are defined below.

- 1-unit transfer: Transfer driven by the DMAC. This transfer involves one read and one write cycle in dual-address mode. It involves one read or one write cycle in single-address mode.
- 1-operand transfer: Consecutive data transfers executed by the DMAC using one channel. (The data transfer count depends on register settings.)
- 1-DMA transfer: Transfer of a number of bytes specified in the byte count register. They are located between the start address and end address.
- Channel number: n = 0, 1, …, 6, 7
- Request factor number: k = 1, 2, …, 8, m = 0, 1, 2, …, 8

46.4.2 Register Description

(1) Register read/write restrictions

Restrictions on register reads and writes are given below. The system operation may fail if the integrity of the following register operations is not guaranteed:

1. Writing a 1 into any read-only register bit or reserved area is prohibited. Do not set any value other than the specified values.
2. There are cases in which a nonzero value is read from a read-only bit. Such a value must not be rewritten.
3. Writing into any registers (bits) that are disallowed for writes during operation is prohibited while some operation is in progress (reads are allowed). The operating state of the F1DMAC can be identified by reading the F1DMAC operation register or by identifying the end of the F1DMAC transfer.
4. All of the F1DMAC registers must be allocated to non-cache area.

(2) Terms and abbreviations used in this document

A term that is used in this document is explained below.

1. "Software reset" refers to a forced reset into the F1DMAC internal circuit. This means that any attempt to effect a module reset while the F1DMAC is running normally might place the F1DMAC peripheral hardware into an inoperative state.

(3) List of F1DMAC(0/1) Registers

The register configuration of the F1DMAC(0) registers is summarized in table 46.11 and that of the F1DMAC(1) registers is summarized in table 46.12. The relationship between the processing modes and register states is given in table 46.13.

Table 46.11 F1DMAC(0) Register Configurations

Register Name	Abbreviation	R/W	Address	Access Size
F1DMAC0 DMA current source address register 0	F1DMAC0_DMCSADR0	R/W	H'FE8F 8000	32
F1DMAC0 DMA current destination address register 0	F1DMAC0_DMCDADR0	R/W	H'FE8F 8004	32
F1DMAC0 DMA current byte count register 0	F1DMAC0_DMCBCT0	R/W	H'FE8F 8008	32
F1DMAC0 DMA mode register 0	F1DMAC0_DMMOD0	R/W	H'FE8F 800C	32
F1DMAC0 DMA current source address register 1	F1DMAC0_DMCSADR1	R/W	H'FE8F 8010	32
F1DMAC0 DMA current destination address register 1	F1DMAC0_DMCDADR1	R/W	H'FE8F 8014	32
F1DMAC0 DMA current byte count register 1	F1DMAC0_DMCBCT1	R/W	H'FE8F 8018	32
F1DMAC0 DMA mode register 1	F1DMAC0_DMMOD1	R/W	H'FE8F 801C	32
F1DMAC0 DMA current source address register 2	F1DMAC0_DMCSADR2	R/W	H'FE8F 8020	32
F1DMAC0 DMA current destination address register 2	F1DMAC0_DMCDADR2	R/W	H'FE8F 8024	32
F1DMAC0 DMA current byte count register 2	F1DMAC0_DMCBCT2	R/W	H'FE8F 8028	32
F1DMAC0 DMA mode register 2	F1DMAC0_DMMOD2	R/W	H'FE8F 802C	32
F1DMAC0 DMA current source address register 3	F1DMAC0_DMCSADR3	R/W	H'FE8F 8030	32
F1DMAC0 DMA current destination address register 3	F1DMAC0_DMCDADR3	R/W	H'FE8F 8034	32
F1DMAC0 DMA current byte count register 3	F1DMAC0_DMCBCT3	R/W	H'FE8F 8038	32
F1DMAC0 DMA mode register 3	F1DMAC0_DMMOD3	R/W	H'FE8F 803C	32
F1DMAC0 DMA current source address register 4	F1DMAC0_DMCSADR4	R/W	H'FE8F 8040	32
F1DMAC0 DMA current destination address register 4	F1DMAC0_DMCDADR4	R/W	H'FE8F 8044	32
F1DMAC0 DMA current byte count register 4	F1DMAC0_DMCBCT4	R/W	H'FE8F 8048	32
F1DMAC0 DMA mode register 4	F1DMAC0_DMMOD4	R/W	H'FE8F 804C	32
F1DMAC0 DMA current source address register 5	F1DMAC0_DMCSADR5	R/W	H'FE8F 8050	32
F1DMAC0 DMA current destination address register 5	F1DMAC0_DMCDADR5	R/W	H'FE8F 8054	32
F1DMAC0 DMA current byte count register 5	F1DMAC0_DMCBCT5	R/W	H'FE8F 8058	32
F1DMAC0 DMA mode register 5	F1DMAC0_DMMOD5	R/W	H'FE8F 805C	32
F1DMAC0 DMA current source address register 6	F1DMAC0_DMCSADR6	R/W	H'FE8F 8060	32
F1DMAC0 DMA current destination address register 6	F1DMAC0_DMCDADR6	R/W	H'FE8F 8064	32
F1DMAC0 DMA current byte count register 6	F1DMAC0_DMCBCT6	R/W	H'FE8F 8068	32
F1DMAC0 DMA mode register 6	F1DMAC0_DMMOD6	R/W	H'FE8F 806C	32
F1DMAC0 DMA current source address register 7	F1DMAC0_DMCSADR7	R/W	H'FE8F 8070	32
F1DMAC0 DMA current destination address register 7	F1DMAC0_DMCDADR7	R/W	H'FE8F 8074	32

