Section 1-A SH-Mobile AP4 Overview

1-A.1 Overview of SH-Mobile AP4

The features of this LSI are listed in table 1.1.

Table1-A.1 Features of this LSI

Item		Features
System CPU	CPU	- ARM Cortex-A8 - 800MHz operation - VIC (vector interrupt function) incorporated - Supports the core standby mode - Trust Zone support - Jazzle-RCT
	VFP	- VFP support
	DSP	- NEON support
	MMU	- MMU support
	Cache	- I-Cache 32K Bytes(L1) - D-Cache 32K Bytes(L1) - Unified Cache 256K Bytes(L2)
	ETM	- Cortex-A8 ETM support - Coresignt ETB (4K Bytes) incorporated
Realtime CPU	CPU	- Renesas Technology original architecture (SH4AL-DSP) - 400MHz operation - RISC-type instruction set (upward compatible with SH series) - Super scalar design which executes two instructions simultaneously - Virtual address space: 4Gbytes - Eight-stage pipeline - Supports the core standby mode
	User break controller (UBC)	- For AP realtime CPU All of address, data values, access types, and data sizes can be specified as break conditions - Sequential break function supported Two break channels
	User debugging interface (H-UDI)	- E10A emulator for AP realtime CPU supported - Realtime branch trace - 4-Kbyte on-chip memory for executing high-speed emulation program

Item		Features
	DSP	- 400MHz operation - Mixture of 16-bit and 32-bit instructions - Multiplier, ALU, and barrel shifter - Extended Hardvard architecture for DSP data bus - Maximum of four parallel operations - Zero-overhead repeat loop control
	Memory management unit (MMU)	- 4-Gbyte address space, 256 address spaces (8-bit ASID) - Single virtual memory mode and multiple virtual memory mode - Supports multiple page sizes: 1 Kbyte, 4 Kbytes, 8 Kbytes, 64 Kbytes, 256 Kbytes, 1 Mbyte, 4 Mbytes, and 64 Mbytes - 4-entry full associative TLB for instructions - 64-entry full associative TLB for instructions and operands - Address mapping allows direct access to TLB contents
	Cache memory	- Instruction cache (IC) 32-Kbyte, 4-way set associative 32-byte block length - Operand cache (OC) 32-Kbyte, 4-way set associative 32-byte block length Selectable write mode (copy-back or write-through)
	X/Y memory	- Four independent read/write ports 8-/16-/32-bit operand access from CPU with virtual address Maximum two 16-bit access from DSP 8-/16-/32-bit operand access from CPU with physical address or instruction fetch access from CPU 8-/16-/32-/64-bit or 16-/32-byte access by external requests - Total of 16 Kbytes Memory protective functions specialized for DSP access in addition to memory protective functions for CPU access
Interrupt controller (INTC)		- 32 interrupt pins which can detect external interrupts - Fall/rise/high level/low level detection is selectable. - On-chip peripheral interrupts: Priority can be specified for each module - Supports Trust Zone

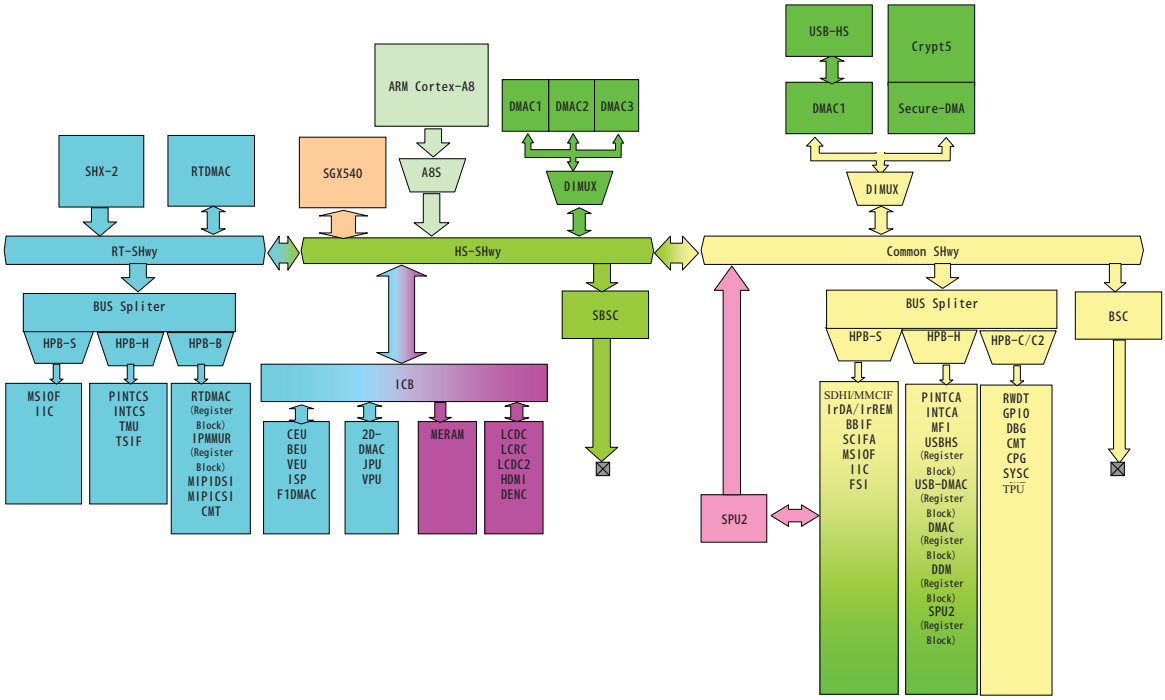
Item	Features
Direct memory access controller (DMAC)	- 18 channels for system domain, 12 channels for realtime domain - Address space: 4 Gbytes on architecture - Data transfer length: Bytes, words(2 bytes), longwords(4 bytes), 8 bytes, 16 bytes, 32 bytes and 64bytes - Maximum number of transfer times: 16,777,216 times - Address mode: Dual address mode - Transfer request: Selectable from on-chip peripheral module request and auto request - Bus mode: Selectable from cycle steal mode (normal mode and intermittent mode) and burst mode - Priority: Selectable from fixed channel priority mode and round-robin mode - Interrupt request: Supports interrupt request to CPU at the end of data transfer - Repeat function: Automatically resets the transfer source, destination, and count at the end of DMA transfer - Reload function: Automatically resets the transfer source, destination at the end of the specified number of DMA transfers - Half end interrupt, n/4 transfer end interrupt, m/8 transfer end interrupt support - High-speed transfer to peripheral modules with multi-byte transfer function(16 bit x 8, 32 bit x 4)
Timer Unit (TMU)	- 2 sets of 3 channel 32-bit timer (in realtime domain) - Auto-reload type 32-bit down counter - Internal prescaler for SUBϕ - Interrupt request
Timer pulse Unit (TPU)	- 4 channel 16-bit timers - Each channel outputs PWM
Compare match Timer (CMT)	- 32-bit timer, 10 channel (16 bits/32 bits can be selected) - Source clock : RCLK/system clock - Compare match function provided - Interrupt requests - 1 of 10 channel supports DMA request

Item	Features
Clock-synchronized serial interface with FIFO (MSIOF)	- Internal 5 channels (MSIOF: 4 channels on system domain, 1 channel on real-time domain) - Internal 64 Byte transmit FIFOs/internal 256 Byte receive FIFOs - Clock synchronous serial master/slave mode, support full-duplex communication Supports 8/16 bit data and 16-bit stereo audio input/output Support 24bit stereo audio input/output Sampling rate clock input selectable from SUBϕ and external pin Internal prescaler - SPI master/slave mode, support full-duplex communication Serial clock(SCK) rise/fall edge selectable for data sampling timig SCK clock phase selectable for transmit timing 3 slave devices selectable Transmit/receive data length selectable from 8, 16, 32bits - Interrupt request, DMAC request, and DMA multi-byte transfer supported
Serial communication interface with FIFO (SCIFA)	- 6 channels - Internal 64-byte transmit/receive FIFOs - High-speed UART - Internal prescaler for SUBϕ - Clock synchronous serial communications possible - Support edge selection function - Interrupt request, DMAC request and DMA multi-byte transfer supported
Serial communication interface with FIFO (SCIFB)	- 1channel - Internal 256-byte transmit/receive FIFOs - High-speed UART - Internal prescaler for SUBϕ - Clock synchronous serial communications possible - Support edge selection function - Interrupt request, DMAC request and DMA multi-byte transfer supported
I2C bus interface (IIC)	- 5 channels - Supports single master transmission/reception - Interrupt request - DMAC request

Item	Features
NAND flash memory controller (FLCTL)	- Directly connected memory interface with NAND-type flash memory - Read/write in sectors - Two types of transfer modes: Command access mode and sector access mode (512-byte data + 16-byte management code: with ECC) - Supports up to 16Gbit of flash memory - 4 symbols correction - Interrupt request, DMAC request and DMA multi-byte transfer supported - Bus arbitration functions between BSC(NOR Flash) access and FLCTL access - Supports 2K Byte page
Multifunctional interface (MFI)	- One channel (BSC and asynchronous bus are connected between 2 CPUs) - Data can be read/written in 32 bits from/to shared on-chip RAM (MFRAM: 1 Kbyte) between CPUs - MFRAM is accessible from MFI/CPU. - Data can be transferred between CPUs using MFRAM and interrupt function along with software. - Seven external source bits for controlling 128 types of interrupts
Multifunctional interface2 (MFI2)	- Interface providing high-speed data transfer to/from external devices that cannot share any system buses - Data can be read/written in 32 bits from/to on-chip RAM (MFRAM: 8 KBytes) - Also direct accessing to DDR-RAM of SH-Mobile is available. - MFRAM is accessible from MFI/CPU. - Data can be transferred between this LSI and external devices using MFRAM and interrupt function along with software. - Internal boot access that considers MFRAM a reset vector - Internal semaphore register in MFI that allows read modify write transfer when reading data from baseband side - Seven external source bits for controlling 128 types of interrupts
USB Host & Function Module (USB)	- 2 channels supported - USB Host -Compliance with USB2.0 -Support OTG Dual-Role devices - USB Function -Compliance with USB2.0 (High-Speed) -Module input Clock: 48MHz, internally 480MHz generated - Interrupt request - Internal dedicated DMA - 3.3V power for USB-PHY can be off while not using.

Item	Features
Encryption Engine (Crypto Cell5.2)	- PKA Engine -Diffie-Hellman -RSA - Hash Engine -SHA1 -SHA-256 -MD5 - Bulk Encryption Engine -DES,3DES -AES - Internal Digital Random Number Generator (RNG) - On-chip secure DMA as SHwy master - Multi-Flow Manager function is added.
Sound Processing Unit (SPU2)	- On-chip Audio-DSP (24-bit Dual MAC) - Dedicated DMAC: 3 channels - Direct connection interface with FSI, FMSI, and BBIF2 - PRAM 192K Byte, XRAM 192K Byte, YRAM 96K Byte
IPMMU	- Hardware IP makes memory area (controlled by OS) accessible by virtual address. - Compatible with MMU of ARMv6 architecture - Hardware page table walk function - 64 entry TLB - IP which can use IPMMU is as below. ISP, CEU, VEU, BEU, VPU, 2D-DMAC, LCDC, JPU, RT-DMAC
Capture Engine Unit (CEU)	- CEU Block (image capturing from camera module) (a)Camera module interface Data (8 bits: YCbCr 4:2:2), horizontal sync signal (HD), vertical sync signal (VD) JPEG camera interface with data enable and variable data length capturing as parallel interface Connection with MIPI-CSI2 interface (b) Size of captured image: 15M pixels, 8M pixels, 5M pixels, 3M pixels, 2M pixels UXGA, SXGA, XGA, VGA, CIF, QVGA, QCIF, QQVGA, Sub-QCIF,48 x 48, (configuration is up to 8000 x 8000) (c) Output image format: YCbCr4:2:2, YCbCr4:2:0, JPEG data (d) Image format conversion function Reduced image generating prefilter function YCbCr 4:2:2 to YCbCr4:2:2, YCbCr4:2:0 YCbCr format(Y:8bit /CbCr:16bit) (e) Edge selection for capture clock (f) Frame drop function (1/2, 1/3, 1/4, 1/5, 1/6 drop)

Item	Features
Video Engine Unit (VEU)	VEU block (Image processing in memory) - 4 blocks are embedded. (2 blocks have FIR filter) (a) Video image processing function Input image format: YCbCr image (Y/CbCr plane image), RGB image (RGB pack image) Output image format: YCbCr image (Y/CbCr plane image), RGB image (RGB pack image) Image processing function: -Scaling image generating filter function (input up to 8188 x 8188, output up to 4092 x 4092) - YcbCr to RGB / RGB to YCbCr conversion function - Dithering function (in RGB color subtraction) (b) Filter processing function - Mirroring, vertical inversion, point symmetry - Deblocking filter - Median filter (c) Video image processing and filter processing combined operation.
Blend Engine unit (BEU)	BEU block (Image blending) - 3 blocks are embedded. (a) Blend function - Input image format: YCbCr image (Y/CbCr plane image), A+YCbCr image (A+YCbCr pack image), RGB image (RGB pack image), ARGB Image (ARGB pack image), A+RGB image (A + RGB pack image) - Output image format: YCbCr image (Y/CbCr plane image), A+YCbCr image (A+YCbCr pack image),RGB image (RGB pack image), ARGB image (ARGB pack image), A+RGB image (A + RGB pack image) (b) OSD function - Input format: RGB, ARGB/ YCbCr, AYCbCr image - Output format: RGB, ARGB/ YCbCr, AYCbCr image (c) Blend and OSD operation Two PinP planes and one OSD plane can be blended simultaneously (d) Results of processing are written back to memory
2 Dimensional DMAC (2DDMAC)	- Supports 8 channels transfer (In case of YUV, channels are assigned to Y plane and UV plane respectively). - Supports the image clipping by 1-pixel for RGB and by 2-pixel for YUV. - Function to inverse vertically or horizontally and rotate 90, 270 degree - The format conversion between various RGB formats - The image is scaled up by a factor of 2 in the X direction and the Y direction, respectively



Item	Features
Video Processing Unit (VPU)	- Applicable standard: - H.264 : High Profile, Main Profile, Baseline Profile - MPEG-2: Main Profile - MPEG-4: Advanced Simple Profile (*) - H.263: Baseline - VC-1: Simple Profile, Main Profile, Advanced Profile Note: (*) Some Tools (ASO/FMO/RS) are not supported - Image size: Sub-QCIF to D1, 1280X720, 1920X1080 - Bit Rate: Maximum 40 Mbps
LCD- Controller (LCDC)	- Supported LCD panel: TFT color LCD, WXGA+ - Input data format: 8, 12, 16, 18, 24, or 32bpp - LCD driver interface — Specialized LCD bus, independent of memory bus — RGB interface or 80-series CPU bus interface selectable — Bus width: 8, 9, 12, 16, 18, or 24 bits — One-pixel one-time, two-time, or three-time transfer mode selectable — Signal polarity and SYNC output timing and width programmable in RGB interface — Access cycle programmable in 80-series CPU bus interface - Dot clock: Bus clock, peripheral clock, or external clock selectable as the source clock - Display data fetch: Continuous mode according to the refresh rate of the LCD panel and one-shot mode according to the frame rate of the movie are supported. Image data can be fetched only for updated sections. - Maximum Display Size : 1440 x 900 - Built-in 256-entry, 24-bit-output color palette - Interrupt can be generated it on the user-specified line - Maximum 1.5MByte Frame data cache available on ICB. Auto-refresh on ICB without external memory accessing - Blend function - MIPI-DSI (Max. 850MHz, 4lane) connectable
Media RAM (MERAM)	- 1.5MByte size - Manageable up to maximum 32line buffer - Can be used as Read-fill Buffer & Write-back Buffer for Multi-Media-IPs such as VPU, VEU,etc. - Can be used as intermediate buffer between 2 Multi-Media-IPs. - On-chip tile linear conversion supported in IPMMU of MERAM. - Read-fill and Write-back Buffers are managable by a block. Buffer size for IP which performs tile access can be reduced. - Relevant IPs : CEU, VEU0-3, BEU0-2, 2D-DMAC, VPU, LCDC, JPU, ISP & SHwy Bus target.

Item	Features
JPEG Processing Unit (JPU)	- Conforming specification: JPEG baseline - Operating precision: Conforming to JPEG Part 2, ISO-IEC10918-2 - Color format: YCbCr 4:2:2, YCbCr 4:2:0 - Quantization tables: Four tables - Huffman tables: Four tables (two AC tables, two DC tables) - Target markers: Start of image (SOI), start of frame type 0 (SOF0), start of scan (SOS), define quantization tables (DQT), define Huffman tables (DHT), define restart interval (DRI), restart (RSTm), end of image (EOI)
3D Graphic Engine	- Imagination Technologies SGX 540 - Universal Scalable Shader Engine(USSE) - Programmable architecture - Latency tolerant architecture - Internal True Colour - Video processing for multi-standard video decode and encode - API Support :OpenGL ES1.1/2.0,Open VG, Direct 3D Mobile
TS Interface (TSIF)	- 1 channel - Serial TS data input - Filters for 26 kinds of PIDs in total (The PID values of PAT and CAT packets are fixed. For PCR, video, and audio packets, the PID values are predefined.) - ISDB-T 3-segment compliant (Max. 2Mbps) - DMA Multi byte transfer
FIFO attached Serial Interface (FSI/FMSI)	- 24bit Stereo Quality (FMSI also supports 16bit) - Supports PCM & I2S formats - Supports SPDIF - Serial Input/Output can be directly connected with external A/D, D/A converter. - Connected with SPU2 internally
IrDA controller (IrDA)	- IrDA 1.1/1.3 compliant , SIR/MIR/FIR supported - Auto receive mode available. - Transfer unit : Frame
MIPI camera serial interface 2 (CSI2)	- 2 channels (MAIN:4 lanes , SUB :2 lanes) data interface - SUB channels can receive YUB420, YUB422 and generic format packet with CEU. - MAIN channels can receive RAW8,RAW10 and RAW12 format packet with ISP. - Frequency: up to 850MHz / Lane
MIPI display serial interface (DSI)	- 2 channels (4 lanes and 2 lanes) for main and sub displays - Supports video mode output linked to LCDC(RGB565, RGB666, loosely-packed666, RGB888) - DMA controller included for command mode, 4ch transfer available - Interleaved command packet output in video mode supported. - Frequency: up to 850MHz / Lane
HDMI	- HDMI v1.3a / DVI v1.0 Transmitter with HDCP v1.2 compliant - HDMI PHY Integrated - Internal NV memory for HDCP Key - 5.1ch multi-channel Audio supported up to 192kHz - CEC support

Item	Features
Image Signal Processor (ISP)	- Max 16M pixels Still Images & Full HD1080p Movie images - Recoding format: JPEG (DCF / Exif2.21 compliant), DPOF (Ver1.1), YCbCr4:2:2 file - Sensor format: 8/10bit RAW - 3A controller: AF, AE and AWB - Lens Shading & Distortion Compensation for Sensor - Defect Pixel Correction for Sensor - Anti-Shake Image Stabilization Functions - Intelligent Image Noise Reduction Features: Multi-band Filter, Specific Color Filter
MIPI-HSI	- Interface providing high-speed data transfer to/from external devices. - MIPI HSI ver 1.01.00 base - Two pairs of uni-directional transmitter/receiver pairs, where both pairs consist of two data signals and two control signals. - Transfer speed: 100Mbit/sec(Max)
MMCIF	- eMMC controllable - Data bus : 1/4/8 bit MMC mode (not support SPI mode) - Support block transfer (not support stream transfer) - Block size in multi-block transfer : 512 byte
SD card host interface (SDHI)	- 3 channels supported - SD memory & I/O card interface - Card Detection Function - Interrupt Request & DMA transfer request - High-Speed support - High Capacity support
Bus State Controller (BSC)	- Supports 6 Physical address areas in total: two areas (areas 0 and 2) of up to 128 Mbytes each, one area (area 4) of up to 64 Mbytes, and three areas (areas 5A, 5B and 6A) of up to 32 Mbytes each. Chip select signal assigned to each area respectively. - Data bus width: 16 bits - Setup/Hold timing setting individually at Read/Write - Address/Data Multiplexed memory support (Up to 1Gbit case) - Address/Data Non-Multiplexed memory support (Up to 1Gbit case) - Synchronous access & Page access functions of the asynchronous bus added - 4/8 word changeable in Page-mode - BS Pulse width adjustment function available
Bus State controller for SDRAM (SBSC)	- LPDDR2-SDRAM(S4) can be directly connected - Up to 2Git memory x2 can be connected - Data bus width 64/32 bit - Auto Refresh / Self Refresh/ Partial Refresh Supported - Deep-Power-Down-Mode supported - Auto Pre-charge Mode / Bank Active Mode

Item	Features
Clock Pulse Generator (CPG)	- Generates the clocks from 26MHz External Clock (EXTAL1). Maximum CPU Clock System : 806MHz (Zϕ), Real Time : 398.6MHz(Iϕ) Maximum BUS Clock SHwy (RT/HS/Common) : 199.3MHz(ZSϕ) Maximum SDRAM bus clock : 199.3MHz(ZB3ϕ) Media Clock : 99.7MHz (Bϕ) BSC bus clock : 99,7MHz(ZBϕ) Maximum Peripheral Clock 99.7MHz(HPϕ) - Power-Down Mode supported. Core-Standby Mode supported. Module-Standby Mode supported
System Controller (SYSC)	- Control for Internal Power-Domain (Power-On, Shut Down & Resume) - Booting & reset controls for System-CPU, Real-Time CPU
RCLK Watchdog timer (RWDT)	- Internal 32-bit watchdog timer operated by RCLK RCLK input is necessary for LSI operation. - Programmable Overflow time-period : minimum 7.8ms~maximun 30min
I/O Port	- Individual setting below available for pins except some pins. Output ON/Off, Input On/Off, Pull-Down On/Off, Pull-Up On/Off, GPIO On/Off - Set & reset function for Port Data Register supported.
Endien	- Little Endian support
Package	- 12mm x 12mm , Height is T.B.D., Number of pins is 561., POP
Voltage	- I/O: 2.7~3.6V (Power Switching Macro) 1.65V~1.95V(eSD)/2.7V~3.6V (SDHI) 3.0V~3.6V (USB) 1.65V~1.95V (Others) - LPDDR2-SDRAM I/O: 1.14V~1.28V (1.2V typ.) - HDMI: 1.1V~1.2V , 2.25V~ 2.75V - Core: 1.1V~1.2V (1.15VTyp.)
Process	45nm Low Power CMOS Process Technology

1-A.2 SH-Mobile AP4 Block

Section 1-B Address Maps

1-B.1 Overview of Address Map

In this LSI, the domains are connected by a bridge, and each domain can access the other domain's resource through the bridge address defined by each domain. The address defined by each domain is used to access the same position in the memory space and common resources.

Table 1-B.1 Address Maps 1

Address	Target	Remarks
H'00000000 to H'07FFFFFF	BSC	Area 0 *4
H'08000000 to H'0FFFFFFF	BSC	Area 2 *4
H'10000000 to H'13FFFFFF	BSC	Area 4
H'14000000 to H'15FFFFFF	BSC	Area 5A
H'16000000 to H'17FFFFFF	BSC	Area 5B
H'18000000 to H'19FFFFFF	BSC	Area 6A
H'1A000000 to H'1BFFFFFF	BSC	Area 6B
H'1C000000 to H'1DFFFFFF	BSC	Area 7A
H'1E000000 to H'1FFFFFFF	BSC	Area 7B
H'20000000 to H'2FFFFFFF	BSC	H'00000000 to H'0FFFFFFF mirrored
H'30000000 to H'37FFFFFF	BSC	H'00000000 to H'07FFFFFF mirrored
H'38000000 to H'3FFFFFFF	Router	Address error *1
H'40000000 to H'5FFFFFFF	SBSC1	DRAM areas 0 and 1 *3
H'60000000 to H'7FFFFFFF	Router	Address error *1
H'80000000 to H'BFFFFFFF	Router	Address error *1
H'C0000000 to H'DFFFFFFF	Router	Address error *1
H'E0000000 to H'E0FFFFFF	Router	Address error *1
H'E1000000 to H'E1FFFFFF	Router	Address error *1
H'E2000000 to H'E2FFFFFF	Router	Address error *1
H'E3000000 to H'E3FFFFFF	Router	Address error *1
H'E4000000 to H'E4FFFFFF	Router	Address error *1

Address	Target	Remarks
H'E5000000 to H'E54FFFFF	AP realtime core	On-chip memory in AP-realtime core (XYRAM)
H'E5500000 to H'E56FFFFF	ICB register/MERAM	MERAM start address is H'E5580000
H'E5700000 to H'E5FFFFFF	Router	Address error *1
H'E6000000 to H'E6FFFFFF	HPBC	Peripheral module (system domain)
H'E7000000 to H'E7FFFFFF	HPBD	Peripheral module (system domain)
H'E8000000 to H'E81FFFFF	ICB register/MERAM	MERAM start address is H'E8080000 (mirror address for AP RT core)
H'E8200000 to H'EFFFFFFF	Router	Address error *1
H'F0000000 to H'FB3FFFFF	Router	Address error *1
H'FB400000 to H'FB7FFFFF	Router	Address error *1
H'FB800000 to H'FBFFFFFF	Router	Address error *1
H'FC000000 to H'FCFFFFFF	DBG/H-UDI	DBG/H-UDI
H'FD000000 to H'FDFFFFFF	3DG	Control register
H'FE000000 to H'FE0FFFFF	DMAC	Control register
H'FE100000 to H'FE3FFFFF	SPU	Control register
H'FE400000 to H'FE7FFFFF	SBSC1	Control register
H'FE800000 to H'FE8FFFFF	ICB	Image IP (VPU, VIO, JPU, or LCDC)
H'FE900000 to H'FEBFFFFF	ICB	Image IP (VPU, VIO, JPU, or LCDC)
H'FEC00000 to H'FEFFFFFF	BSC	Control register
H'FF000000 to H'FF1FFFFF	AP-realtime core	Error
H'FF200000 to H'FF3FFFFF	UBC/VCR	UBC/VCR
H'FF400000 to H'FF6FFFFF	Router	Note: The AP-system core indicates memory in the core.
H'FF700000 to H'FFBFFFFF	Router	Router registers and reserved area for router *2
H'FFC00000 to H'FFFFFFFF	HPB	Peripheral module (realtime domain)

Notes: 1. If access is made to an address error area, an error log is generated in the AP realtime core or a data abort is generated in the AP system core.
2. The router registers are the arbitration registers (RTPRARCR*, HSPRARCR* and CMPRARCR*) described in section 1-F, Bus Functions. The other addresses are reserved for use by the router. If access is made to such an address, an error response or an undefined value will be read.
3. For SDRAM area divisions, refer to section 7, Bus State Controller for SDRAM (SBSC).
4. If the EXTEND bit in the BSC common control register (CMNCR) is set to 1, CS0 and CS2 are merged to create a space of 256 Mbytes.

Notes: 1. The relevant interrupt is processed as one interrupt source in the belonging domain, and it is necessary to read the interrupt source register to determine the interrupt.
2. For details on the register for switching the BBIF2 address, refer to section 1-F.4, HPB Bus Functions.
3. Accessed either from H'E6xx xxxx or H'E7xx xxxx. There is no functional difference due to the address selected. The arbitration of the access from H'E6xx xxxx or H'E7xx xxxx is done by hardware.

1-B.1.1 32-Bit Addressing Mode of AP-Realtime Core and Virtual and Physical Addresses

This LSI has the SH4AL-DSP core with extended functions and the addressing mode is changed from 29-bit mode in a conventional product to 32-bit mode. The differences between 29-bit addressing mode and 32-bit addressing mode are the relationship between the virtual addresses and physical addresses and their control method. For details, refer to section 3.3.

1-B.1.2 ROM Debugging Mode

This LSI supports ROM debugging mode. By using ROM debugging mode, a ROM program which is used for booting the internal ROM can be placed in an external memory to be debugged. This function is performed by switching the destination address to be fetched immediately after a boot from the internal ROM (for usual ROM boot mode) to BSC (for ROM debugging mode). The addresses to be accessed are automatically changed by hardware, which allows the software to debug the ROM program without any specific processing for ROM debugging mode. For details on the LSI boot mode settings, see section 11.1.3, Operating Modes.

Table 1-B.3 Address translation in ROM debugging mode

	AP-System Core
Address before translation by hardware *1	From 0x0000_0000
Address after translation by hardware	From 0x1000_0000
Range for address translation	Variable within range from 4 Kbytes to 512 Kbytes (Initial value: 4 Kbytes*2)

Notes: 1. The CPU starts program execution from PC address 0, which is translated to 0x1000_0000 by hardware.
2. APARMABAREA can be changed by using an instruction within 4 Kbytes after the ROM debugging mode booting. For details on APARMBAREA, see section 2.2.2.

1-B.1.3 Chip Version Registers

This LSI has the following three chip version registers. The register values are determined as shown in the bit field description in the following table unless otherwise specified in Errata or Technical Update.

Table 1-B.4 Chip Version Registers

Address	Register Name	Bit Field	Remarks
0xE600101C	CCCR (Common chip code register)	[31:16] Reserved [15:8]: Major number (AP4 = 0x2D) [7:4]: ES number (integer part –1) [3:0]: ES number (fraction part)	Accessible from all CPUs
0xFF000044	PRR (Product register)	[31:16] Reserved [15:8]: Major number (AP4 = 0x2D) [7:4]: ES number (integer part –1) [3:0]: ES number (fraction part)	Accessible only from AP_RT

Section 1-C Overview of Power Management

1-C.1 Power supply Management

To reduce the Leakage power consumption, this LSI is divided into various functional groups. Each functional group is assigned to a separate or multiple hierarchal power domains. The power supply to each area is controlled independently by a module called system controller (SYSC) which is located in C5 area whose power is always on. The leakage power can be reduced by shutting down the power supply of areas which are not required to operate according to the operating scenario.

As explained above, the power of areas which are not required to operate for a particular operating scenario can be turned off. To avoid the functional conflicts, the overall power domain is structured in hierarchal fashion as shown in figure 1-C.1. The bottom layer is an always power on area which is named as C5. Modules that are required to operate at all time are placed in this area. For example, modules required to process wakeup requests (System controller, Wakeup Controller) are placed in C5 area. Refer to Table 1-C.1 for list of module placed in each power domain. Modules that are rarely used are located in upper layers and modules used very often are located in lower layers

Figure 1-C.1 shows the power domain view and hierarchal relation between various power domains.

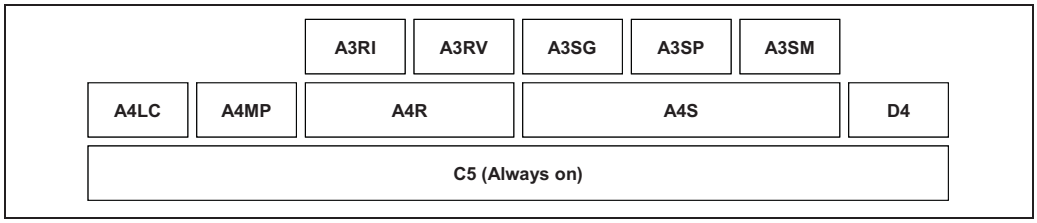

Figure 1-C.1 Power supply area hierarchy

Table 1-C.1 shows the modules located in each power Domain.

Table 1-C.1 Module assignment of each power Domain

	Area	Module
Common	C5	SYSC, PowerControlParts, GPIO, PAD (IO macro), HDMI-Phy, DBG

	A3RI	ISP
	A4LC	MERAM, LCDC, DSI
	A4MP	SPU2, FSI, FMSI, BBIF2

1-C.1.1 Backup registers

To speed up the wakeup time, the contents of some resources whose power is going to be turned off need to be preserved. The basic idea to implement it is to take a back up of those registers before shutting them down. So each resource will have a corresponding backup register which is placed in always power on area. All these backup registers are collectively placed in a module called Backup Module.

When the power is turned on these resources are initialized with the value stored in backup registers. The Backup registers are initialized only on power on reset or C5 area reset.

1-C.1.2 Power supply ON/OFF sequence

Power supply of each area of this LSI is controlled by SYSC. By Setting Power Down/Wakeup Control registers of SYSC, power down, wakeup requests can be generated .By accessing Power Status Control Register of SYSC, status of each power area can be monitored. Wakeup requests are also generated by wake up interrupts from external pin and peripheral modules. The areas (other than CPU) which can be waken up by wakeup interrupts are selected by SYSC configuration Registers.

The Basic flow of Power down and wakeup sequences is as follows.

(1) Power down Sequence

1. Check the write permission of bits in power down control registers by performing a read access to the corresponding Write block Control register.
2. Write 1 to the bit/bits of power down control registers to generate a power down request for corresponding areas. If the DLYED bit is also set along with these bits, the power down request is generated when CPU executes SLEEP/WFI instruction. If the DLYED bit is not set the power-down request is generated immediately. The power-down sequence starts immediately when the power-down request is issued and the system controller is in IDLE state. When the System controller is not IDLE, the generated requests are stored internally and power down sequence is executed when the System controller returns to the IDLE state.

The power down sequence is executed by SYSC in conjunction with CPG. The power down sequence is implements as follows.

A. The SYSC provides information of areas whose power is going to be turned off and issues a power down request to CPG.

B. The CPG issues area reset to the areas which are going to be turned off after bringing down the internal busses to IDLE state. Once it confirms that all the modules in that area are initialized, it stops the clock supply to that area even turns off PLL if the PLL off condition is met. Then, CPG sends back a power-down acknowledgement to the SYSC.

C. When power of an area is turned down, the output signals of that area are driven to unknown state, which might lead to drive the modules connected to those outputs also into unknown state. Therefore SYSC broadcasts a signal to all the modules which are receiving the outputs of modules whose areas is going to be turned down. From here on this broadcasting signal is called as ***Power isolation request*1*** and cell used by this signal to mask those unknown outputs are called as ***Power isolation Cell*1***.

D. As a last step in the sequence, SYSC issues a power down request to the corresponding Power Switch Controller .When the SYSC receives an acknowledgement from the Power

Switch Controller SYSC returns to IDLE state and clears the bits of the power control register.

(1) Wakeup Control

Wakeup sequence is triggered by wakeup request. The sources of Wakeup Requests

① By Setting up Wakeup control registers of SYSC
② By Wakeup interrupts generated by external pins and peripheral modules.

The sequence of operations when wakeup request is generated by Wakeup control register is as follows.

1. Check the write permission of bits in wakeup control registers by performing a read access to the corresponding Write block Control register.
2. Write 1 to the bit/bits of Wakeup control registers to generate a wakeup request for corresponding areas. The Wakeup request is generated immediately when bits in the wakeup control register are set. The wakeup sequence starts immediately when the wakeup request is issued and the system controller is in IDLE state. When the System controller is not IDLE, the generated requests are stored internally and wakeup sequence is executed when the System controller returns to the IDLE state.

The Wakeup sequence is also executed by SYSC in conjunction with CPG. The Wakeup sequence is implements as follows.

A. The SYSC issues a power-on request to the corresponding power switch controller and waits for acknowledgement signal.
   When turning on power switches of multiple areas, SYSC issues the power-on requests one at a time, it does not issue the request to all power switch controllers simultaneously. At first the power-on request is issued to area in the lower hierarchy. When it receives acknowledgement from the power switch controller of that area, it issues a power on request to the areas in the next level of that hierarchy and so on. When two areas of the same hierarchy are to wake up, the order of request generation is hardware dependent.
B. The SYSC issues a wakeup request to the CPG after all power switches are turned on and stable external clock is supplied to LSI.
C. The CPG continues to assert area reset which was issued at the time of power down sequence. CPG starts providing clock supply to all the modules which are going to be waken up. It restarts PLL circuits if PLL on condition is met. Once CPG confirms that all the modules of that area are properly initialized, it sends back wakeup acknowledgement to the SYSC.

D. When the SYSC receives the wakeup acknowledgment signal from CPG, it cancels power isolation request and signals CPG to release area reset to all modules. Then SYSC returns to IDLE state and clears the bits of wakeup control register are cleared to 0.

E. As a final step, CPG release area reset to all modules of that area

The wakeup procedure is same for wakeup requests generated by wakeup interrupts also. The wakeup interrupts are detected from various sources and a cumulative wakeup interrupt signals is generated for both SYS and RT domains as WakekupS, WakeupR respectively. Asserting these signals generates wakeup requests to the corresponding CPU. The areas that can be waken up by WakeUpS or WakeUpR are selected by Wakeup Selection control registers of SYSC.

.

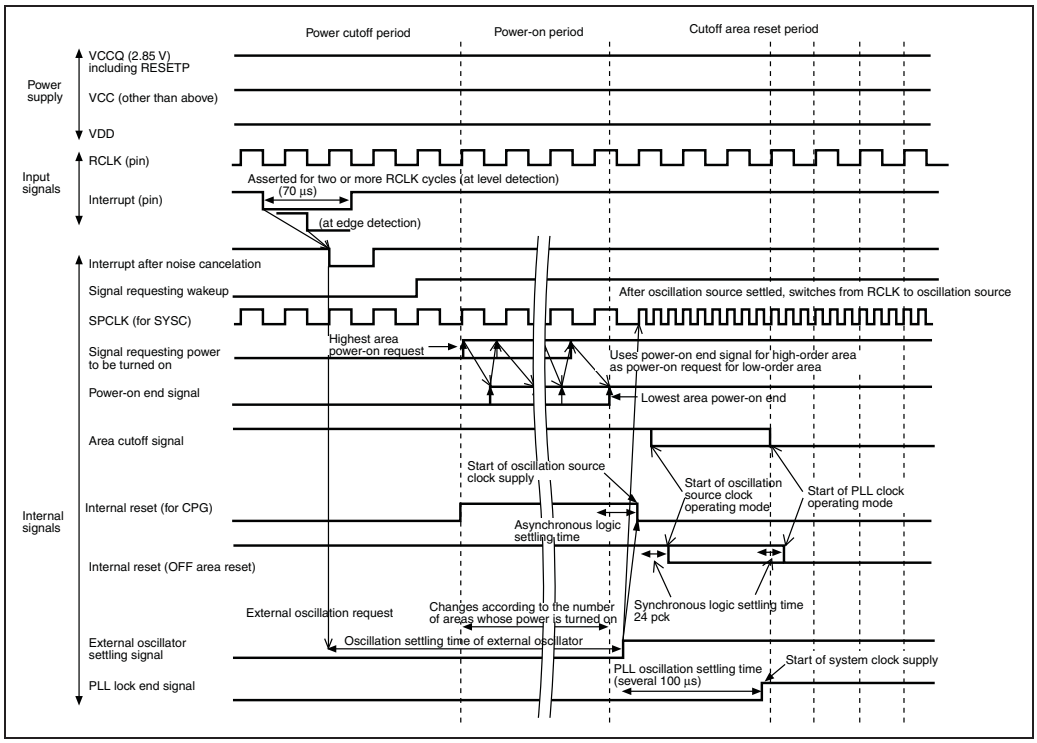

Figure 1-C.2 Wakeup Sequence by WakeUpR/WakeUpS Signal

1-C.2 Low Power State Definitions

The Following Low Power States are supported for this LSI

(1) CPU Power saving modes

- Sleep mode
  Clock supply to CPU is halted. The power of the CPU is on.
- Core Standby mode
  Clock supply to CPU is halted. The power of logic block of the CPU core is turned off, but the contents of memory modules of CPU (Cache, etc.,) are retained.

(2) Low Leakage mode

- Power-off
  Power supply of a specified power area is turned off. Refer to 1-C.1 and section 13, System controller (SYSC).

(3) Clock supply control

- Module stop
  Clock supply to a specified module is halted. Module stop is controlled by Module Stop control registers in CPG.
- Clock stop
  Whole clock domain of the specified clock is halted. Clock stop is controlled by clock control registers in CPG.

Section 1-D Overview of Reset

1-D.1 Reset Types

This LSI has five types of resets: power-on reset, system reset, power supply area reset, manual reset and software reset.

(1) Power-on Reset

A power-on reset is a reset to initialize all internal resources of this LSI. A power-on reset stops all processing and cancels the processing of all events that are yet to be processed. Two types of power on reset are defined for this LSI: “hard power-on reset” and “soft power on reset”.

A hard power-on reset is a reset controlled through the input pin RESETP, and it must be used when power is supplied to this LSI. The RESETP pin is a reset pin assumed to be asserted only when the power supply to this LSI is turned on, but asserting this pin in the normal operating state does not cause a problem. Following is a hard power-on reset sequence:

1. All external pins of the LSI are immediately transited to the reset state and kept that state until the hard power-on sequence finishes.
2. During power-on reset by RESETP pin is asserted, the power supply to internal power supply area are cut off, except an area which power is always on. After releasing RESETP pin, all internal power supply areas of the LSI are turned on sequentially.
3. Oscillation of the external clock (EXTAL1 and EXTAL2) inputs is enabled and operation is halted until the external clock input becomes stable.
4. All internal resources of the LSI are initialized.
5. The external pins are released from the reset state, and the boot sequence is started. Internal resets are negated and master processor starts instruction fetch from boot address.

A soft power-on reset is a reset controlled by reset control registers (RESCNT, RESCNT2) in the SYSC. The SRESLNK bit of RESCNT register in SYSC specifies whether the reset is handled as soft power on reset or as a system reset. See table 1-D.2 for detail of trigger of soft power on reset. Following is a soft power-on reset sequence:

1. If the power supply to certain area is off, the power supply is turned on until all of internal power supply areas of the LSI become powered on. If all of the internal power area is already on, this step is skipped.

2. If oscillation of the external clock (EXTAL1) input is halted, oscillation is enabled and operation is halted until the external clock input becomes stable. If the external clock input is already supplied, this step is skipped.
3. All internal resources of the LSI are initialized except some registers in SYSC.
4. Internal resets are negated and master processor starts instruction fetch from boot address.

Followings are example of internal resource not initialized by a soft power on reset.

- Example 1: Resources related to on-chip debugger in debug mode.
  Since these resources are saved, debugging of the reset sequence is possible.
- Example 2: Resources related to boot
  Though boot address of a hard power-on reset is determined by the setting of the mode pins, boot address after soft power-on reset can be set by the following registers: RBAR, SBAR of SYSC.

(2) System Reset

A system reset is a reset to re-execute from the initial state but keeping the status of D4 area and C5 area. A system reset is controlled through the input pin RESETA and reset control registers (RESCNT, RESCNT2) in the SYSC. A system reset stops all processing and cancels processing of all events that are yet to be processed. The SRESLNK bit of RESCNT register in SYSC specifies whether the reset is handled as soft power on reset or as a system reset. See table 1-D.2 for detail of trigger of system reset. Following is a system reset sequence:

1. If the power supply to certain area is off, the power supply is turned on until all of internal power supply areas of the LSI become powered on. If all of the internal power area is already on, this step is skipped.
2. If oscillation of the external clock (EXTAL1) input is halted, oscillation is enabled and operation is halted until the external clock input becomes stable. If the external clock input is already supplied, this step is skipped.
3. All internal resources of the LSI are initialized except D4 area and C5 area.
4. Internal resets are negated and master processor starts instruction fetch from boot address.

(3) Power Supply Area Reset

A power-supply area reset is a reset to initialize certain power supply area when the power supply of the area becomes off, and the power supply of the area becomes on. This reset is kept asserted until power of the relevant area is turned on again.

(4) Software Reset

A software reset is a reset to initialize specified module. A software reset can be issued by writing to the software reset register in CPG. For details, refer to the section 11.CPG.

Figure 1.13 is a diagram which shows the relationship between the power-on reset, system reset, power supply area reset, and software reset in this LSI.

(5) Manual Reset

A manual reset is a reset generated by RT-CPU core. Power supply area of RT domain (A3RI, A3RV and A4R) is initialized by the manual reset.

Figure 1-D.1 is a diagram of reset in this LSI.