Register Name	Abbreviation	R/W	Address	Access Size
F1DMAC0 DMA current byte count register 7	F1DMAC0_DMCBCT7	R/W	H'FE8F 8078	32
F1DMAC0 DMA mode register 7	F1DMAC0_DMMOD7	R/W	H'FE8F 807C	32

46.4.3 F1DMAC0/1 DMA Current Source Address Register n (F1DMAC0/1_DMCSADRn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CSA[31:0]															
Initial value:	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSA[31:0]															
Initial value:	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CSA[31:0]	H'???? ????	R/W	Source address A31 to A0

This register is intended to set the start address of a transfer source. The value in this register is transferred to the work source address register when a DMA transfer begins. The value might be returned at the end of the operand transfer. This is not done if the rotate option (SAMOD = 011) is selected for the source.

If the source address reload function is enabled, the value in the DMA reload source address register (F1DMAC0/1_DMRSADRn) is returned to this DMA current source address register at the end of a DMA transfer.

This register should be set regardless of whether the reload function is enabled.

Notes:

1. Set this register so that a DMA transfer will use addresses aligned to an appropriate address boundary for the transfer unit size selected with DMMODn.SZSEL.
2. Write to this register only when both these conditions exist:
   (1) The relevant channel is not involved in 1-operand transfer (DMA arbitration status register (F1DMAC0/1_DMASTS) DASTS = 0 for that channel).
   (2) DMA transfer is prohibited (DMA start control register (F1DMAC0/1_DMSCNT) DMST = 0 or DMA control register B (F1DMAC0/1_DMCNTBn) DEN = 0).
   If a write to this register occurs in any other case, proper operation is not guaranteed.

46.4.4 F1DMAC0/1 DMA Current Destination Address Register n (F1DMAC0/1_DMCDADRn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CDA[31:0]															
Initial value:	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CDA[31:0]	H'???? ????	R/W	Destination address A31 to A0

This register is intended to set the start address of a transfer destination. The value in this register is transferred to the work destination address register when a DMA transfer begins. It might be returned at the end of the operand transfer. This is not done if the rotate option (DAMOD = 011) is selected for the destination.

If the destination address reload function is enabled, the value in the DMA reload destination address register (F1DMAC0/1_DMRDADRn) is returned to this DMA current destination address register at the end of a DMA transfer.

This register should be set regardless of whether the reload function is enabled.

Notes:

1. Set this register so that a DMA transfer will use addresses aligned to an appropriate address boundary for the transfer unit size selected with DMMONDn.SZSEL.
2. Write to this register only when both these conditions exist:
   (1) The relevant channel is not involved in one-operand transfer (DMA arbitration status register (F1DMAC0/1_DMASTS) DASTS = 0 for that channel).
   (2) DMA transfer is prohibited (DMA start control register (F1DMAC0/1_DMSCNT) DMST = 0 or DMA control register B (F1DMAC0/1_DMCNTBn) DEN = 0).
   If a write to this register occurs in any other case, proper operation is not guaranteed.

46.4.5 F1DMAC0/1 DMA Current Byte Count Register n (F1DMAC0/1_DMCBCTn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	CBC[25:0]									
Initial value:	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

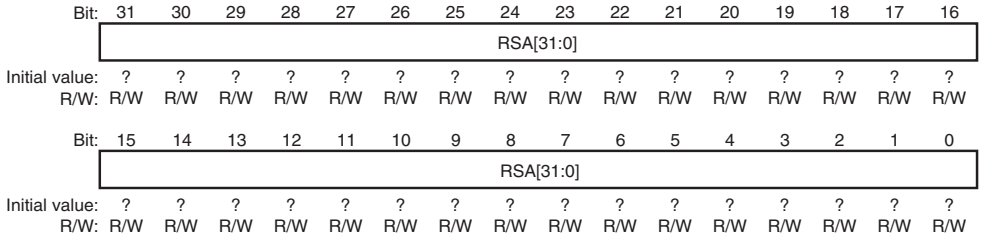
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CBC[25:0]															
Initial value:	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All ?	R	Reserved These bits are always read as 0. The write value should always be 0.
25 to 0	CBC[25:0]	All ?	R/W	Number of DMA transfer bytes

This register is intended to specify the number of DMA transfer bytes. The value in this register is transferred to the work byte count register when a DMA transfer begins. That value is decremented by the specified number of transfer bytes upon each 1-unit transfer. The decrement values are shown below.

- -1 for a transfer unit size of 8 bits (SZSEL = 000)
- -2 for a transfer unit size of 16 bits (SZSEL = 001)
- -4 for a transfer unit size of 32 bits (SZSEL = 010)
- -8 for a transfer unit size of 64 bits (SZSEL = 011)
- -16 for a transfer unit size of 128 bits (SZSEL = 100)

When the value in the work byte counter register becomes H’000 0000, the DMA transfer ends (due to the byte count = 0). At this time, the associated bit in the DMA transfer end detect register (F1DMAC0/1_DMEDET) is set to 1.



When the channel for DMA transfer is switched or when the DMA transfer ends (while the byte count reload function is disabled), the value in the work byte count register is returned to this register. When the DMA transfer ends (while the byte count reload function is enabled), the value in the DMA reload byte count register (F1DMAC0/1_DMRBCTn) is returned to this register.

This register should be set regardless of whether the reload function is enabled or disabled.

Notes:

1. If H'000 0000 is set, a maximum number of 64 Mbytes are transferred.
2. Set this register so that the byte count will be equal to 0 when the last data are transferred during DMA transfer.
3. Write to this register only when both these conditions exist:
   (1) The relevant channel is not involved in one-operand transfer (DMA arbitration status register (F1DMAC0/1_DMASTS) DASTS = 0 for that channel).
   (2) DMA transfer is prohibited (DMA start control register (F1DMAC0/1_DMSCNT) DMST = 0 or DMA control register B (F1DMAC0/1_DMCNTBn) DEN = 0).
   If a write to this register occurs in any other case, proper operation is not guaranteed.

46.4.6 F1DMAC0/1 DMA Reload Source Address Register n (F1DMAC0/1_DMRSADRn)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RSA[31:0]	H'???? ????	R/W	Reload source address A31 to A0

This register is intended to set an address which should be reloaded in the DMA current source address register (F1DMAC0/1_DMCSADRn).