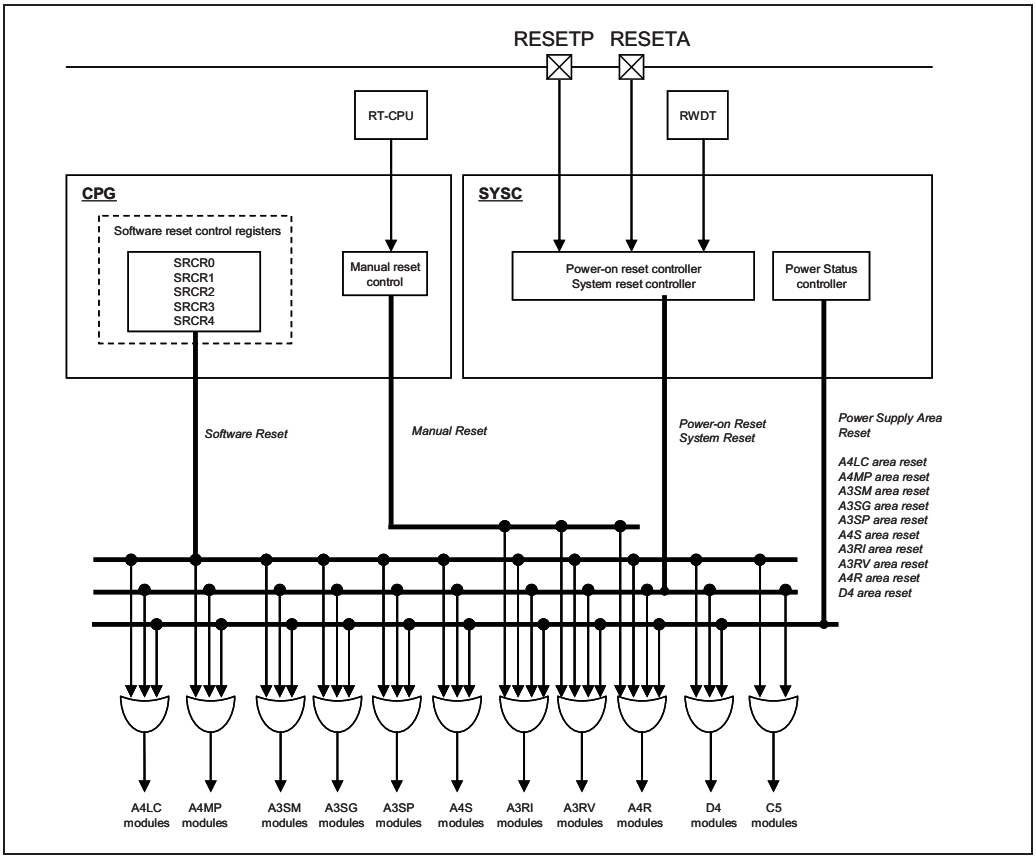

Figure 1-D.1 Reset Diagram

Software reset	Writing to software reset register in CPG
Manual Reset	Exception event of RT-CPU core

Section 1-E Overview of Clock

Figure 1-E.1 is a diagram of clock in this LSI. The clock frequency internal this LSI is configurable by settings of Clock Pulse Generator (CPG) registers.

The clock pulse generator has three PLL: PLLC0, PLLC1 and PLLC2. Clock output of PLLC0, PLLC1 and PLLC2 are supplied to the divider circuits in the subsequent stage.

The PLLC0 generates a base clock for SYS-CPU core (Zϕ).

The PLLC1 generates a base clock for the common divider which generates system clocks (Iϕ, ZGϕ, Bϕ, M1ϕ, CSIRϕ, ZTRϕ, ZTϕ, HPϕ, ISPBϕ, ISPMϕ, ZSϕ, ZBϕ, ZB3ϕ, CPϕ, DLLϕ)

The PLLC2 generates a base clock for the dedicated dividers which are prepared as special clock sources for the auxiliary clocks (SUBϕ, SUB2ϕ, SPUϕ, FMSIϕ, FMSOϕ, FSIAϕ, FSIBϕ, DSITϕ, DSIP0ϕ, DSIP1ϕ, HDMIϕ, VOUϕ, VCK1ϕ VCK2ϕ, VCK3ϕ). The input of dedicated dividers is selectable such as 1/2 of the PLLC1 output, the PLLC2 output, etc.

The division ratios supported by the common divider are 1/2, 1/3, 1/4, 1/6, 1/8, 1/12, 1/16, 1/18, 1/24, 1/32, 1/36, 1/48, 1/72 and 1/96. The division ratios supported by the dedicated dividers are 1/1 to 1/64.

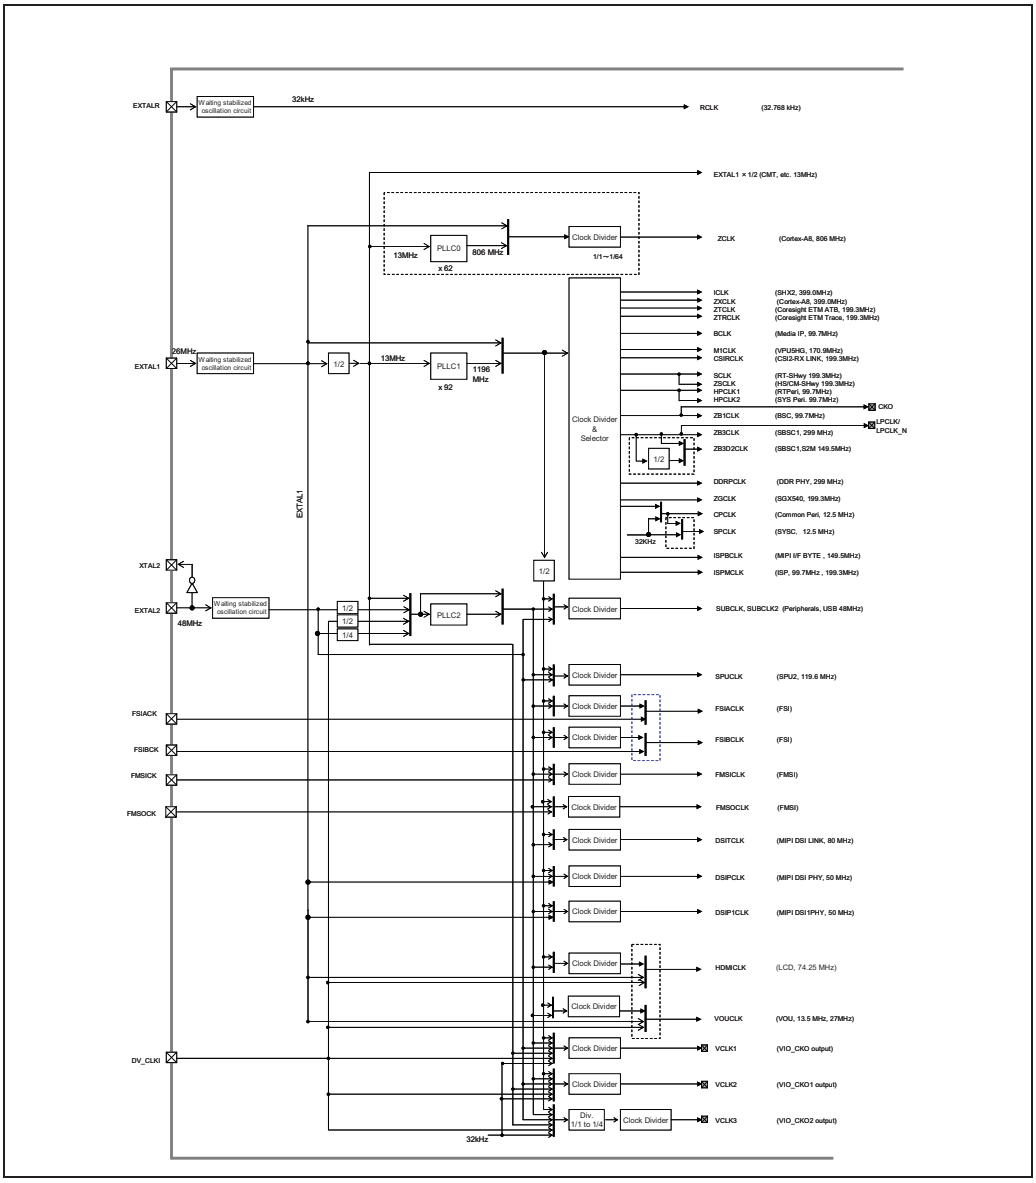

Figure 1-E.1 Clock Diagram

1-E.1 Clock Domain

Table 1-E.1 shows clock domain in this LSI.

Table 1-E.1 Clock Domain

Domain	Name	Source	Function
SYS	Zϕ	SYS-CPU divider	SYS-CPU core clock
RT	Iϕ	Common divider	RT-CPU core clock
SYS	ZXϕ	Common divider	SYS-CPU SHwy I/F clock
SYS	ZGϕ	Common divider	SGX540 clock
RT	Bϕ	Common divider	Multimedia module clock
RT	M1ϕ	Common divider	Video Processing Unit clock
RT/SYS	HPϕ	Common divider	High-speed peripheral clock
RT	CSIRϕ	Common divider	CSI2-RX Link module
RT	ISPBϕ	Common divider	Camera ISP byte clock
RT	ISPMϕ	Common divider	Camera ISP main clock
SYS	ZTRϕ	Common divider	Debug trace clock
SYS	ZTϕ	Common divider	ATB clock
RT/SYS/ COM	ZSϕ	Common divider	RT-SHwy, HS-SHwy, COM-SHwy
COM	ZBϕ	Common divider	BSC clock (External bus)
COM	ZB3ϕ	Common divider	SBSC clock
COM	DDRPϕ	Common divider	DDR PHY
COM	CPϕ	Common divider	Common domain peripheral clock
RT/SYS	SUBϕ	SUB clock divider	Sub clock, USB clock
SYS	SUB2ϕ	SUB clock divider	Sub clock (for A4MP domain)
SYS	SPUϕ	SPU clock divider	SPU2
SYS	FMSIϕ	FMSI clock divider	FMSI
SYS	FMSOϕ	FMSO clock divider	FMSI
SYS	FSIAϕ	FSIA clock divider	FSI
SYS	FSIBϕ	FSIB clock divider	FSI
RT	DSITϕ	DSIT clock divider	DSI-TX Link
RT	DSIPϕ	DSIP clock divider	DSI-TX PHY0
RT	DSIPϕ	DSIP clock divider	DSI-TX PHY1
SYS	HDMIϕ	HDMI clock divider	HDMI
RT	VOUϕ	VOU clock divider	VOU
RT/SYS/COM	-	-	EXTAL1 x 1/2
RT/SYS/COM	RCLK	EXTALR	RTC clock (32.768 kHz)

1-E.2 Clock Inputs

Table 1.E-2 shows the clock sources and their related pins.

Table 1.E-2 Clock Sources and Related Pins

Pin Name	Description
EXTALR	The RTC clock (32.768kHz) input. The RTC clock oscillation setup cycles are fixed at 64 RCLK cycles.
EXTAL1	The main clock (26 MHz) input.
XTAL1L	Enables the TCXO output. A high-current output buffer (16 mA) is used in consideration of the TCXO element power being driven directly. This pin becomes high-level output at a power-on.
EXTAL2	The sub clock (48 MHz, etc.) input.
XTAL2	Outputs amplified negative feedback of EXTAL2 for a crystal oscillating circuit. At a power-on reset, output of the oscillator is enabled. When a clock generated by an oscillator is input to the EXTAL2 pin, the XTAL2 pin should be open.

1-E.3 PLL Configuration

Table 1-E.3 shows the setting of each PLL.

Table 1-E.3 Setting of Each PLL

Domain	Reference Clock	Maximum Operating Frequency	Multiplication Ratio	Function
PLLC0	EXTAL1 × 1/2 (13 MHz when EXTAL1 = 26 MHz)	806 MHz	40 to 62 (valiable)	SYS-CPU core
PLLC1	EXTAL1 × 1/2 (13 MHz when EXTAL1 = 26 MHz)	1196 MHz	40 to 92 (variable)	RT-CPU core System bus
PLLC2	EXTAL1 × 1/2 EXTAL2 × 1/2 DV_CLKI × 1/2 EXTAL2 × 1/4	1040 MHz	40 to 80 (variable)	Sub clock system Peripheral modules

1-E.4 Oscillation Control

Clock oscillation can be halted when a clock input is unnecessary in a low power consumption mode. For EXTAL2/XTAL2 input clocks, clock oscillation circuit is turned-off by register. For EXTAL1, XTAL1L signal is asserted at specified condition, and halt external TCXO.

Each clock input is re-oscillated when clock input is required. At this time, the oscillation setup time is automatically counted by hardware, and clock supply restarts after oscillation setup time expired.

Figure 1-E.2 is a diagram of the oscillation control circuit.

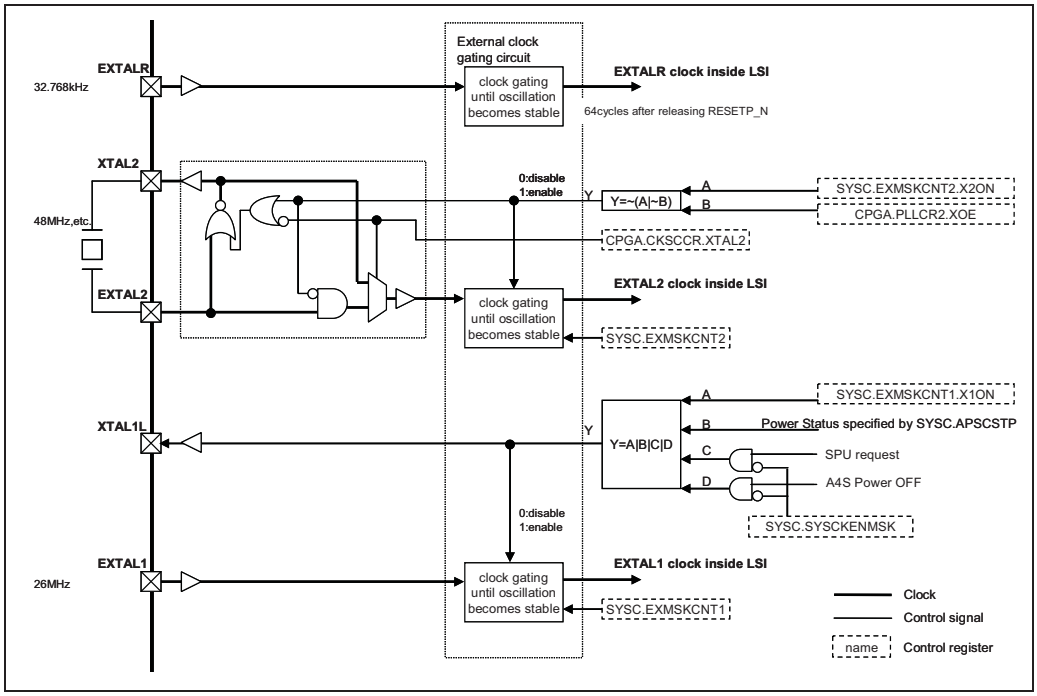

Figure 1-E.2 Oscillation Control Circuit

1-E.5 Limitations on Clock frequency ratio

Table 1-E.4 shows the limitations of clock frequency ratio.

Table 1-E.4 Limitations on Clock frequency ratio

Domain	Clock	Clock Limitation	Clock frequency Ratio	Remarks
RT	Iϕ:ZSϕ	Clock ratio of integers	Iϕ:Sϕ=N:1 (N=16,12,8,6,4,3,2,1)	
	Iϕ:HPϕ	Clock ratio of integers	Iϕ:HPϕ=N:1 (N=16,12,8,6,4,3,2,1)	
	ZSϕ:Bϕ	Clock ratio of integers	ZSϕ:Bϕ=N:1 (N=16,12,8,6,4,3,2,1)	ZSϕ:Bϕ=1:1is not available if CSI2-RX is operating.
System	ZXϕ:ZSϕ	Clock ratio of integers	ZXϕ:ZSϕ=N:1 (N=16,12,8,6,4,3,2,1)	
	ZSϕ:HPϕ	Clock ratio of integers	ZSϕ:HPϕ=N:1 (N=16,12,8,6,4,3,2,1)	
	ZSϕ:ZBϕ	Clock ratio of integers	ZSϕ:ZBϕ=N:1 (N=16,12,8,6,4,3,2,1)	
Other	HPϕ, TCK	Relation between frequency values	HPϕ>TCK	

Section 1-F Bus Functions

1-F.1 Bus Configuration

Bus and bridge connection diagrams

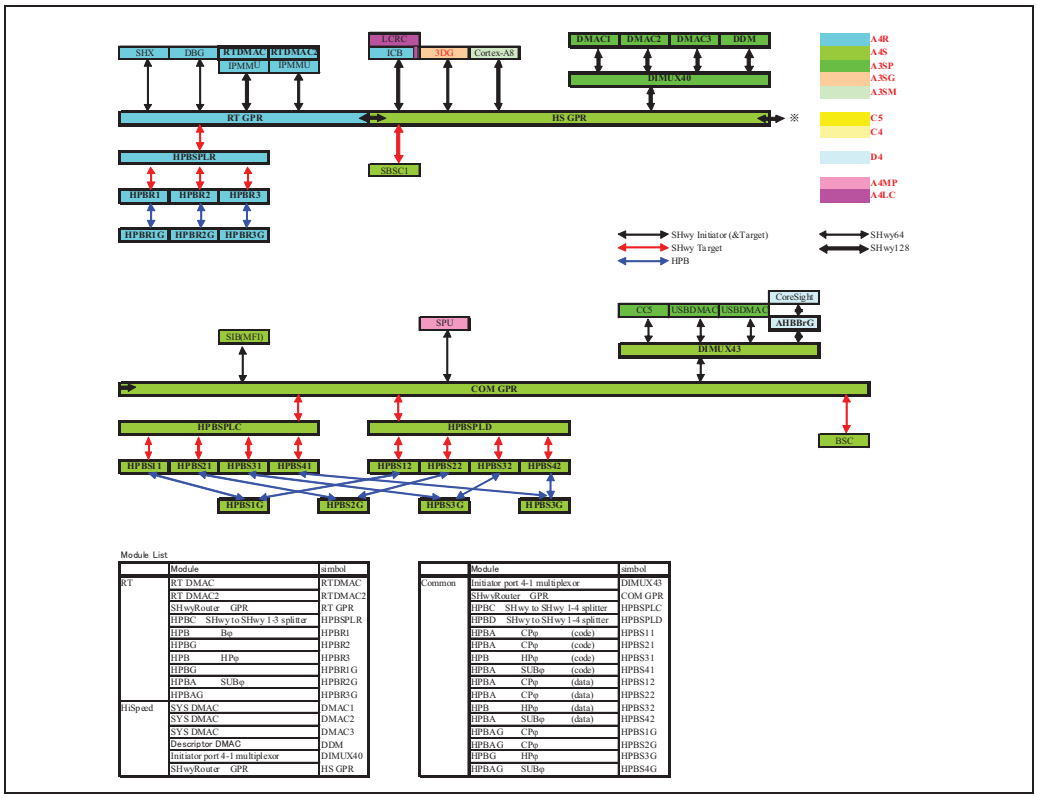

Fig 1-F-1SHwy Bus Connection Diagram

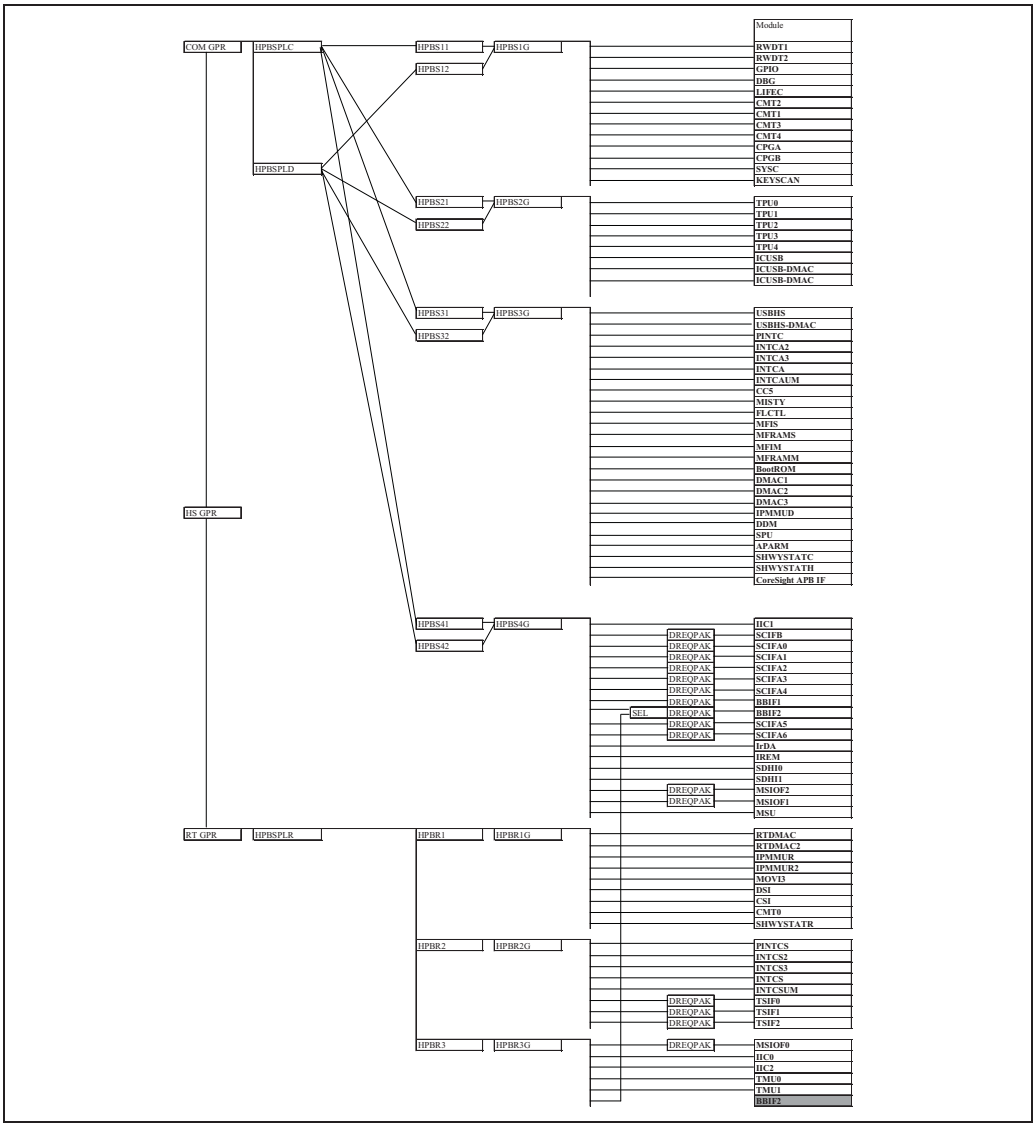

Fig 1-F -2HPB Bus Connection Diagram

Data bus widths and operating clocks of buses

The table below shows the data bus widths and operating clocks of the buses that appear in the above figure.

Bus		Data Bus Width	Operating Clock
1	Media Bus	32 bits, 64 bits	Bϕ (bck)
2	SHwy(RT/SYS/Common)	128bits,64 bits	ZSϕ (zsck)
3	HP Bus(RT)	8 bits, 16 bits, 32 bits	Bϕ (bck), HPϕ (hpck)
4	HP Bus(Common/System)	8 bits, 16 bits, 32 bits	CPϕ (cpck), HPϕ (hpck)
5	HP Bus (UART modules)	8 bits, 16 bits, 32 bits	SUBϕ (subck)

Bridges

The buses shown in Fig1-F-1. ”SHwy connection diagram” are mutually connected by the following bridges:

Bridge	Connected Data Bus (A)	Connected Data Bus (B)
Inter Connect Buffer (ICB)	1. Media Bus	2. SHwy (HS)
HPB Splitter(RT/Common)	3. SHwy (RT/Common)	3. SHwy (RT/Common)
SHwy-HPB Bridge (RT)	2. SHwy (RT)	4. HP Bus (RT)
SHwy-HPB Bridge (Common/System)	3. SHwy (Common)	5. HP Bus (Common/System)

Latencies that pass bridges are approximately as follows:

Bridge	Latency (Unit: Cycle)	Number of Pass Cycles When Clock Ratio Is 1:1
SHwy router	Both read and write: Request: 1 Response: 1	(Despite the access size): total 2 cycles
HPBC/D SHwy Target Bridge	Read: Request: Bus (A) 1 + bus (B) 1*[1] Response: Bus (B) 1 to bus (B) 4 + bus (A) 1*[1] Write: Request: Bus (A) 1 to bus (A) 4 + bus (B) 1*[1] Response: Bus (B) 1 + bus (A) 1*[1]	4-byte read (write): total 4 cycles 32-byte read (write): total 7 cycles
SHwy-HPB Bridge	Both read and write: Request: Bus (A) 1 + bus (B) 2 Response: Bus (B) 1 + bus (A) 1	(Despite the access size):total 5 cycles (The total number of cycles of the request depends on the HPB data bus width.)

Notes: 1. This depends on the data burst length.

When the CPU accesses main memory targets, the total latencies of the bridges and buses are as follows: In this case, the clock ratio is 1:1 and 32-byte burst transfer is used.

Bus Master	Memory Target	Number of Cycles
AP-System core	SDRAM(AP)	2
	MERAM	7
	XYRAM	7
	Asynchronous RAM, flash memory	2
	MFI RAM (Sys)	16
	MFI RAM (RT)	19
AP-Realtime core	SDRAM (AP)	2
	MERAM	2
	XYRAM	0
	Asynchronous RAM, flash memory	7
	MFI RAM (RT)	16
	MFI RAM (Sys)	19

Asynchronous RAM and flash memory connection

BSC and FLCTL modules access asynchronous RAM and flash memory. The BSC module arbitrates between asynchronous RAM and flash memory.

The arbitration method is as follows:

BSC < FLCTL: Fixed priority

1-F.2 SHwy Bus Functions

1-F.2.1 Arbitration Functions

The following two arbitration modes are supported for SBSC1 and MERAM of SHwy GPR(Global Packet Router) .

- Urgent Transfer arbitration
- Grant-Times-Based arbitration

Capture/Display IP requests are High-Priority by default, and always proceed to Grant-times-based arbitration.

Grant-Times-Based arbitration is used by the other normal priority IP, or the case that suppress high-priority request by setting PRI control register.

(1) Urgent Transfer Arbitration

A specific initiator (bus master) can request urgent transfer. Each initiator sets a Pri value. The request having the maximum Pri value precedes other requests. If the Pri value is urgent transfer (H'9 to H'F), the request having this values precedes the priority settings of the normal transfer arbitration result.

Initiator	Normal Transfer (H'0, H'8)*1	Urgent Transfer (H'9 to H'F)	Purpose of Urgent Transfer
AP-Realtime core	H'8	H'C	Interrupt (BL=1)
DBG	H'8	H'E	Debugging by debugger
RTDMAC	H'0	H'9 to H'F	Any values can be set in registers.
SYSDMAC, USBDMAC	H'0	H'9 to H'F	Any values can be set in registers.
ICB	H'0	H'1 to H'F	Insufficient remaining quantity of image IP buffer
AP-SYSTEM core	H'0	H'9 to H'F	Any values can be set in registers.

Note: *1 In the SHwy standard, only H'8 indicates "normal transfer." H'0 to H'7 indicate "low priority transfer." This chip treats also H'0 as normal transfer because it is not equipped with the low priority transfer function.

The table below shows the registers that control Pri values.

Initiator	Register	Address	Bit
RTDMAC	RDM1CHCRB_0	H'FFC1 812C	3-0
	RDM1CHCRB_1	H'FFC1 813C	3-0
	RDM1CHCRB_2	H'FFC1 814C	3-0
	RDM1CHCRB_3	H'FFC1 815C	3-0

	RDM1CHCRB_4	H'FFC1 817C	3-0
	RDM1CHCRB_5	H'FFC1 818C	3-0
RTDMAC2	RDM2CHCRB_0	H'FFC2 812C	3-0
	RDM2CHCRB_1	H'FFC2 813C	3-0
	RDM2CHCRB_2	H'FFC2 814C	3-0
	RDM2CHCRB_3	H'FFC2 815C	3-0
	RDM2CHCRB_4	H'FFC2 817C	3-0
	RDM2CHCRB_5	H'FFC2 818C	3-0
SYSDMAC	DM1CHCRB_0	H'FE00 812C	3-0
	DM1CHCRB_1	H'FE00 813C	3-0
	DM1CHCRB_2	H'FE00 814C	3-0
	DM1CHCRB_3	H'FE00 815C	3-0
	DM1CHCRB_4	H'FE00 817C	3-0
	DM1CHCRB_5	H'FE00 818C	3-0
	DM2CHCRB_0	H'FE01 812C	3-0
	DM2CHCRB_1	H'FE01 813C	3-0
	DM2CHCRB_2	H'FE01 814C	3-0
	DM2CHCRB_3	H'FE01 815C	3-0
	DM2CHCRB_4	H'FE01 817C	3-0
	DM2CHCRB_5	H'FE01 818C	3-0
	DM3CHCRB_0	H FE02 812C	3-0
	DM3CHCRB_1	H'FE02 813C	3-0
	DM3CHCRB_2	H'FE02 814C	3-0
	DM3CHCRB_3	H'FE02 815C	3-0
	DM3CHCRB_4	H'FE02 817C	3-0
	DM3CHCRB_5	H'FE02 818C	3-0
USBDMAC	USBDMACHCR_0	H'E68A 0034	11-8
	USBDMACHCR_1	H'E68A 0054	11-8
AP-SYSTEM core	APARMPRI	H'E6F1 0000	3-0

Any values can be set in the above registers. If you want to use urgent transfer, however, set a value from 9 to 15. Operations are not supported that correspond to 1 to 8.

(2) Grant-Times-based arbitration

SHwy router has parameters per initiator, “*acnum* : the number of requests that grants continuously” and ”*wnum* : the number of request-waiting cycle ” by register.

SHwy router has the following counters,

account : the rest of accepting numbers that current initiator’s request

wcount : the rest of waiting cycles that current initiator’s request

SHwy router arbitration acts by these two counters, and adjusts bus occupation by the register.

When *account* is zero and *wcount* is zero, SHwy router switches accepting initiator by round-robin order.

The adjustment of “Grant-Times-based arbitration” is available by setting the register XXPRARCR. The figure below shows an example of setting the SHwy register and the operation of the register.

AI=ICB acnum AS=3DG acnum ADI=SYSCPU acnum ADB=DMAC acnum
WI=ICB wnum WS=3DG wnum WDI=SYSCPU wnum WDB=DMAC wnum

case #1
AI=0 AS=0 ADI=0 ADB=0
WI=0 WS=0 WDI=0 WDB=0
Same as normal round-robin

ICB	req	(1)	1	1	1	(1)	1	1	(1)	1	1
3DG	req	1	(1)					1	1	(1)	
SYSCPU	req	1	1	(1)	1	1	(1)	1	1	1	(1)
DMAC	req	1	1	1	(1)	1	1	(1)	1	1	1
	acount	0	0	0	0	0	0	0	0	0	0
	wcount	0	0	0	0	0	0	0	0	0	0

case #2
AI=3 AS=0 ADI=0 ADB=0
WI=0 WS=0 WDI=0 WDB=0
ICB:3DG:SYSCPU:DMAC = 4:1:1:1

ICB	req	(1)	(1)	(1)	(1)	1	1	1	(1)	(1)	(1)

Example of Setting HS-SHwy Register of Grant-Times-based arbitration

1-F.2.2 Arbitration Registers (RealTime GPR)

Name	Register Abbreviation	R/W	Initial Value	Address	Access Size (Bits)
PRI control register	RTPRPRICR	R/W	H'0000 001E	H'FF800018	32
HS-GPR arbitration register 1	RTPRARCR11	R/W	H'0000 0000	H'FF800030	32
HS-GPR arbitration register 2	RTPRARCR12	R/W	H'0000 0000	H'FF800038	32
Error contorol register	RTPRERRMSK	R/W	H'0000 0000	H'FF800090	32

Register States in Each Operating Mode

Register Abbreviation	Power-on Reset	AP Reset	SYS-CPU Sleep	RT-CPU Sleep
RTPRPRICR	Initialized	Initialized	Retained	Retained
RTPRARCR11	Initialized	Initialized	Retained	Retained
RTPRARCR12	Initialized	Initialized	Retained	Retained
RTPRERRMSK	Initialized	Initialized	Retained	Retained

The above registers are allocated to the A4R power supply area. Turning off the power supply in this area initializes the settings.

PRI Control Register (RTPRPRICR)

RTPRPRICR sets Pri value control. This register enable priority checking when there is a request comes along with priority.

bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	HSPR	RDM2	RDMPR	DBPR	SHPR
init-val	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bits 0: RT-CPU Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 1: Debug Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 2: RT-DMAC Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 3: RT-DMAC2 Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 4: HS-GPR Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 31 to 5: Reserved

These bits are always read as 0. The write value should always be 0.

HS-GPR Arbitration Control Register 1 (RTPRARCR11)

RTPRARCR11 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WDB[5:0]						ADB[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WSH[5:0]						ASH[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (RT-CPU)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (RT-CPU)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (Debug)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (Debug)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

HS-GPR Arbitration Control Register 2 (RTPRARCR12)

RTPRARCR12 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WRDM2[5:0]						ARDM2[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WRDM[5:0]						ARDM[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (RT-DMAC)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (RT-DMAC)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (RT-DMAC2)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (RT-DMAC2)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Error Control Register (RTPRERRMSK)

RTPRERRMSK sets error response control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	ERRMSK[1:0]	
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	0	R/W	R/W

Bit 0: Error mask

0: normal operation

1:Suppress error response when initiator accesses reserved address.

(Caution) If error response is masked, initiator cannot notice these errors. It causes system freeze. Do not set this register as usual.

Bits 1: Error mask

0: normal operation

1:Suppress error response when target ports response are error response.

(Caution) If error response is masked, initiator cannot notice these errors. It causes system freeze. Do not set this register as usual.

Bits 31 and 2: Reserved

These bits are always read as 0. The write value should always be 0.

1-F.2.3 Arbitration Registers (HS GPR)

Name	Register Abbreviation	R/W	Initial Value	Address	Access Size (Bits)
PRI control register	HSPRPRICR	R/W	H'0000 0000	H'FFA00018	32
SBSC1 arbitration register 1	HSPRARCR11	R/W	H'0000 0000	H'FFA00030	32
SBSC1 arbitration register 2	HSPRARCR12	R/W	H'0000 0000	H'FFA00038	32
SBSC1 arbitration register 3	HSPRARCR13	R/W	H'0000 0000	H'FFA00040	32
ICB arbitration register 1	HSPRARCR21	R/W	H'0000 0000	H'FFA00050	32
ICB arbitration register 2	HSPRARCR22	R/W	H'0000 0000	H'FFA00058	32
ICB arbitration register 3	HSPRARCR23	R/W	H'0000 0000	H'FFA00060	32
COM-GPR arbitration register 1	HSPRARCR31	R/W	H'0000 0000	H'FFA00070	32
COM-GPR arbitration register 2	HSPRARCR32	R/W	H'0000 0000	H'FFA00078	32
COM-GPR arbitration register 3	HSPRARCR33	R/W	H'0000 0000	H'FFA00080	32
Error control register	HSPRERRMSK	R/W	H'0000 0000	H'FFA00090	32
SBSC1 priority setting register 1	HSPRPRICNT11	R/W	H'4040 4040	H'FFA000A0	32
SBSC1 priority setting register 2	HSPRPRICNT12	R/W	H'0000 4040	H'FFA000A8	32
SBSC1 priority setting register 3	HSPRPRICNT13	R/W	H'0000 0000	H'FFA000B0	32

Register States in Each Operating Mode

Register Abbreviation	Power-on Reset	AP Reset	SYS-CPU Sleep	RT-CPU Sleep
HSPRPRICR	Initialized	Retained	Retained	Retained
HSPRARCR11	Initialized	Retained	Retained	Retained
HSPRARCR12	Initialized	Retained	Retained	Retained

HSPRPRICNT11	Initialized	Retained	Retained	Retained
HSPRPRICNT12	Initialized	Retained	Retained	Retained
HSPRPRICNT13	Initialized	Retained	Retained	Retained

The above registers are allocated to the A4S power supply area. Turning off the power supply in this area initializes the settings.

PRI Control Register 1 (HSPRPRICR)

HSPRPRICR sets Pri value control. This register enable priority checking when there is a request comes along with priority.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	CMPR	DMPR	AMPR	ICPR	G3PR	RTPR
init-val :	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W :	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bits 0: RT-GPR Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 1: 3DG Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 2: ICB Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 3: SYS-CPU Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 4: SYS-DMAC Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 5: Com-GPR Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 31 to 6: Reserved

These bits are always read as 0. The write value should always be 0.

SBSC1 Arbitration Control Register 1 (HSPRARCR11)

HSPRARCR11 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WG3[5:0]						AG3[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WRT[5:0]						ART[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

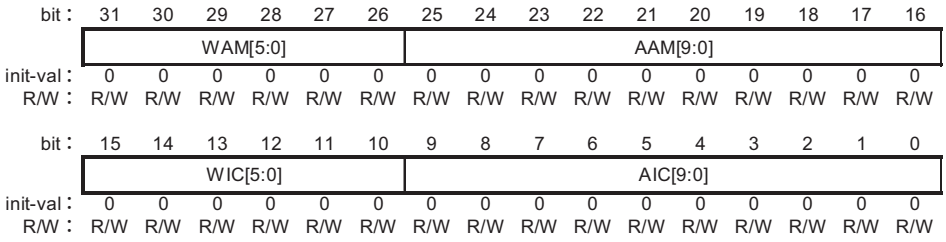
Bits 9 to 0: acnum (RT-GPR)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (RT-GPR)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (3DG)



Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (3DG)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

SBSC1 Arbitration Control Register 2 (HSPRARCR12)

HSPRARCR12 sets arbitration control parameters.

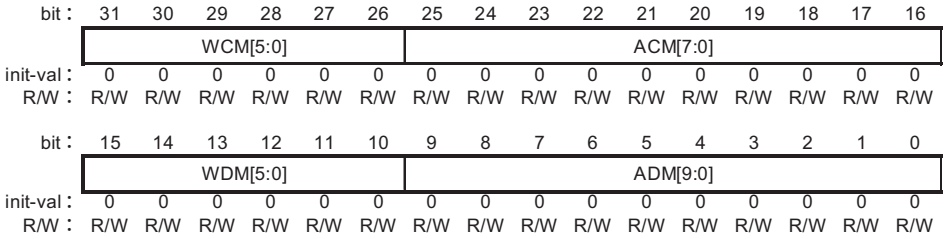
Bits 9 to 0: acnum (ICB)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (ICB)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (SYS-CPU)



Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (SYS-CPU)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

SBSC1 Arbitration Control Register 3 (HSPRARCR13)

HSPRARCR13 sets arbitration control parameters.

Bits 9 to 0: acnum (SYS-DMAC)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (SYS-DMAC)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (Com-GPR)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (Com-GPR)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

ICB Arbitration Control Register 1 (HSPRARCR21)

HSPRARCR21 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WG3[5:0]						AG3[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WRT[5:0]						ART[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (RT-GPR)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (RT-GPR)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (3DG)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (3DG)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

ICB Arbitration Control Register 2 (HSPRARCR22)

HSPRARCR22 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WAM[5:0]						AAM[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WIC[5:0]						AIC[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (ICB)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (ICB)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (SYS-CPU)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (SYS-CPU)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

ICB Arbitration Control Register 3 (HSPRARCR23)

HSPRARCR23 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WCM[5:0]						ACM[7:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WDM[5:0]						ADM[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (SYS-DMAC)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (SYS-DMAC)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (Com-GPR)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (Com-GPR)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Com-GPR Arbitration Control Register 1 (HSPRARCR31)

HSPRARCR31 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WG3[5:0]						AG3[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (RT-GPR)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (RT-GPR)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (3DG)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (3DG)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Com-GPR Arbitration Control Register 2 (HSPRARCR32)

HSPRARCR32 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WAM[5:0]						AAM[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (ICB)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (ICB)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (SYS-CPU)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (SYS-CPU)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Com-GPR Arbitration Control Register 3 (HSPRARCR33)

HSPRARCR33 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WCM[5:0]						ACM[7:0]

Bits 9 to 0: acnum (SYS-DMAC)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (SYS-DMAC)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (Com-GPR)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (Com-GPR)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Error Control Register (HSPRERRMSK)

HSPRERRMSK sets error response control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	ERRMSK[1:0]	
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	0	R/W	R/W

Bit 0: Error mask

0: normal operation

1:Suppress error response when initiator accesses reserved address.

(Caution) If error response is masked, initiator cannot notice these errors. It causes system freeze. Do not set this register as usual.

Bits 1: Error mask

0: normal operation

1:Suppress error response when target ports response are error response.

(Caution) If error response is masked, initiator cannot notice these errors. It causes system freeze. Do not set this register as usual.

Bits 31 and 2: Reserved

These bits are always read as 0. The write value should always be 0.

SBSC1 Priority Setting Register 1 (HSPRPRICNT11)

HSPRPRICNT11 sets control parameters of urgent transfer to SBSC1.

bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PCNT_AB[7:0]								PCNT_ICB[7:0]							
init-val	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PCNT_G3[7:0]								PCNT_RT[7:0]							
init-val	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 7 to 0: number of times of urgent transfer requests which is granted continuously (RT-GPR)

Bits 15 to 8: number of times of urgent transfer requests which is granted continuously (3DG)

Bits 23 to 16: number of times of urgent transfer requests which is granted continuously (ICB)

Bits 31 to 24: number of times of urgent transfer requests which is granted continuously (SYS-CPU)

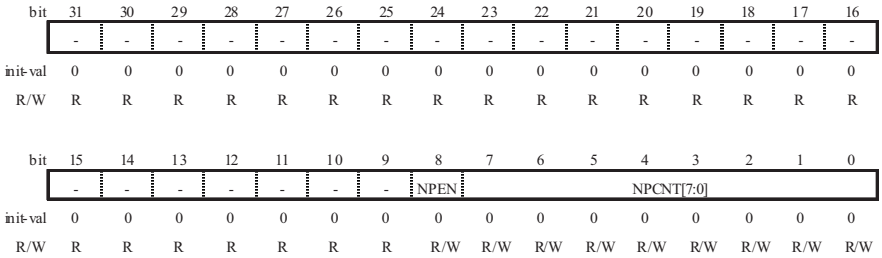
SBSC1 Priority Setting Register 2 (HSPRPRICNT12)

HSPRPRICNT12 sets control parameters of urgent transfer to SBSC1.

bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PCNT_CM[7:0]								PCNT_DM[7:0]							
init-val	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 7 to 0: number of times of urgent transfer requests which is granted continuously (SYS-DMAC)



Bits 15 to 8: number of times of urgent transfer requests which is granted continuously (Com-GPR)

Bits 31 to 16: Reserved

SBSC1 Priority Setting Register 3 (HSPRPRICNT13)

HSPRPRICNT13 sets control parameters of urgent transfer to SBSC1.

If this register is set, SHwy router temporally cancels Pri value specified cycles before when the times of urgent transfer to SBSC1 reach the PCNT** register value, and switching to the next urgent transfer.

Bits 7 to 0: ZS cycles of urgent transfer requests canceled when NPEN=1.

Bits 8: enables cancelling cycles of urgent transfer

0 : disable

1: enable

Bits 31 to 9: Reserved

1-F.2.4 Arbitration Registers (Com GPR)

Name	Register Abbreviation	R/W	Initial Value	Address	Access Size (Bits)
PRI control register	CMPRPRICR	R/W	H'0000 01FF	H'FF700018	32
SBSC1 arbitration register 1	CMPRARCR11	R/W	H'0000 0000	H'FF700030	32
SBSC1 arbitration register 2	CMPRARCR12	R/W	H'0000 0000	H'FF700038	32
SBSC1 arbitration register 3	CMPRARCR13	R/W	H'0000 0000	H'FF700040	32
SBSC1 arbitration register 4	CMPRARCR14	R/W	H'0000 0000	H'FF700048	32
SBSC1 arbitration register 5	CMPRARCR15	R/W	H'0000 0000	H'FF700050	32
HS-GPR arbitration register 1	CMPRARCR21	R/W	H'0000 0000	H'FF700060	32

CMPRPRICNT12	Initialized	Retained	Retained	Retained
CMPRPRICNT13	Initialized	Retained	Retained	Retained
CMPRPRICNT14	Initialized	Retained	Retained	Retained

The above registers are allocated to the A4S power supply area. Turning off the power supply in this area initializes the settings.

PRI Control Register 1 (CMPRPRICR)

CMPRPRICR sets Pri value control. This register enable priority checking when there is a request comes along with priority.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	HSPR	HSPR0
init-val :	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bits 0: HS-GPR0 Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 1: HS-GPR1 Pri control

0:SHwy router ignores Pri value.

1: SHwy router checks Pri value.

Bits 8 to 2: Reserved

No function is assigned. The write value should always be initial value.