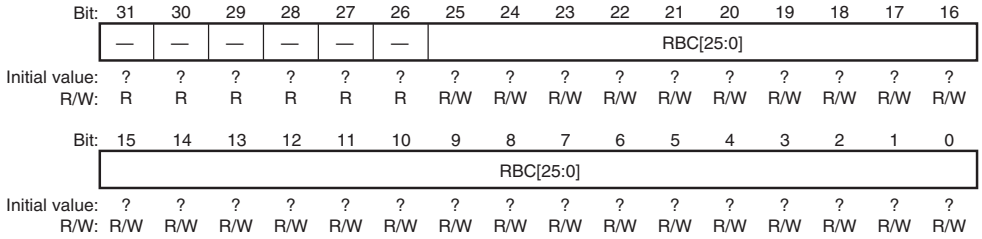
To enable the reload function, set the DMA source address reload function enable bit (SRLOD) of DMA control register A (F1DMAC0/1_DMCNTAn) to 1. Also, set the address in both the DMA current source address register (F1DMAC0/1_DMCSADRn) and DMA reload source address register (F1DMAC0/1_DMRSADRn).

Note: Set this register so that a DMA transfer will use addresses aligned to an appropriate address boundary for the transfer unit size selected with DMMODn.SZSEL.

46.4.7 F1DMAC0/1 DMA Reload Destination Address Register n (F1DMAC0/1_DMRDADRn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RDA[31:0]															
Initial value:	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDA[31:0]															
Initial value:	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDA[31:0]	H'???? ????	R/W	Reload destination address A31 to A0

This register is intended to set an address which should be reloaded in the DMA current destination address register (F1DMAC0/1_DMCDADRn).

To enable the reload function, set the DMA destination address reload function enable bit (F1DMAC0/1_DRLOD) of DMA control register A (F1DMAC0/1_DMCNTAn) to 1. Also, set the address in both the DMA current destination address register (F1DMAC0/1_DMCDADRn) and DMA reload destination address register (F1DMAC0/1_DMRDADRn).

Note: Set this register so that a DMA transfer will use addresses aligned to an appropriate address boundary for the transfer unit size selected with DMMODn.SZSEL.

46.4.8 F1DMAC0/1 DMA Reload Byte Count Register n (F1DMAC0/1_DMRBCTn)

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All ?	R	Reserved These bits are always read as 0. The write value should always be 0.
25 to 0	RBC[25:0]	H'???? ????	R/W	Number of DMA reload transfer bytes

This register is intended to set a byte count which should be reloaded in the DMA current byte count register (F1DMAC0/1_DMCBCTn).

To enable the reload function, set the DMA byte count reload function enable bit (F1DMAC0/1_BRLOD) of DMA control register A (F1DMAC0/1_DMCNTAn) to 1. Also, set the byte count in both the DMA current byte count register (F1DMAC0/1_DMCBCTn) and DMA reload byte count register (F1DMAC0/1_DMRBCTn).

Note: Set this register so that the byte count will be 0 when the last data are transferred during DMA transfer.

46.4.9 F1DMAC0/1 DMA Mode Register n (F1DMAC0/1_DMMODn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	OPSEL[27:24]				—	—	—	—	—	SZSEL[18:16]		
Initial value:	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?	?

3	SACT	B'?	R/W	Source DMA Active-Signal Output Control 0: Does not output the source DMA active signal. 1: Outputs the source DMA active signal at the time of read access.
2	DACT	B'?	R/W	Destination DMA Active-Signal Output Control 0: Does not output the destination DMA active signal. 1: Outputs the destination DMA active signal at the time of write access.

Bit	Bit Name	Initial Value	R/W	Description
1 to 0	DTCM[1:0]	B'??	R/W	DMA End Signal Output Control 00: Stop the TC signal output. 01: Output the TC signal in the last read cycle. 10: Output the TC signal in the last write cycle. 11: Output the TC signal after DMA transfer.

Note: Write to this register only when both these conditions exist:

(1) The relevant channel is not involved in one-operand transfer (DMA arbitration status register (F1DMAC0/1_DMASTS) DASTS = 0 for that channel).

(2) DMA transfer is prohibited (DMA start control register (F1DMAC0/1_DMSCNT) DMST = 0 or DMA control register B (F1DMAC0/1_DMCNTBn) DEN = 0).
If a write to this register occurs in any other case, proper operation is not guaranteed.