Bits 31 to 9: Reserved

These bits are always read as 0. The write value should always be 0.

SBSC2 Arbitration Control Register 1 (CMPRARCR11)

CMPRARCR11 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WHS1[5:0]						AHS1[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WHS0[5:0]						AHS0[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (HS-GPR0)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (HS-GPR0)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 25 to 16: acnum (HS-GPR1)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 26: wnum (HS-GPR1)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

SBSC2 Arbitration Control Register 2 (CMPRARCR12)

CMPRARCR12 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bits 31 to 0: Reserved

These bits are always read as 0. The write value should always be 0.

SBSC2 Arbitration Control Register 3 (CMPRARCR13)

CMPRARCR13 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WDMX[5:0]						ADMX[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (CC5/USBDMAC/Coresight)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (CC5/USBDMAC/Coresight)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 16: Reserved

These bits are always read as 0. The write value should always be 0.

SBSC2 Arbitration Control Register 4 (CMPRARCR14)

CMPRARCR14 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WSP[5:0]						ASP[9:0]									
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 9 to 0: acnum (SPU)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (SPU)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 16: Reserved

These bits are always read as 0. The write value should always be 0.

SBSC2 Arbitration Control Register 5 (CMPRARCR15)

CMPRARCR15 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bits 31 to 0: Reserved

These bits are always read as 0. The write value should always be 0.

HS-GPR Arbitration Control Register 1 (CMPRARCR21)

CMPRARCR21 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

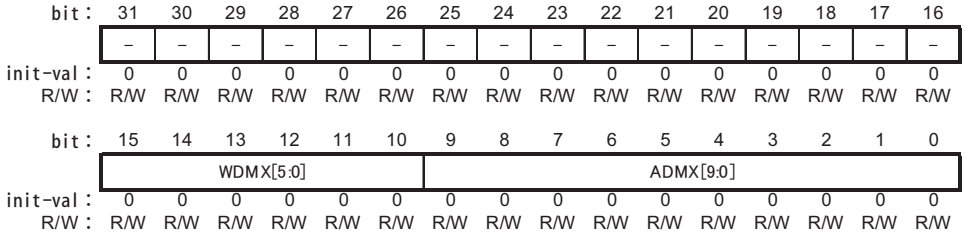
Bits 31 to 0: Reserved

These bits are always read as 0. The write value should always be 0.

HS-GPR Arbitration Control Register 2 (CMPRARCR22)

CMPRARCR22 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R



bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bits 31 to 0: Reserved

These bits are always read as 0. The write value should always be 0.

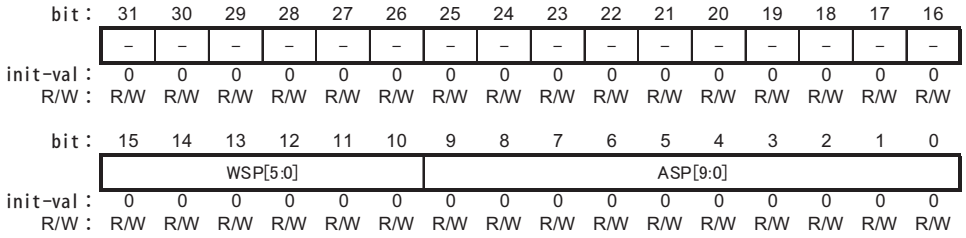
HS-GPR Arbitration Control Register 3 (CMPRARCR23)

CMPRARCR23 sets arbitration control parameters.

Bits 9 to 0: acnum (CC5/USBDMAC/Coresight)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (CC5/USBDMAC/Coresight)



Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 16: Reserved

These bits are always read as 0. The write value should always be 0.

HS-GPR Arbitration Control Register 4 (CMPRARCR24)

CMPRARCR24 sets arbitration control parameters.

Bits 9 to 0: acnum (SPU)

Set the number of requests that accepted continuously when arbitration mode is Grant-Times-based arbitration.

Bits 15 to 10: wnum (SPU)

Set the number of request-waiting cycle when arbitration mode is Grant-Times-based arbitration.

Bits 31 to 16: Reserved

These bits are always read as 0. The write value should always be 0.

HS-GPR Arbitration Control Register 5 (CMPRARCR25)

CMPRARCR25 sets arbitration control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bits 31 to 0: Reserved

These bits are always read as 0. The write value should always be 0.

Error Control Register (CMPRERRMSK)

CMPRERRMSK sets error response control parameters.

bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	ERRMSK[1:0]	
init-val :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	0	R/W	R/W

Bit 0: Error mask

0: normal operation

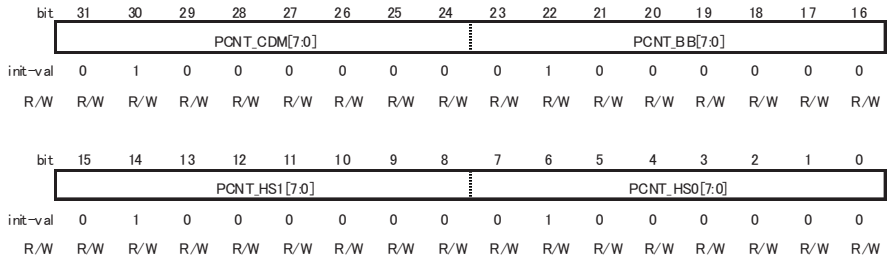
1:Suppress error response when initiator accesses reserved address.

(Caution) If error response is masked, initiator cannot notice these errors. It causes system freeze. Do not set this register as usual.

Bits 1: Error mask

0: normal operation

1:Suppress error response when target ports response are error response.



(Caution) If error response is masked, initiator cannot notice these errors. It causes system freeze. Do not set this register as usual.

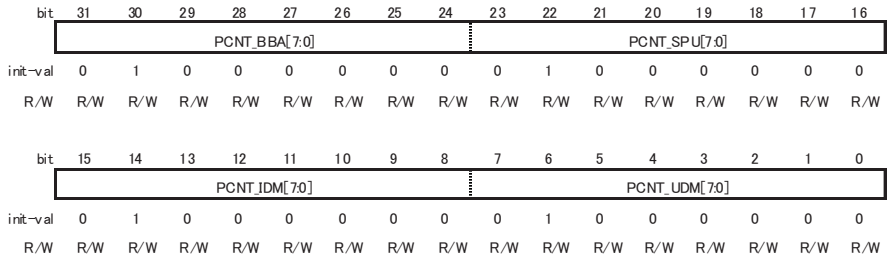
Bits 31 and 2: Reserved

These bits are always read as 0. The write value should always be 0.

SBSC2 Priority Setting Register 1 (CMPRPRICNT11)

CMPRPRICNT11 sets control parameters of urgent transfer to SBSC2.

Bits 7 to 0: number of times of urgent transfer requests which is granted continuously (HS-GPR)



Bits 15 to 8: Reserved

Bits 23 to 16: Reserved

Bits 31 to 24: Reserved

SBSC2 Priority Setting Register 2 (CMPRPRICNT12)

CMPRPRICNT12 sets control parameters of urgent transfer to SBSC2.

Bits 7 to 0: number of times of urgent transfer requests which is granted continuously (CC5/USB-DMAC/CoreSight)

Bits 15 to 8: Reserved

Bits 23 to 16: number of times of urgent transfer requests which is granted continuously (SPU)

Bits 31 to 24: Reserved

SBSC2 Priority Setting Register 3 (CMPRPRICNT13)

CMPRPRICNT13 sets control parameters of urgent transfer to SBSC2.

bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	PCNT_SB[7:0]							
init-val	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 31 to 0: Reserved

SBSC2 Priority Setting Register 4 (CMPRPRICNT14)

CMPRPRICNT14 sets control parameters of urgent transfer to SBSC2.

If this register is set, SHwy router temporally cancels Pri value specified cycles before when the times of urgent transfer to SBSC1 reach the PCNT** register value, and switching to the next urgent transfer.

bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
init-val	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	NPEN	NPCNT[7:0]							
init-val	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bits 7 to 0: ZS cycles of urgent transfer requests canceled when NPEN=1.

Bits 8: enables cancelling cycles of urgent transfer

0 : disable

1: enable

Bits 31 to 9: Reserved

1-F.2.5 Setting a bus-occupancy rate via an arbitration control register

(1) Calculation of register values

(a) *acnum*: Number of requests that grants continuously

In the case register value for each initiator is A,B,C,D,E and F, bus occupation of initiator A is:

A/(A+B+C+D+E+F)

If sum of A to F equal to 100, bus occupation is A% .

For example, setting of HS-GPR can be calculated as follows:
ICB : 15%=int(15/(15+25+25+10+0+25))*100=int(15/100)*100=15
SYS-CPU : 25%=int(25/(15+25+25+10+0+25))*100=int(25/100)*100=25
Com-GPR : 25%=int(25/(15+25+25+10+0+25))*100=int(25/100)*100=25
SYS-DMAC : 10%=int(10/(15+25+25+10+0+25))*100=int(10/100)*100=10
3DG : 0%=0
RT-GPR : 25%=int(25/(15+25+25+10+0+25))*100=int(25/100)*100=25

Bus occupation of each initiator can be calculated if sum of A to F equal to 100 or other value.
Setting value larger, a initiator can access more continuously.
Specially to SDRAM , its effective bus transfer rate increases when accessing address is continuous. So if register value is set larger, total effective bus rate is higher.

On the other hand, arbitration waiting time is increased; worst time of a request is longer.

(b) *wnum*: the number of request-waiting cycle

If initiator's request is not asserted, SHwy router's arbitration switches to other initiator even if register value *acnum* is set to large value.

Register value *wnum* can be used when bus occupation ratio of an initiator is decreased by interruption of other initiator's request.

If *wnum* is set, SHwy router is not switch arbitration to other initiator in *wnum* cycles if current initiator's request is not asserted.

But, setting *wnum* can cause increasing time any initiator's request is not accepted. So if *wnum* is set larger value, total effective bus rate is lower.

(2) About lock transfer

Executing the TAS.B instruction of AP-RTCPU or the SWAP instruction of AP-SYSCPU or BBCPU requires exclusive control of memory. To achieve this, perform lock transfer for SHwy. If any of the three CPUs performs lock transfer, other initiators stop access to SHwy. In the lock transfer control range, the request resource shown in appendix C.2.2 serves as a unit of lock transfer.

(3) Arbitration decision priority

The priority of decision between arbitration controls is as follows:

Lock transfer > urgent transfer > Grant-times-based arbitration

1-F.2.6 Possible Bus Conflict

The SHwy bus (RT/HS/Common) in the AP domain is a star-type bus configuration. The SHwy protocol is a split transaction where request transmission and response reception are independent.

Request resources and response resources are allocated as follows:

Router	req/res	Resource #	Target
RT system	request	0	HS-GPR
		1	Others*[1]
	response	0	AP-Realtime core (SHX)
		1	Others*[2]
HS system	request	0	SBSC1
		1	ICB
		2	Com-GPR
		3	Others*[3]
	response	0	AP-SYSTEM core
		1	ICB
		2	Others*[4]
			Com-GPR
		3	RT-GPR
Common system	request	0	SBSC2
		1	HS-GPR
		2	BSC
		3	Others*[5]
	response	0	HS-GPR
		1	Others*[6]

Notes: 1. RT-HPB, Debug
2. HS-GPR, RTDMAC, Debug
3. 3DG
4. SYSDMAC, 3DG
5. Common-HPB, SPU
6. SPU, MFI

Access destinations where resource allocation differs can be simultaneously accessed without being affected each other. If both CPUs in the AP domain simultaneously access different memory targets, possible conflict in the SHwy request resource is as follows:

From AP-Realtime Core	From AP-SYSTEM Core	Possible Conflict in SHwy
APL SDRAM (SBSC1)	BSC	No conflict
	MERAM	No conflict
	MFI RAM (Sys)	No conflict
Asynchronous RAM, flash memory(BSC)	SBSC1	No conflict
	MERAM	No conflict
	MFI RAM (Sys)	No conflict
MERAM	SBSC1	No conflict
	BSC	No conflict
	MFI RAM (Sys)	No conflict
MFI RAM (Sys)	SBSC1	No conflict
	BSC	No conflict
	MERAM	No conflict

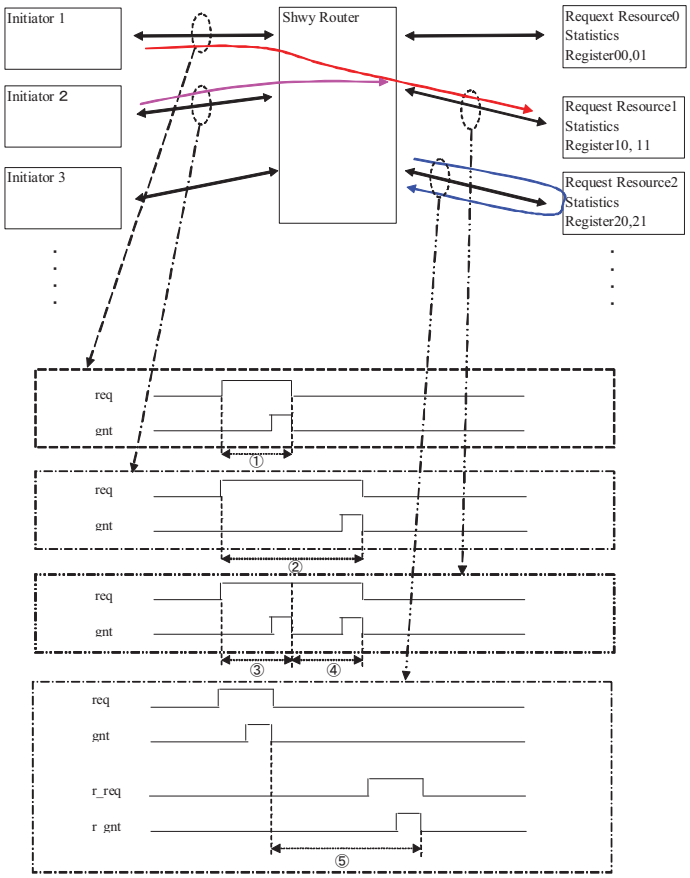
1-F.2.7 HPB Addresses in System Domain

The addresses of peripheral modules connected to the HPB in the system domain are allocated to the following two locations on the memory map:

(1) H'E6000000 to H'E6FFFFFF(HPB Code)

(2) H'E7000000 to H'E7FFFFFF(HPB Data)

(1) and (2) are not mere shadow addresses and are connected to the ports independent of SHwy.



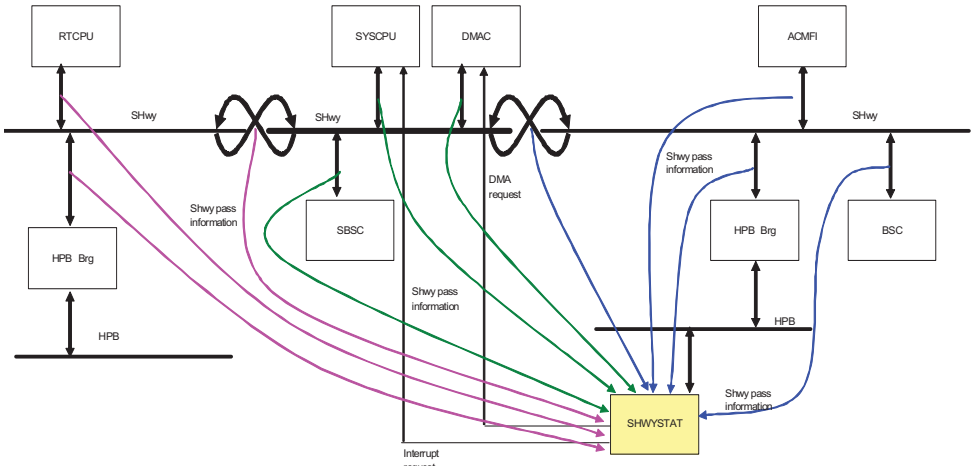
The HPB in SystemDomain is a star-type bus configuration. For this reason, the addresses in (1) and (2) can be accessed independently and simultaneously without intervention to any two modules if they are not the same module.

For example, setting DMA transfer and program read from MFI in H'E7000000 in (2) and reading the register for interrupt processing from H'E6000000 in (1) provides high-speed interrupt processing without being affected by burst RW operations such as DMA transfer that require a long time.

1-F.3 SHwy Statistics Function (SHWYSTAT)

1-F.3.1 Summary

SHWYSTAT is a module that collects the statistical information of pass requests for SHwy. It measures and records time differences between req(request) and gnt(grant) signals of each initiators and targets. Recorded informations can be confirmed the amount of access and the generation of delay by the competition.



Transaction Filter is OFF:
③、④ is increased to Statistics Register 10,11,12. Statistics Register 40,41.42 is invalid.

Transaction Filter is ON:
When Initiator1 is selected, ① is increased to Statistics Register40,41,42 and ③ is increased to Statistics Register10,11,12.

When Initiator2 is selected, ② is increased to Statistics Register40,41,42 and ④ is increased to Statistics Register10,11,12.

Data that SHWYSTAT collects

Following figure indicates the connection relationship of SHWYSTAT.

SHWYSTAT connection relationship

1-F.3.2 Function

1-F.3.2.1 Summary

- Collecting of statistical information of request waiting time on SHwy
  - Initiator filter
  - Address range filter
  - Enable setting of each filters at the same time
- Collecting of target response information
  - Time from request receipt completion to response arrival completion
  - Initiator filter
- Double registers, Continuous measurement
- Interrupt request signal
- DMA request signal
- Counter that indicate completion of measurement

1-F.3.2.2 SHWYSTAT Registers

(1) **Register List**

Name	Register Abbreviation	R/W	Initial Value	Address	Access Size (Bits)
Transaction statistics control register	SHST??CR	R/W	H'0000 0000	H'XXXX0000	32
Interrupt control register	SHST??IR	R/W	H'0000 0000	H'XXXX0004	32

(2) Register function

Transaction Statistics Control Register

The transaction statistics control registers specifies statistical collection start and how to collect statistical information.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
						AM	SM2	SM1					COM	RUN	MD	GO
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 11	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	AM	0	R/W	Enable Address mask 0: Disable 1: Enable
9	SM2	0	R/W	Enable Initiator ID mask2 0: Disable 1: Enable
8	SM1	0	R/W	Enable Initiator ID mask1 0: Disable 1: Enable
7 to 4	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	COM	0	R/W	Enable synchronized operation to Com-SHWYSTAT 0: Disable 1: Enable
2	RUN	0	R	Operation Status 0: No operating 1: Operating
1	MD	0	R/W	Select execution mode 0: Normal mode 1: Continuous mode
0	GO	0	R/W	Measurement Start

Interrupt Control Register

The interrupt control register controls the enable/disable of interrupt factor from SHWYSTAT.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TEM	ADM	-	-	-	-	-	-	TE	AD	-	-	-	-	-	IE
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31to16	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	TEM	0	R/W	Interrupt mask by the measurement completion(Once measurement completion when the continuous mode is set) 0: Enable interrupt mask 1: Disable interrupt mask
14	ADM	0	R/W	Interrupt mask by the specified access detection. 0: Enable interrupt mask 1: Disable interrupt mask
13to8	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	TE	0	R/W	This bit indicates whether interrupt is occurred or not by the measurement completion(Once measurement completion when the continuous mode is set) It is cleared to 0 when 0 is written, and is retained when 1 is written. 0: The measurement is not completed yet 1: The measurement is completed.
6	AD	0	R/W	This bit indicates whether the interrupt by the specified access detection occurred or not. It is cleared to 0 when 0 is written, and is retained when 1 is written. 0: The specified access is not detected. 1: The specified access is detected.
5to1	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	IE	0	R/W	Enable interrupt output from SHWYSTAT.

DMA Transfer Control Register

The DMA transfer control register controls the DMA request. It is possible to collect measurement results by DMA in the continuous mode.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	DACK_CNT							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DACK_NUM								-	-	-	-	-	-	DM	DE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31to24	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
23to16	DACK_CNT	0	R	These bits indicate the number of registers that DMA transfer is completed. They are always 0 when DE=0. They are initialized to 0, when the measurement is completed at DE=1 and DMA is ready to transfer. When DACK_CNT value is equal to DACK_NUM value, DMA completes.
15to8	DACK_NUM	0	R/W	These bits indicate the number of registers to be transferred by DMA. Set value of “(Number of registers)-1”. In the 32byte DMA transfer, set value rounded up to multiple of four.
7to2	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	DM	0	R/W	DMA transfer unit 0: Long word(4byte) 1: 32byte
0	DE	0	R/W	Enable DMA request output 0: Disable DMA request 1: Enable DMA request

DMA Transfer Data Register

The DMA transfer data register is used as DMA source address to collect measurement results in the continuous mode. DMA can read SHWYSTAT register data sequentially. This register can’t be read by CPU.

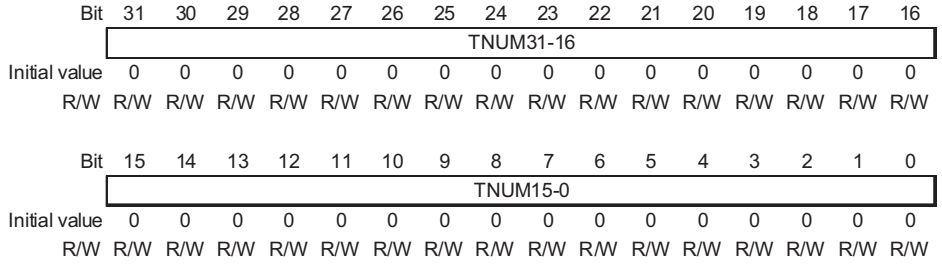
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DATA31-16															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATA15-0															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31to0	DATA	0	R	Register value transferred by DMA.

Measurement Frequency Counter Register

The measurement frequency counter register counts the frequency of measurement completion in the continuous mode. It is cleared to 0 when written.

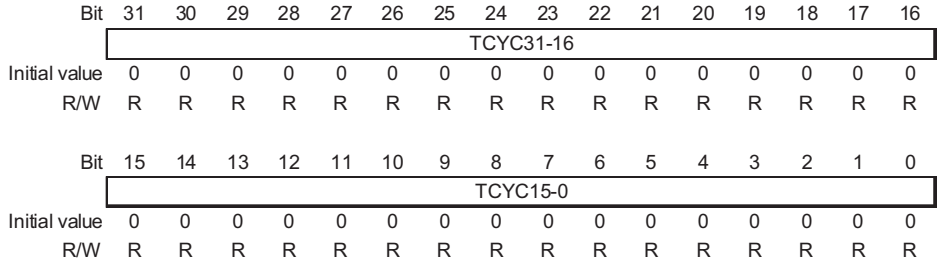


Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNT31-16															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNT15-0															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31to0	CNT	0	R/W	Frequency of the measurement completion

Measurement Cycle Set Register



The measurement cycle set register sets the measurement period. In the continuous mode, it sets once setting period. The period of 1 cycle is calculated as 1 SHwy clock cycle.

Bit	Bit Name	Initial Value	R/W	Descriptions
31to0	TNUM	0	R/W	Measurement cycle

Passage Cycle Count Register

The passage cycle count register indicates the number of passage cycle during the measurement period. In the continuous mode, it indicates once setting period.

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	TCYC	0	R	Number of Passage Cycle

Address Mask Register1

The address mask register1 sets the top address to collect statistic information. The address to specify is the 16 byte unit.

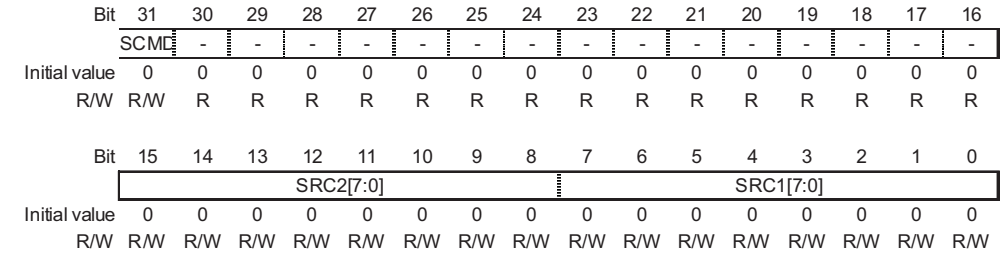
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDMSK1[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDMSK1[15:4]												-	-	-	-
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 4	ADDMSK1	0	R/W	Address mask top address
3 to 0	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Address Mask Register2

The address mask register2 sets the end address to collect statistic information. The address to specify is the 16 byte unit. It is necessary to set the value more than that of the address mask register1.



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDMSK2[31-16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDMSK2[15-4]												-	-	-	-
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 4	ADDMSK2	0	R/W	Address mask end address
3 to 0	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Transaction Mask Register

The transaction mask register sets the condition to mask transaction ID.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SCMD	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRC2[7:0]								SRC1[7:0]							
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	SCMD	0	R/W	Enable direct ID mode. It is used to collect access information from HSGPR to ComGPR. SRC1≦SRC2 Only SM=01 is valid in the direct ID mode.
30to16	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
15to8	SRC2	0	R/W	Masking by Initiator. Refer to the below table.
7to0	SRC1	0	R/W	Masking by Initiator. Refer to the below table.

SRC1/2	Initiator
H'00	Default
H'01	RT-CPU
H'02	SYS-CPU
H'03	RT-DMAC
H'04	SYS-DMAC,DDM
H'05	ICB
H'06	SGX
H'07	USBDMAC0
H'08	USBDMAC1
H'09	SPU
H'0A	CC5
H'0B	ACMFI
H'0C	CoreSight

The data pass from HS-GPR to Com-GPR has 2 passes, HPB pass and others. To collect statistics information of each passes, it sets as follows.

It is mandatory to set 0 to SM2 bit of SHSTCMCR register to apply the direct ID mode.

It sets 1 to SCMD bit of SHSTCMCR register to apply the direct ID mode.

To collect information of HPB access, set H'01 to SRC1 bits of SHSTCMTM register and set H'50 to SRC2 bits of SHSTCMTM register.

To collect information of other targets access, set H'00 to SRC1 bits of SHSTCMTM register and set H'50 to SRC2 bits of SHSTCMTM register.

Transaction Statistic Register l0

Transaction statistics register l0 indicates the statistical results of request resource l (l = 0,1,2,3).

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MAX[15:0]															
Initila value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	SUM[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	SUM[31:0]	H'0000 0000	R	Sum of ZSϕ Cycles from req Assert to gnt Assert The average number of ZSϕ Cycles from req Assert to gnt Assert can be calculated by dividing this sum by the number of pass requests.

Transaction Statistics Register m2

Transaction statistics register m2 indicates the statistical results between an initiator and router. (m=4,5) It is necessary to specify a filter per initiator.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCNT[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCNT[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	TCNT	0	R	Number of pass requests.

Transaction Statistics Register n0

Transaction statistics register n0 indicates the statistics results of target n. (n=6,7,8,9,10,11)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MAX[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MIN[15:0]															
Initial value	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	MAX[15:0]	H'0000	R	Maximum Number of ZSϕ Cycles from req Assert completion to r_req Assert completion.
15 to 0	MIN[15:0]	H'FFFF	R	Minimum Number of ZSϕ Cycles from req Assert completion to r_req Assert completion.

Transaction Statistics Register n1

Transaction statistics register n1 indicates the statistics results of target n. (n=6,7,8,9,10,11)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SUM[31:16]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SUM[15:0]															
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	SUM[31:0]	H'0000 0000	R	Sum of ZSϕ Cycles from req Assert completion to r_req Assert completion The average number of ZSϕ Cycles from req Assert completion to r_req Assert completion can be calculated by dividing this sum by the number of pass requests.

1-F.3.2.3 Explanation of SHWYSTAT operation

The following process makes collecting SHwy statistic information possible.

(1) Setting parameters to collect statistic information.

(2) Start and Stop.

1-F.3.2.3.1 Method to set parameters

1-F.3.2.3.1.1 Kinds of data that is able to collect

The following information is able to be collected.

- Statistic information of request resources
- Statistic information of target responses
- Generation information of specified accesses

The following section is explained about each setting to collect information.

1-F.3.2.3.1.2 Statistic information of request resources

It is necessary to set the measurement cycle set register before SHWYSTAT execution. Using the transaction mask and the address mask, it is possible to collect more detail information. Statistic information is recorded to registers corresponding to each resource after the measurement cycle was set and it starts the measurement.

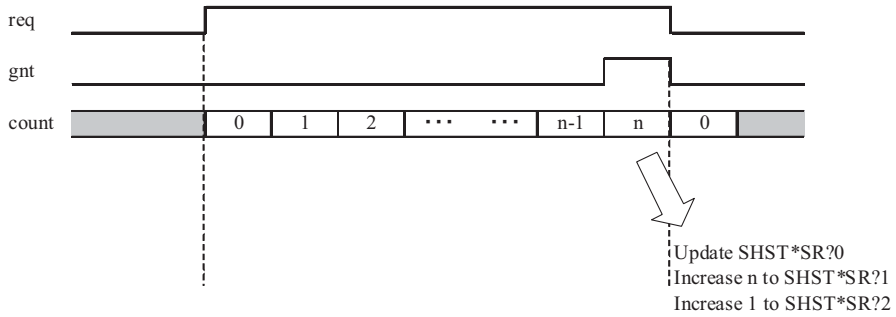

Figure 1-F-3 Cycle recorded in transaction statistics register l0tol2 and m0tom2

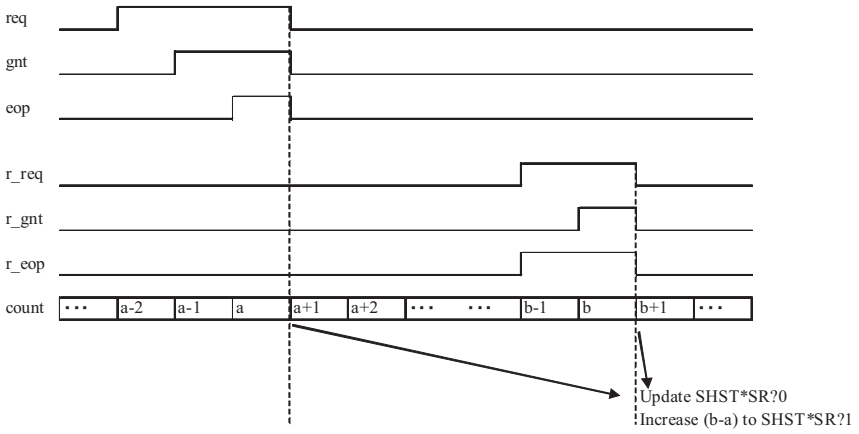
	RT SHWYSTAT	HS SHWYSTAT	COM SHWSTAT
Transaction Statistics Register 00to02	HS-GPR	SBSC1	HS-GPR
Transaction Statistics Register 10to12	Other *1	ICB	BSC
Transaction Statistics Register 20to22	n.a.	Com-GPR	Other *3
Transaction Statistics Register 30to32	n.a.	Other *2	n.a.

*1 RT-HPB,SHX,Debug



*2 RT-GPR, SGX Registers

*3 Com/SYS-HPB

1-F.3.2.3.1.3 Statistic information of target responses

It is possible to collect statistic information of target responses accessed by the initiator specified to SRC1 bits in the transaction mask register. The address mask is not corresponded. Setting SRC1 bits to collect statistic information is necessary. If not set, the register value is invalid. The average number can be calculated by dividing by the value of the transaction statistics register 42(SHSTXXSR42).

To collect statistic information of target responses, it is mandatory to start SHWYSTAT when there is no access to targets.

	RT SHWYSTAT	HS SHWYSTAT	COM SHWYSTAT
Transaction Statistics Register 60to61	SHX	RT-GPR*	HS-GPR*
Transaction Statistics Register 70to71	DBG	SGX	BSC
Transaction Statistics Register 80to81	RT-HPB	ICB	HPB(0xE6??)
Transaction Statistics Register 90to91	HS-GPR*	SBSC1	HPB(0xE7??)
Transaction Statistics Register 100to101	n.a.	COM-GPR*	n.a.
Transaction Statistics Register 110to111	n.a.	COM-GPR(HPB)*	n.a.

*It can not be measured the correct max/min cycle number because GPR bridge has some targets.

1-F.3.2.3.1.4 Measurement filter

The transaction statistics information register 00-32 can be collected statistic information filtered by the address mask and the transaction ID mask. These filters are specified by SM1, SM2 and AM bits of the transaction control register, the address mask register1, 2 and the transaction mask register.

- Case1: Specified address mask and SRC1 mask, it is recorded in (address & SRC1) conditions.
- Case2: Specified address mask and SRC2 mask, it is recorded in (address & SRC2) conditions.
- Case3: Specified SRC1 mask and SRC2 mask, it is recorded in (SRC1 | SRC2) condition.
- Case 4: Specified all (Address, SRC1 and SRC2) mask, it is recorded in (SRC1|SRC2) & address conditions.

The transaction statistics information register 40-52 can be collected statistic information filtered by the address mask and the transaction ID mask. These filters are specified by SM1,SM2 and AM bits of the transaction control register, the address mask register1,2 and the transaction mask register. It is mandatory for the transaction statistics register 40-42 to specify SRC1 bit, and it is mandatory for the transaction statistics register 50-52 to specify SRC2 bit.

- Case1: Specified address mask and SRC1 mask, it is recorded in address & SRC1 conditions.
- Case2: Specified address mask and SRC2 mask, it is recorded in address & SRC2 conditions.

It is mandatory for the transaction statistics register 60-111 to specify SRC1 bit. It is possible to collect information by specifying only SRC1 bits, however it is mandatory to set SM bit of the transaction control register to get pass request number.

1-F.3.2.3.1.5 Generation information of specified accesses

It sets the address mask register1, 2 or the transaction mask register. If AD bit of the interrupt control register is 1 and the specified access generates, the specified access interruption can be occurred.

1-F.3.2.3.2 Start and Stop

1-F.3.2.3.2.1 Measurement start

- Setting contents of the measurement
- Setting the measurement period

- Clear the measurement frequency counter (the Continuous mode)

After setting above-mentioned, SHWYSTAT can be started when 1 is written to GO bit of the transaction control register.

Setting example:

Getting statistic information of Real-Time CPU

Register : SHST??TM write data: H'00000001

The measurement period = 30ms

ZSϕ200MHz(Cycle: 5ns), 30ms/5ns=6000000 = H'005B8D80

Register: SHST??TN write data: H'005B8D80

Getting the address range of H'E6050000 to H'E6060000

Register: SHST??AM1 write data: H'E6050000

Register: SHST??AM2 write data: H'E6060000

Enable the measurement completed interruption

Register: SHST??IR write data: H'00008001

Start the measurement. (Enable SRC1 mask and address mask)

Register: SHST??CR write data: H'00000501

1-F.3.2.3.2.2 Continuous mode

The continuous mode setting adds the measurement frequency count clear and MD=1 of the control register to 1-F.3.2.3.2.1 settings.

Setting example:

Clear the measurement frequency counter

Register: SHST??CNT write data: H'00000000

Start the measurement. (Enable SRC1 mask and address mask)

Register: SHST??CR write data: H'00000503

In the case of the execution in the continuous mode, it is necessary for the measurement cycle set register to set sufficient measurement period to execute the interrupt handle and DMA transfer. The measurement cycle counter can be checked whether the interrupt handle and DMA transfer are in time or not. If the value of the cycle counter increase by one, their handles are in time, however an increase in two or more is not.

SHWYSTAT repeats the measurement while operating in the continuous mode. The way to stop the continuous mode set MD=0, GO=0 of the statistic control register. Setting MD=0,GO=0 is stopped SHWYSTAT at once. The last measurement period is not guaranteed.

1-F.3.2.3.2.3 Collecting statistic results by DMA

SHWYSTAT can request DMA transfer when the measurement was completed.

Setting example:

Get all register values by DMA

Register: SHST??DMR write data: H'00360001

Set the DMA transfer data register address to the DMA source address register

Register: DM??SAR write data: H'XXXX0100

XXXX: RT=H'FFCF, HS=H'E6F3, CM=H'E6F2

1-F.3.2.3.2.4 Synchronize mode

The synchronize mode can be executed 3-domain (Real-Time, Hi-Speed and Common) SHWYSTAT modules by the trigger of Common-SHWYSTAT execution.

Real-Time and Hi-Speed SHWYSTAT are set 1 to COM bit of each statistic control register. After that, Real-Time, Hi-Speed and Common SHWYSTAT start all together when Common SHWYSTAT is set to start. All SHWYSTAT can stop when set stopping Common-SHWYSTAT (set MD=0, GO=0 of the statistics control register).

1-F.3.2.3.2.5 Measurement end

When the passage cycle count register is 0, SHWYSTAT stops the measurement. It can be stopped SHWYSTAT to write 0 to GO bit of the statistic control register while operating. To stop SHWYSTAT in the continuous mode, it is mandatory to write 0 to MD bit and GO bit at the same time.

1-F.3.2.4 Notes

1-F.3.2.4.1 About the register retained period

The register retained period indicates as follows when it is unreset and unclear.

Normal mode:

All registers are retained until the next execution.

Continuous mode:

When the interruption is valid, all registers are retained until the measurement completion interrupt factor is cleared. After cleared it, they are updated when next measurement is completed. If the interrupt factor is not cleared until the next measurement completion, registers are not updated.

When the DMA transfer is valid, all registers are retained until DMA transfer is completed. After DMA completed, they are updated when next measurement is completed. If DMA is not completed until the next measurement completion, registers are not updated.

When neither the interruption nor DMA request is valid, all registers are updated when the next measurement is completed.

Clear of registers:

All registers are cleared when the measurement frequency cycle register is cleared to 0. It does not depend on the mode.

1-F.3.2.4.2 About the measurement cancel

It forbids to stop SHWYSTAT by the module stop control register in CPG module. Especially in the case of using the interruption and DMA, it causes error to stop by the module stop, because the interruption and DMA may keep request.

1-F.4 HPB Bus Functions

1-F.4.1 Bus Control Registers

The HPB has bus control registers.

HPB Registers

Name	Register Abbreviation	R/W	Initial Value	Address	Access Size (Bits)
HPB control register 0	HPBCTRL0	R/W	H'0000 0000	H'E6001010	32
HPB control register 1	HPBCTRL1	R/W	H'0000 0000	H'E6001014	32
HPB control register 2	HPBCTRL2	R/W	H'0000 0000	H'E6001018	32

About dynamic module stop (DMS)

The above logic is individually installed in the Bdrivers of the bus and bridge.

However, INT dynamic module stop is clock stop control in the module, so performance changes such as latency increase do not occur according to settings.

1-F.4.2 Bus Semaphore Control Registers

The modules connected to the CommonHPB bus use this bus to support exclusive control via semaphores.

Overview

- Each module has a semaphore.
- In SHwy, the initiator srcID is used to identify the SHwy bus and control access privilege.
- By default (semaphore open status), common resources can be freely accessed.
- The master processor can forcibly acquire semaphores. It can also access common resources even if no semaphore is acquired.
- An access error occurs if an attempt is made to access a common resource when no semaphore is acquired. Information related to this access error is reflected in the register.
- Read access is possible even if no semaphore is acquired.
- Timeout counters support the timeout function based on CPϕ (ON/OFF (initial value) by bit 31).
- The initiator that acquired a semaphore is authorized to write counter values.

1-F.4.2.1 Common HPB Semaphore Control Registers

Name	Register Abbreviation	R/W	Initial Value	Address	Access Size (Bits)

Master ID Register

The master ID register indicates SrcID of the master CPU on the SHwy bus.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MPSRC[7:0]								—	—	—	—	—	—	—	—
Initial value:	*	*	*	*	*	*	*	*	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 24	MPSRC7 to MPSRC0	- (Refer to Descriptions)	R	Master CPU ID Indicate the SrcID of the master CPU on the SHwy bus. The initial value depends on and varies with boot mode. H'01: AP realtime CPU H'40: AP system CPU
23 to 0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Master Access Control Register

The master access control register controls the forced acquisition function of the master CPU. Setting of this register is applied to all bus semaphores. Only the master CPU can write this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SMF GETC	NOSM	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

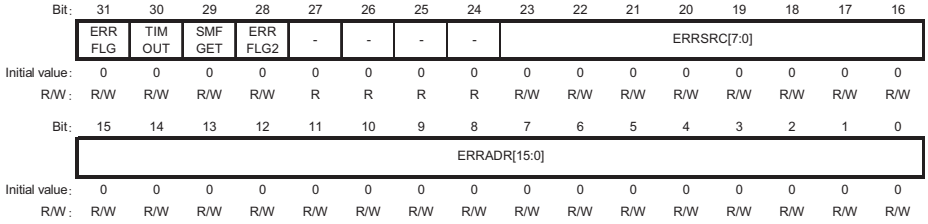
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	SMFGETC	0	R/W	Forced Semaphore Acquisition Control by Master CPU 0: The master CPU cannot forcibly acquire semaphores. 1: The master CPU can forcibly acquire semaphores.
30	NOSM	0	R/W	Write Access Control by Master CPU when Semaphore Is not Acquired 0: The master CPU cannot be write-accessed when no semaphore is acquired. 1: The master CPU can be write-accessed even if no semaphore is acquired.
29 to 0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

(Bit assignment is common to XXXX (GPIO, DBG, CMT2, CPGA, and SYSC).)

XXXX Semaphore Acquisition ID Register

The XXXX semaphore acquisition ID register controls semaphore acquisition and displays the semaphore acquisition state.



Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SMSRC[7:0]								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SMGET
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 24	SMSRC7 to SMSRC0	H'00	R	Indicate the SrcID of the SHwy bus of the CPU that acquired the semaphore. H'00: Open state H'01: AP realtime CPU H'40: AP system CPU H'64: ACMFI
23 to 1	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SMGET	0	W	Acquires and opens semaphores. If SMSRC7 to SMSRC0 are H'00, semaphores can be acquired. If they are not H'00, semaphores cannot be acquired. These bits are automatically cleared to 0 after write. 1: Semaphore acquisition (this bit is read as 0) 0: Semaphore open

XXXX Semaphore Error Register

The XXXX semaphore error register indicates the information displayed if an access error occurs when no semaphore is acquired.

Bit	Bit Name	Initial Value	R/W	Descriptions
31	ERRFLG	0	R/W	Indicates whether an access error occurred when no semaphore is acquired. This bit is cleared to 0 when written to 0. 1: An access error occurred. 0: No access error occurred.
30	TIMOUT	0	R/W	Indicates whether the semaphore was forcibly opened due to timeout. This bit is cleared to 0 when written to 0. 1: The semaphore was forcibly opened. 0: The semaphore was not forcibly opened.
29	SMFGET	0	R/W	Indicates whether the master CPU forcibly acquired semaphores. This bit is cleared to 0 when written to 0. 1: The master CPU forcibly acquired semaphores. 0: The master CPU did not forcibly acquire semaphores.
28	ERRFLG2	0	R/W	Indicates whether an access occurred when semaphore is opened. This bit is cleared to 0 when written to 0. 1: An access occurred when semaphore is opened. 0: No access occurred when semaphore is opened.
27 to 24	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

23 to 16	ERRSRC7 to ERRSRC0	H'00	R/W	Indicate the SrcID of SHwy bus of the CPU where the access error occurred when no semaphore is acquired. These bits are retained while ERRFLG or ERRFLG2 is 1. These bits are cleared to 0 when written to 0. H'01: AP realtime CPU H'40: AP system CPU H'64: ACMFI
15 to 0	ERRADR15 to ERRADR0	H'0000	R/W	Indicate the lower 16 bits of the address of the CPU where the access error occurred when no semaphore is acquired attempted to access. These bits are retained while ERRFLG or ERRFLG2 is 1. These bits are cleared to 0 when written to 0.

XXXX Semaphore Timeout Setting Register

The XXXX semaphore timeout setting register controls semaphore acquisition timeout and sets time.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TORN	TIMEOUT[30:16]														
Initial value:	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TIMEOUT[15:0]															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TOEN	0	R/W	Enables or disables semaphore acquisition timeout setting. 1: Disables semaphore acquisition timeout setting. 0: Enables semaphore acquisition timeout setting.
30 to 0	TIMEOUT30 to TIMEOUT0	H'7FFF_FFFF	R/W	Set semaphore acquisition timeout time. A unit of semaphore acquisition timeout time is the number of CPϕ cycles.

XXXX Semaphore Timeout Counter

The XXXX semaphore timeout counter displays the time that lasts to semaphore acquisition timeout.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	TIMEOUTCOUNT[30:16]														
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TIMEOUTCOUNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
31 to 0	TIMEOUTCOUNT30 to TIMEOUTCOUNT0	H'0000_0000	R	Down counter that indicates the time that lasts to semaphore acquisition timeout. A unit of semaphore acquisition timeout is the number of CPϕ cycles.

1-F.4.2.2 Semaphore Control Range

The registers shown by module in the following address range are subject to semaphore control:

module	Semaphore Control Target Addresses
GPIO	H'E6050000 to H'E605FFFF
DBG	H'E6108000 to H'E610FFFF
CMT2	H'E6134000 to H'E6137FFF
CPG	H'E6158000 to H'E615FFFF
SYSC	H'E6188000 to H'E618FFFF

1-F.4.2.3 Semaphore acquisition and open procedure

When the master CPU forcibly acquires no semaphore

Acquisition:

1. Check if the semaphore is open according to the SMSRC bits of the semaphore acquisition ID register.
2. Write 1 to the SMGET bit of the semaphore acquisition ID register.
3. Check if the SMSRC bits of the semaphore acquisition ID register indicate the own SrcID. If the SMSRC bits indicate the own SrcID, acquire the semaphore. If the SMSRC bits do not indicate the own SrcID, return to Step 1.

Open:

1. Write 0 to the SMGET bit of the semaphore acquisition ID register.

When the master CPU forcibly acquires a semaphore

Acquisition:

1. Check if the semaphore is open according to the SMSRC bits of the semaphore acquisition ID register.
2. Write 1 to the SMGET bit of the semaphore acquisition ID register.
3. Check if the SMSRC bits of the semaphore acquisition ID register indicate the own SrcID. If the SMSRC bits indicate the own SrcID, acquire the semaphore. If the SMSRC bits do not indicate the SrcID, return to Step 1.
4. Clear the error in the semaphore error register in advance.

Open:

1. Check if the own write error exists in the semaphore error register (the master CPU does not require this check).
2. If the own write error exists in the semaphore error register, reacquire the semaphore and open it again from the error location. If the error does not exist, write 0 to the SMGET bit of the semaphore acquisition ID register.

	APL-RT	Readable only	Readable only	Readable/writable

When not used, bus semaphores can be accessed in the same way when there is no bus semaphore. The master processor also has the access function that ignores semaphore acquisition and the forced semaphore acquisition function. These functions are provided mainly to prevent deadlocks resulting from semaphores.

Due to these specifications, a hardware function is unavailable that fully blocks semaphore access when no semaphore is acquired. For this reason, it is important to honor the following software agreement between CPUs: When exclusive control is performed, semaphores are accessed after they are acquired and they are not accessed if they are not acquired.

1-F.4.2.4 About the timeout counter register

The timeout counter register sets a semaphore acquisition timeout time. When a semaphore is acquired, the values in this semaphore timeout setting register are set in the down counter in the semaphore controller. When the down counter becomes 0, the semaphore is forcibly opened. The timeout counter register indicates the current values of the down counter. The current values of the down counter are reset to the values set in the TIMEOUT30 to TIMEOUT0 bits of the semaphore timeout setting register:

- When a semaphore is acquired
- When the semaphore timeout setting register is write-accessed

When set 0 to the TIMEOUT30 to TIMEOUT0 bits, the semaphore is forcibly opened. It doesn't depend on the timeout counter operation.

1-F.5 Security Function

To prevent the entire system from being destroyed and altered by an incorrect program, install the access protection function in registers related to the system.

Name	Register Abbreviation	R/W	Initial Value	Address	Access Size (Bits)
RBAR protection setting register	GRDRBAR	R/W	H'0000 0000	H'E6001500	32
SBAR protection setting register	GRDSBAR	R/W	H'0000 0000	H'E6001504	32

Register States in Each Operating Mode

Register Abbreviation	Power-on Reset	System Reset	A4S Area Reset
GRDRBAR	Initialized	Initialized	Retained
GRDSBAR	Initialized	Initialized	Retained

For details, refer to section 1-D Overview of reset.

1-F.5.1 SBAR Protection Setting Register

The 32-bit SBAR protection setting register protects SBAR register write protection.

This register has the register write protection function that authorizes only CPUs with access permission to change the settings.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	CPUTYPE[1:0]		REGWP	—	—	—	—	—	—	—	WPRSP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BBWP	APWP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26, 25	CPUTYPE [1:0]	00	R	These bits indicate which CPUs are authorized to change the settings of this register. 00: All CPUs are authorized to change the settings. 01: Only AP-SH is authorized to change the settings. 10: Only AP-ARM is authorized to change the settings. 11: Only ACMFI is authorized to change the settings. To set the setting change authorization of this register, write 1 to the REGWP bit at the same time. The CPU that set this register is automatically set as the CPU authorized to change the settings. When B'0 is written to the REGWP bit, these bits are cleared to B'00. This clearing authorizes all CPUs to change the settings.

Bit	Bit Name	Initial Value	R/W	Descriptions
24	REGWP	0	R/W	Register Change Authorization Setting Bit This bit sets whether the CPU that set this register allows other CPUs to change the settings of this register. 0: Allows all CPUs to change the settings of this register. 1: Allows only the CPU that set this register to change the settings of this register. After 1 is written, this bit is automatically cleared to 0. When this bit is set to 1, the type of CPU that set this register is set in CPUTYPE. After changing the values of this register, read this register and check via software to see if this bit is cleared to 0 and the set CPU type is reflected in CPUTYPE. Then start memory area access. Write from the CPU, which is indicated by CPUTYPE and not authorized to change the settings, is disabled.
23 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	WP_RSP	0	R/W	This bit sets whether to respond to the error when the write-protected area is write-accessed. 0: Responds to the error. 1: Does not respond to the error. Write from the CPU, which is indicated by CPUTYPE and not authorized to change the settings, is disabled.
15 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	BB_WP	0	R/W	BB Resource* Write Authorization Setting Bit 0: Write to SBAR is authorized. 1: Write to SBAR is not authorized. Write from the CPU, which is indicated by CPUTYPE and not authorized to change the settings, is disabled.
0	AP_WP	0	R/W	AP Resource* Write Authorization Setting Bit 0: Write to SBAR is authorized. 1: Write to SBAR is not authorized. Write from the CPU, which is indicated by CPUTYPE and not authorized to change the settings, is disabled.

Note: * AP resources: AP-SH, AP-ARM, AP-DMAC (RT-DMAC, SYS-DMAC), AP-JTAG, and others (image IP, MBXL)
BB resources: ACMFI

1-F.5.2 RBAR Protection Setting Register

The contents of the RBAR protection setting register are the same as those of the SBAR protection setting register.

Section 2 AP-System Core

2.1 Overview

The AP-System core is a core block equipped with ARM Cortex-A8. For details on the functions of Cortex-A8, see its respective Technical Reference Manual.

Table2.1 Feature of the AP-System Core Block

Item	Features
CPU(*1)	• ARM Cortex-A8：r3p1 • ARM architecture v7-A • TrustZone Security Extensions • Configurations Level 1 Instruction cache: 32k bytes (8k bytes x 4 ways) Level 1 Data cache : 32k bytes (8k bytes x 4 ways) Level 2 cache: 256k bytes (32k bytes x 8 ways) • MMU support • NEON and VFPv3 support • Operating clock CPU core : 800MHz(Zϕ), AXI bus : 400MHz(ZXϕ) • Low power mode Power shutdown mode Core standby mode(*2) Power is shut down except for the level 2 cache. Because level 2 cache information remains, boot can be performed faster than usual reset. Sleep mode • Trace macro (ETM) ETM architecture: Ver.3.3 External trace data output data width: 8 bits External trace clock output (TRACECLK): Divide ATCLK by 2. (Data is output at edges of a clock.)
Bus Bridge	• A8S bus bridge connects AXI bus and SHwy bus. • Address translation is performed to the physical address start space (Max: 512 kbytes) according to the settings of the SBAR register in the SYSC. • Commutative SHwy access priority (register setting) • Supports N:1 as the clock ratio of the AXI bus clock (ZXϕ) and SHwy (ZSϕ) (See the clock ratio restrictions in the chapter of CPG)
Debug	• Supports the cross break between AP-System core and AP-Realtime core.

*1 For details, see related ARM manuals.

CPU : Cortex™-A8 Revision r3p1 Technical Reference Manual

*2 “Dormant Mode” in ARM documents.

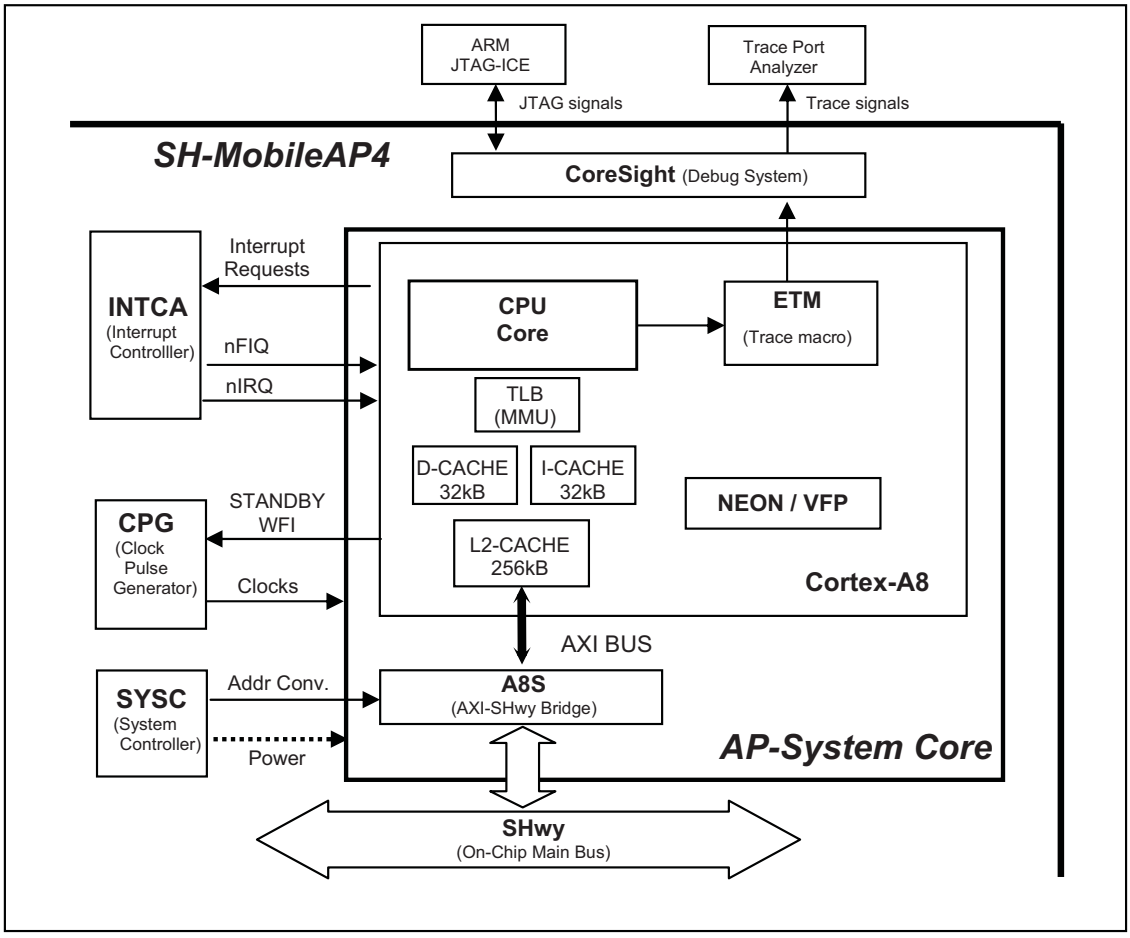

Figure2.1 AP-System Core Block Diagram

2.2 Control Registers

Table 2.2 shows the control register configuration related to the AP-System core. Table 2.3 shows the register state in each operating mode. These AP-System core registers are initialized by A4S area reset because of they are not on A3SM area on which AP-System core is but on A4S area.

Table2.2 Register Configuration

Register Name	Register Abbreviation	R/W	Address	Access Size
Priority register	APARMPRI	R/W	H'E6F1 0000	32
Address translation area register	APARMBAREA	R/W	H'E6F1 0020	32

APARMBAREA	Initialized	Initialized	Retained	Initialized	Initialized	Retained	Retained

* See “2.7 Power-Down Mechanism”

2.2.1 Priority Register (APARMPRI)

APARMPRI controls priority values when the APL-ARM block accesses SHwy. The value of the PRI bits is output as a priority value. For details on SHwy including how to use the PRI signal, see chapter 1-F, Bus Function.

Note: The setting of this register takes effect after a few cycles. It depends on the bus clock ratio of SHwy and HPB.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	PRI[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
3 to 0	PRI[3:0]	1000	R/W	Priority value This bit is a priority value for access to SHwy.

2.2.2 Address Translation Area Register (APARMBAREA)

The bus bridge circuit has the physical address translation function. This function is controlled by the SYSC boot address register (SBAR). Access to the start space (maximum 512k bytes) including the reset address is translated into access to the physical address space indicated with the SBAR[31:12] bit. For details on the SBAR bits, see the SYSC manual.

The APARMBAREA register specifies an address area to be translated. Table 2.4 shows the details of the address translation using the APARMBAREA register and the SBAR[31:12] bit.

Note: When changing registers related to the address translation function, be careful not to switch an area that is being accessed from a translation target to an out-of-translation target or from an out-of-translation target to a translation target. There is no problem with changes for increasing the translation target area by changing the APARMBAREA register by programming the translation target area.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

2 to 0	BAREA[2:0]	100	R/W	Area size of the address translation target (from address 0) 000：4k bytes 001：8k bytes 010：16k bytes 011：32k bytes 100：64k bytes 101：128k bytes 110：256k bytes 111：512k bytes

Table2.4 Address Translation with the BAREA Bits and SBAR Register

(ADDR[31:0] are physical addresses before translation)

BAREA[2:0]	Translation target area	Physical address after translation
B'000	H'0000 0000～H'0000 0FFF	{SBAR[31:12],ADDR[11:0]}
B'001	H'0000 0000～H'0000 1FFF	{SBAR[31:13],ADDR[12:0]}
B'010	H'0000 0000～H'0000 3FFF	{SBAR[31:14],ADDR[13:0]}
B'011	H'0000 0000～H'0000 7FFF	{SBAR[31:15],ADDR[14:0]}
B'100	H'0000 0000～H'0000 FFFF	{SBAR[31:16],ADDR[15:0]}
B'101	H'0000 0000～H'0001 FFFF	{SBAR[31:17],ADDR[16:0]}
B'110	H'0000 0000～H'0003 FFFF	{SBAR[31:18],ADDR[17:0]}
B'111	H'0000 0000～H'0007 FFFF	{SBAR[31:19],ADDR[18:0]}

2.3 AXI-SHwy Bridge (A8S)

A8S is the bus bridge between AXI bus from Cortex-A8 and SHwy that is the on-chip main bus. The AXI buses and SHwy can operate at different frequencies. Only the frequencies of an integral ratio N that is set with the FRQCRB and FRQCRC registers of the CPG are supported. The AXI buses must be set to a clock frequency that is the same as or faster than that of SHwy. Priority values for access to SHwy can be changed with the APARMPRI register.

The notes and restrictions of the load/store function of the Cortex-A8 are described below:

[Notes and restrictions of the load/store function of Cortex-A8]

- Exclusive load/store instruction

  Even if using the LDREX, STREX, or CLREX instruction, it is not reflected on SHwy. Thus, these instructions can be used only for the exclusion between threads on Cortex-A8. These instructions cannot be used for the exclusive processing between Cortex-A8 and other bus masters (AP-Realtime Core).

- Load multiple instruction (LDM)

  Use the LDM instruction only for memory devices (external memories via BSC or SBSC, or internal memories such as MFRAM, MERAM, and XYRAM).

  When the start and end addresses are not on an 8 bytes boundary, read access for an area not to be accessed occurs. Specifically, in the case that (8m + 4) bytes are read from address 8n (n, m: integer), and the case that 8m bytes are read from address (8n + 4), 4 bytes may be read from address (8n + 8m + 4). If this instruction is used for access to control registers whose state or contents, such as FIFO, is changed by read operation, unexpected operation may occur. This problem does not apply to the Store Multiple (STM) instruction. Thus, writing is not performed to an area not to be accessed.

  For details of the cache control and the memory attribute setting, see 2.5.1.

2.4 Internal Memory

The Cortex-A8 core is equipped with the instruction cache (32k bytes), data cache (32k bytes), and level 2 cache (256k bytes). The TCM is not mounted. In core standby mode that is one of the power-down mechanisms, power is supplied to the SRAM of level 2 cache. For details, see section 2.7.2, Core Standby Mode.

2.5 Notes for Settings

2.5.1 Memory Attribute

The followings are restrictions on the memory attributes in the case of the memory write access. If you ignore these restrictions, the write access will cause unexpected results. There is not restriction in case of the read access.

MERAM and External memories accessed via SBSC

No restriction

SMFRAM, ACMFRAM

The memory attribute must be the below.

- Strongly-ordered(default) ({TEX,C,B}=00000)(*)
- Shareable/Non-Shareable Device({TEX,C,B}=00001 or 01000)(*)
- L2 Read/Write-Back Write-Allocate Cacheable({TEX,C,B}=101xx)(*)

External memories accessed via BSC

The memory attribute must be the below.

- Strongly-ordered(default)({TEX,C,B}=00000)(*)
- Shareable/Non-Shareable Device({TEX,C,B}=00001 or 01000)(*)

(*) In case that “Memory Region Remap” is enabled in OS, the bit pattern of {TEX,C,B} is different.

2.5.2 Level 2 Cache Setting

- The latency of both L2 Data RAM and L2 Tag RAM has to be 3 cycles. The default value of “Tag RAM latency” bit of “c9, L2 Cache Auxiliary Control Register” is 2 cycles. Before you enable level 2 cache, “Tag RAM latency” bit must be set to 3cycles. The default value of “Data RAM latency” bit is 3 cycles.
- The default setting of “Way-Size” is 32k bytes and the default setting of “Associativity” is 8-Way. You can not change them.
- The followings are necessary to enable level 2 cache.
  - Enable level 1 cache with setting “C” bit of “c1, Control Register” to 1(ON).
  - Set “L2EN” bit of “c1, Auxiliary Control Register” to 1(ON).
    The default setting of “L2EN” bit of “c1, Auxiliary Control Register” is 1(ON). Usually, you do not have to set “L2EN” bit.

For detail of CP15 register, see Cortex-A8 manual.

2.6 Interface with the Interrupt Controller

The Cortex-A8 core supports interrupts by two interrupt signals (nFIQ and nIRQ). The AP-System core creates seven types of interrupt request signals listed in table 2.5 for INTCA.

Table2.5 Interrupt Sources Created by the AP-System Core

Interrupt Source	Interrupt generation module	Description
PMUIRQ	Cortex-A8	Interrupt request of the performance monitor
COMMTX	Cortex-A8	Transmission of the debugger communication channel
COMMRX	Cortex-A8	Reception of the debugger communication channel
CTIIRQ	Cortex-A8	CTI(Cross Trigger I/F) interrupt
DMAEXTERRIRQ	Cortex-A8	PLE error interrupt
DMAIRQ	Cortex-A8	Interrupt of PLE non-secure transmission complete
DMASIRQ	Cortex-A8	Interrupt of PLE secure transmission complete

2.7 Power-Down Mechanism

2.7.1 Overview

The AP-System core supports the following three power-down modes.

- Power shutdown mode
- Core standby mode (Power shutdown except for some SRAMs)
- Sleep mode (Clock stop)

In power shutdown mode, the power of the AP-System core is shut down. This mode is intended to be used at long-time interrupt wait, and achieves the reduction of power consumption including leakage current cut-off. The system boots up from the reset vector at its return from power shutdown mode. For detail of the power-down mode control, see chapter 13 “SYSC”.

Core standby mode is a power shutdown mode in a state where the power of some SRAMs in the Cortex-A8 core is maintained (the contents of them are maintained). Because the contents of SRAMs are maintained, boot return time is shorter than the power shutdown mode. In this mode, level 2 cache is retained and the application is expected to be executed in a cache hit state immediately after boot because the cache contents are maintained.

Sleep mode is a mode stopping only clocks. This mode does not perform power shutdown. Although the reduction of power consumption can be achieved as compared with a state where clocks are supplied, leakage current still exists. For details of sleep mode and core standby mode, see chapter 11 “CPG”.

note: MSTPAS(AP-System core module stop) bit in RESCNT register of SYSC is for control only A8S bridge clock and program execution of CPU. You can not use MSTPAS bit to cut off the power consumption because AP-System core clock is not stopped by the bit.

2.7.2 Core Standby Mode

Figure 2.2 shows a block diagram of continuous power supply in core standby mode. Power supply to the SRAMs of level2 cache is kept. The power of SRAMs used for the instruction cache, the data cache and branch prediction system is shut down.

The system boots up from the reset vector at its return from core standby mode. ACMFRAM in AP4 is recommended to be used as a boot memory to avoid the access to a low-speed extrinsic memory.

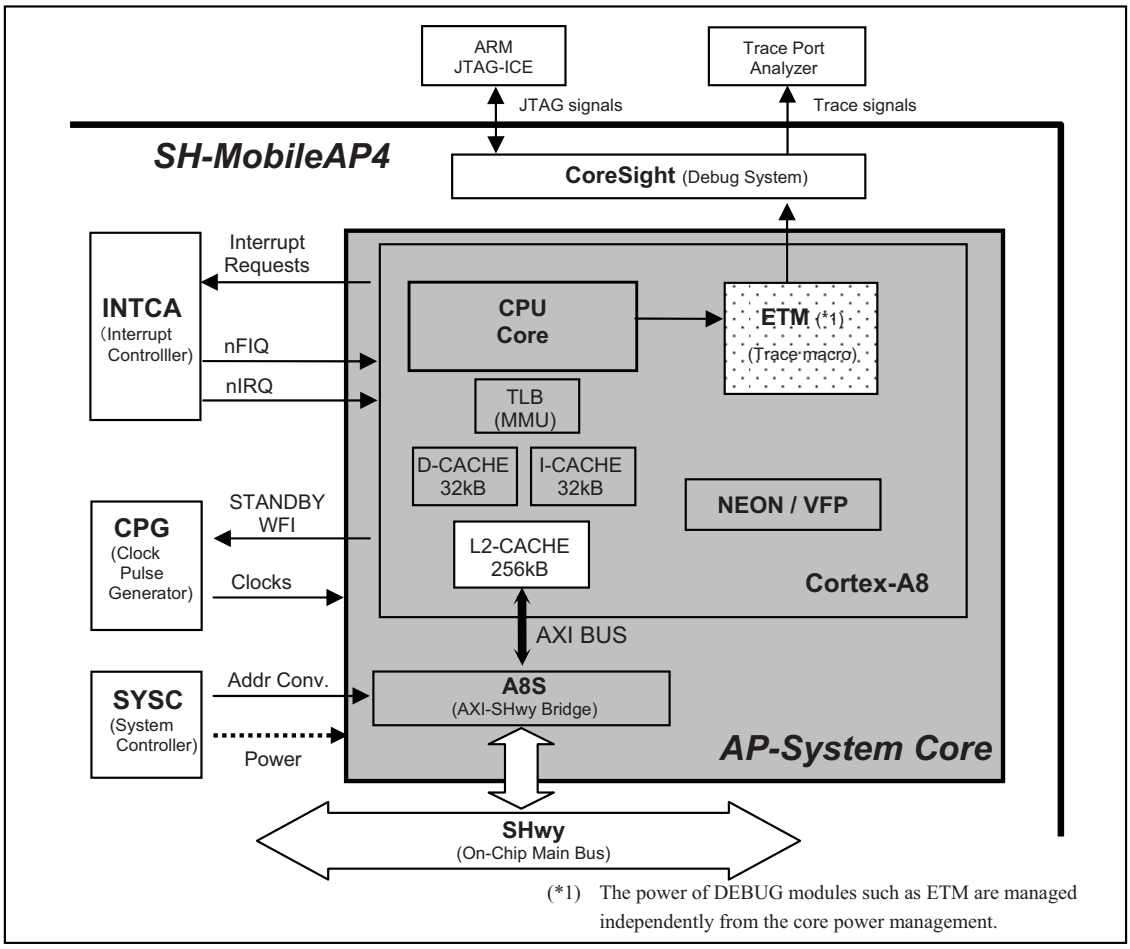

Figure2.2 Power Supply Parts in Core Standby Mode (white area)

2.8 APB Interface for DEBUG

Cortex-A8 has APB interface to access DEBUG modules register. You can access the interface via SHwy and CoreSignt block. Table2.6 shows the address of the APB interface.

Table2.6 Address of APB interface and Access Target

Address	Target
H'E6F8 E000～H'E6F8 EFFF	DEBUG Register
H'E6F8 F000～H'E6F8 FFFF	ETM Control Register
H'E6F9 0000～H'E6F9 0FFF	CTI Control Register

Section 3 AP-Realtime Core

3.1 Overview of the AP-Realtime Core

The AP-Realtime (AP-RT) core block is a RISC microprocessor equipped with a 32-kbyte instruction cache, a 32-kbyte operand cache, a 16-kbyte X/Y memory, and a 4-kbyte instruction memory (IL memory). The architecture of the core is SH4AL-DSP, which is 32-bit RISC type Super H architecture CPU (SH) with the digital signal processing (DSP) extended function.

Table 3.1 shows the features of the AP-RT core block.

For details on the SH4AL-DSP core, see SH4AL-DSP Software Manual and SH4AL-DSP Extended Function Software Manual.

The SH4AL-DSP core of the AP-RT core block supports the extended functions.

Table 3.1 Features of the AP-Realtime Core Block

Item	Features
CPU (SH4AL-DSP) (Extended function support)	• Renesas Technology original architecture • Upward compatible with SH-1, SH-2, and SH3-DSP at object code level • 32-bit internal data bus • General register file Sixteen 32-bit general registers (eight 32-bit shadow registers) Seven 32-bit control registers Four 32-bit system registers • RISC-type instruction set (upward compatible with SH series) Instruction length: 16-bit fixed length for improved code efficiency Load/store architecture Delayed branch instructions Conditional execution Instruction set based on C language • Superscalar architecture (providing simultaneous execution of two instructions) • Instruction execution time: Up to two instructions/cycle • Virtual address space: 4 Gbytes • Space identifier ASIDs: 8 bits, 256 virtual address spaces • Internal multiplier • Supports core standby mode • Eight-stage pipeline

Item	Features
DSP unit	• Mixture of 16-bit and 32-bit instructions • 32-bit or 40-bit internal data bus • Supports a multiplier, ALU, and barrel shifter 32-bit multiplier supporting 16 bits × 16 bits • Supports large DSP data register files Six 32-bit data registers Two 40-bit data registers • Supports the extended Harvard architecture for the DSP data bus Two data buses One instruction bus • Four parallel operations can be performed at the maximum. ALU, multiplication, and two load/store operations • Two addressing units to generate two simultaneous memory access addresses • Supports DSP data addressing modes Increment, and indexing (with or without modulo addressing) • Supports the zero-overhead repeat loop control • Supports conditional execution instructions • Supports user DSP mode and privileged DSP mode
Memory management unit (MMU)	• 256 address spaces (identified by an 8-bit ASID) of 4 Gbytes each • 32-bit physical address space • Single virtual memory mode and multiple virtual memory mode • Supports multiple page sizes: 1 kbyte, 4 kbytes, 8 kbytes, 64 kbytes, 256 kbytes, 1 Mbyte, 4 Mbytes, and 64 Mbytes • Four-entry full associative TLB for instructions • 64-entry full associative TLB for instructions and operands • Supports software-controlled replacement and random-counter replacement algorithm • TLB contents can be accessed directly by address mapping.

Item	Features
Cache memory	• Instruction cache (IC) 32-kbyte, 4-way set associative 32-byte block length • Operand cache (OC) 32-kbyte, 4-way set associative 32-byte block length Selectable write methods (copy-back/write-through)
X/Y memory	• Four independent read/write ports 8-, 16-, or 32-bit operand access from the CPU with virtual addresses Up to two 16-bit accesses from the DSP 8-, 16-, or 32-bit operand access from the CPU with physical addresses, and instruction fetch access from the CPU 8-, 16-, 32-, or 64-bit and 16- or 32-byte access through external requests • Total of 16 kbytes • Supports the memory protective mechanism dedicated to DSP access as well as to CPU access
IL memory	• Three independent read/write ports Instruction fetch access from the CPU with virtual addresses Instruction fetch access from the CPU with physical addresses and 8-, 16-, or 32-bit operand access from the CPU 8-, 16-, 32-, or 64-bit and 16- or 32-byte access through external requests • Total of 4 kbytes

3.2 AP-Realtime (SH) Core Block Diagram

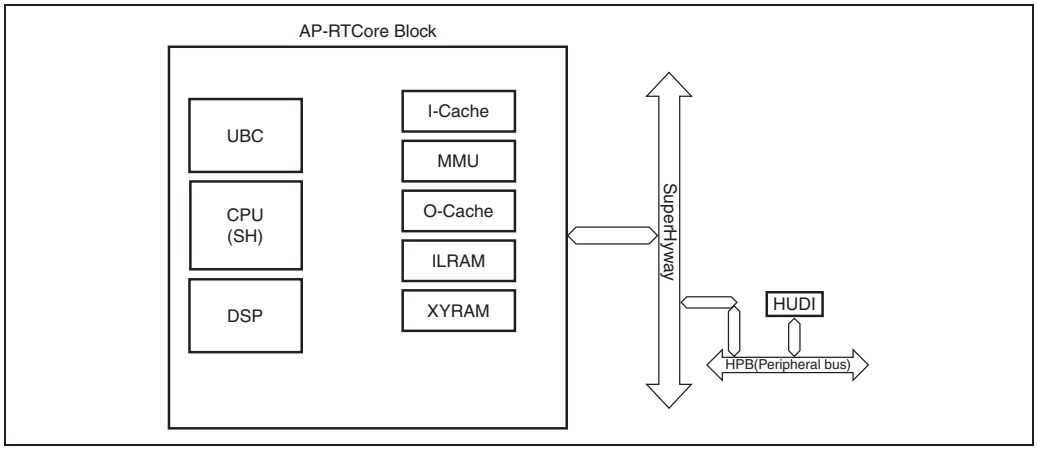

Figure 3.1 AP-Realtime (SH) Core Block Diagram

3.3 32-bit Address Extended Mode

The SH4AL-DSP core embedded in this LSI supports 32-bit address extended mode and the 32-bit boot function. For details on 32-bit address extended mode and the 32-bit boot function, see SH4AL-DSP Extended Function Software Manual.

After the AP-RT (SH) core is booted, the privileged space mapping buffer (PMB) is initialized by the hardware as described below. "SZ=B'11" indicates 512 Mbytes. Entry 0 specifies the mapping of the P1 area, and entry 1 specifies that of the P2 area. The treatment of the P1 area and P2 area is compatible with former products using the SH4AL-DSP core.

Table 3.2 PMB Configuration after Boot

Entry	VPN31 to VP24	PPN31 to PPN24	V	SZ21 and SZ0	C	UB	WT
0	B'1000 0000	B'0000 0000	1	B'11	1	0	1
1	B'1010 0000	B'0000 0000	1	B'11	0	0	0

[Legend]

VPN : Virtual page number

PPN : Physical page number

V : Validity bit (0: Invalid, 1: Valid)

SZ : Page size bits
(B'00: 16-Mbyte page, B'01: 64-Mbyte page, B'10: 128-Mbyte page, B'11: 512-Mbyte page)

C : Cacheability bit (0: Not cacheable, 1: Cacheable)

UB : Buffered write bit (0: Buffered write, 1: Unbuffered write)

WT : Write-through bit (0: Copy-back mode, 1: Write-through mode)

For this LSI, it is recommended to change the PMB configuration from the initial configuration described in Table 3.2 to the appropriate configuration for the system just after boot by the software running on the AP-Realtime core.

Table 3.3 Sample PMB Configuration

Entry	VPN31 to VP24	PPN31 to PPN24	V	SZ21 and SZ0	C	UB	WT
0	B'1000 0000	B'0100 0000	1	B'11	1	0	0
1	B'1010 0000	B'0000 0000	1	B'11	0	0	0

Table 3.3 shows a sample PMB configuration.

Entry 0 is a 512-Mbyte page. Accesses to virtual addresses from H'8000 0000 to H'9FFF FFFF are translated to physical addresses H'4000 0000 to H'5FFF FFFF. This is a setting for treating the SDRAM space as a cachable region. Note that accesses to virtual addresses from H’80000000 to H’9FFFFFFF are incompatible with the former P1 area, which was mapped to physical addresses from H'0000 0000 to H'1FFF FFFF.

Entry 1 is a 512-Mbyte page. With this configuration, accesses to the former P2 area (virtual addresses from H'A000 0000 to H'BFFF FFFF) are translated to physical addresses H'0000 0000 to H'1FFF FFFF with non-cachable attribute, that is, compatible mapping with 29-bit physical address mode.

The above PMB configuration is a sample. Please build the suitable configuration to your system combining page sizes and attributes.

3.4 Core Standby Mode

The SH4AL-DSP core embedded in this LSI supports the core standby mode in which power supply to the logical block in the core is shut off. Power to the memories (I-Cache, O-Cache, ILRAM, and XYRAM) in the core is not shut off to keep the contents of them. To enter the core standby mode, issue the SLEEP instruction in a state where the CPU core standby bit (CSTBY) of the CPGA RealTime Standby Control Register (RTSTBCR) is set. The core exits from the core standby mode by usual interrupts. At this time, registers in the core are initialized because the logical block of the core is reset. Save the contents of the registers into the memory before entering the core standby mode and restore the register values after exit in order to return the core to the state before the core standby mode. The IL memory is recommended as the save area of register values. In addition, the IL memory can be the place locating the routines for entering and exiting the core standby mode.

Section 4 IPMMU

This LSI has three IPMMU modules. Each IPMMU module provides the translation function that translates virtual addresses into physical addresses (= SHwy addresses) to respective SHwy initiator modules. With this function, initiator modules (for ICB/LMB, IP accessing SHwy via ICB/LMB) can access memory with virtual addresses.

4.1 Overview of IPMMUs

4.1.1 Features

- One IPMMU module exists for each SHwy initiator (total of three IPMMU modules).
  - IPMMUI: For ICB/LMB
  - IPMMUR: For RT-DMAC1
  - IPMMUR2: For RT-DMAC2
- Provides the MMU function compatible with ARMv6 to the first 2 Gbytes of the virtual address space (H'0000 0000 to H'7FFF FFFF).
  - Each of IPMMUR and IPMMUR2 has a 64-entry TLB.
  - IPMMUI has a 96-entry TLB.
  - Hardware page table walk function
  - Treats access rights as privileges.
  - Protects access rights in three levels: read/write approved, only read approved, access disapproved.
  - Does not support protection with domains.
- Provides the PMB (privileged space mapping buffer) function compatible with SH4AL-DSP to the latter 1 Gbyte of the virtual address space (H'8000 0000 to H'BFFF FFFF).
  - Includes a 16-entry PMB.

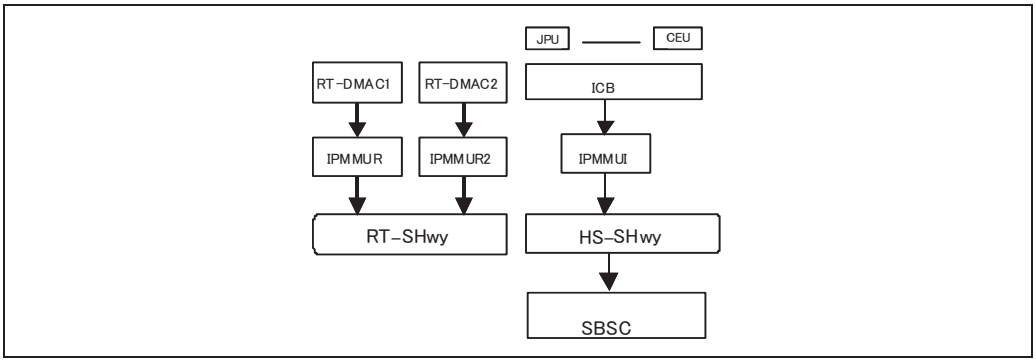

Figure 4.1 Relationship between IPMMUs and Other Modules

4.1.2 Address Space

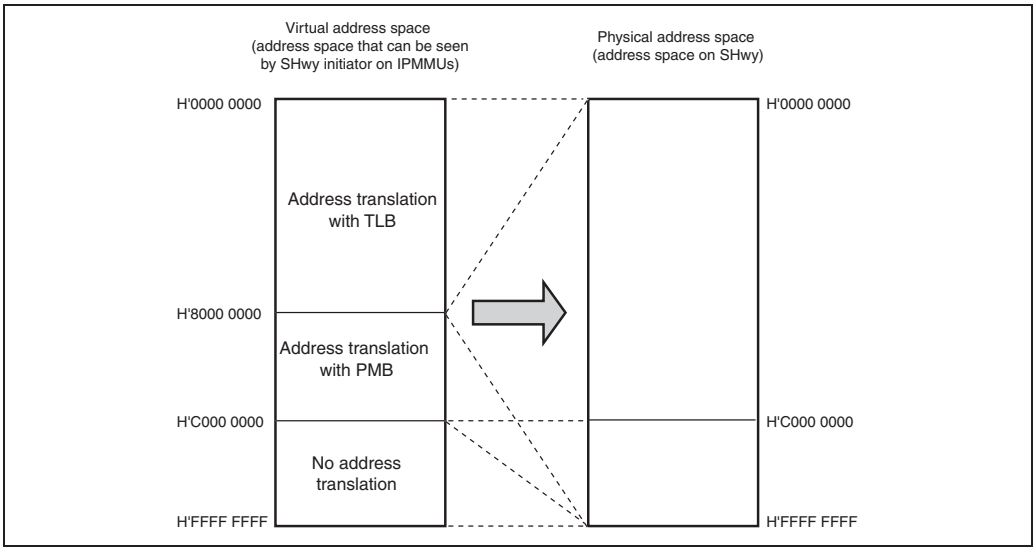

Figure 4.2 Relationship between the Address Spaces

4.2 Register Description

Table 4.1 shows the register configuration and memory configuration of IPMMUs. Table 4.2 shows the register state in each processing mode.

Table 4.1 Register Configuration and Memory Configuration

Register Name	Register Abbreviation	R/W	Address *1	Access Size
IPMMU control register 1	IMCTR1	R/W	H'xxxx x000	32
IPMMU control register 2	IMCTR2	R/W	H'xxxx x004	32
IPMMU status register	IMSTR	R/W	H'xxxx x008	32
IPMMU exception address register	IMEAR	R/W	H'xxxx x00C	32
IPMMU ASID register	IMASID	R/W	H'xxxx x010	32
IPMMU translation table base register	IMTTBR	R/W	H'xxxx x014	32
IPMMU translation table base control register	IMTTBCR	R/W	H'xxxx x018	32
IPMMU DMAC channel enable control register *2	IMDCEN	R/W	H'xxxx x020	32
IPMMU PMB address array 0 to IPMMU PMB address array 15	IMPMBA0 to IMPMBA15	R/W	H'xxxx x080 to H'xxxx x0BC	32
IPMMU PMB data array 0 to IPMMU PMB data array 15	IMPMBD0 to IMPMBD15	R/W	H'xxxx x0C0 to H'xxxx x0FC	32

Note: *1 The "xxxx x" parts in the Address column are as follows according to IPMMUs:
IPMMUI: FE951
IPMMUR: FFC30
IPMMUR2:FFC40
*2 IMDCEN exist only on IPMMUR and IPMMUR2

Table 4.2 Register State in Each Processing Mode

Register Abbreviation	Reset [*1]	Module Standby
IMCTR1	Initialized	Retained
IMCTR2	Initialized	Retained
IMSTR	Initialized	Retained
IMEAR	Initialized	Retained
IMASID	Initialized	Retained
IMTTBR	Initialized	Retained
IMTTBCR	Initialized	Retained
IMDCEN [*2]	Initialized	Retained
IMPMBA0 to IMPMBA15	Initialized	Retained
IMPMBD0 to IMPMBD15	Initialized	Retained

Note: *1 Please refer to “1-D. Overview of Reset” for the reset condition.
In case of IPMMUI, these registers are initialized by ICB’s software reset.
*2 IMDCEN exist only on IPMMUR and IPMMUR2

4.2.1 IPMMU Control Register 1 (IMCTR1)

IMCTR1 controls the address translation function with the TLB of IPMMUs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	INTEN	FLUSH	TLBEN
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	—	R	Reserved These bits are always read as 0. The write value should always be 0.
2	INTEN	0	R/W	Specifies whether to issue interrupt requests when an exception event occurs. Interrupt requests are reported to INTCS. 0: Interrupt requests are not issued. 1: Interrupt requests are issued.
1	FLUSH	0	W	When this bit is set to 1, all entries of TLB are disabled. This bit is always read as 0.
0	TLBEN	0	R/W	TLB Enable When this bit is 0, address translation is not performed to access to addresses H'0000 0000 to H'7FFF FFFF. Addresses are passed to SHwy without translation. 0: Address translation with TLB is disabled. 1: Address translation with TLB is enabled.

4.2.2 IPMMU Control Register 2 (IMCTR2)

IMCTR2 specifies the address translation function with the PMB of IPMMUs.

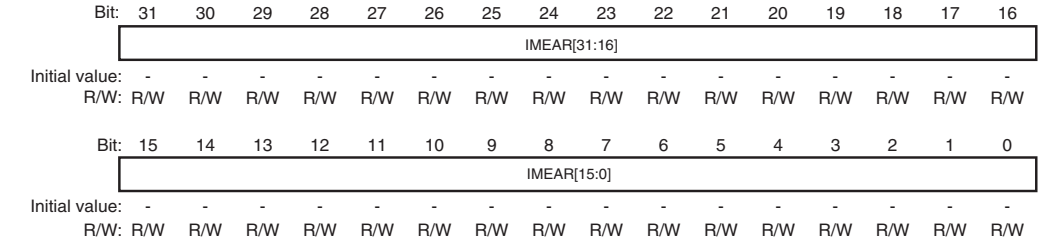
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	PMBEN
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	—	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PMBEN	0	R/W	PMB Enable When this bit is 0, address translation is not performed to access to addresses H'8000 0000 to H'BFFF FFFF. Addresses are passed to SHwy without translation. 0: Address translation with PMB is disabled. 1: Address translation with PMB is enabled.

4.2.3 IPMMU Status Register（IMSTR）

IMSTR records exception events that have occurred while IPMMUs are running.

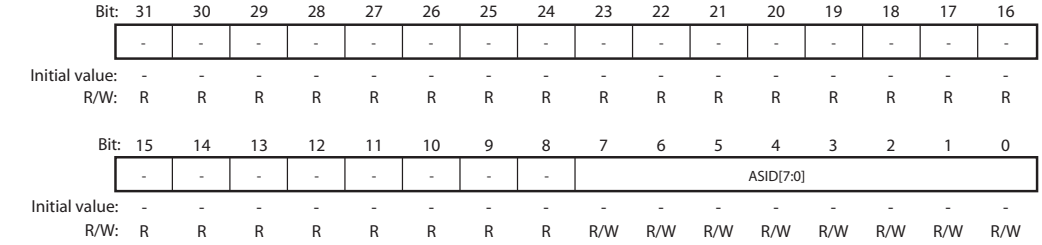


Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	MHIT	-	ABORT	PF	TF
Initial value:	-	-	-	-	-	-	-	-	-	-	-	0	-	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	—	R	Reserved These bits are always read as 0. The write value should always be 0.
4	MHIT	0	R/W	This bit is automatically set to 1 by the hardware when either of the following exceptions occurs. TLB multiple hits PMB multiple hits PMB miss This bit can be cleared by writing 0 with software.
3	—	—	R	Reserved This bit is always read as 0. The write value should always be 0.
2	ABORT	0	R/W	This bit is automatically set to 1 by the hardware when an error response is returned for a hardware page table walk. This bit can be cleared by writing 0 with software.
1	PF	0	R/W	This bit is automatically set to 1 by the hardware when an access right violation occurs. This bit can be cleared by writing 0 with software.
0	TF	0	R/W	This bit is automatically set to 1 by the hardware when a translation fault occurs due to a hardware page table walk. This bit can be cleared by writing 0 with software.