(1) OPSEL (1-Operand Transfer Data Count Select) Bits

Use these bits to select a 1-operand transfer data count. The selected number of units of data are repeatedly transferred. Channel arbitration does not take place during any 1-operand transfer.

These bits have no effect if the non-stop transfer option is selected with the DMA transfer condition select bit (DSEL = 11) of DMA control register A (F1DMAC0/1_DMCNTAn).

Note 1: Set the DMA current byte count register (F1DMAC0/1_DMCBCTn) to H000 0000 for the last operand transfer.

- When the transfer unit size is 8 bits (SZSEL = 000):
  Number equal to an integer multiple of the 1-operand transfer data count (× 1, × 2, × 3, etc.)
- When the transfer unit size is 16 bits (SZSEL = 001):
  Number equal to the 1-operand transfer data count times a multiple of 2 (× 2, × 4, × 6, etc.)
- When the transfer unit size is 32 bits (SZSEL = 010):
  Number equal to the 1-operand transfer data count times a multiple of 4 (× 4, × 8, × 12, etc.)
- When the transfer unit size is 64 bits (SZSEL = 011):
  Number equal to the 1-operand transfer data count times a multiple of 8 (× 8, × 16, × 24, etc.)
- When the transfer unit size is 128 bits (SZSEL = 100):
  Number equal to the 1-operand transfer data count times a multiple of 16 (× 16, × 32, × 48, etc.)

If anything else is specified, proper operation is not guaranteed. (see section 46.4.5, F1DMAC0/1 DMA Current Byte Count Register n (F1DMAC0/1_DMCBCTn), and section 46.4.8, F1DMAC0/1 DMA Reload Byte Count Register n (F1DMAC0/1_DMRBCTn), for details).

(2) SZSEL (Transfer Unit Size Select) Bits

Use these bits to select the 1-unit transfer size.

This unit of transfer can be a byte (8 bits), half word (16 bits), word (32 bits), double word (64 bits) or quad word (128 bits).

The selected size should not exceed the bit width of the data bus supported by the source and destination for DMA transfer. This data bus width is specific to hardware.

Note: For fly-by transfer, set the value equal to the bit width of the target SDRAM device (F1 port).

(3) SAMOD (Source Address Direction Control) Bits

Use these bits to select a count direction for the source address.

If these bits are set to 100 (2D addressing), the destination address direction control bits (DAMOD) cannot be set to 100.

Notes: 1. These bits have no effect if the fly-by transfer direction bits (FBDIR) are set to 10 for fly-by mode (i.e., if the F1 bus is selected for the source).
2. For pipeline-mode DMA transfer to the SDRAM device, select only 001 (increment), 011 (rotate) or 100 (2D addressing). Do not select 000 (factory fixed) or 010 (decrement).

(4) DAMOD (Destination Address Direction Control) Bits

Use these bits to select a count direction for the destination address.

If these bits are set to 100 (2D addressing), the source address direction control bits (SAMOD) cannot be set to 100.

Notes: 1. These bits have no effect if the fly-by transfer direction bits (FBDIR) are set to 01 for fly-by mode (i.e., if the F1 bus is selected for the destination).
2. For pipeline-mode DMA transfer to the SDRAM device, select only 001 (increment), 011 (rotate) or 100 (2D addressing). Do not select 000 (factory fixed) or 010 (decrement).

Table 46.14 shows the counter decrement and increment values for the DMA source/destination address register (see section 46.4.40, Rotate Function, for details about the rotate function for addressing mode). If 2D addressing is selected with these bits (SAMOD or DAMOD), the current 2D addressing registers and reload 2D addressing registers are enabled (these registers are described in section 46.4.18 and later).

For pipeline or fly-by transfer to an external device or module which supports burst access, be sure to select 001 (increment), 011 (rotate) or 100 (2D addressing).

Table 46.14 Counter Increment/Decrement Values for the DMA Source/Destination Address Register

	Addressing Mode SAMOD or DAMOD				
Transfer Unit Size Select Bits (SZSEL)	**000 (Factory-fixed)**	**001 (Plus)**	**010 (Minus)**	**011 (Rotate)**	**100 (2D)**
000 (8 bits)	±0	+1	-1	+1	+1
001 (16 bits)	±0	+2	-2	+2	+2
010 (32 bits)	±0	+4	-4	+4	+4
011 (64 bits)	±0	+8	-8	+8	+8
100 (128 bits)	±0	+16	-16	+16	+16

(5) SACT (Source DMA Active-Signal Output Control) Bit

Use this bit to control the output of the source DMA active signal (DMAACTS_N) associated with the request factor specified with the DCTG bits.

If this bit is set to 0, the DMAACTS_N signal is fixed at the "H" level and is not output as a valid signal.

If set to 1, the DMAACTS_N signal is set at the "L" level and output as a valid signal for the second and subsequent DMAC read cycles.

If the software trigger is selected with the DMA request factor select bits (DCTG), the DMAACTS0_N signal is output.

(6) DACT (Destination DMA Active-Signal Output Control) Bit

Use this bit to control the output of the destination DMA active signal (DMAACTD_N) associated with the request factor specified with the DCTG bits.

If this bit is set to 0, the DMAACTD_N signal is fixed at the "H" level and is not output as a valid signal.

If set to 1, the DMAACTD_N signal is set at the "L" level and is output as a valid signal for the second and subsequent DMAC write cycles.

If the software trigger is selected with the DMA request factor select bits (DCTG), the DMAACTD0_N signal is output.

(7) DTCM (DMA End Signal Output Control) Bits

Use these bits to control the output of the DMA end signal (DMATC_N) which is provided when the DMA transfer end condition is detected.

If these bits are set to 00, the DMATC_N signal is fixed at the "H" level and is not output as a valid signal when DMA transfer ends.

If set to 01, the DMATC_N signal is output as a valid signal during the cycle subsequent to the read cycle immediately before the end of DMA transfer.

If set to 10, the DMATC_N signal is output as a valid signal during the cycle subsequent to the write cycle immediately before the end of DMA transfer.

If set to 11, the DMATC_N signal is output as an "L" pulse signal for one clock at the time of DMA transfer end interrupt.

If the software trigger is selected with the DMA request factor select bits (DCTG), the DMATC0_N signal is output.

If a request factor from the on-chip peripheral circuit is selected with the DMA request factor select bits (DCTG), the DMATC_N signal is not output as a valid signal regardless of the settings of the DTCM bits.

If the fly-by mode is selected (MDSEL = 10), set the DTCM bits to 00.

7 to 6	—	B'00	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5 to 0	DCTG[5:0]	All 0	R/W	DMA Request Factor Select 000000: Software trigger 000001 - 001000: DMA request signal 001001 and above: Reserved (Refer to table 46.3, F1DMAC(0) Source Assignments and table 46.4, F1DMAC(1) Source Assignments.)

Notes: Change the bits of DMA control register A (F1DMAC0/1_DMCNTAn) other than its reload function enable bits (BRLOD, SRLOD and DRLOD) only when both these conditions exist:

1. The relevant channel is not involved in 1-operand transfer (DMA arbitration status register (F1DMAC0/1_DMASTS) DASTS = 0 for that channel).
2. DMA transfer is prohibited (DMA start control register (F1DMAC0/1_DMSCNT) DMST = 0 or DMA control register B (F1DMAC0/1_DMCNTBn) DEN = 0).
   If a write to this register occurs in any other case, proper operation is not guaranteed.

(1) MDSEL (DMA Transfer Mode Select) Bits

Use these bits to select a DMA transfer mode.

If these bits are set to 00, the cycle stealing mode is selected.

If set to 01, the pipeline mode is selected.

If set to 10, the fly-by mode is selected.

Do not set these bits to 11. If this is done, proper operation is not guaranteed (see 46.4.33, DMA Transfer Modes, for details).

Notes: 1. The non-stop transfer option (DSEL = 11) cannot be selected for pipeline mode (MDSEL = 01) if the source or destination is an SDRAM device.
2. The non-stop transfer option (DSEL = 11) cannot be selected for fly-by mode (MDSEL = 10).