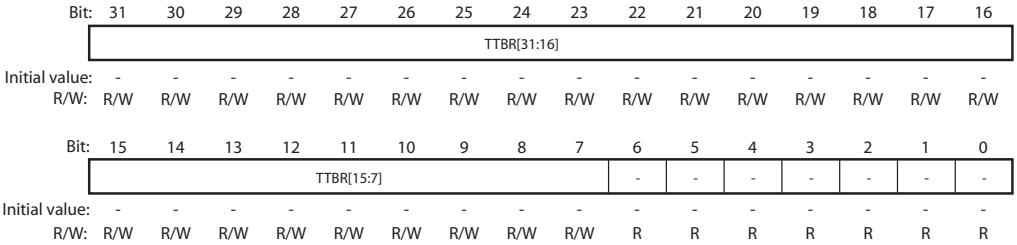
4.2.4 IPMMU Exception Address Register (IMEAR)



IMEAR records the virtual address causing the last exception event that has occurred while IPMMUs are running.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	EAR[31:0]	Undefined	R/W	These bits record the virtual address causing the last exception event that has occurred.

4.2.5 IPMMU ASID Register (IMASID)



IMASID specifies ASID values used when IPMMUs perform address translation with TLB.

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	—	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	ASID	Undefined	R/W	These bits specify ASID values used for address translation with TLB.

4.2.6 IPMMU Translation Table Base Register（IMTTBR）

IMTTBR specifies the physical address that is the base of the first level page table seen by IPMMUs.

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	TTBR	Undefined	R/W	These bits specify the physical address that is the base of the first level page table. When TTBCR2 to TTBCR0 = B'001, TTBR31 to TTBR13 are used. When TTBCR2 to TTBCR0 = B'010, TTBR31 to TTBR12 are used. When TTBCR2 to TTBCR0 = B'011, TTBR31 to TTBR11 are used. When TTBCR2 to TTBCR0 = B'100, TTBR31 to TTBR10 are used. When TTBCR2 to TTBCR0 = B'101, TTBR31 to TTBR9 are used. When TTBCR2 to TTBCR0 = B'110, TTBR31 to TTBR8 are used. When TTBCR2 to TTBCR0 = B'111, TTBR31 to TTBR7 are used.
6 to 0	—	—	R	Reserved These bits are always read as 0. The write value should always be 0.

4.2.7 IPMMU Translation Table Base Control Register（IMTTBCR）

IMTTBCR specifies the size of the first level page table seen by IPMMUs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	TTBCR[2:0]		
Initial value:	-	-	-	-	-	-	-	-	-	-	-	-	-	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	—	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	TTBCR	B'001	R/W	These bits specify the size of the first level page table. B'000: Reserved (Do not set this value.) B'001: 8 kbytes (Address space is 2 Gbytes.) B'010: 4 kbytes (Address space is 1 Gbyte.) B'011: 2 kbytes (Address space is 512 Mbytes.) B'100: 1 kbyte (Address space is 256 Mbytes.) B'101: 512 bytes (Address space is 128 Mbytes.) B'110: 256 bytes (Address space is 64 Mbytes.) B'111: 128 bytes (Address space is 32 Mbytes.) Allocate the first level page table to the boundary of the above table sizes. For example, when TTBCR2 to TTBCR0 = B'001, allocate the first level page table to an 8-kbyte boundary.

4.2.8 IPMMU DMAC channel enable (IMDCEN)[*1]

IMDCEN specifies a validity of TLB address translation for each channel of RT-DMAC[*2].

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value :	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	CH5EN	CH4EN	CH3EN	CH2EN	CH1EN	CH0EN
Initial value :	–	–	–	–	–	–	–	–	–	–	1	1	1	1	1	1
R/W :	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

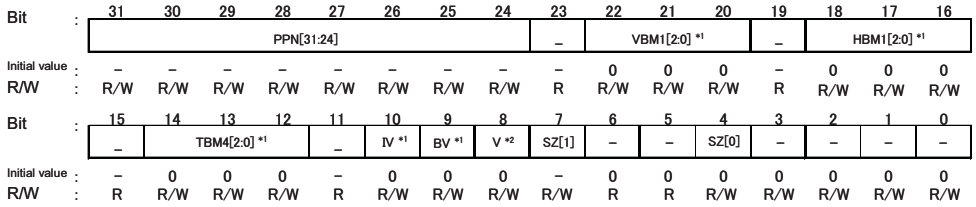
Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	—	R	Reserved These bits are always read as 0. The write value should always be 0.
5	CH5EN	B’1	R/W	This bit specifies a validity of TLB address translation for RT-DMAC channel 5.
4	CH4EN	B’1	R/W	This bit specifies a validity of TLB address translation for RT-DMAC channel 4.
3	CH3EN	B’1	R/W	This bit specifies a validity of TLB address translation for RT-DMAC channel 3.
2	CH2EN	B’1	R/W	This bit specifies a validity of TLB address translation for RT-DMAC channel 2
1	CH1EN	B’1	R/W	This bit specifies a validity of TLB address translation for RT-DMAC channel 1
0	CH0EN	B'1	R/W	This bit specifies a validity of TLB address translation for RT-DMAC channel 0.

Note: *1 IMDCEN exist only on IPMMUR and IPMMUR2.

*2 In case of IPMMUR ,this shows RT-DMAC1. In case of IPMMUR2, this shows RT-DMAC2.

4.2.9 IPMMU PMB Address Array n (IMPMBAn)

IMPMBAn (n = 0 to15) specifies the virtual page number of the PMB of IPMMUs.



Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VPN[31:24]								-	-	-	-	-	-	-	-
Initial value:	-	-	-	-	-	-	-	-	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	V	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	VPN[31:24]	Undefined	R/W	Virtual Page Number For 16-Mbyte page, VPN31 to VPN24 are used. For 64-Mbyte page, VPN31 to VPN26 are used. For 128-Mbyte page, VPN31 to VPN27 are used. For 512-Mbyte page, VPN31 to VPN29 are used.
23 to 9	—	All 0	R	Reserved Writing to this bit is ignored.
8	V	0	R/W	Validity Bit 0: Invalid 1: Valid
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

4.2.10 IPMMU PMB Data Array n (IMPMBDn)

IMPMBDn (n=0 to15) specifies the physical page number and page size of the PMB of IPMMUs.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	PPN[31:24]	Undefined	R/W	Physical Page Number For 16-Mbyte page, PPN31 to PPN24 are used. For 64-Mbyte page, PPN31 to PPN26 are used. For 128-Mbyte page, PPN31 to PPN27 are used. For 512-Mbyte page, PPN31 to PPN29 are used.
23	—	0	R	Reserved Writing to this bit is ignored.
22 to 20	VBM1[2:0] *1	All 0	R/W	Set (number of vertical bits to apply tile-linear translation) −1 in this bit.
19	—	0	R	Reserved Writing to this bit is ignored.
18 to 16	HBM1[2:0] *1	All 0	R/W	Set (number of horizontal bits to apply tile-linear translation) −1 in this bit.
15	—	0	R	Reserved Writing to this bit is ignored.
14 to 12	TBM4[2:0] *1	All 0	R/W	Set (number of horizontal bits not to apply tile-linear translation) −4 in this bit
11	—	0	R	Reserved Writing to this bit is ignored.

Bit	Bit Name	Initial Value	R/W	Description
10	IV *1	0	R/W	Line-Interleaved Address Translation Enable When this bit is set to 1, line-interleaved address conversion is performed with SB = HBM1 + 1 + TBM4 + 4. 0: Disabled 1: Enabled
9	BV *1	0	R/W	Tile-Linear Address Translation Enable When this bit is set to 1, line-interleaved address conversion is performed with SB = HBM1 + 1 + TBM4 + 4. 0: Disabled 1: Enabled
8	V *2	0	R/W	Validity Bit 0: Invalid 1: Valid
7	SZ[1]	Undefined	R/W	Page size [1] This bit specifies the page size together with bit 4. 00: 16-Mbyte page 01: 64-Mbyte page 10: 128-Mbyte page 11: 512-Mbyte page
6 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	SZ[0]	Undefined	R/W	Page size [0]
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: *1 These bits exists only on IPMMUI. These bits are reserved bits on IPMMUR and IPMMUR2. If BV or IV are set 1 in IPMMUI, the address which is after translation becomes the target of TLB/PMB translation again.

*2 In the case of IPMMUI, the address translation become valid by setting 1 to this bit. However IPPMBAn.V should be set 1'b1 in case of BV=1'b1 or IV=1'b1.

4.3 Functions of IPMMUs

4.3.1 Access with TLB

When the TLBEN bit in IMCTR1. is set to 1, address translation with TLB is applied to access to the address area from H'0000 0000 to H'7FFF FFFF.

Figure 4.3 shows the translation flow.

When a translation fault occurred due to a hardware page table walk, or an access right violation occurred, or a hardware page table walk failed (an error response was returned), an address to be accessed is translated to an address for which an error response is surely returned, and access is performed. Additionally, the corresponding exception event bit in IMSTR is set to 1.

When multiple TLB entries are hit, an address to be accessed is translated to an undefined address, and access is performed. Additionally, the MHIT bit in IMSTR is set to 1.

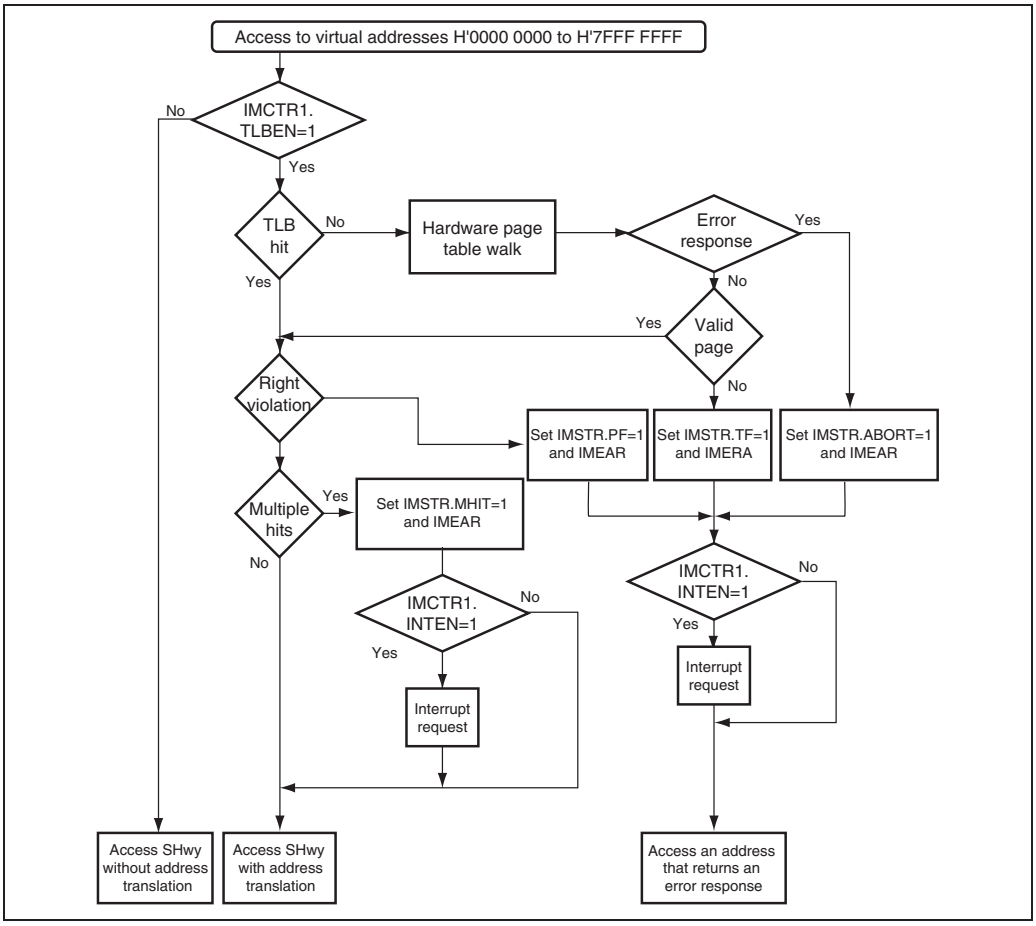


Figure 4.3 Translation Flow with TLB

4.3.2 Access with PMB

When the PMBEN bit in IMCTR2. is set to 1, address translation with PMB is applied to access to the address area from H'8000 0000 to H'BFFF FFFF.

Figure 4.4 shows the translation flow.

When no PMB entry is hit, an address to be accessed is translated to an address for which an error response is surely returned, and access is performed. Additionally, the MHIT bit in IMSTR is set to 1.

When multiple PMB entries are hit, an address to be accessed is translated to an undefined address, and access is performed. Additionally, the MHIT bit of IMSTR is set to 1.

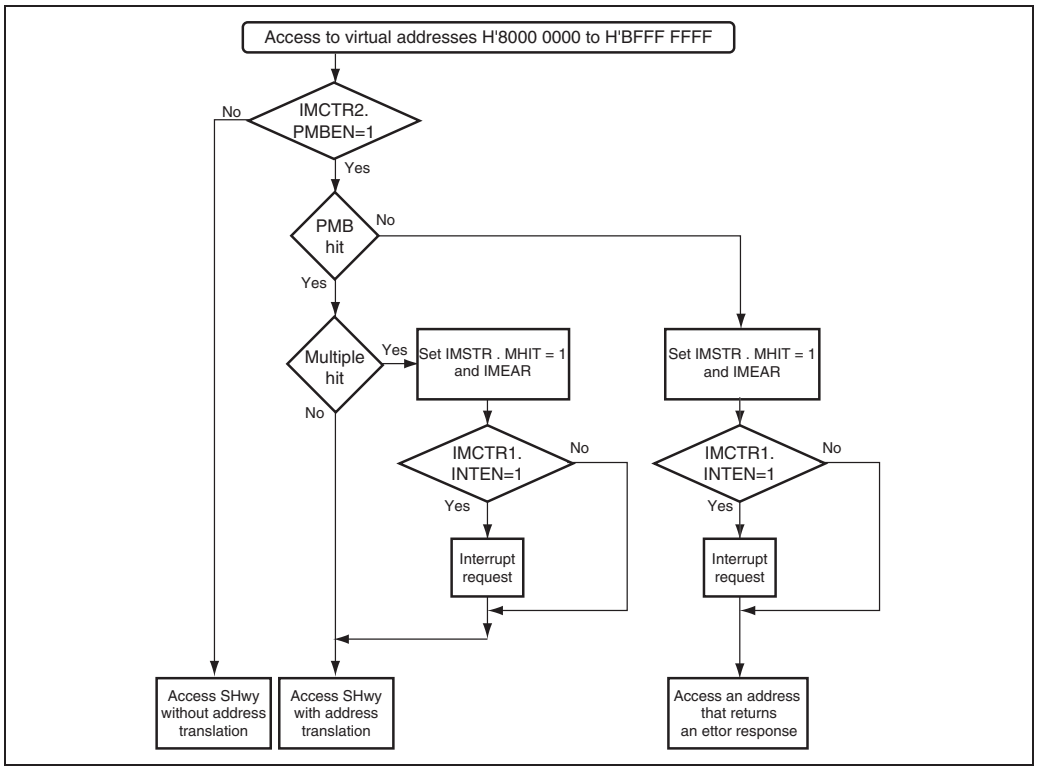

Figure 4.4 Translation Flow with PMB

4.3.3 Tile-Linear Address Translation (only on IPMMUI)

When the associated modules make tiled access to the virtual address space, it is to discrete addresses. This degrades the efficiency in accessing the external SDRAM. The PMB translation of IPMMU can reorder addresses to be accessed during virtual to physical translation so that they are accessed in a liner order instead of in a tiled order.

As an example, assume (image) data that is stride bytes wide is located in a virtual address space, and an initiator divides the space into tiles, each of them Blk_h bytes wide with Blk_v lines, to access it on a per tile basis.

If the lower address of the initiator is VADR[m:0], the access pattern in the physical address space can be rearranged linearly by generating the physical address PADR[m:0] as follows (m is 23, 25, 26, or 28 depending on the page size of the PMB):

PADR[m:TB+VB+HB] ←VADR[m:TB+VB+HB]

PADR[TB+VB+HB-1:TB+VB] ←VADR[TB+HB-1:TB]

PADR[TB+VB-1:TB] ←VADR[TB+HB+VB-1:TB+HB]

PADR[TB-1:0] ←VADR[TB-1:0]

Provided

TB = log2(Blk_h)

HB = log2(stride)TB,

VB = log2(Blk_v)

where stride, Blk_h, and Blk_v must be a 2's power

Since access by the VPU to the encoding or reference plane and access that the 2D-DMAC makes to use the rotation function are tile addressing, it is possible to improve the efficiency of access to the external SDRAM by accessing it via the virtual address space with tile-linear translation by this translation function.

Note that in order to access data correctly in the physical address space generated via the virtual address space by the tile-linear address translation function the access must be made via the virtual address space with the same translation setting.

Note also that accessing the virtual address space with tile-linear address translation from the modules that use linear addressing (all modules other than the VPU and 2D-DMAC if it is not set for rotation) leads to degrade of the efficiency of SDRAM access. If this access is needed, set the ICB function to block line transfer mode and horizontal division mode (the HDV bit in the MEnnSSARA register is 1) and use the horizontal division size along with Blk_h. In doing so, the number of block lines set for the ICB does not need to be equal to Blk_v and may be smaller, but the greater value improves the efficiency of SDRAM access.

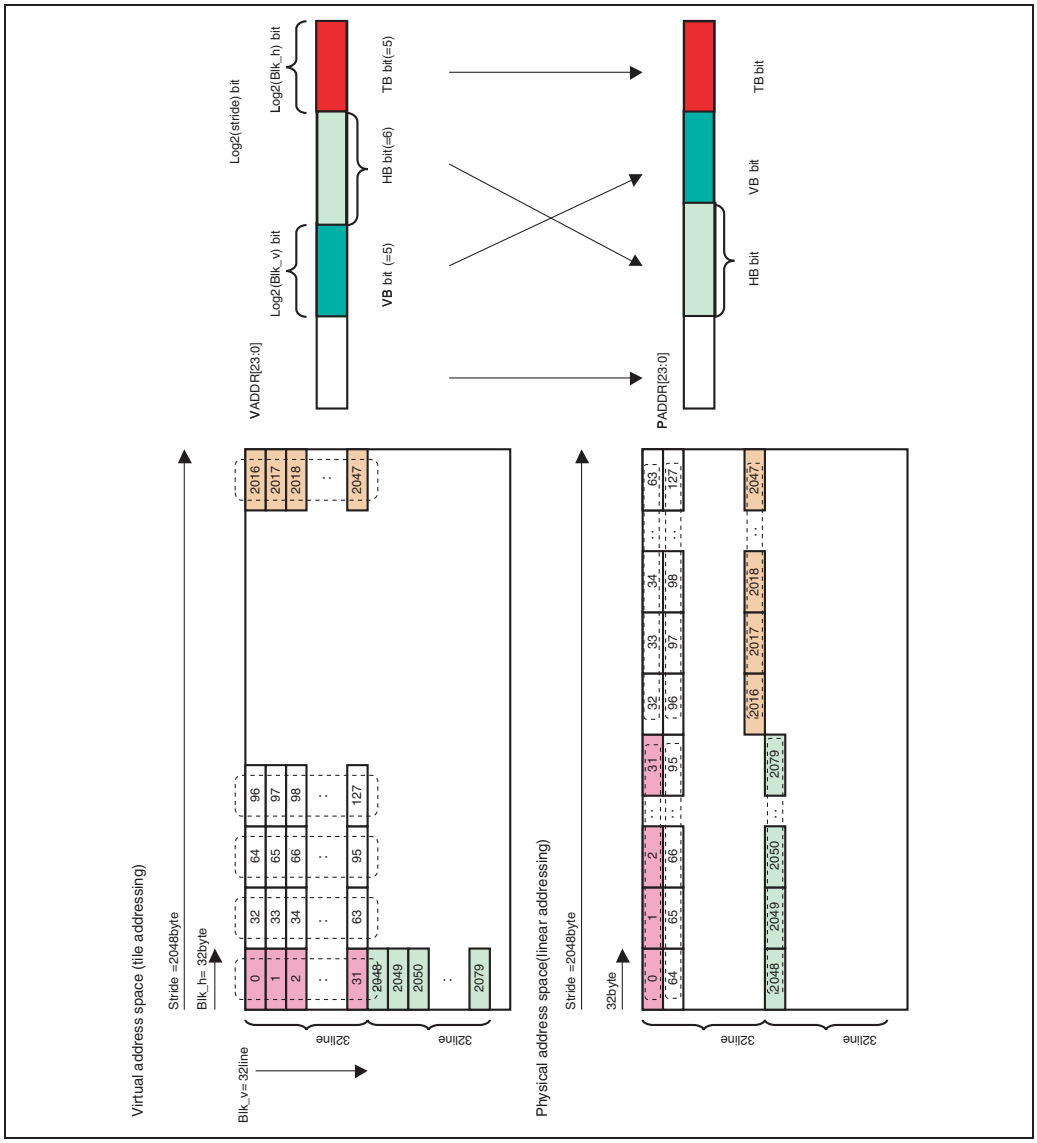

Figure 4.5 Virtual Address Space (Tile Addressing) and Physical Address Space (Linear Addressing)

4.3.4 Line-Interleaved Address Translation (Only on IPMMUI)

This function is intended mainly to handle CbCr planes for the YUV420 format. The CbCr planes in the YUV420 format are accessed in units of the same line width and the half number of lines compared to Y planes. Line-interleaved address translation allows them to be accessed in units of the half of the line width and the same number of lines compared to Y planes.

For example, if an image that is 1280 bytes wide is to be located to an area with stride = 2Kbytes, normally large areas in both Y/CbCr planes are wasted. However, data in the CbCr plane can be located to the area that was to be wasted in the Y plane by using the line-interleaved address translation function on the CbCr plane.

PADR[m:SB+1] ←VADR[m-1:SB]

PADR[SB] ←VADR[6]

PADR[SB-1] ←VADR[m]

PADR[SB-2:6] ←VADR[SB-1:7]

PADR[5:0] ←VADR[5:0]

Note that SB is log2(stride) and stride must be a 2's power. Note also that m is 23, 25, 26, or 28 depending on the page size of the PMB. If both line-interleaved address translation and tile-linear address translation are enabled simultaneously, tile-linear address translation is applied after line-interleaved address translation.

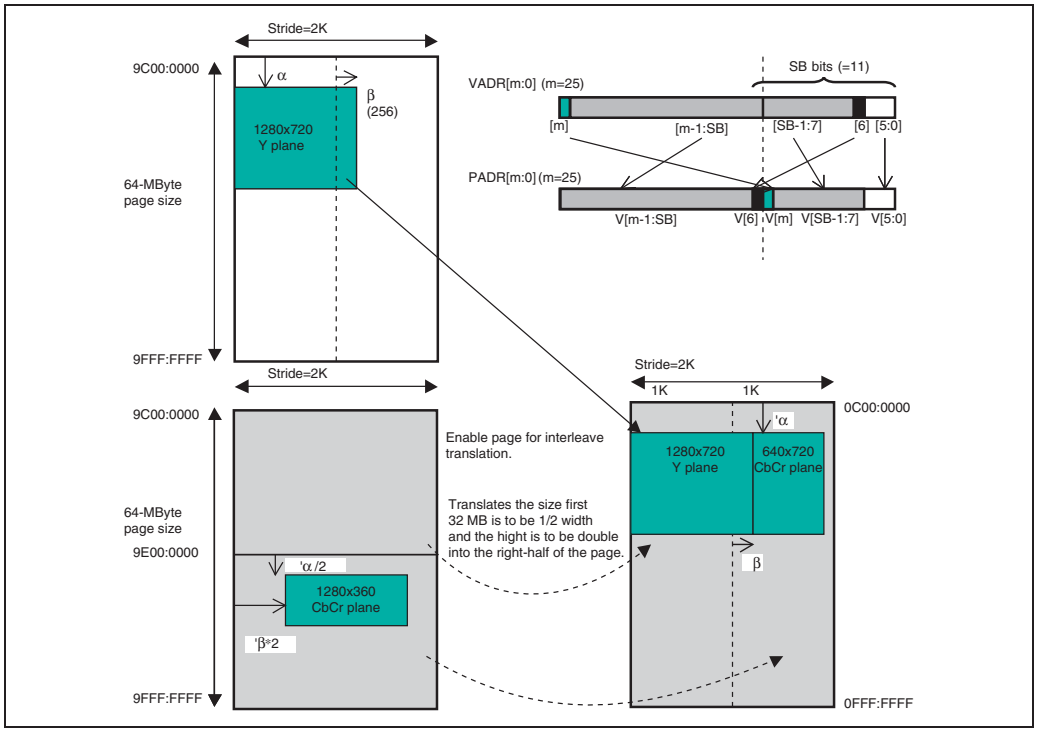

Figure 4.6 Line-Interleaved Address Translation

4.3.5 Access that is out of Address Translation

Access to the address area from H'C000 0000 to H'FFFF FFFF is out of address translation regardless of the settings of IPMMUs. SHwy is accessed with an original address without address translation.

4.4 How to Set IPMMUs

4.4.1 TLB Setting

- Set the ASID of a process that has a virtual address space to be shared by the IPMMUs in IMASID register.
- Set the base address of the first level page table of the above process in the IMTTBR register.
- In the following cases, write 1 to the FLUSH bit in IMCTR1 to disable the TLB in IPMMUs.
  - Virtual pages are deleted from the page table on the memory.
  - Another physical page is allocated to the existing virtual page.
  - The attribute of the existing page is changed.
- When a page that has not existed before is newly added, TLB does not need to be disabled (because a new page is not cached originally).

4.5 Usage Notes

The module stop of IPMMUs interworks with the module stop of modules connected to higher levels. Before setting values to the register or PMB of IPMMUs, cancel the module stop.

- IPMMUI is controlled by the module stop bit (MSTPCR0[7]) of ICB.
- IPMMUR is controlled by the module stop bit (MSTPCR0[21]) of RT-DMAC1.
- IPMMUR2 is controlled by the module stop bit (MSTPCR0[23]) of RT-DMAC2.

The power area of IPMMUs is the same as that of modules connected to higher levels.

- The power area of IPMMUI is A4R that is the same as ICB/LMB.
- The power area of IPMMUR is A4R that is the same as RT-DMAC1.
- The power area of IPMMUR2 is A4R that is the same as RT-DMAC2.

When you invalidate specific PMB entry n among the PMB entries which are validated once, please perform the following procedure.

(1) Write 1’b0 to IMPMBDn[8]. (In case of IPMMUI, write 2’b00 to IMPMBDn[10:9], too)
(2) Write 1’b1 to IMCRT1[1] to Flush TLB.

When you have performed (2), the invalidation of PMB's entry n is finished.

Section 5 Interrupt Controller (INTC)

The interrupt controller (INTC) determines the priority of interrupt sources and controls interrupt requests to the AP-Realtime core and AP-System core.

The INTC consists of the interrupt controller for the AP-System core (INTCA), the interrupt controller for the AP-Realtime core (INTCS), and the pin interrupt controller (PINTC); they respectively control interrupts to the AP-System core, those to the AP-Realtime core, and those from external pins. Some of the INTCA and INTCS registers set the priority of each interrupt, and interrupt requests are processed according to the user-set priority.

5.1 Features

(a) INTCA

- Fifteen levels of interrupt priority can be set
- IRQ pins interrupts can be set

  Thirty-two interrupts (IRQ pins interrupts) can be input through external pins, which can be used to request wakeup from power cutoff state. For each interrupt, detection of the rising or falling edge, detection of the level or edge, priority level, and enabling or disabling of the interrupt can be specified separately through the INTCA. interrupts can also be sent to the INTCS from the same IRQ pins and the conditions for those interrupts can be specified separately from the INTCA settings.
- IRQ pins interrupts and ARM-IRQ exception by INTCA peripheral modules interrupts can be set. IRQ pins interrupts and INTCA peripheral request are combined into one signal, and it is sent to IRQ port of AP-System core. Request from INTCA can be controlled by IRQ disable bit (7th bit) of program status register (CPSR) of AP-System core. The ARM-IRQ exception interrupt handler reads INTFLGA only once and determines the interrupt source. Reading from INTFLGA automatically sets the level of the accepted interrupt source to INTLVLA and automatically masks interrupts whose priority levels are equal to or lower than the INTLVLA value.
- INTCS peripheral interrupts can be sent to the AP-System core

  Interrupt signals from the peripheral modules assigned to the INTCS are combined into one signal, and it is sent to the INTCA as one peripheral interrupt. This interrupt signal can be masked independently from the mask settings for the AP-Realtime core. When the AP-System core accepts this interrupt, the AP-System core can read the AP-System core individual interrupt source register (INTEVTSA) in the INTCS during AP-System core interrupt handler processing and process the peripheral interrupt assigned to the INTCS. A setting can be made in the INTCA to mask all peripheral interrupts sent from the INTCS.

- User-mode interrupt disabling function
  Specifying an interrupt mask level in the user interrupt mask level register A (USERIMASKA) disables interrupts that are not higher in priority than the specified mask level in user mode.

(b) INTCS

- Fifteen levels of interrupt priority can be set
  By setting the interrupt priority registers, the priority levels of on-chip peripheral module interrupts can be selected from 15 levels for individual request sources.
- NMI interrupt can be set
  The NMI interrupt can be generated through the register settings in the CPG. The INTCS detects an interrupt request when the register value is changed from 1 to 0. The NMI interrupt is kept pending while the BL bit in SR is 1.

- IRQ pins interrupts can be set

  Thirty-two interrupts (IRQ pins interrupts) can be input through external pins, which can be used to request wakeup from power cutoff state. For each interrupt, detection of the rising or falling edge, detection of the level or edge, priority level, and enabling or disabling of the interrupt can be specified through the INTCS. Interrupts can also be sent to the INTCA from the same IRQ pins and the conditions for those interrupts can be specified separately from the INTCS settings.
- INTCA peripheral interrupts can be sent to the AP-Realtime core

  Interrupt signals from the peripheral modules assigned to the INTCA are combined into one signal, and it is sent to the INTCS as one peripheral interrupt. This interrupt signal can be masked independently from the mask settings for the AP-System core. When the AP-Realtime core accepts this interrupt, the AP-Realtime core can read the AP-Realtime core individual interrupt source register (INTEVTAS) in the INTCA during AP-Realtime core interrupt handler processing and process the peripheral interrupt assigned to the INTCA. A setting can be made in the INTCS to mask all peripheral interrupts sent from the INTCA.
- User-mode interrupt disabling function

  Specifying an interrupt mask level in the user interrupt mask level register S (USERIMASKS) disables interrupts that are not higher in priority than the specified mask level in user mode.

(c) LSI Internal Communication Interrupts and Wakeup Function

- A specified event in the internal connections of the LSI can be used to generate a request to the AP-System core for wakeup from power cutoff state or an interrupt.
- A specified event in the internal connections of the LSI can be used to generate a request to the AP-RealTime core for wakeup from power cutoff state or an interrupt.

A block diagram of the INTC is shown in figure 5.1.

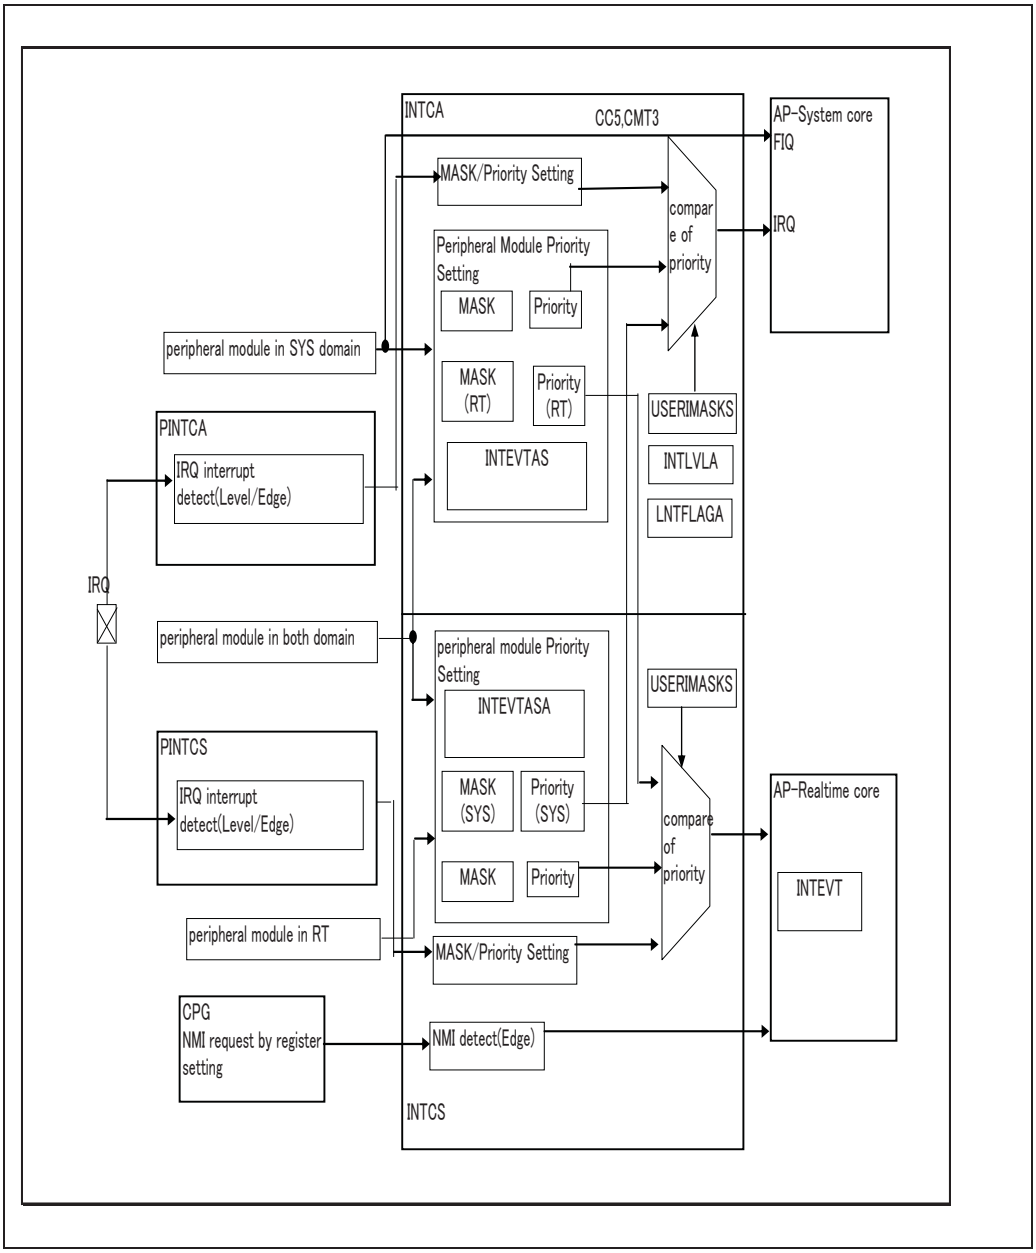

Figure 5.1 Block Diagram of INTC

5.2 Input/Output Pins

Table 5.1 shows the INTC pin configuration.

Table 5.1 Pin Configuration

Pin Name	Function	I/O	Description
IRQ31 to IRQ0	Interrupt input pins IRQ31 to IRQ0	Input	Input of IRQ31 to IRQ0 interrupt request signals

5.3 Register Descriptions

This section describes the registers of INTCA, INTCS.

5.3.1 INTCA Register Configuration

Table 5.2 shows the INTCA register configuration. Table 5.3 shows the register states in each operating mode.

Table 5.2 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size

(1) Interrupt Control Register 1A (ICR1A)

ICR1A specifies the detection mode for external interrupt input pins IRQ7 to IRQ0 individually: rising edge, falling edge, low level, or high level. Note that the chattering removal period is set by ICR3 , ICR4.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRQ0SA				IRQ1SA				IRQ2SA				IRQ3SA			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ4SA				IRQ5SA				IRQ6SA				IRQ7SA			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ0SA	0000	R/W	IRQn Sense Select
27 to 24	IRQ1SA	0000	R/W	These bits select whether interrupt request signals from pins IRQ7 to IRQ0 are detected at a rising edge, a falling edge, a low level, a high level, or at both of a rising edge and a falling edge.
23 to 20	IRQ2SA	0000	R/W	
19 to 15	IRQ3SA	0000	R/W	
15 to 12	IRQ4SA	0000	R/W	
11 to 8	IRQ5SA	0000	R/W	
7 to 4	IRQ6SA	0000	R/W	
3 to 0	IRQ7SA	0000	R/W	

IRQnSA	Detection Mode
0000	Interrupt request is detected at a falling edge of IRQn input
0001	Interrupt request is detected at a rising edge of IRQn input
0010	Interrupt request is detected at a low level of IRQn input
0011	Interrupt request is detected at a high level of IRQn input
0100	Interrupt request is detected at both edges of IRQn input

[Legend]
n = 0 to 7

(2) Interrupt Control Register 2A (ICR2A)

ICR2A specifies the detection mode for external interrupt input pins IRQ15 to IRQ8 individually: rising edge, falling edge, low level, or high level. Note that the chattering removal period is set by ICR5 , ICR6.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRQ8SA				IRQ9SA				IRQ10SA				IRQ11SA

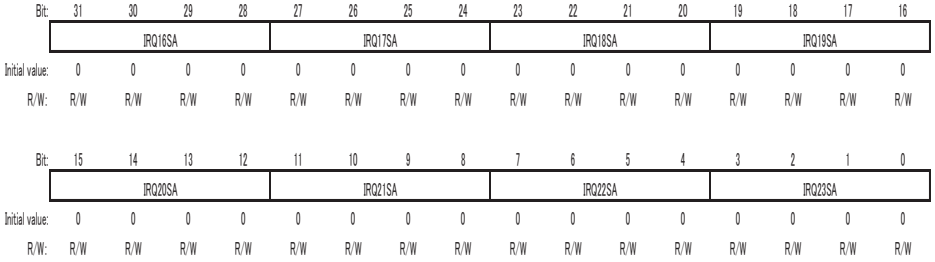
	IRQ12SA				IRQ13SA				IRQ14SA				IRQ15SA			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ8SA	0000	R/W	IRQn Sense Select
27 to 24	IRQ9SA	0000	R/W	These bits select whether interrupt request signals from pins IRQ8 to IRQ15 are detected at a rising edge, a falling edge, a low level, a high level, or at both of a rising edge and a falling edge.
23 to 20	IRQ10SA	0000	R/W	
19 to 15	IRQ11SA	0000	R/W	
15 to 12	IRQ12SA	0000	R/W	
11 to 8	IRQ13SA	0000	R/W	
7 to 4	IRQ14SA	0000	R/W	
3 to 0	IRQ15SA	0000	R/W	

IRQnSA	Detection Mode
0000	Interrupt request is detected at a falling edge of IRQn input
0001	Interrupt request is detected at a rising edge of IRQn input
0010	Interrupt request is detected at a low level of IRQn input
0011	Interrupt request is detected at a high level of IRQn input
0100	Interrupt request is detected at both edges of IRQn input

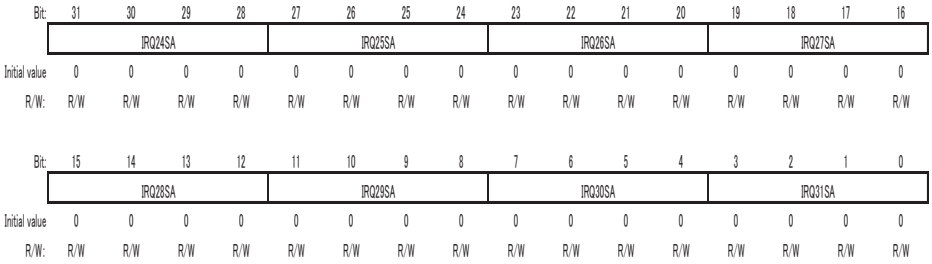
[Legend]
n = 8 to 15

(3) Interrupt Control Register 3A (ICR3A)

ICR3A specifies the detection mode for external interrupt input pins IRQ23 to IRQ16 individually: rising edge, falling edge, low level, or high level. Note that the chattering removal period is set by ICR7, ICR8.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRQ16SA				IRQ17SA				IRQ18SA				IRQ19SA			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ20SA				IRQ21SA				IRQ22SA				IRQ23SA			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



31 to 28	IRQ16SA	0000	R/W	IRQn Sense Select These bits select whether interrupt request signals from pins IRQ16 to IRQ23 are detected at a rising edge, a falling edge, a low level, a high level, or at both of a rising edge and a falling edge.
27 to 24	IRQ17SA	0000	R/W	
23 to 20	IRQ18SA	0000	R/W	
19 to 15	IRQ19SA	0000	R/W	
15 to 12	IRQ20SA	0000	R/W	
11 to 8	IRQ21SA	0000	R/W	
7 to 4	IRQ22SA	0000	R/W	
3 to 0	IRQ23SA	0000	R/W	

IRQnSA	Detection Mode
0000	Interrupt request is detected at a falling edge of IRQn input
0001	Interrupt request is detected at a rising edge of IRQn input
0010	Interrupt request is detected at a low level of IRQn input
0011	Interrupt request is detected at a high level of IRQn input
0100	Interrupt request is detected at both edges of IRQn input

[Legend]
n = 16 to 23

(4) Interrupt Control Register 4A (ICR4A)

ICR4A specifies the detection mode for external interrupt input pins IRQ31 to IRQ24 individually: rising edge, falling edge, low level, or high level. Note that the chattering removal period is set by ICR9, ICR10.

31 to 28	IRQ24SA	0000	R/W	IRQn Sense Select These bits select whether interrupt request signals from pins IRQ24 to IRQ31 are detected at a rising edge, a falling edge, a low level, a high level, or at both of a rising edge and a falling edge.
27 to 24	IRQ25SA	0000	R/W	
23 to 20	IRQ26SA	0000	R/W	
19 to 15	IRQ27SA	0000	R/W	
15 to 12	IRQ28SA	0000	R/W	
11 to 8	IRQ29SA	0000	R/W	
7 to 4	IRQ30SA	0000	R/W	
3 to 0	IRQ31SA	0000	R/W	

IRQnSA	Detection Mode
0000	Interrupt request is detected at a falling edge of IRQn input
0001	Interrupt request is detected at a rising edge of IRQn input
0010	Interrupt request is detected at a low level of IRQn input
0011	Interrupt request is detected at a high level of IRQn input
0100	Interrupt request is detected at both edges of IRQn input

[Legend]
n = 24 to 31

(5) Interrupt Flag Register (INTFLGA)

INTFLGA is a 32-bit read-only register that can only be accessed by the CPU. It holds the encoded interrupt request flag. When this register is read, the accepted interrupt code is stored in INTEVTA, the interrupt level of the accepted interrupt source is stored in the lower four bits of INTLVLA, and the INTLVLA value before update is stored in INTLVLB.

The ARM-IRQ interrupt handler reads INTFLGA only once and determines the interrupt source. If this register is read multiple times, the interrupt flag may be cleared unexpectedly.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	EVTCODEA									-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 5	EVTCODEA	H'000	R	Interrupt Code These bits hold the interrupt code. For details, see table 5.10 and 5.11.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

(6) Interrupt Event Register (INTEVTA)

INTEVTA is a 32-bit register that can be read from or written to by the CPU.

The INTFLGA value is written to this register through hardware by reading from INTFLGA with the ARM-IRQ interrupt handler.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	EVTCODEA									-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 5	EVTCODEA	H'000	R/W	Interrupt Code These bits hold the interrupt code. For details, see table 5.10 and 5.11.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

(7) Interrupt Level Register A (INTLVLA)

INTLVLA is an 8-bit readable/writable register that specifies the level to mask interrupts. When the level of an interrupt is not higher in priority than the level specified in this register, the interrupt is masked.

The interrupt level of the accepted interrupt source is stored in the lower four bits of this register by reading from INTFLGA. This automatically masks the interrupts whose priority levels are equal to or lower than that of the accepted interrupt source.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	LEVELA			
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	LEVELA	H'00	R/W	Interrupt Level When the level of an interrupt is not higher than the level specified in these bits, the interrupt is masked.

(8) Interrupt Level Register B (INTLVLB)

When INTLVLA is automatically updated by INTFLGA reading, the previous INTLVLA value is saved in INTLVLB. This register can be read and written to by the CPU.

When execution returns from the interrupt handler, the INTLVLB value should be written back to INTLVLA by software to restore the interrupt mask level.

Note that the INTLVLB should be saved in the stack when multiple interrupts are accepted.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	LEVELB			
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	LEVELB	H'00	R/W	Interrupt Level These bits store a backup of the INTLVLA value.