(2) DSEL (DMA Transfer Condition Select) Bits

Use these bits to select a type of DMA transfer.

If these bits are set to 00, a single-operand transfer is performed.

If set to 01, a consecutive-operand transfer is performed.

If set to 11, a non-stop transfer is performed (see section 46.4.34, DMA Transfers, for details).

Do not set these bits to 10. If this is done, proper operation cannot be guaranteed.

(3) FBDIR (DMA Fly-by Transfer Direction Select) Bits

Use these bits to select a fly-by transfer direction.

If these bits are set to 01, a transfer from the SDRAM device to the F1DMAC-connected module is performed.

If set to 10, a transfer from the F1DMAC-connected module to the SDRAM device is performed.

These bits are only valid for fly-by mode (MDSEL = 10).

If a wrong transfer direction is selected, proper operation is not guaranteed.

(4) STRG (Input Sense Mode Select) Bits

Use these bits to select an input sense mode, based on the request factor selected with the DMA request factor select bits (DCTG), for DMA request signals which are input to the DMAC. These bits are valid when the request factor is a DMA request signal (DCTG = 000001 to 111111).

If the software trigger is selected with the request factor select bits (DCTG = 000000), set the STRG bits to 00 for rising-edge sensing.

(5) BKEEP (Bus Mastership Keep Function Enable) Bit

Use this bit, associated with the selected channel, to control whether the request for slave bus mastership should be still valid when there is a subsequent DMA transfer request after the preceding operand transfer.

If this bit is set to 0, the request for bus mastership is negated until the next operand transfer begins. If any other bus master issues an access request while the request is negated, the F1DMACI/F for each slave can accept that access request.

If set to 1, the request for slave bus mastership continues to be valid until the next operand transfer begins. Then, the subsequent operands are transferred one after another. If any other bus master issues an access request while the request is valid, the F1DMACI/F for each slave cannot accept that access request.

This bit is enabled only when the fly by mode is selected (MDSEL = 10).

(6) 2DRLOD (2D Reload Function Enable) Bit

Use this bit to select whether to enable or disable reloading data into the six current 2D addressing registers when the DMA transfer end condition is detected.

If this bit is cleared to 0, no data are reloaded into the six current 2D addressing registers.

If set to 1, the contents of the six 2D addressing registers are reloaded into the current 2D addressing registers when the DMA transfer end condition is detected.

If the 2D addressing function is not implemented, this bit should be always read as 0.

(7) BRLOD (DMA Byte Count Reload Function Enable) Bit

Use this bit to select whether to enable or disable reloading the byte count when the DMA transfer end condition is detected.

If this bit is cleared to 0, no data are reloaded.

If set to 1, the contents of the DMA reload byte count register (F1DMAC0/1_DMRBCTn) are reloaded into the DMA current byte count register (F1DMAC0/1_DMCBCTn) when the DMA transfer end condition is detected.

(8) SRLOD (DMA Source Address Reload Function Enable) Bit

Use this bit to select whether to enable or disable reloading the source address when the DMA transfer end condition is detected.

If this bit is cleared to 0, no data are reloaded.

If set to 1, the contents of the DMA reload source address register (F1DMAC0/1_DMRSADRn) are reloaded into the DMA current source address register (F1DMAC0/1_DMCSADRn) when the DMA transfer end condition is detected.

(9) DRLOD (DMA Destination Address Reload Function Enable) Bit

Use this bit to select whether to enable or disable reloading the destination address when the DMA transfer end condition is detected.

If this bit is cleared to 0, no data are reloaded.

If set to 1, the contents of the DMA reload destination address register (F1DMAC0/1_DMRDADRn) are reloaded into the DMA current destination address register (F1DMAC0/1_DMCDADRn) when the DMA transfer end condition is detected.

(10) DCTG (DMA Request Factor Select) Bits

Use these bits to select a DMA request factor.

(Refer to table 46.3, F1DMAC(0) Source Assignments and table 46.4, F1DMAC(1) Source Assignments.)