(9) Interrupt Priority Register 00A (INTPRI00A)

INTPRI00A is a register that specifies priority levels from 15 to 0 for external interrupt input pins IRQ7 to IRQ0.

Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRQ0A				IRQ1A				IRQ2A				IRQ3A			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ4A				IRQ5A				IRQ6A				IRQ7A			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

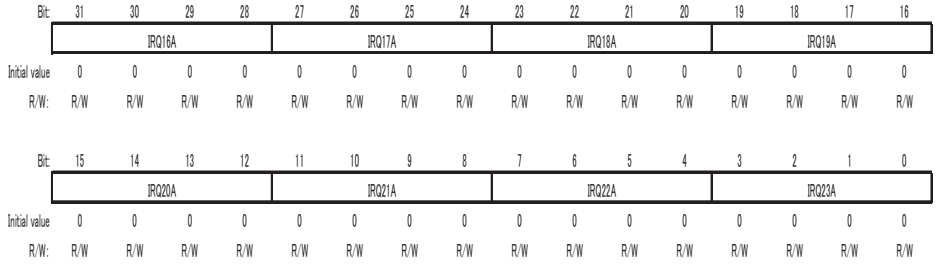
Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ0A	H'0	R/W	These bits specify the priority level for each interrupt source in 4-bit units.
27 to 24	IRQ1A	H'0	R/W	
23 to 20	IRQ2A	H'0	R/W	
19 to 16	IRQ3A	H'0	R/W	
15 to 12	IRQ4A	H'0	R/W	
11 to 8	IRQ5A	H'0	R/W	
7 to 4	IRQ6A	H'0	R/W	
3 to 0	IRQ7A	H'0	R/W	

(10) Interrupt Priority Register 10A (INTPRI10A)

INTPRI10A is a register that specifies priority levels from 15 to 0 for external interrupt input pins IRQ15 to IRQ8.

Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRQ8A				IRQ9A				IRQ10A				IRQ11A			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



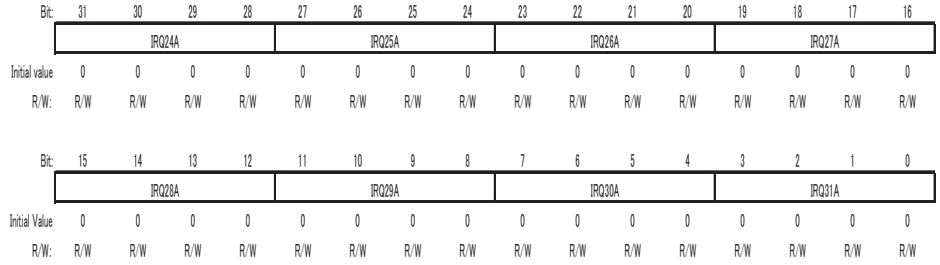
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ12A				IRQ13A				IRQ14A				IRQ15A			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ8A	H'0	R/W	These bits specify the priority level for each interrupt source in 4-bit units.
27 to 24	IRQ9A	H'0	R/W	
23 to 20	IRQ10A	H'0	R/W	
19 to 16	IRQ11A	H'0	R/W	
15 to 12	IRQ12A	H'0	R/W	
11 to 8	IRQ13A	H'0	R/W	
7 to 4	IRQ14A	H'0	R/W	
3 to 0	IRQ15A	H'0	R/W	

(11) Interrupt Priority Register 20A (INTPRI20A)

INTPRI20A is a register that specifies priority levels from 15 to 0 for external interrupt input pins IRQ23 to IRQ16.

Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).



Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ16A	H'0	R/W	These bits specify the priority level for each interrupt source in 4-bit units.
27 to 24	IRQ17A	H'0	R/W	
23 to 20	IRQ18A	H'0	R/W	
19 to 16	IRQ19A	H'0	R/W	
15 to 12	IRQ20A	H'0	R/W	
11 to 8	IRQ21A	H'0	R/W	
7 to 4	IRQ22A	H'0	R/W	
3 to 0	IRQ23A	H'0	R/W	

(12) Interrupt Priority Register 30A (INTPRI30A)

INTPRI30A is a register that specifies priority levels from 15 to 0 for external interrupt input pins IRQ31 to IRQ24.

Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ24A	H'0	R/W	These bits specify the priority level for each interrupt source in 4-bit units.
27 to 24	IRQ25A	H'0	R/W	
23 to 20	IRQ26A	H'0	R/W	
19 to 16	IRQ27A	H'0	R/W	
15 to 12	IRQ28A	H'0	R/W	
11 to 8	IRQ29A	H'0	R/W	
7 to 4	IRQ30A	H'0	R/W	
3 to 0	IRQ31A	H'0	R/W	

(13) Peripheral Interrupt Priority Registers AA to OA, AA3 to UA3 (IPRAA to IPROA, IPRAA3 to IPRUA3)

IPRAA to IPROA and IPRAA3 to IPRUA3 are registers that specify priority levels from 15 to 0 for on-chip peripheral module interrupts.

Four modules are assigned to each register. Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).

Table 5.4 shows the correspondence between the peripheral modules requesting interrupts and the peripheral interrupt priority registers.

IPRAA to IPROA:

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IPR0nA				IPR1nA				IPR2nA				IPR3nA			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

IPRAA3 to IPRUA3:

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

(14) Interrupt Source Register 00A (INTREQ00A)

INTREQ00A is a register that indicates interrupt requests from external input pins IRQ7 to IRQ0. This register value is not affected by the INTPRI00A setting or the interrupt masks specified with INTMSK00A.

When edge-detection mode is set for an IRQ pin (ICR1A.IRQnSA = B'00 or B'01), an interrupt request is cleared by writing 0 to the corresponding IRQnA bit after reading IRQnA = 1; write 1 to the other bits.

Bit:	7	6	5	4	3	2	1	0
	IRQ0A	IRQ1A	IRQ2A	IRQ3A	IRQ4A	IRQ5A	IRQ6A	IRQ7A
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ0A	0	R/W	IRQn Interrupt Request
6	IRQ1A	0	R/W	Indicates whether there is an interrupt request input to the IRQn pin.
5	IRQ2A	0	R/W	[When edge-detection mode is selected (ICR1A.IRQnSA = B'00 or B'01)]
4	IRQ3A	0	R/W	When reading:
3	IRQ4A	0	R/W	0: No interrupt request has been detected
2	IRQ5A	0	R/W	1: An interrupt request has been detected
1	IRQ6A	0	R/W	When writing:
0	IRQ7A	0	R/W	0: Each bit is cleared by writing 0 after reading 1
				1: Writing 1 is ignored
				[When level-detection mode is selected (ICR1A.IRQnSA = B'10 or B'11)]
				When reading:
				0: The corresponding interrupt pin has not been asserted
				1: The corresponding interrupt pin has been asserted
				When writing:
				Writing 0 or 1 is ignored.

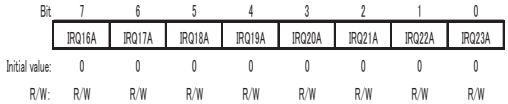
[Legend]
n = 0 to 7

(15) Interrupt Source Register 10A (INTREQ10A)

INTREQ10A is a register that indicates interrupt requests from external input pins IRQ15 to IRQ8. This register value is not affected by the INTPRI10A setting or the interrupt masks specified with INTMSK10A.

When edge-detection mode is set for an IRQ pin (ICR2A.IRQnSA = B'00 or B'01), an interrupt request is cleared by writing 0 to the corresponding IRQnA bit after reading IRQnA = 1; write 1 to the other bits.

Bit:	7	6	5	4	3	2	1	0
	IRQ 8A	IRQ 9A	IRQ 10A	IRQ 11A	IRQ 12A	IRQ 13A	IRQ 14A	IRQ 15A
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



Bit	Bit Name	Initial Value	R/W	Description
7	IRQ8A	0	R/W	IRQn Interrupt Request
6	IRQ9A	0	R/W	Indicates whether there is an interrupt request input to the IRQn pin.
5	IRQ10A	0	R/W	[When edge-detection mode is selected (ICR2A.IRQnSA = B'00 or B'01)]
4	IRQ11A	0	R/W	When reading:
3	IRQ12A	0	R/W	0: No interrupt request has been detected
2	IRQ13A	0	R/W	1: An interrupt request has been detected
1	IRQ14A	0	R/W	When writing:
0	IRQ15A	0	R/W	0: Each bit is cleared by writing 0 after reading 1
				1: Writing 1 is ignored
				[When level-detection mode is selected (ICR2A.IRQnSA = B'10 or B'11)]
				When reading:
				0: The corresponding interrupt pin has not been asserted
				1: The corresponding interrupt pin has been asserted
				When writing:
				Writing 0 or 1 is ignored.

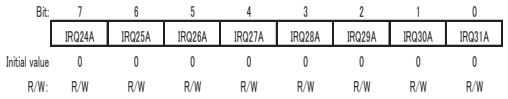
[Legend]
n = 8 to 15

(16) Interrupt Source Register 20A (INTREQ20A)

INTREQ20A is a register that indicates interrupt requests from external input pins IRQ23 to IRQ16. This register value is not affected by the INTPRI20A setting or the interrupt masks specified with INTMSK20A.

When edge-detection mode is set for an IRQ pin (ICR3A.IRQnSA = B'00 or B'01), an interrupt request is cleared by writing 0 to the corresponding IRQnA bit after reading IRQnA = 1; write 1 to the other bits.

Bit	7	6	5	4	3	2	1	0
	IRQ16A	IRQ17A	IRQ18A	IRQ19A	IRQ20A	IRQ21A	IRQ22A	IRQ23A
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



Bit	Bit Name	Initial Value	R/W	Description
7	IRQ16A	0	R/W	IRQn Interrupt Request
6	IRQ17A	0	R/W	Indicates whether there is an interrupt request input to the IRQn pin.
5	IRQ18A	0	R/W	[When edge-detection mode is selected (ICR3A.IRQnSA = B'00 or B'01)]
4	IRQ19A	0	R/W	When reading:
3	IRQ20A	0	R/W	0: No interrupt request has been detected
2	IRQ21A	0	R/W	1: An interrupt request has been detected
1	IRQ22A	0	R/W	When writing:
0	IRQ23A	0	R/W	0: Each bit is cleared by writing 0 after reading 1
				1: Writing 1 is ignored
				[When level-detection mode is selected (ICR3A.IRQnSA = B'10 or B'11)]
				When reading:
				0: The corresponding interrupt pin has not been asserted
				1: The corresponding interrupt pin has been asserted
				When writing:
				Writing 0 or 1 is ignored.

[Legend]
n = 16 to 23

(17) Interrupt Source Register 30A (INTREQ30A)

INTREQ30A is a register that indicates interrupt requests from external input pins IRQ31 to IRQ24. This register value is not affected by the INTPRI30A setting or the interrupt masks specified with INTMSK30A.

When edge-detection mode is set for an IRQ pin (ICR4A.IRQnSA = B'00 or B'01), an interrupt request is cleared by writing 0 to the corresponding IRQnA bit after reading IRQnA = 1; write 1 to the other bits.

Bit:	7	6	5	4	3	2	1	0
	IRQ24A	IRQ25A	IRQ26A	IRQ27A	IRQ28A	IRQ29A	IRQ30A	IRQ31A
Initial value	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ24A	0	R/W	IRQn Interrupt Request
6	IRQ25A	0	R/W	Indicates whether there is an interrupt request input to the IRQn pin.
5	IRQ26A	0	R/W	[When edge-detection mode is selected (ICR4A.IRQnSA = B'00 or B'01)]
4	IRQ27A	0	R/W	When reading:
3	IRQ28A	0	R/W	0: No interrupt request has been detected
2	IRQ29A	0	R/W	1: An interrupt request has been detected
1	IRQ30A	0	R/W	When writing:
0	IRQ31A	0	R/W	0: Each bit is cleared by writing 0 after reading 1
				1: Writing 1 is ignored
				[When level-detection mode is selected (ICR4A.IRQnSA = B'10 or B'11)]
				When reading:
				0: The corresponding interrupt pin has not been asserted
				1: The corresponding interrupt pin has been asserted
				When writing:
				Writing 0 or 1 is ignored.

[Legend]
n = 31 to 24

(18) Interrupt Mask Register 00A (INTMSK00A)

INTMSK00A is a register that masks interrupt requests from external interrupt input pins IRQ7 to IRQ0.

To clear an interrupt mask, write 1 to the corresponding bit in INTMSKCLR00A. Writing 0 to the corresponding bit in INTMSK00A does not affect the bit value.

Bit:	7	6	5	4	3	2	1	0
	IRQ0A	IRQ1A	IRQ2A	IRQ3A	IRQ4A	IRQ5A	IRQ6A	IRQ7A
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ0A	0	R/W	IRQn Interrupt Mask
6	IRQ1A	0	R/W	0: The corresponding interrupt is not masked
5	IRQ2A	0	R/W	1: The corresponding interrupt is masked
4	IRQ3A	0	R/W	
3	IRQ4A	0	R/W	
2	IRQ5A	0	R/W	
1	IRQ6A	0	R/W	
0	IRQ7A	0	R/W	

[Legend]
n = 0 to 7

(19) Interrupt Mask Register 10A (INTMSK10A)

INTMSK10A is a register that masks interrupt requests from external interrupt input pins IRQ15 to IRQ8.

To clear an interrupt mask, write 1 to the corresponding bit in INTMSKCLR10A. Writing 0 to the corresponding bit in INTMSK10A does not affect the bit value.

Bit:	7	6	5	4	3	2	1	0
	IRQ8A	IRQ9A	IRQ 10A	IRQ 11A	IRQ 12A	IRQ 13A	IRQ 14A	IRQ 15A
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ8A	0	R/W	IRQn Interrupt Mask
6	IRQ9A	0	R/W	0: The corresponding interrupt is not masked
5	IRQ10A	0	R/W	1: The corresponding interrupt is masked
4	IRQ11A	0	R/W	
3	IRQ12A	0	R/W	
2	IRQ13A	0	R/W	
1	IRQ14A	0	R/W	
0	IRQ15A	0	R/W	

[Legend]
n = 8 to 15

(20) Interrupt Mask Register 20A (INTMSK20A)

INTMSK20A is a register that masks interrupt requests from external interrupt input pins IRQ23 to IRQ16.

To clear an interrupt mask, write 1 to the corresponding bit in INTMSKCLR20A. Writing 0 to the corresponding bit in INTMSK20A does not affect the bit value.

Bit	7	6	5	4	3	2	1	0
	IRQ16A	IRQ17A	IRQ18A	IRQ19A	IRQ20A	IRQ21A	IRQ22A	IRQ23A
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ16A	0	R/W	IRQn Interrupt Mask
6	IRQ17A	0	R/W	0: The corresponding interrupt is not masked
5	IRQ18A	0	R/W	1: The corresponding interrupt is masked
4	IRQ19A	0	R/W	
3	IRQ20A	0	R/W	
2	IRQ21A	0	R/W	
1	IRQ22A	0	R/W	
0	IRQ23A	0	R/W	

[Legend]
n = 23 to 16

(21) Interrupt Mask Register 30A (INTMSK30A)

INTMSK20A is a register that masks interrupt requests from external interrupt input pins IRQ31 to IRQ24.

To clear an interrupt mask, write 1 to the corresponding bit in INTMSKCLR30A. Writing 0 to the corresponding bit in INTMSK30A does not affect the bit value.

Bit:	7	6	5	4	3	2	1	0
	IRQ24A	IRQ25A	IRQ26A	IRQ27A	IRQ28A	IRQ29A	IRQ30A	IRQ31A
Initial value	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ24A	0	R/W	IRQn Interrupt Mask
6	IRQ25A	0	R/W	0: The corresponding interrupt is not masked
5	IRQ26A	0	R/W	1: The corresponding interrupt is masked
4	IRQ27A	0	R/W	
3	IRQ28A	0	R/W	
2	IRQ29A	0	R/W	
1	IRQ30A	0	R/W	
0	IRQ31A	0	R/W	

[Legend]
n = 31 to 24

(22) Interrupt Mask Clear Register 00A (INTMSKCLR00A)

INTMSKCLR00A is a write-only register that clears the mask settings for interrupts from external interrupt input pins IRQ7 to IRQ0.

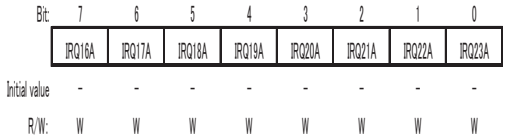
Bit:	7	6	5	4	3	2	1	0
	IRQ0A	IRQ1A	IRQ2A	IRQ3A	IRQ4A	IRQ5A	IRQ6A	IRQ7A
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ0A	—	W	IRQn Interrupt Mask Clear
6	IRQ1A	—	W	0: Writing 0 is ignored
5	IRQ2A	—	W	1: Clears the corresponding interrupt mask
4	IRQ3A	—	W	When reading:
3	IRQ4A	—	W	An undefined value will be read.
2	IRQ5A	—	W	
1	IRQ6A	—	W	
0	IRQ7A	—	W	

[Legend]
n = 0 to 7

(23) Interrupt Mask Clear Register 10A (INTMSKCLR10A)

INTMSKCLR10A is a write-only register that clears the mask settings for interrupts from external interrupt input pins IRQ15 to IRQ8.



Bit:	7	6	5	4	3	2	1	0
	IRQ 8A	IRQ 9A	IRQ 10A	IRQ 11A	IRQ 12A	IRQ 13A	IRQ 14A	IRQ 15A
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ8A	—	W	IRQn Interrupt Mask Clear
6	IRQ9A	—	W	0: Writing 0 is ignored
5	IRQ10A	—	W	1: Clears the corresponding interrupt mask
4	IRQ11A	—	W	When reading:
3	IRQ12A	—	W	An undefined value will be read.
2	IRQ13A	—	W	
1	IRQ14A	—	W	
0	IRQ15A	—	W	

[Legend]
n = 8 to 15

(24) Interrupt Mask Clear Register 20A (INTMSKCLR20A)

INTMSKCLR20A is a write-only register that clears the mask settings for interrupts from external interrupt input pins IRQ23 to IRQ16.

Bit:	7	6	5	4	3	2	1	0
	IRQ16A	IRQ17A	IRQ18A	IRQ19A	IRQ20A	IRQ21A	IRQ22A	IRQ23A
Initial value	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ16A	—	W	IRQn Interrupt Mask Clear
6	IRQ17A	—	W	0: Writing 0 is ignored
5	IRQ18A	—	W	1: Clears the corresponding interrupt mask
4	IRQ19A	—	W	When reading:
3	IRQ20A	—	W	An undefined value will be read.
2	IRQ21A	—	W	
1	IRQ22A	—	W	
0	IRQ23A	—	W	

[Legend]
n = 16 to 23

(25) Interrupt Mask Clear Register 30A (INTMSKCLR30A)

INTMSKCLR30A is a write-only register that clears the mask settings for interrupts from external interrupt input pins IRQ31 to IRQ24.

Bit:	7	6	5	4	3	2	1	0
	IRQ24A	IRQ25A	IRQ26A	IRQ27A	IRQ28A	IRQ29A	IRQ30A	IRQ31A
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ24A	—	W	IRQn Interrupt Mask Clear
6	IRQ25A	—	W	0: Writing 0 is ignored
5	IRQ26A	—	W	1: Clears the corresponding interrupt mask
4	IRQ27A	—	W	When reading:
3	IRQ28A	—	W	An undefined value will be read.
2	IRQ29A	—	W	
1	IRQ30A	—	W	
0	IRQ31A	—	W	

[Legend]
n = 24 to 31

(26) Peripheral Interrupt Mask Registers 0A to 13A,0A3 to 10A3 (IMR0A to IMR13A,IMR0A3 to IMR10A3)

IMR0A to IMR13A and IMR0A3 to IMR10A3 are registers that mask on-chip peripheral module interrupts. To mask an interrupt, write 1 to the corresponding bit in IMR0A to IMR13A and IMR0A3 to IMR10A3. Peripheral module interrupts not used should be masked.

To clear an interrupt mask, write 1 to the corresponding bit in IMCR0A to IMCR13A and IMR0A3 to IMR10A3. Writing 0 to the corresponding bit in IMR0A to IMR13A and IMR0A3 to IMR10A3 does not affect the bit value.

Table 5.5 shows the correspondence between the bits in IMR0A to IMR13A and IMR0A3 to IMR10A3 and the interrupt sources.

IMR0A to IMR13A:

Bit:	7	6	5	4	3	2	1	0
	IMRn 0A	IMRn 1A	IMRn 2A	IMRn 3A	IMRn 4A	IMRn 5A	IMRn 6A	IMRn 7A
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

IMR0A3 to IMR10A3:

Bit:	7	6	5	4	3	2	1	0
	IMRm 0A3	IMRm 1A3	IMRm 2A3	IMRm 3A3	IMRm 4A3	IMRm 5A3	IMRm 6A3	IMRm 7A3
Initial value	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

IMR0A to IMR13A:

Bit	Bit Name	Initial Value	R/W	Description
7	IMRn0A	0	R/W	Interrupt Mask
6	IMRn1A	0	R/W	Masks the interrupt request corresponding to each bit. See table 5.5 for the correspondence between IMR and each interrupt source.
5	IMRn2A	0	R/W	
4	IMRn3A	0	R/W	When writing:
3	IMRn4A	0	R/W	0: Writing 0 is ignored
2	IMRn5A	0	R/W	1: Masks the corresponding interrupt request
1	IMRn6A	0	R/W	When reading:
0	IMRn7A	0	R/W	0: The corresponding interrupt request is accepted
				1: The corresponding interrupt request is masked

[Legend]
n = 0 to 13

IMR0A3 to IMR10A3:

Bit	Bit Name	Initial Value	R/W	Description
7	IMRm0A3	0	R/W	Interrupt Mask
6	IMRm1A3	0	R/W	Masks the interrupt request corresponding to each bit. See table 5.5 for the correspondence between IMR and each interrupt source.
5	IMRm2A3	0	R/W	
4	IMRm3A3	0	R/W	When writing:
3	IMRm4A3	0	R/W	0: Writing 0 is ignored
2	IMRm5A3	0	R/W	1: Masks the corresponding interrupt request
1	IMRm6A3	0	R/W	When reading:
0	IMRm7A3	0	R/W	0: The corresponding interrupt request is accepted
				1: The corresponding interrupt request is masked

[Legend]
m = 0 to 10

(27) Peripheral Interrupt Mask Clear Registers 0A to 13A, 0A3 to 10A3 (IMCR0A to IMCR13A,IMCR0A3 to IMCR10A3)

IMCR0A to IMCR13A and IMCR0A3 to IMCR10A3 are write-only registers that clear the mask settings for the on-chip peripheral module interrupts. Table 5.5 shows the correspondence between the bits in IMCR0A to IMCR13A and IMCR0A3 to IMCR10A3 and the interrupt sources.

IMCR0A to IMCR13A:

Bit:	7	6	5	4	3	2	1	0
	IMCRn 0A	IMCRn 1A	IMCRn 2A	IMCRn 3A	IMCRn 4A	IMCRn 5A	IMCRn 6A	IMCRn 7A
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

IMCR0A3 to IMCR10A3:

Bit:	7	6	5	4	3	2	1	0
	IMCRm 0A3	IMCRm 1A3	IMCRm 2A3	IMCRm 3A3	IMCRm 4A3	IMCRm 5A3	IMCRm 6A3	IMCRm 7A3
Initial value	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

IMCR0A to IMCR13A:

Bit	Bit Name	Initial Value	R/W	Description
7	IMCRn0A	—	W	Interrupt Mask Clear
6	IMCRn1A	—	W	Clears the mask setting for the interrupt corresponding to each bit. See table 5.5 for the correspondence between IMCR and each interrupt source.
5	IMCRn2A	—	W	
4	IMCRn3A	—	W	When writing:
3	IMCRn4A	—	W	0: Writing 0 is ignored
2	IMCRn5A	—	W	1: Clears the corresponding interrupt mask
1	IMCRn6A	—	W	When reading:
0	IMCRn7A	—	W	An undefined value will be read.

[Legend]
n = 0 to 13

IMCR0A3 to IMCR10A3:

Bit	Bit Name	Initial Value	R/W	Description
7	IMCRm0A3	—	W	Interrupt Mask Clear
6	IMCRm1A3	—	W	Clears the mask setting for the interrupt corresponding to each bit. See table 5.5 for the correspondence between IMCR and each interrupt source.
5	IMCRm2A3	—	W	
4	IMCRm3A3	—	W	When writing:
3	IMCRm4A3	—	W	0: Writing 0 is ignored
2	IMCRm5A3	—	W	1: Clears the corresponding interrupt mask
1	IMCRm6A3	—	W	When reading:
0	IMCRm7A3	—	W	An undefined value will be read.

[Legend]
m = 0 to 10

(28) Peripheral Interrupt Mask Registers 0AS to 13AS, 0AS3 to 10AS3 (IMR0AS to IMR13AS, IMR0AS3 to IMR10AS3)

IMR0AS to IMR13AS and IMR0AS3 to IMR10AS3 are registers that mask on-chip peripheral module interrupts to be sent to the INTCS. To mask an interrupt, write 1 to the corresponding bit in IMR0AS to IMR13AS and IMR0AS3 to IMR10AS3. Peripheral module interrupts not used should be masked.

To clear an interrupt mask, write 1 to the corresponding bit in IMCR0AS to IMCR13AS. Writing 0 to the corresponding bit in IMR0AS to IMR13AS and IMR0AS3 to IMR10AS3 does not affect the bit value.

Table 5.5 shows the correspondence between the bits in IMR0AS to IMR13AS and IMR0AS3 to IMR10AS3 and the interrupt sources.

IMR0AS to IMR13AS:

Bit:	7	6	5	4	3	2	1	0
	IMRn 0AS	IMRn 1AS	IMRn 2AS	IMRn 3AS	IMRn 4AS	IMRn 5AS	IMRn 6AS	IMRn 7AS
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

IMR0AS3 to IMR10AS3:

Bit:	7	6	5	4	3	2	1	0
	IMRm 0AS3	IMRm 1AS3	IMRm 2AS3	IMRm 3AS3	IMRm 4AS3	IMRm 5AS3	IMRm 6AS3	IMRm 7AS3
Initial value	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IMRn0AS	0	R/W	Interrupt Mask
6	IMRn1AS	0	R/W	Masks the interrupt request corresponding to each bit. See table 5.5 for the correspondence between IMR and each interrupt source.
5	IMRn2AS	0	R/W	
4	IMRn3AS	0	R/W	When writing:
3	IMRn4AS	0	R/W	0: Writing 0 is ignored
2	IMRn5AS	0	R/W	1: Masks the corresponding interrupt request
1	IMRn6AS	0	R/W	When reading:
0	IMRn7AS	0	R/W	0: The corresponding interrupt request is accepted
				1: The corresponding interrupt request is masked

[Legend]
n = 0 to 13

IMR0AS3 to IMR10AS3:

Bit	Bit Name	Initial Value	R/W	Description
7	IMRm0AS3	0	R/W	Interrupt Mask
6	IMRm1AS3	0	R/W	Masks the interrupt request corresponding to each bit. See table 5.5 for the correspondence between IMR and each interrupt source.
5	IMRm2AS3	0	R/W	
4	IMRm3AS3	0	R/W	When writing:
3	IMRm4AS3	0	R/W	0: Writing 0 is ignored
2	IMRm5AS3	0	R/W	1: Masks the corresponding interrupt request
1	IMRm6AS3	0	R/W	When reading:
0	IMRm7AS3	0	R/W	0: The corresponding interrupt request is accepted
				1: The corresponding interrupt request is masked

[Legend]
n = 0 to 10

(29) Peripheral Interrupt Mask Clear Registers 0AS to 13AS, 0AS3 to 10AS3（IMCR0AS to IMCR13AS,IMCR0AS3 to IMCR10AS3）

IMCR0AS to IMCR13AS and IMCR0AS3 to IMCR10AS3 are write-only registers that clear the mask settings for the on-chip peripheral module interrupts to be sent to the INTCS. Table 5.5

shows the correspondence between the bits in IMCR0AS to IMCR13AS and IMCR0AS3 to IMCR10AS3 and the interrupt sources.

IMCR0AS to IMCR13AS：

Bit:	7	6	5	4	3	2	1	0
	IMCRn 0AS	IMCRn 1AS	IMCRn 2AS	IMCRn 3AS	IMCRn 4AS	IMCRn 5AS	IMCRn 6AS	IMCRn 7AS
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

IMCR0AS3 to IMCR10AS3：

Bit:	7	6	5	4	3	2	1	0
	IMCRm 0AS3	IMCRm 1AS3	IMCRm 2AS3	IMCRm 3AS3	IMCRm 4AS3	IMCRm 5AS3	IMCRm 6AS3	IMCRm 7AS3
Initial value	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

IMCR0AS to IMCR13AS：

Bit	Bit Name	Initial Value	R/W	Description
7	IMCRn0AS	—	W	Interrupt Mask Clear
6	IMCRn1AS	—	W	Clears the mask setting for the interrupt corresponding to each bit. See table 5.5 for the correspondence between IMCR and each interrupt source.
5	IMCRn2AS	—	W	
4	IMCRn3AS	—	W	When writing:
3	IMCRn4AS	—	W	0: Writing 0 is ignored
2	IMCRn5AS	—	W	1: Clears the corresponding interrupt mask
1	IMCRn6AS	—	W	When reading:
0	IMCRn7AS	—	W	An undefined value will be read.

[Legend]
n = 0 to 13

IMCR0AS3 to IMCR10AS3：

Bit	Bit Name	Initial Value	R/W	Description
7	IMCRm0AS3	—	W	Interrupt Mask Clear
6	IMCRm1AS3	—	W	Clears the mask setting for the interrupt corresponding to each bit. See table 5.5 for the correspondence between IMCR and each interrupt source.
5	IMCRm2AS3	—	W	
4	IMCRm3AS3	—	W	When writing:
3	IMCRm4AS3	—	W	0: Writing 0 is ignored
2	IMCRm5AS3	—	W	1: Clears the corresponding interrupt mask
1	IMCRm6AS3	—	W	When reading:
0	IMCRm7AS3	—	W	An undefined value will be read.

[Legend]
m = 0 to 13

Note: —: Reserved. An undefined value will be read. Writing is ignored.

* Bit 3 of IMR8AS/IMCR8AS is reserved. In the AP-Realtime core, the TTI20 interrupt should be handled directly by the INTCS.

(30) User Interrupt Mask Level Register A (USERIMASKA)

USERIMASKA is a register that specifies the level of interrupts to be accepted. As this register is allocated to a 64-Kbyte page that differs from the area of the other INTCA registers, only USERIMASKA can be accessed in user mode by translating its address to the domain that can be accessed in user mode through the MMU.

When the level of an interrupt is not higher than the interrupt level specified in the UIMASKA bit, the interrupt is masked. Specifying H'F masks all interrupts except for NMI. The interrupt with a higher level than that specified in the UIMASKA bit is accepted only when the corresponding interrupt mask bit in the interrupt mask register is 0 (interrupt enabled) and the INTLVLA setting is lower than the level of that interrupt. The UIMASKA value does not change even after an interrupt is accepted.

This register is initialized to H'00000000 (all interrupts enabled) by a power-on reset. To prevent unintentional modification, this register can only be written to with bits 31 to 24 set to H'A5.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	UIMASKA				-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R/W	Reserved These bits are always read as 0. Be sure to write H'A5 to these bits when writing to the UIMASKA bit.
23 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 4	UIMASKA	H'0	R/W	User Interrupt Mask Level The interrupt is masked when the level of an interrupt is not higher than this value.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

(31) AP-Realtime Core Individual Interrupt Source Register (INTEVTAS)

INTEVTAS is a read-only register that indicates the code for the source of the interrupt sent from each peripheral module to the AP-Realtime core.

For the interrupt source code, refer to the list of INTCA interrupt sources (table 5.11). The interrupt signals from the peripheral modules assigned to the INTCA are combined into one signal, and this signal is sent to the INTCS as a peripheral interrupt. The code for this interrupt signal is H'FE0 as shown in the list of INTCS interrupt sources (table 5.13). When the AP-Realtime core accepts this interrupt, the AP-Realtime core can process the peripheral interrupt assigned to the INTCA by reading this register within the AP-Realtime interrupt handler.

The interrupt signal sent from the INTCA to the AP-Realtime core can be masked by the INTAMASK setting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	EVTCODEAS									-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 5	EVTCODEAS	H'02F	R	Interrupt Code These bits hold the interrupt code. For details, see table 5.11.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

(32) AP-Realtime Core Interrupt Mask Register (INTSMASK)

INTSMASK indicates whether to mask all interrupts sent to the AP-System core from the peripheral modules on the INTCS side. INTSMASK is located in the INTCA and controlled by the AP-System core. When the MASK bit in this register is set to 1, no interrupts are sent to the AP-System core regardless of the IMCR*SA setting.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	MASK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	MASK	0	R/W	Interrupt Mask Indicates masking of interrupt requests sent to the AP-System core. When reading: 0: Interrupt requests are not masked 1: Interrupt requests are masked

(33) FIQ status register A (FIQSRA)

FIQSRA is a read-only register. FIQ interrupt can be confirmed by reading this register when ARM-FIQ interrupt.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NMIL	-	-	-	-	-	-	-	-	-	-	-	-	CRYFL	CMT 3FL	NMIFL
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	CC5FL	0	R	CC5 Interrupt Request Detection Indicates whether a CC5 interrupt request signal has been detected. This is a read-only bit. 0: CC5 interrupt request has not been detected 1: CC5 interrupt request has been detected
1	CMT3FL	0	R	CMT3 Interrupt Request Detection Indicates whether a CMT3 interrupt request signal has been detected. This is a read-only bit. 0: CMT3 interrupt request has not been detected 1: CMT3 interrupt request has been detected
0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

(34) IRQ Status Check Register 0(ISCR0)

ISCR0 has bits that can monitor the status of the IRQ pins and a block bit (FIQBL) that can mask the NMI pin interrupt. When the FIQBL bit is set to 1, the FIQ interrupt sent to the AP-System core can be masked but this does not affect the operation of the NMIFCRA.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	FIQBL
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

2	SC29	X	R	IRQ29 Pin Status Check 0: Low-level input to the IRQ29 pin 1: High-level input to the IRQ29 pin
1	SC30	X	R	IRQ30 Pin Status Check 0: Low-level input to the IRQ30 pin 1: High-level input to the IRQ30 pin
0	SC31	X	R	IRQ31 Pin Status Check 0: Low-level input to the IRQ31 pin 1: High-level input to the IRQ31 pin

Pulse Interrupt Flag Register 0A (IFLG0A)

IFLG0A is a register that has a flag bit for indicating the TTI20 interrupt request to the AP-System core. This bit does not change when the TTI20 interrupt is masked with IMR8A.

The interrupt request can be cleared by writing 0 to the TTI20 bit after reading TTI20 = 1.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	TTI20
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TTI20	0	R/W	TTI20 Interrupt Request Indicates a TTI20 interrupt request. When reading: 0: No TTI20 interrupt has been requested to the AP-System core 1: A TTI20 interrupt request has been requested to the AP-System core When writing: 0: Cleared to 0 only after reading 1 1: Writing 1 is ignored

(36) Pseudo-Interrupt Setting Register 0A (SIR0A)

SIR0A is a register to generate an interrupt from a source that is different from the usual one in a specific interrupt.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	TTI20
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TTI20	0	R/W	TTI20 Pseudo-Interrupt Setting This bit can be used to debug the TTI20 interrupt routine when the BB side is stopped. 0: TTI20 interrupt 1: RCLK/512 is changed to a TTI20 interrupt detection signal

(37) DIRC Interrupt Setting Register (DIRCR)

DIRCR is a register to generate an interrupt when a specific bit is set to 1.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	DIRC
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DIRC	0	R/W	DIRC Interrupt Setting 0: DIRC interrupt is not generated 1: DIRC interrupt is generated

(38) Secure control register (LIFEC_SEC_SRC)

LIFEC_SEC_SRC is register that control interrupt from IP of CIPHER.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	CC5	–	–	–
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31～5	—	All 1	R	These bits are always read as 0. The write value should always be 0.
4	—	1	R/W	Don’t write this bit 0.
3	CC5INT	1	R/W	CC5 interrupt setting 0: CC5 is issued to AP-System core as usual interrupt 1: CC5 is issued to AP-System core as FIQ (fast interrupt)
2～0	—	All 1	R/W	Don’t write this bit 0.

5.3.2 INTCS Register Configuration

Table 5.6 shows the INTCS register configuration. Table 5.7 shows the register states in each operating mode.

Table 5.6 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
Interrupt control register 0S	ICR0S	R/W	H'FFD1 0000	32

Note: * For details, refer to section 1-D Overview of reset.

(1) Interrupt Control Register 0S (ICR0S)

ICR0S specifies the detection mode for external interrupt input pins IRQ7 to IRQ0 individually: rising edge, falling edge, low level, or high level.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ0SS				IRQ1SS				IRQ2SS				IRQ3SS			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ4SS				IRQ5SS				IRQ6SS				IRQ7SS			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ0SS	0000	R/W	IRQn Sense Select
27 to 24	IRQ1SS	0000	R/W	These bits select whether interrupt request signals from pins IRQ7 to IRQ0 are detected at a rising edge, a falling edge, a low level, a high level, or at both of a rising edge and a falling edge.
23 to 20	IRQ2SS	0000	R/W	
19 to 16	IRQ3SS	0000	R/W	
15 to 12	IRQ4SS	0000	R/W	
11 to 8	IRQ5SS	0000	R/W	
7 to 4	IRQ6SS	0000	R/W	
3 to 0	IRQ7SS	0000	R/W	

IRQnSS	Detection Mode
0000	Interrupt request is detected at a falling edge of IRQn input
0001	Interrupt request is detected at a rising edge of IRQn input
0010	Interrupt request is detected at a low level of IRQn input
0011	Interrupt request is detected at a high level of IRQn input
0100	Interrupt request is detected at both edges of IRQn input

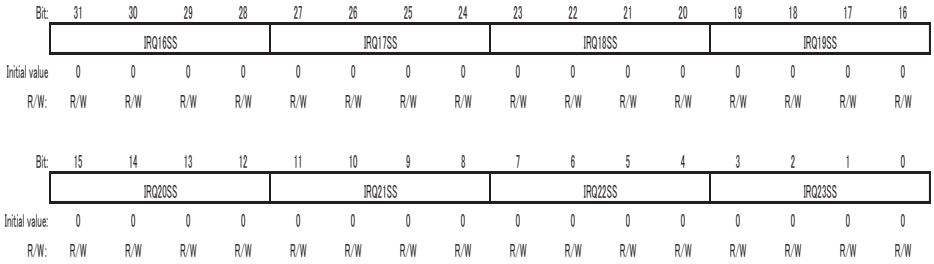
[Legend]
n = 0 to 7

(2) Interrupt Control Register 1S (ICR1S)

ICR1S specifies the detection mode for external interrupt input pins IRQ15 to IRQ8 individually: rising edge, falling edge, low level, or high level.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ8SS				IRQ9SS				IRQ10SS				IRQ11SS			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ12SS				IRQ13SS				IRQ14SS				IRQ15SS			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



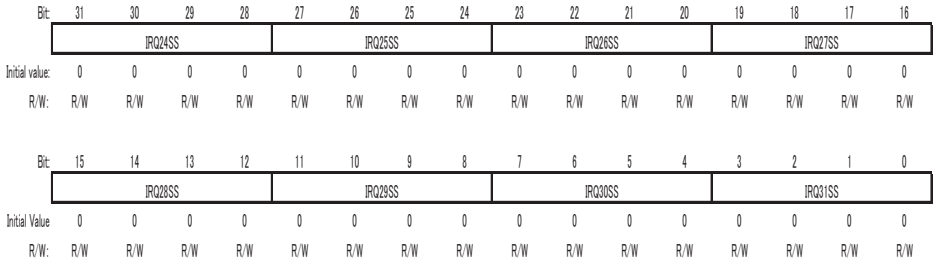
Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ8SS	0000	R/W	IRQn Sense Select
27 to 24	IRQ9SS	0000	R/W	These bits select whether interrupt request signals from pins IRQ8 to IRQ15 are detected at a rising edge, a falling edge, a low level, a high level, or at both of a rising edge and a falling edge.
23 to 20	IRQ10SS	0000	R/W	
19 to 16	IRQ11SS	0000	R/W	
15 to 12	IRQ12SS	0000	R/W	
11 to 8	IRQ13SS	0000	R/W	
7 to 4	IRQ14SS	0000	R/W	
3 to 0	IRQ15SS	0000	R/W	

IRQnSS	Detection Mode
0000	Interrupt request is detected at a falling edge of IRQn input
0001	Interrupt request is detected at a rising edge of IRQn input
0010	Interrupt request is detected at a low level of IRQn input
0011	Interrupt request is detected at a high level of IRQn input
0100	Interrupt request is detected at both edges of IRQn input

[Legend]
n = 8 to 15

(3) Interrupt Control Register 2S (ICR2S)

ICR2S specifies the detection mode for external interrupt input pins IRQ23 to IRQ16 individually: rising edge, falling edge, low level, or high level.



Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ16SS	0000	R/W	IRQn Sense Select
27 to 24	IRQ17SS	0000	R/W	These bits select whether interrupt request signals from pins IRQ16 to IRQ23 are detected at a rising edge, a falling edge, a low level, a high level, or at both of a rising edge and a falling edge.
23 to 20	IRQ18SS	0000	R/W	
19 to 16	IRQ19SS	0000	R/W	
15 to 12	IRQ20SS	0000	R/W	
11 to 8	IRQ21SS	0000	R/W	
7 to 4	IRQ22SS	0000	R/W	
3 to 0	IRQ23SS	0000	R/W	

IRQnSS	Detection Mode
0000	Interrupt request is detected at a falling edge of IRQn input
0001	Interrupt request is detected at a rising edge of IRQn input
0010	Interrupt request is detected at a low level of IRQn input
0011	Interrupt request is detected at a high level of IRQn input
0100	Interrupt request is detected at both edges of IRQn input

[Legend]
n = 16 to 23

(4) Interrupt Control Register 3S (ICR3S)

ICR3S specifies the detection mode for external interrupt input pins IRQ31 to IRQ24 individually: rising edge, falling edge, low level, or high level.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ24SS	0000	R/W	IRQn Sense Select
27 to 24	IRQ25SS	0000	R/W	These bits select whether interrupt request signals from pins IRQ24 to IRQ31 are detected at a rising edge, a falling edge, a low level, a high level, or at both of a rising edge and a falling edge.
23 to 20	IRQ26SS	0000	R/W	
19 to 16	IRQ27SS	0000	R/W	
15 to 12	IRQ28SS	0000	R/W	
11 to 8	IRQ29SS	0000	R/W	
7 to 4	IRQ30SS	0000	R/W	
3 to 0	IRQ31SS	0000	R/W	

IRQnSS	Detection Mode
0000	Interrupt request is detected at a falling edge of IRQn input
0001	Interrupt request is detected at a rising edge of IRQn input
0010	Interrupt request is detected at a low level of IRQn input
0011	Interrupt request is detected at a high level of IRQn input
0100	Interrupt request is detected at both edges of IRQn input

[Legend]
n = 24 to 31

(5) Interrupt Control Register 3 (ICR3)

ICR3 is a register to set the chattering removal time for edge detection with external interrupt input pins IRQ3 to IRQ0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRQ0STS1[1:0]		IRQ0STS2[5:0]						IRQ1STS1[1:0]		IRQ1STS2[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

5 to 0	IRQ11STS2	H'00	R/W	

IRQnSTS1	Chattering Period Clock
B'00	1 ms
B'01	2 ms
B'10	4 ms
B'11	8 ms

IRQnSTS2	Chattering Removal Time
H'00	None
H'01 to H'3F	Chattering period clock × IRQnSTS2 ms

[Legend]
n = 8 to 11

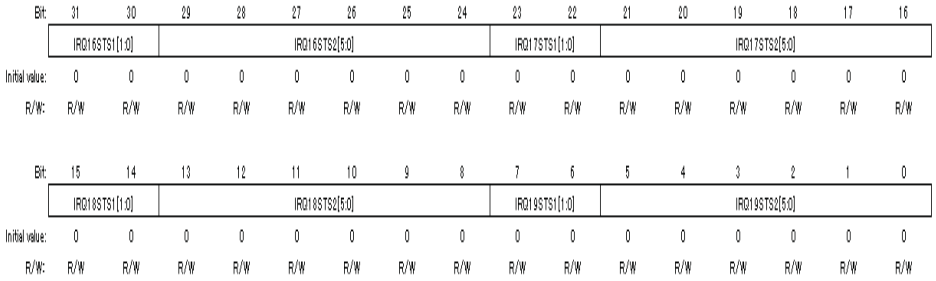
(8) Interrupt Control Register 6 (ICR6)

ICR6 is a register to set the chattering removal time for edge detection with external interrupt input pins IRQ15 to IRQ12.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRQ12STS1[1:0]		IRQ12STS2[5:0]						IRQ13STS1[1:0]		IRQ13STS2[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ14STS1[1:0]		IRQ14STS2[5:0]						IRQ15STS1[1:0]		IRQ15STS2[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	IRQ12STS1	B'00	R/W	IRQn Scan Timing
29 to 24	IRQ12STS2	H'00	R/W	These bits set the chattering removal time for the IRQ12 to IRQ15 pins
23, 22	IRQ13STS1	B'00	R/W	
21 to 16	IRQ13STS2	H'00	R/W	
15, 14	IRQ14STS1	B'00	R/W	
13 to 8	IRQ14STS2	H'00	R/W	
7, 6	IRQ15STS1	B'00	R/W	
5 to 0	IRQ15STS2	H'00	R/W	



IRQnSTS1	Chattering Period Clock
B'00	1 ms
B'01	2 ms
B'10	4 ms
B'11	8 ms

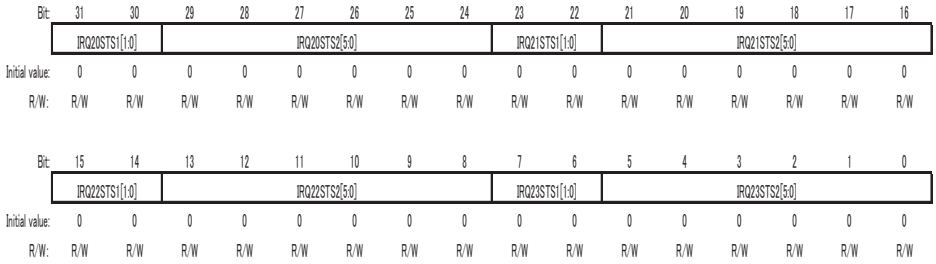
IRQnSTS2	Chattering Removal Time
H'00	None
H'01 to H'3F	Chattering period clock × IRQnSTS2 ms

[Legend]
n = 12 to 15

(9) Interrupt Control Register 7 (ICR7)

ICR7 is a register to set the chattering removal time for edge detection with external interrupt input pins IRQ19 to IRQ16.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	IRQ16STS1	B'00	R/W	IRQn Scan Timing
29 to 24	IRQ16STS2	H'00	R/W	These bits set the chattering removal time for the IRQ16 to IRQ19 pins
23, 22	IRQ17STS1	B'00	R/W	
21 to 16	IRQ17STS2	H'00	R/W	
15, 14	IRQ18STS1	B'00	R/W	
13 to 8	IRQ18STS2	H'00	R/W	
7, 6	IRQ19STS1	B'00	R/W	
5 to 0	IRQ19STS2	H'00	R/W	



IRQnSTS1	Chattering Period Clock
B'00	1 ms
B'01	2 ms
B'10	4 ms
B'11	8 ms

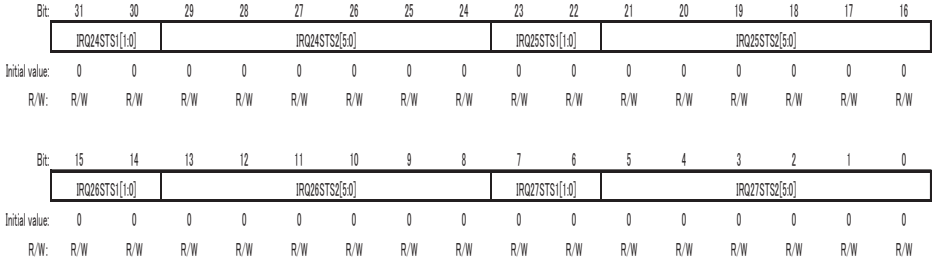
IRQnSTS2	Chattering Removal Time
H'00	None
H'01 to H'3F	Chattering period clock × IRQnSTS2 ms

[Legend]
n = 16 to 19

(10) Interrupt Control Register 8 (ICR8)

ICR8 is a register to set the chattering removal time for edge detection with external interrupt input pins IRQ23 to IRQ20.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	IRQ20STS1	B'00	R/W	IRQn Scan Timing
29 to 24	IRQ20STS2	H'00	R/W	These bits set the chattering removal time for the IRQ20 to IRQ23 pins
23, 22	IRQ21STS1	B'00	R/W	
21 to 16	IRQ21STS2	H'00	R/W	
15, 14	IRQ22STS1	B'00	R/W	
13 to 8	IRQ22STS2	H'00	R/W	
7, 6	IRQ23STS1	B'00	R/W	
5 to 0	IRQ23STS2	H'00	R/W	



IRQnSTS1	Chattering Period Clock
B'00	1 ms
B'01	2 ms
B'10	4 ms
B'11	8 ms

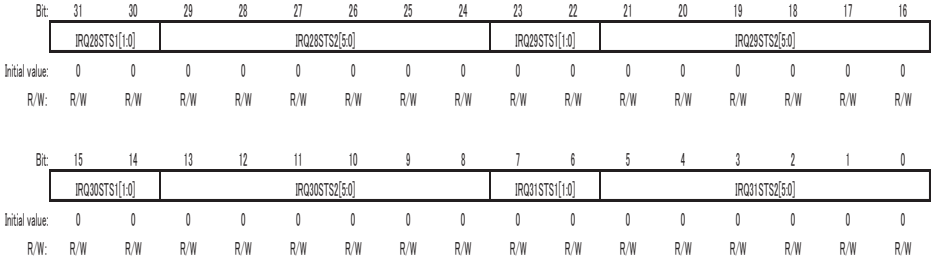
IRQnSTS2	Chattering Removal Time
H'00	None
H'01 to H'3F	Chattering period clock × IRQnSTS2 ms

[Legend]
n = 23 to 20

(11) Interrupt Control Register 9 (ICR9)

ICR9 is a register to set the chattering removal time for edge detection with external interrupt input pins IRQ27 to IRQ24.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	IRQ24STS1	B'00	R/W	IRQn Scan Timing
29 to 24	IRQ24STS2	H'00	R/W	These bits set the chattering removal time for the IRQ24 to IRQ27 pins
23, 22	IRQ25STS1	B'00	R/W	
21 to 16	IRQ25STS2	H'00	R/W	
15, 14	IRQ26STS1	B'00	R/W	
13 to 8	IRQ26STS2	H'00	R/W	
7, 6	IRQ27STS1	B'00	R/W	
5 to 0	IRQ27STS2	H'00	R/W	



IRQnSTS1	Chattering Period Clock
B'00	1 ms
B'01	2 ms
B'10	4 ms
B'11	8 ms

IRQnSTS2	Chattering Removal Time
H'00	None
H'01 to H'3F	Chattering period clock × IRQnSTS2 ms

[Legend]
n = 27 to 24

(12) Interrupt Control Register 10 (ICR10)

ICR10 is a register to set the chattering removal time for edge detection with external interrupt input pins IRQ31 to IRQ28.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	IRQ28STS1	B'00	R/W	IRQn Scan Timing
29 to 24	IRQ28STS2	H'00	R/W	These bits set the chattering removal time for the IRQ28 to IRQ31 pins
23, 22	IRQ29STS1	B'00	R/W	
21 to 16	IRQ29STS2	H'00	R/W	
15, 14	IRQ30STS1	B'00	R/W	
13 to 8	IRQ30STS2	H'00	R/W	
7, 6	IRQ31STS1	B'00	R/W	
5 to 0	IRQ31STS2	H'00	R/W	

IRQnSTS1	Chattering Period Clock
B'00	1 ms
B'01	2 ms
B'10	4 ms
B'11	8 ms

IRQnSTS2	Chattering Removal Time
H'00	None
H'01 to H'3F	Chattering period clock × IRQnSTS2 ms

[Legend]
n = 28 to 31

(13) Interrupt Priority Register 00S (INTPRI00S)

INTPRI00S is a register that specifies priority levels from 15 to 0 for external interrupt input pins IRQ7 to IRQ0.

Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRQ0S				IRQ1S				IRQ2S				IRQ3S			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ4S				IRQ5S				IRQ6S				IRQ7S			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

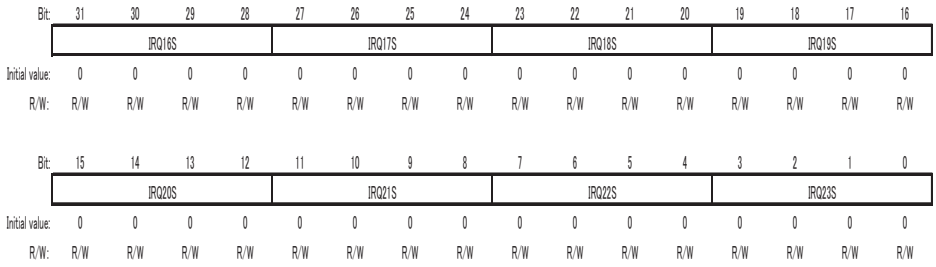
Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ0S	H'0	R/W	These bits specify the priority level for each interrupt source in 4-bit units.
27 to 24	IRQ1S	H'0	R/W	
23 to 20	IRQ2S	H'0	R/W	
19 to 16	IRQ3S	H'0	R/W	
15 to 12	IRQ4S	H'0	R/W	
11 to 8	IRQ5S	H'0	R/W	
7 to 4	IRQ6S	H'0	R/W	
3 to 0	IRQ7S	H'0	R/W	

(14) Interrupt Priority Register 10S (INTPRI10S)

INTPRI10S is a register that specifies priority levels from 15 to 0 for external interrupt input pins IRQ15 to IRQ8.

Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IRQ8S				IRQ9S				IRQ10S				IRQ11S			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



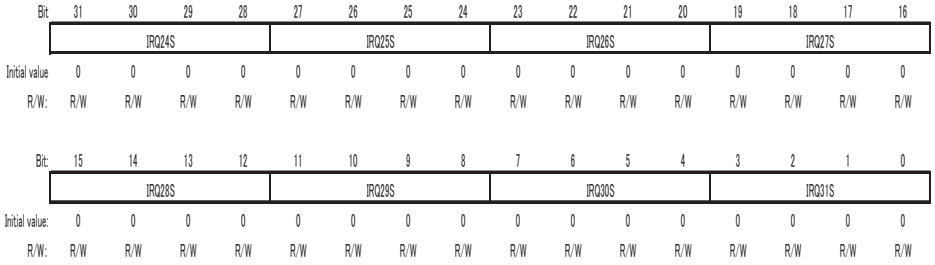
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ12S				IRQ13S				IRQ14S				IRQ15S			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ8S	H'0	R/W	These bits specify the priority level for each interrupt source in 4-bit units.
27 to 24	IRQ9S	H'0	R/W	
23 to 20	IRQ10S	H'0	R/W	
19 to 16	IRQ11S	H'0	R/W	
15 to 12	IRQ12S	H'0	R/W	
11 to 8	IRQ13S	H'0	R/W	
7 to 4	IRQ14S	H'0	R/W	
3 to 0	IRQ15S	H'0	R/W	

(15) Interrupt Priority Register 20S (INTPRI20S)

INTPRI20S is a register that specifies priority levels from 15 to 0 for external interrupt input pins IRQ23 to IRQ16.

Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).



Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ16S	H'0	R/W	These bits specify the priority level for each interrupt source in 4-bit units.
27 to 24	IRQ17S	H'0	R/W	
23 to 20	IRQ18S	H'0	R/W	
19 to 16	IRQ19S	H'0	R/W	
15 to 12	IRQ20S	H'0	R/W	
11 to 8	IRQ21S	H'0	R/W	
7 to 4	IRQ22S	H'0	R/W	
3 to 0	IRQ23S	H'0	R/W	

(16) Interrupt Priority Register 30S (INTPRI30S)

INTPRI10S is a register that specifies priority levels from 15 to 0 for external interrupt input pins IRQ31 to IRQ24.

Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	IRQ24S	H'0	R/W	These bits specify the priority level for each interrupt source in 4-bit units.
27 to 24	IR25S	H'0	R/W	
23 to 20	IRQ26S	H'0	R/W	
19 to 16	IRQ27S	H'0	R/W	
15 to 12	IRQ28S	H'0	R/W	
11 to 8	IRQ29S	H'0	R/W	
7 to 4	IRQ30S	H'0	R/W	
3 to 0	IRQ31S	H'0	R/W	

(17) Peripheral Interrupt Priority Registers AS to MS ,AS3 to PS3（IPRAS to IPRMS,IPRAS3 to IPRPS3）

IPRAS to IPRMS and IPRAS3 to IPRPS3 are registers that specify priority levels from 15 to 0 for on-chip peripheral module interrupts.

Four modules are assigned to each register. Each 4-bit group is set with a value from H'F (1111) to H'0 (0000) to specify the interrupt priority level for the corresponding interrupt. Setting H'F means priority level 15 (the highest level); H'0 means priority level 0 (the request is masked).

Table 5.8 shows the correspondence between the peripheral modules requesting interrupts and the peripheral interrupt priority registers.

IPRAS to IPRMS:

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IPR0nS				IPR1nS				IPR2nS				IPR3nS			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

IPRAS3 to IPRPS3:

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IPR0nS3				IPR1nS3				IPR2nS3				IPR3nS3			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

(18) Interrupt Source Register 00S (INTREQ00S)

INTREQ00S is a register that indicates interrupt requests from external input pins IRQ7 to IRQ0. This register value is not affected by the INTPRI00S setting or the interrupt masks specified with INTMSK00S.

When edge-detection mode is set for an IRQ pin (ICR0S.IRQnSS = B'00 or B'01), an interrupt request is cleared by writing 0 to the corresponding IRQnS bit after reading IRQnS = 1; write 1 to the other bits.

Bit:	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ0S	0	R/W	IRQn Interrupt Request
6	IRQ1S	0	R/W	Indicates whether there is an interrupt request input to the IRQn pin.
5	IRQ2S	0	R/W	
4	IRQ3S	0	R/W	[When edge-detection mode is selected (ICR0S.IRQnSS = B'00 or B'01)]
3	IRQ4S	0	R/W	When reading:
2	IRQ5S	0	R/W	0: No interrupt request has been detected
1	IRQ6S	0	R/W	1: An interrupt request has been detected
0	IRQ7S	0	R/W	When writing:
				0: Each bit is cleared by writing 0 after reading 1
				1: Writing 1 is ignored
				[When level-detection mode is selected (ICR0S.IRQnSS = B'10 or B'11)]
				When reading:
				0: The corresponding interrupt pin has not been asserted
				1: The corresponding interrupt pin has been asserted
				When writing:
				Writing 0 or 1 is ignored.

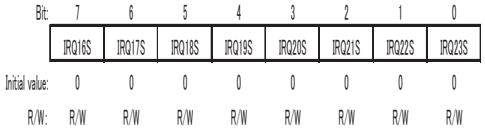
[Legend]
n = 0 to 7

(19) Interrupt Source Register 10S (INTREQ10S)

INTREQ10S is a register that indicates interrupt requests from external input pins IRQ15 to IRQ8. This register value is not affected by the INTPRI10S setting or the interrupt masks specified with the INTMSK10S.

When edge-detection mode is set for an IRQ pin (ICR1S.IRQnSS = B'00 or B'01), an interrupt request is cleared by writing 0 to the corresponding IRQnS bit after reading IRQnS = 1; write 1 to the other bits.

Bit:	7	6	5	4	3	2	1	0
	IRQ 8S	IRQ 9S	IRQ 10S	IRQ 11S	IRQ 12S	IRQ 13S	IRQ 14S	IRQ 15S
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



Bit	Bit Name	Initial Value	R/W	Description
7	IRQ8S	0	R/W	IRQn Interrupt Request
6	IRQ9S	0	R/W	Indicates whether there is an interrupt request input to the IRQn pin.
5	IRQ10S	0	R/W	[When edge-detection mode is selected (ICR1S.IRQnSS = B'00 or B'01)]
4	IRQ11S	0	R/W	When reading:
3	IRQ12S	0	R/W	0: No interrupt request has been detected
2	IRQ13S	0	R/W	1: An interrupt request has been detected
1	IRQ14S	0	R/W	When writing:
0	IRQ15S	0	R/W	0: Each bit is cleared by writing 0 after reading 1
				1: Writing 1 is ignored
				[When level-detection mode is selected (ICR1S.IRQnSS = B'10 or B'11)]
				When reading:
				0: The corresponding interrupt pin has not been asserted
				1: The corresponding interrupt pin has been asserted
				When writing:
				Writing 0 or 1 is ignored.

[Legend]
n = 8 to 15

(20) Interrupt Source Register 20S (INTREQ20S)

INTREQ20S is a register that indicates interrupt requests from external input pins IRQ23 to IRQ16. This register value is not affected by the INTPRI20S setting or the interrupt masks specified with the INTMSK20S.

When edge-detection mode is set for an IRQ pin (ICR2S.IRQnSS = B'00 or B'01), an interrupt request is cleared by writing 0 to the corresponding IRQnS bit after reading IRQnS = 1; write 1 to the other bits.

Bit:	7	6	5	4	3	2	1	0
	IRQ16S	IRQ17S	IRQ18S	IRQ19S	IRQ20S	IRQ21S	IRQ22S	IRQ23S
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ16S	0	R/W	IRQn Interrupt Request
6	IRQ17S	0	R/W	Indicates whether there is an interrupt request input to the IRQn pin.
5	IRQ18S	0	R/W	[When edge-detection mode is selected (ICR2S.IRQnSS = B'00 or B'01)]
4	IRQ19S	0	R/W	When reading:
3	IRQ20S	0	R/W	0: No interrupt request has been detected
2	IRQ21S	0	R/W	1: An interrupt request has been detected
1	IRQ22S	0	R/W	When writing:
0	IRQ23S	0	R/W	0: Each bit is cleared by writing 0 after reading 1
				1: Writing 1 is ignored
				[When level-detection mode is selected (ICR2S.IRQnSS = B'10 or B'11)]
				When reading:
				0: The corresponding interrupt pin has not been asserted
				1: The corresponding interrupt pin has been asserted
				When writing:
				Writing 0 or 1 is ignored.

[Legend]
n = 16 to 23

(21) Interrupt Source Register 30S (INTREQ30S)

INTREQ30S is a register that indicates interrupt requests from external input pins IRQ31 to IRQ24. This register value is not affected by the INTPRI30S setting or the interrupt masks specified with the INTMSK30S.

When edge-detection mode is set for an IRQ pin (ICR3S.IRQnSS = B'00 or B'01), an interrupt request is cleared by writing 0 to the corresponding IRQnS bit after reading IRQnS = 1; write 1 to the other bits.

Bit:	7	6	5	4	3	2	1	0
	IRQ24S	IRQ25S	IRQ26S	IRQ27S	IRQ28S	IRQ29S	IRQ30S	IRQ31S
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ24S	0	R/W	IRQn Interrupt Request
6	IRQ25S	0	R/W	Indicates whether there is an interrupt request input to the IRQn pin.
5	IRQ26S	0	R/W	
4	IRQ27S	0	R/W	[When edge-detection mode is selected (ICR3S.IRQnSS = B'00 or B'01)]
3	IRQ28S	0	R/W	When reading:
2	IRQ29S	0	R/W	0: No interrupt request has been detected
1	IRQ30S	0	R/W	1: An interrupt request has been detected
0	IRQ31S	0	R/W	When writing:
				0: Each bit is cleared by writing 0 after reading 1
				1: Writing 1 is ignored
				[When level-detection mode is selected (ICR3S.IRQnSS = B'10 or B'11)]
				When reading:
				0: The corresponding interrupt pin has not been asserted
				1: The corresponding interrupt pin has been asserted
				When writing:
				Writing 0 or 1 is ignored.

[Legend]
n = 31 to 24

(22) Interrupt Mask Register 00S (INTMSK00S)

INTMSK00S is a register that masks interrupt requests from external interrupt input pins IRQ7 to IRQ0.

To clear an interrupt mask, write 1 to the corresponding bit in INTMSKCLR00S. Writing 0 to the corresponding bit in INTMSK00S does not affect the bit value.

Bit:	7	6	5	4	3	2	1	0
	IRQ0S	IRQ1S	IRQ2S	IRQ3S	IRQ4S	IRQ5S	IRQ6S	IRQ7S
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ0S	0	R/W	IRQn Interrupt Mask
6	IRQ1S	0	R/W	0: The corresponding interrupt is not masked
5	IRQ2S	0	R/W	1: The corresponding interrupt is masked
4	IRQ3S	0	R/W	
3	IRQ4S	0	R/W	
2	IRQ5S	0	R/W	
1	IRQ6S	0	R/W	
0	IRQ7S	0	R/W	

[Legend]
n = 0 to 7

(23) Interrupt Mask Register 10S (INTMSK10S)

INTMSK10S is a register that masks interrupt requests from external interrupt input pins IRQ15 to IRQ8.

To clear an interrupt mask, write 1 to the corresponding bit in INTMSKCLR10S. Writing 0 to the corresponding bit in INTMSK10S does not affect the bit value.

Bit:	7	6	5	4	3	2	1	0
	IRQ8S	IRQ9S	IRQ10S	IRQ11S	IRQ12S	IRQ13S	IRQ14S	IRQ15S
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ8S	0	R/W	IRQn Interrupt Mask
6	IRQ9S	0	R/W	0: The corresponding interrupt is not masked
5	IRQ10S	0	R/W	1: The corresponding interrupt is masked
4	IRQ11S	0	R/W	
3	IRQ12S	0	R/W	
2	IRQ13S	0	R/W	
1	IRQ14S	0	R/W	
0	IRQ15S	0	R/W	

[Legend]
n = 8 to 15

(24) Interrupt Mask Register 20S (INTMSK20S)

INTMSK20S is a register that masks interrupt requests from external interrupt input pins IRQ23 to IRQ16.

To clear an interrupt mask, write 1 to the corresponding bit in INTMSKCLR20S. Writing 0 to the corresponding bit in INTMSK20S does not affect the bit value.

Bit:	7	6	5	4	3	2	1	0
	IRQ16S	IRQ17S	IRQ18S	IRQ19S	IRQ20S	IRQ21S	IRQ22S	IRQ23S
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ16S	0	R/W	IRQn Interrupt Mask
6	IRQ17S	0	R/W	0: The corresponding interrupt is not masked
5	IRQ18S	0	R/W	1: The corresponding interrupt is masked
4	IRQ19S	0	R/W	
3	IRQ20S	0	R/W	
2	IRQ21S	0	R/W	
1	IRQ22S	0	R/W	
0	IRQ23S	0	R/W	

[Legend]
n = 16 to 23

(25) Interrupt Mask Register 30S (INTMS30S)

INTMSK30S is a register that masks interrupt requests from external interrupt input pins IRQ31 to IRQ24.

To clear an interrupt mask, write 1 to the corresponding bit in INTMSKCLR30S. Writing 0 to the corresponding bit in INTMSK30S does not affect the bit value.

Bit:	7	6	5	4	3	2	1	0
	IRQ24S	IRQ25S	IRQ26S	IRQ27S	IRQ28S	IRQ29S	IRQ30S	IRQ31S
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ24S	0	R/W	IRQn Interrupt Mask
6	IRQ25S	0	R/W	0: The corresponding interrupt is not masked
5	IRQ26S	0	R/W	1: The corresponding interrupt is masked
4	IRQ27S	0	R/W	
3	IRQ28S	0	R/W	
2	IRQ29S	0	R/W	
1	IRQ30S	0	R/W	
0	IRQ31S	0	R/W	

[Legend]
n = 24 to 31

(26) Interrupt Mask Clear Register 00S (INTMSKCLR00S)

INTMSKCLR00S is a write-only register that clears the mask settings for interrupts from external interrupt input pins IRQ7 to IRQ0.

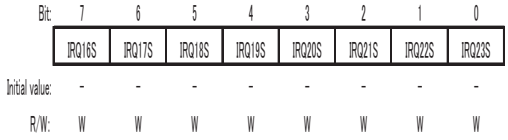
Bit:	7	6	5	4	3	2	1	0
	IRQ0S	IRQ1S	IRQ2S	IRQ3S	IRQ4S	IRQ5S	IRQ6S	IRQ7S
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ0S	—	W	IRQnS Interrupt Mask Clear
6	IRQ1S	—	W	0: Writing 0 is ignored
5	IRQ2S	—	W	1: Clears the corresponding interrupt mask
4	IRQ3S	—	W	When reading:
3	IRQ4S	—	W	An undefined value will be read.
2	IRQ5S	—	W	
1	IRQ6S	—	W	
0	IRQ7S	—	W	

[Legend]
n = 0 to 7

(27) Interrupt Mask Clear Register 10S (INTMSKCLR10S)

INTMSKCLR10S is a write-only register that clears the mask settings for interrupts from external interrupt input pins IRQ15 to IRQ8.



Bit:	7	6	5	4	3	2	1	0
	IRQ 8S	IRQ 9S	IRQ 10S	IRQ 11S	IRQ 12S	IRQ 13S	IRQ 14S	IRQ 15S
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ8S	—	W	IRQnS Interrupt Mask Clear
6	IRQ9S	—	W	0: Writing 0 is ignored
5	IRQ10S	—	W	1: Clears the corresponding interrupt mask
4	IRQ11S	—	W	When reading:
3	IRQ12S	—	W	An undefined value will be read.
2	IRQ13S	—	W	
1	IRQ14S	—	W	
0	IRQ15S	—	W	

[Legend]
n = 8 to 15

(28) Interrupt Mask Clear Register 20S (INTMSKCLR20S)

INTMSKCLR20S is a write-only register that clears the mask settings for interrupts from external interrupt input pins IRQ23 to IRQ16.

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ16S	—	W	IRQnS Interrupt Mask Clear
6	IRQ17S	—	W	0: Writing 0 is ignored
5	IRQ18S	—	W	1: Clears the corresponding interrupt mask
4	IRQ19S	—	W	When reading:
3	IRQ20S	—	W	An undefined value will be read.
2	IRQ21S	—	W	
1	IRQ22S	—	W	
0	IRQ23S	—	W	

[Legend]
n = 16 to 23

(29) Interrupt Mask Clear Register 30S (INTMSKCLR30S)

INTMSKCLR30S is a write-only register that clears the mask settings for interrupts from external interrupt input pins IRQ31 to IRQ24.

Bit:	7	6	5	4	3	2	1	0
	IRQ24S	IRQ25S	IRQ26S	IRQ27S	IRQ28S	IRQ29S	IRQ30S	IRQ31S
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ24S	—	W	IRQnS Interrupt Mask Clear
6	IRQ25S	—	W	0: Writing 0 is ignored
5	IRQ26S	—	W	1: Clears the corresponding interrupt mask
4	IRQ27S	—	W	When reading:
3	IRQ28S	—	W	An undefined value will be read.
2	IRQ29S	—	W	
1	IRQ30S	—	W	
0	IRQ31S	—	W	

[Legend]
n = 24 to 31

(30) Peripheral Interrupt Mask Registers 0S to 12S,0S3 to 7S3 (IMR0S to IMR12S,IMR0S3 to IMR7S3)

IMR0S to IMR12S and IMR0S3 to IMR7S3 are registers that mask on-chip peripheral module interrupts. To mask an interrupt, write 1 to the corresponding bit in IMR0S to IMR12S and IMR0S3 to IMR7S3. Peripheral module interrupts not used should be masked.

To clear an interrupt mask, write 1 to the corresponding bit in IMCR0S to IMCR12S and IMR0S3 to IMR7S3. Writing 0 to the corresponding bit in IMR0S to IMR12S and IMR0S3 to IMR7S3 does not affect the bit value.

Table 5.9 shows the correspondence between the bits in IMR0S to IMR12S and IMR0S3 to IMR7S3 and the interrupt sources.

IMR0S to IMR12S:

Bit:	7	6	5	4	3	2	1	0
	IMRn 0S	IMRn 1S	IMRn 2S	IMRn 3S	IMRn 4S	IMRn 5S	IMRn 6S	IMRn 7S
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

IMR0S3 to IMR7S3:

Bit:	7	6	5	4	3	2	1	0
	IMRm 0S3	IMRm 1S3	IMRm 2S3	IMRm 3S3	IMRm 4S3	IMRm 5S3	IMRm 6S3	IMRm 7S3
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

IMR0S to IMR12S:

Bit	Bit Name	Initial Value	R/W	Description
7	IMRn0S	0	R/W	Interrupt Mask
6	IMRn1S	0	R/W	Masks the interrupt request corresponding to each bit. See table 5.9 for the correspondence between IMR and each interrupt source.
5	IMRn2S	0	R/W	
4	IMRn3S	0	R/W	When writing:
3	IMRn4S	0	R/W	0: Writing 0 is ignored
2	IMRn5S	0	R/W	1: Masks the corresponding interrupt request
1	IMRn6S	0	R/W	When reading:
0	IMRn7S	0	R/W	0: The corresponding interrupt request is accepted
				1: The corresponding interrupt request is masked

[Legend]
n = 0 to 12

IMR0S3 to IMR7S3:

Bit	Bit Name	Initial Value	R/W	Description
7	IMRm0S3	0	R/W	Interrupt Mask
6	IMRm1S3	0	R/W	Masks the interrupt request corresponding to each bit. See table 5.9 for the correspondence between IMR and each interrupt source.
5	IMRm2S3	0	R/W	
4	IMRm3S3	0	R/W	When writing:
3	IMRm4S3	0	R/W	0: Writing 0 is ignored
2	IMRm5S3	0	R/W	1: Masks the corresponding interrupt request
1	IMRm6S3	0	R/W	When reading:
0	IMRm7S3	0	R/W	0: The corresponding interrupt request is accepted
				1: The corresponding interrupt request is masked

[Legend]
m = 0 to 7

(31) Peripheral Interrupt Mask Clear Registers 0S to 12S,0S3 to 7S3(IMCR0S to IMCR12S,IMCR0S3 to IMCR7S3)

IMCR0S to IMCR12S and IMCR0S3 to IMCR7S3 are write-only registers that clear the mask settings for the on-chip peripheral module interrupts. Table 5.9 shows the correspondence between the bits in IMCR0S to IMCR12S and IMCR0S3 to IMCR7S3 and the interrupt sources.

IMCR0S to IMCR12S:

Bit:	7	6	5	4	3	2	1	0
	IMCRn0S	IMCRn1S	IMCRn2S	IMCRn3S	IMCRn4S	IMCRn5S	IMCRn6S	IMCRn7S
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

IMCR0S3 to IMCR7S3:

Bit:	7	6	5	4	3	2	1	0
	IMCRm0S3	IMCRm1S3	IMCRm2S3	IMCRm3S3	IMCRm4S3	IMCRm5S3	IMCRm6S3	IMCRm7S3
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

IMCR0S to IMCR12S:

Bit	Bit Name	Initial Value	R/W	Description
7	IMCRn0S	—	W	Interrupt Mask Clear
6	IMCRn1S	—	W	Clears the mask setting for the interrupt corresponding to each bit. See table 5.9 for the correspondence between IMCR and each interrupt source.
5	IMCRn2S	—	W	
4	IMCRn3S	—	W	When writing:
3	IMCRn4S	—	W	0: Writing 0 is ignored
2	IMCRn5S	—	W	1: Clears the corresponding interrupt mask
1	IMCRn6S	—	W	When reading:
0	IMCRn7S	—	W	An undefined value will be read.

[Legend]
n = 0 to 12

IMCR0S3 to IMCR7S3:

Bit	Bit Name	Initial Value	R/W	Description
7	IMCRm0S3	—	W	Interrupt Mask Clear
6	IMCRm1S3	—	W	Clears the mask setting for the interrupt corresponding to each bit. See table 5.9 for the correspondence between IMCR and each interrupt source.
5	IMCRm2S3	—	W	
4	IMCRm3S3	—	W	When writing:
3	IMCRm4S3	—	W	0: Writing 0 is ignored
2	IMCRm5S3	—	W	1: Clears the corresponding interrupt mask
1	IMCRm6S3	—	W	When reading:
0	IMCRm7S3	—	W	An undefined value will be read.

[Legend]

m = 0 to 7

(32) Peripheral Interrupt Mask Registers 0SA to 12SA,0SA3 to 7SA3 (IMR0SA to IMR12SA,IMR0SA3 to IMR7SA3)

IMR0SA to IMR12SA and IMR0SA3 to IMR7SA3 are registers that mask on-chip peripheral module interrupts to be sent to the INTCA. To mask an interrupt request, write 1 to the corresponding bit in IMR0SA to IMR12SA and IMR0SA3 to IMR7SA3. Peripheral module interrupts not used should be masked.

To clear an interrupt mask, write 1 to the corresponding bit in IMCR0SA to IMCR12SA and IMR0SA3 to IMR7SA3. Writing 0 to the corresponding bit in IMR0SA to IMR12SA and IMR0SA3 to IMR7SA3 does not affect the bit value.

Table 5.9 shows the correspondence between the bits in IMR0SA to IMR12SA and IMR0SA3 to IMR7SA3 and the interrupt sources.

IMR0SA to IMR12SA:

Bit:	7	6	5	4	3	2	1	0
	IMRn 0SA	IMRn 1SA	IMRn 2SA	IMRn 3SA	IMRn 4SA	IMRn 5SA	IMRn 6SA	IMRn 7SA
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

IMR0SA3 to IMR7SA3:

Bit:	7	6	5	4	3	2	1	0
	IMRm 0SA3	IMRm 1SA3	IMRm 2SA3	IMRm 3SA3	IMRm 4SA3	IMRm 5SA3	IMRm 6SA3	IMRm 7SA3
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

IMR0SA to IMR12SA:

Bit	Bit Name	Initial Value	R/W	Description
7	IMRn0SA	0	R/W	Interrupt Mask
6	IMRn1SA	0	R/W	Masks the interrupt request corresponding to each bit. See table 5.9 for the correspondence between IMR and each interrupt source.
5	IMRn2SA	0	R/W	
4	IMRn3SA	0	R/W	When writing:
3	IMRn4SA	0	R/W	0: Writing 0 is ignored
2	IMRn5SA	0	R/W	1: Masks the corresponding interrupt request
1	IMRn6SA	0	R/W	When reading:
0	IMRn7SA	0	R/W	0: The corresponding interrupt request is accepted
				1: The corresponding interrupt request is masked

[Legend]
n = 0 to 12

IMR0SA3 to IMR7SA3:

Bit	Bit Name	Initial Value	R/W	Description
7	IMRm0SA3	0	R/W	Interrupt Mask
6	IMRm1SA3	0	R/W	Masks the interrupt request corresponding to each bit. See table 5.9 for the correspondence between IMR and each interrupt source.
5	IMRm2SA3	0	R/W	
4	IMRm3SA3	0	R/W	When writing:
3	IMRm4SA3	0	R/W	0: Writing 0 is ignored
2	IMRm5SA3	0	R/W	1: Masks the corresponding interrupt request
1	IMRm6SA3	0	R/W	When reading:
0	IMRm7SA3	0	R/W	0: The corresponding interrupt request is accepted
				1: The corresponding interrupt request is masked

[Legend]
m = 0 to 12

(33) Peripheral Interrupt Mask Clear Registers 0SA to 12SA,0SA3 to 7SA3 (IMCR0SA to IMCR12SA,IMCR0SA3 to IMCR7SA3)

IMCR0SA to IMCR12SA and IMCR0SA3 to IMCR7SA3 are write-only registers that clear the mask settings for the on-chip peripheral module interrupts to be sent to the INTCA. Table 5.9 shows the correspondence between the bits in IMCR0SA to IMCR12SA and IMCR0SA3 to IMCR7SA3 and the interrupt sources.

IMCR0SA to IMCR12SA:

Bit:	7	6	5	4	3	2	1	0
	IMCR n0SA	IMCR n1SA	IMCR n2SA	IMCR n3SA	IMCR n4SA	IMCR n5SA	IMCR n6SA	IMCR n7SA
Initial value:	-	-	-	-	-	-	-	-
R/W:	W	W	W	W	W	W	W	W

IMCR0SA3 to IMCR7SA3:

Bit:	7	6	5	4	3	2	1	0
	IMCRm 0SA3	IMCRm 1SA3	IMCRm 2SA3	IMCRm 3SA3	IMCRm 4SA3	IMCRm 5SA3	IMCRm 6SA3	IMCRm 7SA3

* Bit 1 of IMR6AS/IMCR6AS is reserved. In the AP-System core, the TTI20 interrupt should be handled directly by the INTCA.

(34) User Interrupt Mask Level Register S (USERIMASKS)

USERIMASKS is a register that specifies the level of interrupts to be accepted. As this register is allocated to a 64-Kbyte page that differs from the area of the other INTCS registers, only USERIMASKS can be accessed in user mode by translating its address to the corresponding address in area 7 through the MMU.

When the level of an interrupt is not higher than the interrupt level specified in the UIMASKS bit, the interrupt is masked. The interrupt with a higher level than that specified in the UIMASKS bit is accepted only when the corresponding interrupt mask bit in the interrupt mask register is 0 (interrupt enabled) and the IMASK bit setting in SR is lower than the level of that interrupt. The UIMASKS value does not change even after an interrupt is accepted.

This register is initialized to H'00000000 (all interrupts enabled) by a power-on reset or a manual reset. To prevent unintentional modification, this register can only be written to with bits 31 to 24 set to H'A5.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R/W	Reserved These bits are always read as 0. Be sure to write H'A5 to these bits when writing to the UIMASKS bit.
23 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 4	UIMASKS	0000	R/W	User Interrupt Mask Level When the level of an interrupt is not higher than this value, the interrupt is masked.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

(35) AP-System Core Individual Interrupt Source Register (INTEVTSA)

INTEVTSA is a read-only register that indicates the code for the source of the interrupt sent from each peripheral module assigned to the INTCS to the AP-System core.

For the interrupt source code, refer to the list of INTCS interrupt sources (table 5.13). The interrupt signals from the peripheral modules assigned to the INTCS are combined into one signal, and this signal is sent to the INTCA as a peripheral interrupt. The code for this interrupt signal is H'0F80 as shown in the list of INTCA interrupt sources (table 5.11). When the AP-System core accepts this interrupt, the AP-System core can process the peripheral interrupt assigned to the INTCS by reading this register within the AP-System interrupt handler.

The interrupt signal sent from the INTCS to the AP-System core can be masked by the INTSMASK setting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	-	-	EVTCODESA									-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 5	EVTCODESA	H'000	R/W	Interrupt Code These bits hold the interrupt code. For details, see table 5.13.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

(36) NMI Flag Control Register S (NMIFCRS)

NMIFCRS is a register that has an NMI flag (NMIFL bit) that can be read and cleared by software. The NMIFL bit is automatically set to 1 by hardware when the INTCS detects an NMI. This bit can be cleared by writing 0 through software and the NMI request detected by the INTCS is also canceled.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NMIL	-	-	-	-	-	-	-	-	-	-	-	-	-	-	NMIFL
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	NMIL	0	R	NMI Input Level Indicates the level of the NMI signal set by the SFTNMI bit in SYSTBCR of the CPGA. This bit cannot be modified. 0: NMI signal is set low 1: NMI signal is set high
14 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	NMIFL	0	R/W	NMI Interrupt Request Detection Indicates whether an NMI interrupt request signal has been detected. This bit is automatically set to 1 when the INTCS detects an NMI interrupt request. Write 0 to clear the bit. Writing 1 is ignored. 0: NMI interrupt request has not been detected 1: NMI interrupt request has been detected

(37) AP-System Core Interrupt Mask Register (INTAMASK)

INTAMASK indicates whether to mask all interrupts sent to the AP-Realtime core from the peripheral modules on the INTCA side. INTAMASK is located in the INTCS and controlled by the AP-Realtime core. When the MASK bit in this register is set to 1, no interrupts are sent to the AP-Realtime core regardless of the IMCR*AS setting.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	MASK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	MASK	0	R/W	Interrupt Mask Indicates masking of interrupt requests sent to the AP-Realtime core. When reading: 0: Interrupt requests are not masked 1: Interrupt requests are masked

(38) Pulse Interrupt Flag Register 0S (IFLG0S)

IFLG0S is a register that has a flag bit for indicating the TTI20 interrupt request to the AP-Realtime core. This bit does not change when the TTI20 interrupt is masked with IMR6S.

The interrupt request can be cleared by writing 0 to the TTI20 bit after reading TTI20 = 1.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	TTI20
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TTI20	0	R/W	TTI20 Interrupt Request Indicates a TTI20 interrupt request. When reading: 0: No TTI20 interrupt has been requested to the AP-Realtime core 1: A TTI20 interrupt request has been requested to the AP-Realtime core When writing: 0: Cleared to 0 only after reading 1 1: Writing 1 is ignored

(39) Pseudo-Interrupt Setting Register 0A (SIR0A)

SIR0A is a register to generate an interrupt from a source that is different from the usual one for a specific interrupt.

Bit:	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	TTI20
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TTI20	0	R/W	TTI20 Pseudo-Interrupt Setting This bit can be used to debug the TTI20 interrupt routine when the BB side is stopped. 0: TTI20 interrupt 1: RCLK is changed to a TTI20 interrupt detection signal

5.4 Interrupt Sources

There are two types of interrupt sources: IRQ pins, on-chip peripheral modules. Each interrupt has a priority level (15 to 0), with 15 the highest and 1 the lowest. Priority level 0 masks an interrupt, so the interrupt request is ignored.

5.4.1 NMI Interrupt

For the AP-Realtime core, an NMI interrupt can be set by software (SYSTBCR.SFTNMI of CPG). Interrupt request is detected by changing bit value from 1 to 0. NMI interrupt is reserved while SR.BL is 1. SR.IMASK is set automatically when CPUOPM.INTMU or AP-Realtime core is 1. SR.IMASK is not changed when CPUOPM.INTMU is 0.

5.4.2 IRQ pins Interrupts

(a) Interrupts to AP-System Core

IRQ pin interrupts are input from pins IRQ31 to IRQ0, which can be used to request wakeup from the power cutoff state. Sixteen interrupts are sent to the AP-System core separately, and a mask and a priority level can be specified for each interrupt. When level-detection mode is selected for IRQ interrupts by the IRQnSA bits (n = 0 to 7) in ICR1A, IRQnSA bits (n = 8 to 15) in ICR2A, IRQnSA bits (n = 16 to 23) in ICR3A and IRQnSA bits (n = 24 to 31) in ICR4A the pin levels must be retained until the interrupts are accepted and interrupt handling starts. Note that even when edge-detection mode is selected for IRQ pin interrupts, if an interrupt signal pulse width is less than three ZBϕ clock cycles, the interrupt may not be detected. The time it takes for the INTC to detect an interrupt and send it to the CPU is six ZBϕ clock cycles when the INTC is operating. In the case of level detection with the INTC halted, standby cancellation is requested in three RCLK cycles, and in the case of edge detection with the INTC halted, an interrupt is detected immediately by gate delay and standby cancellation is requested. When an IRQ pin is used to request wakeup from the power cutoff state, an IRQ interrupt is generated according to the INTCA register setting after power has been restored.An IRQ interrupt can also be used to request wakeup from the C5 area power cutoff state. In this case, an interrupt occurs because the source is retained.

When an IRQ pins interrupt is accepted by the AP-System core, an IRQ exception is generated in the AP-System core and the IRQ exception interrupt handler is initiated. The IRQ exception handler must first read INTFLGA, which automatically modifies the INTLVLA value to the level of the accepted interrupt and saves the previous INTLVLA value in INTLVLB. The code of the accepted interrupt is stored in INTEVTA. Note that INTFLGA must be read only once. If it is read multiple times, the interrupt flag may be cleared unexpectedly.

(b) Interrupts to AP-Realtime Core

Thirty-two IRQ pin interrupts are also sent to the AP-Realtime core separately, and a mask and a priority level can be specified for each interrupt. When level-detection mode is selected for IRQ interrupts by the IRQnSS bits (n = 0 to 7) in ICR0S , IRQnSS bits (n = 8 to 15) in ICR1S, IRQnSS bits (n = 16 to 23) in ICR2S and IRQnSS bits (n = 24 to 31) in ICR3S , the pin levels must be retained until the interrupts are accepted and interrupt handling starts. Note that even when edge-detection mode is selected for IRQ pins interrupts, if an interrupt signal pulse width is less than three Bϕ clock cycles, the interrupt may not be detected. The time it takes for the INTC to detect an interrupt and send it to the CPU is six ZBϕ clock cycles when the INTC is operating. In the case of level detection with the INTC halted, standby cancellation is requested in three RCLK cycles, and in the case of edge detection with the INTC halted, an interrupt is detected immediately by gate delay and standby cancellation is requested. When an IRQ pin is used to request wakeup from the power cutoff state, an IRQ pins interrupt is generated according to the INTCS register setting after power has been restored. An IRQ pins interrupt can also be used to request wakeup from the C5 area power cutoff state. In this case, an interrupt occurs because the source is retained.