46.4.11 F1DMAC0/1 DMA Control Register Bn (F1DMAC0/1_DMCNTBn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	DEN	—	—	—	—	—	—	—	DREQ

R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	DEN	B'0	R/W	DMA transfer enable 0: Disables DMA transfer. 1: Enables DMA transfer.
23 to 17	—	B'00	R	Reserved These bits are always read as 0. The write value should always be 0.
16	DREQ	B'0	R/W	DMA request 0: Does not generate a DMA request. 1: Generates a DMA request.
15 to 9	—	B'00	R	Reserved These bits are always read as 0. The write value should always be 0.
8	ECLR	B'0	R/W	DMA transfer enable clear 0: Does not clear the DMA transfer enable bit to 0 when the DMA transfer end condition is detected. 1: Clears the DMA transfer enable bit to 0 when the DMA transfer end condition is detected.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	DSCLR	B'0	R/*	DMAC internal status clear Read: This bit is read as 0. Write: 0: Invalid 1: Initializes the DMAC internal status.

Note: If the software trigger is selected as the DMA request factor, the DMA request (DREQ) bit can be set to 1 regardless of the DMA transfer enable (DEN) and DMAC module start (DMST) bit settings and of the operand transfer status. Even if that option is selected, clear the DMA request (DREQ) bit to 0 and write to the DMAC internal status clear (DSCLR) bit only when both these conditions are satisfied:

(1) The relevant channel is not involved in 1-operand transfer (DMA arbitration status register (F1DMAC0/1_DMASTS) DASTS = 0 for that channel).

(2) DMA transfer is prohibited (DMA start control register (F1DMAC0/1_DMSCNT) DMST = 0 or DMA control register B (F1DMAC0/1_DMCNTBn) DEN = 0).
If a write to this register occurs in any other cases, proper operation is not guaranteed.

* Indicate that writing 0 has no effect and that a value of 1 is not held after it is written.

(1) DEN (DMA Transfer Enable) Bit

Use this bit to disable or enable a DMA transfer.

If this bit is set to 0, a DMA transfer via the relevant channel is disabled.

If set to 1, a DMA transfer via the relevant channel is enabled (see section 46.4.35, DMA Startup, for information about the start of DMA transfer).

Even if this bit is 0, the DMA request (DREQ) bit changes due to a DMA request made to the DMAC.

This bit is cleared to 0 automatically when the DMA transfer end condition is detected if the DMA transfer enable (ECLR) bit = 1.

If this bit is cleared to 0 during DMA transfer, the relevant channel can be made inactive after the end of 1-operand transfer (see section 46.4.36 (4), Suspending, Resuming and Aborting a DMA Transfer, for details).

(2) DREQ (DMA Request) Bit

Use this bit to determine the presence or absence of a DMA request.

This bit is available to handle DMA requests if the software trigger is selected with the DMA request factor select bits (DCTG = 000000).

This bit changes depending on the status of the DMA request input to the DMAC regardless of the settings of both DMAC module start bit (DMST) and DMA transfer enable bit (DEN). The conditions which cause the DREQ bit to be set and cleared depend on the settings of both DMA request factor select bit (DCTG) and input sense mode select bit (STRG) as shown below.

<When the Software Trigger Is Selected with the DMA Request Factor Select Bits (DCTG)>

- Setting Condition
  The DREQ bit is set to 1 if 1 is written to it by software. As a result, a DMA request is generated.
- Clearing Condition
  The DREQ bit is cleared to 0 if one of these actions is taken:
  — Write 0 to this bit by software.
  — Start an operand transfer associated with this bit.

<When an Option Other Than the Software Trigger Is Selected with the DMA Request Factor Select Bits (DCTG) and the Level Sense Mode Is Selected>

- Setting Condition

The DREQ bit is set to 1 if there is a match between the level selected with the input sense mode select bit (STRG) and the DMA request input level (i.e., if there is a DMA request).

- Clearing Condition

The DREQ bit is cleared to 0 if there is not a match between the level selected with the input sense mode select bit (STRG) and the DMA request input level (i.e., if there is not a DMA request).