When an IRQ pins interrupt is accepted by the AP-Realtime core, a general exception is generated in the AP-Realtime core and the exception handler is initiated.

When the INTMU bit in the CPU operating mode register (CPUOPM) is set to 1, the interrupt mask level (IMASK) in SR is automatically modified to the level of the accepted interrupt. When the INTMU bit is cleared to 0, the IMASK value in SR is not affected by the accepted interrupt.

5.4.3 On-Chip Peripheral Module Interrupts

On-chip peripheral module interrupts are generated in the peripheral modules classified into the following three groups.

1. Modules whose interrupts should be sent to both the SYS domain and RT domain
2. SYS-domain modules
3. RT-domain modules

Group 1 includes the BBIF2,MSU,SPU,FSI,FMSI,KEYSC,RWDT0,CMT2,3DG,MFIS2. For each interrupt generated in these modules, different masks and priority levels can be specified and different interrupt codes are assigned separately in the INTCA and INTCS.

For each interrupt generated in the modules in group 2, a mask and priority level can be specified in the INTCA and a unique interrupt code is assigned. The interrupts are also sent to the INTCS through one combined signal. For each of the combined interrupts, a mask can be specified

independently from the mask setting for the INTCA and the priority level specified in the INTCA is applied. The AP-Realtime core can identify the individual interrupt source by reading INTEVTAS within the interrupt handler and process the SYS-domain interrupt.

For each interrupt generated in the modules in group 3, a mask and priority level can be specified in the INTCS and a unique interrupt code is assigned. The interrupts are also sent to the INTCA through one combined signal. For each of the combined interrupts, a mask can be specified independently from the mask setting for the INTCS and the priority level specified in the INTCS is applied. The AP-System core can identify the individual interrupt source by reading INTEVTSA within the interrupt handler and process the RT-domain interrupt.

(a) Peripheral Module Interrupts in AP-System

A priority level (from 15 to 0) can be set for each module by writing to IPRAA to IPROA. Not every interrupt source is assigned a different interrupt vector. Sources are reflected in the interrupt flag register (INTFLGA) and then reflected in the interrupt event register (INTEVTA) when INTFLGA is read. It is easy to identify sources by using the value of this code as a branch offset in the exception handling routine.

When an interrupt is sent to the AP-System core, an IRQ exception is generated in the AP-System core and the IRQ exception handler is initiated. The CPU branch destination is determined by the VE bit in the CP15 register c1 of the ARM11 and VTB of the INTCA.

The IRQ exception handler must first read INTFLGA, which automatically modifies the INTLVLA value to the level of the accepted interrupt and saves the previous INTLVLA value in INTLVLB. The code of the accepted interrupt is stored in INTEVTA. Note that INTFLGA must be read only once. If it is read multiple times, the interrupt flag may be cleared unexpectedly.

Hardware determines whether an interrupt is accepted, automatically modifies the INTLVLA value to the level of the accepted interrupt, and saves the previous INTLVLA value in INTLVLB. The code of the accepted interrupt is stored in INTEVTA. The IRQ exception handler must not access INTFLGA.

(b) Peripheral Module Interrupts in AP-Realtime

A priority level (from 15 to 0) can be set for each module by writing to IPRAS to IPRMS and IPRAS3 to IPRRS3. Not every interrupt source is assigned a different interrupt vector. Sources are reflected in the interrupt event register (INTEVT). It is easy to identify sources by using the INTEVT value as a branch offset in the exception handling routine.

When the INTMU bit in CPUOPM is set to 1, the interrupt mask level (IMASK) in SR is automatically modified to the level of the accepted interrupt. When the INTMU bit in CPUOPM is cleared to 0, the IMASK value in SR is not affected by the accepted interrupt.

5.4.4 Notes on Interrupt Clearing and Interrupt Register Settings

The interrupt source flags and interrupt enable bits must be modified only while no interrupts can be accepted. To avoid accepting unintentional interrupts that should have been updated, the necessary internal timing must be ensured by inserting instructions. As shown in (1) and (2) below, read the on-chip peripheral register with the corresponding flag.

If a flag is modified while interrupts can be accepted, execution will branch to the interrupt handling routine with interrupt code = 0; interrupt handling may start depending on the timing relationship between flag updating and interrupt request detection in the LSI. In this case, operation can be continued without causing any problems by returning to the program executed before the branch.

Likewise, care must be taken when modifying the interrupt priority registers and interrupt mask registers. It is recommended to modify these registers while the corresponding interrupt cannot be accepted. After these registers have been modified, if the CPU interrupt settings (the SR register of the AP-RT core and the CPSR register of the AP-System core) are changed and if the order of the action of modifications should be observed, the necessary internal timing can be ensured by reading the modified INTC register once.

(a) ARM Accepting an Interrupt (Including Accepting via INTCS)

After the instruction for clearing an interrupt flag, read that flag register or read a register in the INTCA once. In either case, insert at least one instruction before the SUBS PC, R14, #4 instruction.

(b) SH Accepting an Interrupt (Including Accepting via INTCA)

After the instruction for clearing an interrupt flag, read that flag register twice, or read that flag register once and then read a register in the INTCS once.

Note: About “The corresponding interrupt cannot be accepted”

(1) When ARM can accept interrupt

(2) When SH can accept interrupt

5.4.5 Interrupt Exception Handling and Priority

Tables 5.10 and 5.11 show the interrupt sources, interrupt codes (codes for INTFLGA and INTEVTA), and the interrupt priority in the INTCA. Tables 5.12 and 5.13 show the interrupt sources, codes for the interrupt event register (INTEVT), and the interrupt priority in the INTCS.

The start address of the exception handling routine is common for all interrupt sources. This is why, for instance, the value of INTFLGA or INTEVT is used as an offset at the start of the exception handling routine to branch execution in order to identify the interrupt source.

The start address of the exception handling routine can be set through software using bits 31 to 2 in VTB. In addition, by setting bits 1 and 0 in VTB to 2'b01 or 2'b10 to select the offset mode, a branch can be made to the address indicated by bits 31 to 2 in VTB + (interrupt code value/8) or the address indicated by bits 31 to 2 in VTB + (interrupt code value); different address for each interrupt (vector interrupt).

On-chip peripheral module interrupt priority levels can be set freely between 15 and 0 for each module by using IPRAA to IPROA, IPRAA3 to IPRUA3, IPRAS to IPRMS and IPRAS3 to IPRPS3. A reset assigns priority level 0 to the on-chip peripheral module interrupts.

If the same priority level is assigned to two or more interrupt sources and interrupts from those sources occur simultaneously, their priority is determined according to the default priority indicated in tables 5.11 to 5.13.

Table 5.10 External Interrupt Sources and Priority (INTCA)

Interrupt Source		INTEVT Code	Interrupt Priority (Initial Value)	IPR (Bit Numbers)	Priority within IPR Setting Range	Default Priority
IRQ	IRQ0A	H'0200	15～0(0)	INTPRI00A(31～28)	–	High
	IRQ1A	H'0220	15～0(0)	INTPRI00A(27～24)	–	
	IRQ2A	H'0240	15～0(0)	INTPRI00A(23～20)	–	
	IRQ3A	H'0260	15～0(0)	INTPRI00A(19～16)	–	
	IRQ4A	H'0280	15～0(0)	INTPRI00A(15～12)	–	
	IRQ5A	H'02A0	15～0(0)	INTPRI00A(11～8)	–

5.5 Operation

5.5.1 INTCA Interrupt Sequence

The sequence of interrupt operations is described below.

1. The interrupt request sources send interrupt request signals to the INTCA.
2. The INTCA selects the highest-priority interrupt from the sent interrupt requests according to the interrupt priority registers. Lower-priority interrupts are held pending. If two of these interrupts have the same priority level or if multiple interrupts occur within a single module, the interrupt with the highest priority is selected according to tables 5.10 and 5.11.
3. The priority level of the selected interrupt is compared with the INTLVLA value. If the priority level is higher than the INTLVLA value, the INTCA accepts the interrupt and sends an interrupt request signal to the AP-System core.
4. The AP-System core accepts an interrupt at a break in instructions.
5. The interrupts are disabled after that, and the program counter (PC) is set to the IRQ exception interrupt handler address.

5.5.2 INTCS Interrupt Sequence

The sequence of interrupt operations is described below.

1. The interrupt request sources send interrupt request signals to the INTCS.
2. The INTCS selects the highest-priority interrupt from the sent interrupt requests according to the interrupt priority registers. Lower-priority interrupts are held pending. If two of these interrupts have the same priority level or if multiple interrupts occur within a single module, the interrupt with the highest priority is selected according to tables 5.12 and 5.13.
3. The priority level of the selected interrupt is compared with the interrupt mask level (IMASK) set in SR of the AP-Realtime core. If the priority level is higher than the level set in IMASK, the INTCS accepts the interrupt and sends an interrupt request signal to the AP-Realtime core.
4. The AP-Realtime core accepts an interrupt at a break in instructions.
5. The interrupt source code is set in the interrupt event register (INTEVT).
6. SR and program counter (PC) are saved in SSR and SPC, respectively. R15 is saved in SGR at this time.
7. The BL, MD, and RB bits in SR are set to 1.
8. Execution jumps to the start address of the interrupt exception handling routine (the sum of the value set in the vector base register (VBR) and H'00000600).

9. In the exception handling routine, execution branches with the INTEVT value used, for example, as its offset in order to identify the interrupt source. This enables execution to branch to the routine for handling the individual interrupt source.

Note: When the INTMU bit in the CPU operating mode register (CPUOPM) is set to 1, the interrupt mask level (IMASK) in SR is automatically set to the level of the accepted interrupt. When the INTMU bit is cleared to 0, the IMASK value in SR is not affected by the accepted interrupt.

5.5.3 INTCA Interrupt Handler

The following shows an example of INTCA handler processing when multiple interrupts are not handled.

(1) Interrupt Handler

1. Save the necessary user register contents in the stack.
2. Read INTFLGA once in the IRQ exception handing routine to identify the interrupt source. If it is read multiple times, the interrupt flag may be cleared unexpectedly.
3. Branch with the INTFLGA value used as an offset.
4. Clear the interrupt source in the interrupt handling routine. Perform necessary interrupt processing.
5. Restore the register contents from the stack. INTLVLA has been set to the level of the interrupt accepted by hardware; read INTLVLB and set the contents in INTLVLA.
6. Restore the PC value from the link register (R14), that is, execute the SUBS PC, R14, #4 instruction.

5.5.4 INTCA Interrupt Handler for Handling Multiple Interrupts

When handling multiple interrupts, an interrupt handling routine should include the following procedures.

1. Save the link register (R14), SPSR, and necessary user register contents in the stack.
2. Read INTFLGA to identify the interrupt source.
3. Save the INTLVLB contents in the stack.
4. Branch to a specific interrupt handling routine for the interrupt source with the INTFLGA value used as an offset.
5. Clear the interrupt source in the interrupt handling routine.

6. Enable interrupts. At this time, INTLVLA is automatically modified to the level of the accepted interrupt.
7. Perform necessary interrupt processing. Interrupts can be nested during this processing.
8. Disable interrupts.
9. Set INTLVLA to the INTLVLB value saved in the stack. Restore the user register contents from the stack. After that, restore the link register and SPSR and return to the program executed before the interrupt.

When these procedures are followed in order, an interrupt of higher priority than the one being handled can be accepted if multiple interrupts occur immediately after step 6. This reduces the interrupt response time for urgent processing.

5.5.5 INTCS Interrupt Handler for Handling Multiple Interrupts

When handling multiple interrupts, an interrupt handling routine should include the following procedures.

1. To identify the interrupt source, branch to a specific interrupt handling routine for the interrupt source with the INTEVT code used as an offset.
2. Clear the interrupt source in the interrupt handling routine.
3. Save the SSR and SPC contents in the stack.
4. Clear the BL bit in SR. When the INTMU bit in CPUOPM is set to 1, the interrupt mask level (IMASK) in SR is automatically modified to the level of the accepted interrupt. When the INTMU bit in CPUOPM is cleared to 0, set the IMASK bit in SR by software to the accepted interrupt level.
5. Perform necessary interrupt processing.
6. Set the BL bit in SR to 1.
7. Restore the SSR and SPC contents from memory.
8. Execute the RTE instruction.

When these procedures are followed in order, an interrupt of higher priority than the one being handled can be accepted if multiple interrupts occur immediately after step 4. This reduces the interrupt response time for urgent processing.

5.5.6 Interrupt Disabling Function in User Mode

Setting the interrupt mask level in USERIMASKA or USERIMASKS disables interrupts having an equal or lower priority level than the specified mask level. This function can disable less-urgent interrupts in a task (such as device driver) operating in user mode to accelerate urgent processing.

USERIMASKA and USERIMASKS are allocated to a 4-Kbyte page that is different from the area of the other INTCA and INTCS registers. When accessing USERIMASKA or USERIMASKS in user mode, translate the address through the MMU. In the system that uses a multitasking OS, processes that can access USERIMASKA or USERIMASKS must be controlled by using memory protection functions of the MMU. When terminating the task or switching to another task, be sure to clear USERIMASKA or USERIMASKS to 0 before quitting the task. If the UIMASKA or UIMASKS bits are left set to a non-zero value, interrupts which are not higher in priority than the UIMASKA or UIMASKS level are held disabled, and correct operation may not be performed (for example, the OS cannot switch tasks).

A sample sequence of user-mode interrupt disabling operation is described below.

1. Classify interrupts into A and B shown below, and assign higher interrupt levels to A than B.
   A. Interrupts that should be accepted in the device driver
      (interrupts used by the OS, such as timer interrupts)
   B. Interrupts that should be disabled in the device driver
2. Make the MMU settings so that the address space including USERIMASKA or USERIMASKS can only be accessed by the device driver in which interrupts should be disabled.
3. Branch to the device driver.
4. Specify the UIMASKA or UIMASKS bits so that interrupts B are masked in the device driver operating in user mode.
5. Perform urgent processing in the device driver.
6. Clear the UIMASKA or UIMASKS bits to 0 to return from the device driver processing.

5.5.7 IRQ Chattering Removal

For signals entering at the IRQ31 to IRQ0 pins, chattering can be removed by setting interrupt control registers 3 to 10(ICR3 to 10). Figure 5.2 shows the timing of a chattering removal circuit for a single IRQ.

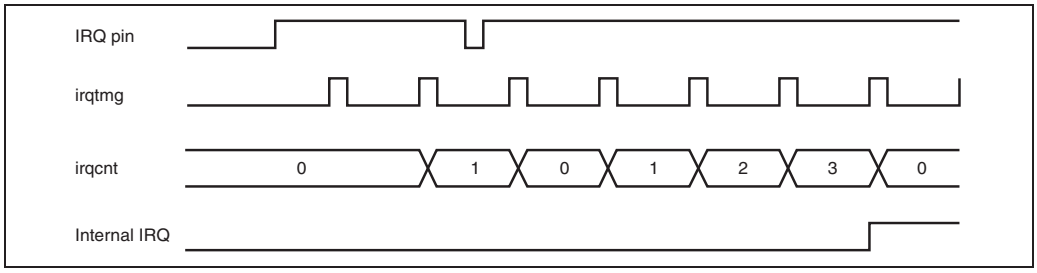

Figure 5.2 Timing of IRQ Chattering Removal Circuit

The operation is entirely based on the EXTALR clock.

The chattering circuit is started when the IRQnSTS2 bits (n = 0 to 31) in interrupt control registers 3 to 10 become something other than H'00. The irqtmg signal, which follows the irqcnt count-up timing, is generated at 1-ms to 8-ms intervals according to IRQnSTS1.

The irqcnt signal inverts all the initial values in the results of the signal detection carried out at EXTALR intervals in the irqtmg period and then counts up when the irqtmg is asserted. In signal detection at EXTALR intervals, if the same value as the initial value is detected within the irqtmg, the irqcnt signal returns to count 0 when the next irqtmg is asserted. When the irqcnt has a value of IRQnSTS2 - 1 and when the irqtmg is asserted, the internal IRQ signal is asserted.

After this, the same operation is repeated with the initial value inverted.

5.6 LSI Internal Communication Interrupts and Wakeup Function (Request to AP Block)

A specified event in the internal connections of the LSI can be used to send a request to the AP-System core for wakeup from the power cutoff state or an interrupt.

A wakeup request is used to start power supply or generate clocks when the power to the AP-System core or INTCA is stopped or when interrupts cannot be accepted because the clock to the AP-System core or INTCA is stopped. When a wakeup request is used to start power supply, execution branches to the reset vector; otherwise, usual interrupt processing is done.

This request is sent together with the interrupt from the MFI to the AP-System core.

5.6.1 LSI Internal Communication Interrupt/Wakeup Function (Request to AP Block) Register Configuration

Table 5.14 shows the LSI internal communication interrupt/wakeup function (request to AP block) register configuration. Table 5.15 shows the register states in each operating mode.

Table 5.14 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
AP block LSI internal communication interrupt/wakeup function register	CCOMIFAP	R/W	H'E605 8000	32
AP block LSI internal communication interrupt/wakeup source register	CCOMIEAP	R	H'E605 8004	32
AP block LSI internal communication interrupt/wakeup source clear register	CCOMICAP	W	H'E605 8008	32

CCOMICAP	Initialized	Retained

Note: * For details, refer to section 1-D Overview of reset.

5.6.2 AP Block LSI Internal Communication Interrupt/Wakeup Function Register (CCOMIFAP)

CCOMIFAP specifies the conditions for interrupt/wakeup requests to the AP-System core, which are caused by specific events in the internal connections of the LSI. This register is in power supply area C5. A wakeup request can be issued even when power is stopped up to power supply area A4R/A4S.

			1	x	1	Enables an interrupt/wakeup request at a high level

[Legend]

x: Don't care

5.6.3 AP Block LSI Internal Communication Interrupt/Wakeup Source Register (CCOMIEAP)

CCOMIEAP is a read-only register that indicates the source of the interrupt/wakeup request issued from CCOMIFAP. The initial value of this register is H'00000000. When level detection is specified and an interrupt is asserted, the corresponding bit among the IE1 to IE0 bits is set to 1.

Bits 31 to 24	IEM	IEV0	IER	IEB	IEV1	0	0	0
Bits 23 to 16	0	0	0	0	0	0	0	0
Bits 15 to 8	0	0	0	0	0	0	0	0
Bits 1 to 0	0	0	0	0	0	0	IE1	IE0

5.6.4 AP Block LSI Internal Communication Interrupt/Wakeup Source Clear Register (CCOMICAP)

CCOMICAP is a write-only register. Writing 1 to a bit clears the corresponding source of the interrupt/wakeup request issued from CCOMIFAP. Before writing to CCOMICAP, be sure to read from CCOMIEAP. The MFI source is retained until the MFI register that issued the request is cleared. When level detection is specified, a write to the IC1 to IC0 bits is ignored.

Bits 31 to 24	0	ICV0	ICR	ICB	ICV1	0	0	0
Bits 23 to 16	0	0	0	0	0	0	0	0
Bits 15 to 8	0	0	0	0	0	0	0	0
Bits 7 to 0	0	0	0	0	0	0	IC1	IC0

5.6.5 Usage Notes When Changing CCOMxxAP

Modify CCOMIFAP, CCOMICAP, and CCOMIEAP using the following procedures in order to guarantee the time until the write operation actually takes effect.

(a) CCOMIFAP

After changing CCOMIFAP, perform a dummy read of CCOMIFAP.

When changing the IFAn, IFBn, or IFCn bit setting, clear the detected source with the procedure below because there is a possibility of detecting a GPIn interrupt.

1. Mask the ACMFI1/2 interrupt using IMR2A[0] of the INTCA.
2. Change the IFAn, IFBn, or IFCn bit setting.
3. Perform dummy read of CCOMIFAP.
4. Write 1 to the relevant bit in CCOMICAP to clear the detected source of GPIn.
5. Perform dummy read of CCOMICAP.
6. Clear masking of the ACMFI1/2 interrupt using IMCR2A[0] of the INTCA.

However, if the IFAn, IFBn, or IFCn bit setting is level detection before and after the change (change from low-level detection to high-level detection or change from high-level detection to low-level detection), this procedure is unnecessary because there is no possibility of detecting a GPIn interrupt.

(b) CCOMICAP

After writing 1 to a bit in CCOMICAP, perform a dummy read of CCOMICAP.

(c) CCOMIEAP

After power-on, a value of 1 may be set due to erroneous detection. Therefore, clear all sources before setting the priority of the ACMFI1/2 interrupt of the INTCA.

5.7 LSI Internal Communication Interrupts and Wakeup Function (Request to SYS from RT)

A specified event in the internal connections of the LSI can be used to send a request to the AP-System core for wakeup from the power cutoff state or an interrupt.

A wakeup request is used to start power supply or generate clocks when the power to the AP-System core or INTCA is stopped or when interrupts cannot be accepted because the clock to the AP-System core or INTCA is stopped. When a wakeup request is used to start power supply, execution branches to the reset vector; otherwise, usual interrupt processing is done.

This request is sent together with the interrupt from the MFI to the AP-System core.

5.7.1 LSI Internal Communication Interrupt/Wakeup Function (Request to SYS) Register Configuration

Table 5.16 shows the LSI internal communication interrupt/wakeup function (request to SYS) register configuration. Table 5.17 shows the register states in each operating mode.

Table 5.16 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
SYS domain LSI internal communication interrupt/wakeup function register	CCOMIFR2S	R/W	H'E605 8060	32
SYS domain LSI internal communication interrupt/wakeup source register	CCOMIER2S	R	H'E605 8064	32

CCOMIER2S	Initialized	Retained
CCOMICR2S	Initialized	Retained

Note: * For details, refer to section 1-D Overview of reset.

5.7.2 LSI Internal Communication Interrupts and Wakeup Function(CCOMIFR2S)

CCOMIFR2S specifies the conditions for interrupt/wakeup requests to the AP-System core, which are caused by specific events in the internal connections of the LSI. This register is in power supply area C5. A wakeup request can be issued even when power is stopped up to power supply area A4R/A4S.

0	1	1	Enables an interrupt/wakeup request at both edge
1	x	0	Enables an interrupt/wakeup request at a low level
1	x	1	Enables an interrupt/wakeup request at a high level

[Legend]

x: Don't care

5.7.3 AP Block LSI Internal Communication Interrupt/Wakeup Source Register (CCOMIER2S)

CCOMIER2S is a read-only register that indicates the source of the interrupt/wakeup request issued from CCOMIFR2S. The initial value of this register is H'00000000. When level detection is specified and an interrupt is asserted, the corresponding bit among the IE7 to IE0 bits is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	IE7	IE6	IE5	IE4	IE3	IE2	IE1	IE0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

5.7.4 AP Block LSI Internal Communication Interrupt/Wakeup Source Clear Register (CCOMICR2S)

CCOMICR2S is a write-only register. Writing 1 to a bit clears the corresponding source of the interrupt/wakeup request issued from CCOMIFR2S. Before writing to CCOMICR2S, be sure to read from CCOMIER2S. The MFI source is retained until the MFI register that issued the request is cleared. When level detection is specified, a write to the IC7 to IC0 bits is ignored.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

5.7.5 Usage Notes When Changing CCOMxxR2S

Modify CCOMIFR2S, CCOMICR2S, and CCOMIER2S using the following procedures in order to guarantee the time until the write operation actually takes effect.

(a) CCOMIFR2S

After changing CCOMIFR2S, perform a dummy read of CCOMIFR2S.

When changing the IFAn, IFBn, or IFCn bit setting, clear the detected source with the procedure below because there is a possibility of detecting a GPIn interrupt.

1. Mask the CPORTR2S interrupt using IMR7A3[6] of the INTCA.
2. Change the IFAn, IFBn, or IFCn bit setting.
3. Perform dummy read of CCOMIFR2S.
4. Write 1 to the relevant bit in CCOMICR2S to clear the detected source of GPIn.
5. Perform dummy read of CCOMICR2S.
6. Clear masking of the CPORTR2S interrupt using IMCR7A3[6] of the INTCA.

However, if the IFAn, IFBn, or IFCn bit setting is level detection before and after the change (change from low-level detection to high-level detection or change from high-level detection to low-level detection), this procedure is unnecessary because there is no possibility of detecting a GPIn interrupt.

(b) CCOMICR2S

After writing 1 to a bit in CCOMICAP, perform a dummy read of CCOMICR2S.

(c) CCOMIER2S

After power-on, a value of 1 may be set due to erroneous detection. Therefore, clear all sources before setting the priority of the CPORTR2S interrupt of the INTCA.

5.8 LSI Internal Communication Interrupts and Wakeup Function (Request to RT from SYS)

A specified event in the internal connections of the LSI can be used to send a request to the AP-Realtime core for wakeup from the power cutoff state or an interrupt.

A wakeup request is used to start power supply or generate clocks when the power to the AP-Realtime core or INTCS is stopped or when interrupts cannot be accepted because the clock to the AP- Realtime core or INTCS is stopped. When a wakeup request is used to start power supply, execution branches to the reset vector; otherwise, usual interrupt processing is done.

This request is sent together with the interrupt from the MFI to the AP- Realtime core.

5.8.1 LSI Internal Communication Interrupt/Wakeup Function (Request to RT) Register Configuration

Table 5.18 shows the LSI internal communication interrupt/wakeup function (request to RT) register configuration. Table 5.19 shows the register states in each operating mode.

Table 5.18 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
RT domain LSI internal communication interrupt/wakeup function register	CCOMIFS2R	R/W	H'E605 8070	32
RT domain LSI internal communication interrupt/wakeup source register	CCOMIES2R	R	H'E605 8074	32

5.8.2 LSI Internal Communication Interrupts and Wakeup Function(CCOMIFS2R)

CCOMIFS2R specifies the conditions for interrupt/wakeup requests to the AP-Realtime core, which are caused by specific events in the internal connections of the LSI. This register is in power supply area C5. A wakeup request can be issued even when power is stopped up to power supply area A4R/A4S.

1	x	1	Enables an interrupt/wakeup request at a high level

[Legend]

x: Don't care

5.8.3 AP Block LSI Internal Communication Interrupt/Wakeup Source Register (CCOMIES2R)

CCOMIES2R is a read-only register that indicates the source of the interrupt/wakeup request issued from CCOMIFS2R. The initial value of this register is H'00000000. When level detection is specified and an interrupt is asserted, the corresponding bit among the IE7 to IE0 bits is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

5.8.4 AP Block LSI Internal Communication Interrupt/Wakeup Source Clear Register (CCOMICS2R)

CCOMICS2R is a write-only register. Writing 1 to a bit clears the corresponding source of the interrupt/wakeup request issued from CCOMIFS2R. Before writing to CCOMICS2R, be sure to read from CCOMIES2R. The MFI source is retained until the MFI register that issued the request is cleared. When level detection is specified, a write to the IC7 to IC0 bits is ignored.

5.8.5 Usage Notes When Changing CCOMxxS2R

Modify CCOMIFS2R, CCOMICS2R, and CCOMIES2R using the following procedures in order to guarantee the time until the write operation actually takes effect.

(a) CCOMIFS2R

After changing CCOMIFS2R, perform a dummy read of CCOMIFS2R.

When changing the IFAn, IFBn, or IFCn bit setting, clear the detected source with the procedure below because there is a possibility of detecting a GPIn interrupt.

1. Mask the CPORTS2R interrupt using IMR7S3[6] of the INTCS.
2. Change the IFAn, IFBn, or IFCn bit setting.
3. Perform dummy read of CCOMIFS2R.
4. Write 1 to the relevant bit in CCOMICS2R to clear the detected source of GPIn.
5. Perform dummy read of CCOMICS2R.
6. Clear masking of the CPORTS2R interrupt using IMCR7S3[6] of the INTCS.

However, if the IFAn, IFBn, or IFCn bit setting is level detection before and after the change (change from low-level detection to high-level detection or change from high-level detection to low-level detection), this procedure is unnecessary because there is no possibility of detecting a GPIn interrupt.

(b) CCOMICS2R

After writing 1 to a bit in CCOMICS2R, perform a dummy read of CCOMICS2R.

(c) CCOMIES2R

After power-on, a value of 1 may be set due to erroneous detection. Therefore, clear all sources before setting the priority of the CPORTS2R interrupt of the INTCS.

Section 6 Bus State Controller (BSC)

The bus state controller (BSC) outputs control signals for various types of memory and external devices that are connected to the external address space. The BSC functions enable this LSI to connect directly with SRAM and other memory storage devices, and external devices.

6.1 Features

The BSC has the following features:

- External address space
  128 Mbytes for each of CS0 and CS2, 64 Mbytes for CS4, and 32 Mbytes for each of CS5A, CS5B, and CS6A (total of 416 Mbytes which is divided into six partial spaces).
  Address spaces CS0 and CS2 can be merged into a 256-Mbyte address space that can be accessed. Address spaces CS5A and CS5B can be merged into 64-Mbyte address spaces that can be accessed.
  Can specify the normal space interface, SRAM interface with byte selection, or burst ROM for each address space
  Can select the data bus width (8 or 16 bits) for each address space
  Controls insertion of wait cycle for each address space
  Controls insertion of wait cycle for each read access and write access
  Can set independent idle cycles in the continuous access for five cases: read-write (in same space/different spaces), read-read (in same space/different spaces), the first cycle is a write access
- Normal space interface
  Supports the interface that can be connected directly to SRAM
  Supports the AD-MUX interface (CS0, CS2, and CS4)
- Burst ROM interface
  High-speed access to the memory having a page-mode function
  High-speed access to the memory having a clock-synchronous burst mode function
  Supports a clock-synchronous burst ROM interface
  Supports the AD-MUX interface (CS0, CS2, and CS4)

- SRAM interface with byte selection
  Supports the interface that can be connected directly to SRAM with byte selection
  Supports Write Enable(WEn_N) control writing
  Supports page mode
  Supports the AD-MUX interface (CS0, CS2, CS4, CS5A, CS5B, and CS6A)
- CKO output stop function
- The BSC operating frequency ZBϕ can be set to 99.6 (= 199.3/2) MHz, 66.4 (= 199.3/3) MHz, 49.8 (= 199.3/4) MHz by changing the common frequency control register (CMFRQCR) in the CPGA.
- Memory protection function
  Can set permissions for reading and writing from the AP module, in 64-Mbit increments, of a 2-Gbit area starting at the initial address of area 0.

A block diagram of the BSC is shown in figure 6.1.

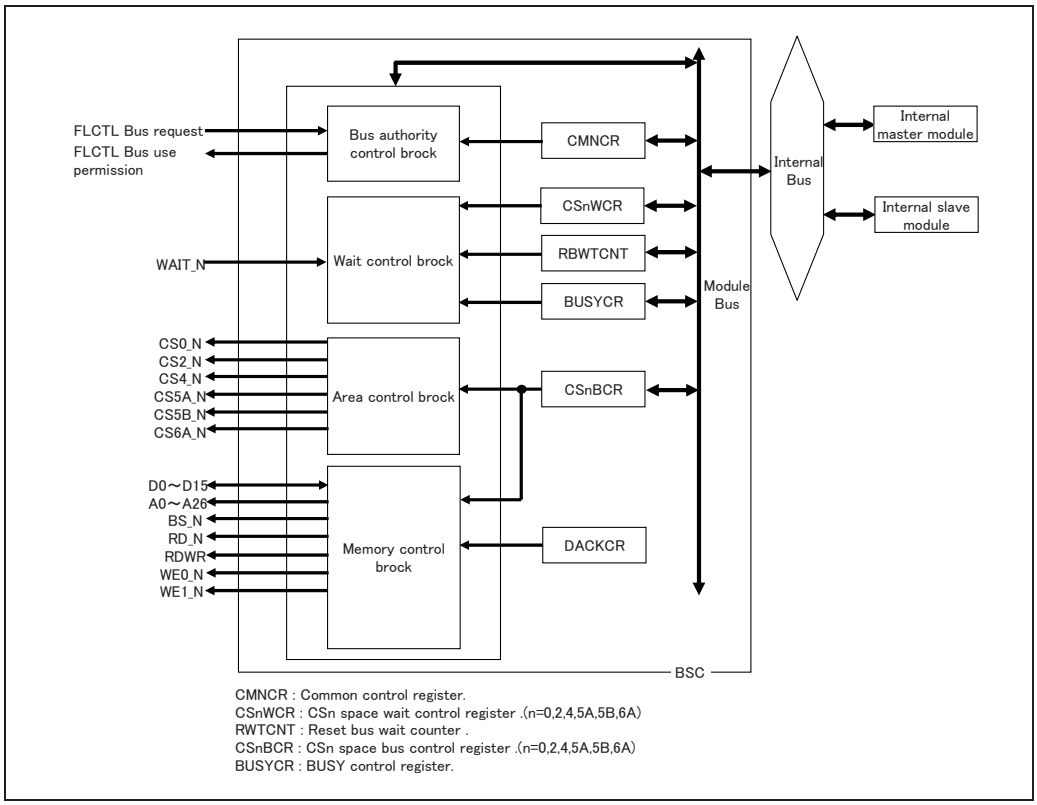

Figure 6.1 Block Diagram of BSC

6.2 Input/Output Pins

Table 6.1 Pin Configuration

Name	Function	I/O	Description
CKO	Bus clock	Output	Bus clock output
A26 to A0	Address bus	Output	Address output
D15 to D0	Data bus	I/O	16-bit bidirectional bus
BS_N	Bus start	Output	Bus start signal This signal is asserted at the start of the bus cycle. This signal is connected to the address valid pin of the memory having the Sync Burst function. In this LSI, this pin is multiplexed with the A0 pin. For burst ROM interface, the wait cycles can be changed.
CS0_N CS2_N CS4_N CS5A_N CS5B_N CS6A_N	Chip select CS0, CS 2, CS 4, CS 5A, CS 5B, CS 6A	Output	Chip select signal for external memory or device. CS5A_N and CS6A_N are active only when the MAP bit in CMNCR is set to 0 and the address map 1 or 3 is selected. When the MAP bit in CMNCR is set to 1 and the address map 2 or 4 is selected, CA5B_N become the chip select signals for the area 5 .CS2_N becomes active only when the EXTEND bit in CMNCR is set to 0 and address map 1 or 2 is selected. When the EXTEND bit in CMNCR is set to 1 and address map 3 or 4 is selected, CS2_N always becomes inactive.
RD_N	Read	Output	Indicates that data is read from an external device.

Name	Function	I/O	Description
RDWR	Read/write	Output	Read/write signal pin
WE1_N	Write to upper byte	Output	Indicates that bits 15 to 8 of external memory or device data are being written to.
WE0_N	Write to lower byte	Output	Indicates that bits 7 to 0 of external memory or device data are being written to.
WAIT_N	External wait input	Input	Inserts a wait cycle between bus cycles for accessing the external space.
BSCMD	CS0 memory type select	Input	Sets the initial value of the CS0 memory type. 0: Normal memory The initial value of pins A26 to A13 is an address. 1: AD-MUX The initial value of pin A0 is BS_N.

6.3 Area Overview

6.3.1 Area Division

In the architecture, this LSI has 32-bit address spaces. In the AP-Realtime core, the address area is classified into P0 to P4 by the upper three bits of the 32-bit address, and each area represents the cache access method. For details, see section 3, AP-Realtime Core. The remaining 29 bits are used for division of the space into six areas (address map 1) or four areas (address map 2) according to the setting of the MAP bit in CMNCR. The BSC performs control for this 29-bit space.

As listed in tables 6.2 to 6.5, this LSI can connect six to four physical areas to each type of memory, and it outputs chip select signals (CS0_N, CS2_N, CS4_N, CS5A_N, CS5B_N, and CS6A_N) for each of them. CS0_N is asserted during area CS 0 access. During area CS 5A access, CS5A_N is asserted when address map 1 is selected, and CS5B_N is asserted when address map 2 is selected.

6.3.2 Shadow Area

Areas CS 0, CS 2, CS 4, CS 5A, CS 5B, and CS 6A are decoded by physical addresses A28 to A25, which correspond to areas B'000 to B'110. Addresses A31 to A29 are ignored. This means that the range of area 0 addresses, for example, is H'0000 0000 to H'07FF FFFF, and its corresponding shadow space is the address space obtained by adding to it H'2000 0000 × n (n = 1 to 6).

6.3.3 Address Map

The external address space has a capacity of 416 Mbytes and is divided into six partial spaces, (address map 1) four partial spaces (address map 2), five partial spaces (address map 3), or three partial spaces (address map 4). The type of memory to be connected and the data bus width are specified for each partial space. The address map for the external address space is listed in tables 6.2 to 6.5.

Table 6.2 Address Map 1 (CMNCR.MAP = 0, CMNCR.EXTEND = 0)

Address	Area	Memory to be Connected	Capacity
H'0000 0000 to H'07FF FFFF	Area 0	Normal memory SRAM with byte selection Burst ROM	128 Mbytes
H'0800 0000 to H'0FFF FFFF	Area 2	Normal memory SRAM with byte selection Burst ROM	128 Mbytes
H'1000 0000 to H'13FF FFFF	Area 4	Normal memory SRAM with byte selection Burst ROM	64 Mbytes
H'1400 0000 to H'15FF FFFF	Area 5A	Normal memory SRAM with byte selection	32 Mbytes
H'1600 0000 to H'17FF FFFF	Area 5B	Normal memory SRAM with byte selection	32 Mbytes
H'1800 0000 to H'19FF FFFF	Area 6A	Normal memory SRAM with byte selection	32 Mbytes
H'1A00 0000 to H'1FFF FFFF	—	Reserved space*	96 Mbytes

Note: * Do not access reserved space. If reserved space is accessed, the operation of this LSI is not guaranteed.

Table 6.3 Address Map 2 (CMNCR.MAP = 1, CMNCR.EXTEND = 0)

Address	Area	Memory to be Connected	Capacity
H'0000 0000 to H'07FF FFFF	Area 0	Normal memory SRAM with byte selection Burst ROM	128 Mbytes
H'0800 0000 to H'0FFF FFFF	Area 2	Normal memory SRAM with byte selection Burst ROM	128 Mbytes
H'1000 0000 to H'13FF FFFF	Area 4	Normal memory SRAM with byte selection Burst ROM (asynchronous)	64 Mbytes
H'1400 0000 to H'17FF FFFF	Area 5*1	Normal memory SRAM with byte selection	64 Mbytes
H'1800 0000 to H'1FFF FFFF	—	Reserved space*2	128 Mbytes

Note: 1. For area 5, CS5BBCR and CS5BWCR are valid.
2. Do not access reserved space. If reserved space is accessed, the operation of this LSI is not guaranteed.

Table 6.4 Address Map 3 (CMNCR.MAP= 0, CMNCR.EXTEND = 1)

Address	Area	Memory to be Connected	Capacity
H'0000 0000 to H'0FFF FFFF	Area 0	Normal memory SRAM with byte selection Burst ROM	256 Mbytes
H'1000 0000 to H'13FF FFFF	Area 4	Normal memory SRAM with byte selection Burst ROM	64 Mbytes
H'1400 0000 to H'15FF FFFF	Area 5A	Normal memory SRAM with byte selection	32 Mbytes
H'1600 0000 to H'17FF FFFF	Area 5B	Normal memory SRAM with byte selection	32 Mbytes
H'1800 0000 to H'19FF FFFF	Area 6A	Normal memory SRAM with byte selection	32 Mbytes
H'1A00 0000 to H'1FFF FFFF	—	Reserved space*	96 Mbytes

Note: * Do not access reserved space. If reserved space is accessed, the operation of this LSI is not guaranteed.

Table 6.5 Address Map 4 (CMNCR.MAP = 1, CMNCR.EXTEND = 1)

Address	Area	Memory to be Connected	Capacity
H'0000 0000 to H'0FFF FFFF	Area 0	Normal memory SRAM with byte selection Burst ROM	256 Mbytes
H'1000 0000 to H'13FF FFFF	Area 4	Normal memory SRAM with byte selection Burst ROM (asynchronous)	64 Mbytes
H'1400 0000 to H'17FF FFFF	Area 5*1	Normal memory SRAM with byte selection	64 Mbytes
H'1800 0000 to H'1FFF FFFF	—	Reserved space*2	128 Mbytes

Note: 1. For area 5, CS5BBCR and CS5BWCR are valid.
2. Do not access reserved space. If reserved space is accessed, the operation of this LSI is not guaranteed.

6.3.4 Memory Bus Width

The memory bus width in this LSI can be set as 8 bits or 16 bits for each area by setting the BSZ bits in CSnBCR (n = 2, 4, 5A, 5B, 6A).

Note that the memory bus width in area 0 is fixed to 16 bits.

6.3.5 Data Alignment

This LSI supports the little endian method for data alignment.

6.4 Register Descriptions

Table 6.6 shows the BSC register configuration. Table 6.7 shows the register states in each operating mode.

Do not access spaces other than CS0 until the completion of the memory interface setting.

6.4.1 Common Control Register (CMNCR)

CMNCR is a 32-bit register that controls the common items for each area.

CMNCR is initialized by a power-on reset. However, CMNCR is not initialized but retains the previous value in standby mode. Do not access external memory other than area 0 until the CMNCR initialization is completed.

R/W :	R	R/W	R	R/W	R	R	R	R	R	R	R	R	R	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	CKODSTP	0	R/W	Clock Operation Specification in Non-Access Cycles When the BROMMD0 bit is set to 1, this bit can specify the operation in non-access cycles. 0: CKO operates in non-access cycles 1: CKO is halted in non-access cycles
23	CKOSTP	0	R/W	Clock Stop Specification 0: CKO operates 1: CKO is halted
22	BROMMD1	0	R/W	Specifies the input data when PH1RD of CSnBCR (n 0, 2, 4, 5A, 5B, 6A) is set. When this bit is set to 1, the value of the D pin is sampled on the rising edge of CKO that is output. 0: Selects direct bus from the D pin 1: Selects fetch from the feedback CKO

Bit	Bit Name	Initial Value	R/W	Description
21	BROMMD0	0	R/W	Clock Output Specification Specifies CKO output. Setting 1 to this bit assures the hold time for CKO of the control signal that is output. 0: Selects the same phase output as the operation clock ZBCK 1: Selects the inverse output of the operation clock ZBCK When inverse output is selected, CKO is halted in non-access cycles.
20 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14	EXTEND	0	R/W	CS0/CS2 Area Size Specification 0: CS0/CS2 area is a 128-Mbyte area 1: The CS0 area is a 256-Mbyte area (The CS2 and CS0 areas are merged.)
13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	MAP	0	R/W	Space Specification Selects the address map for the external address space. The address maps to be selected are shown in tables 6.2 and 6.3. 0: Selects address map 1 or 3 1: Selects address map 2 or 4
11 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4, 3	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
2	A2H	0	R/W	A2 Level Specification for Accesses in Fixed Addressing Mode A2 is a normal output when the DMAC or VIO does not access in fixed addressing mode. 0: Outputs a low level signal from A2 pin 1: Outputs a high level signal from A2 pin
1,0	—	1	R	Reserved These bits are always read as 1. The write value should always be 1.

6.4.2 CSn Space Bus Control Register (CSnBCR) (n = 0, 2, 4, 5A, 5B, 6A)

CSnBCR is a 32-bit readable/writable register that specifies the function of each area, the number of idle cycles between bus cycles, and the bus width.

CSnBCR is initialized by a power-on reset. However, CSnBCR is not initialized but retains the previous value in standby mode. Do not access external memory other than area 0 until the CSnBCR initialization is completed.

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29, 28	IWW[1:0]	11	R/W	Specification for Idle Cycles between Write-Read/Write-Write Cycles Specify the number of idle cycles to be inserted after access to memory that is connected to the space is completed. The target cycles are write-read cycles and write-write cycles. 00: No idle cycle inserted 01: 1 idle cycle inserted 10: 2 idle cycles inserted 11: 4 idle cycles inserted Note: In actual operation, an idle cycle or cycles may be inserted by factors other than specification of these bits.

Bit	Bit Name	Initial Value	R/W	Description
27	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
26, 25	IWRWD[1:0]	11	R/W	Specification for Idle Cycles between Read-Write Cycles in Different Spaces Specify the number of idle cycles to be inserted after access to memory that is connected to the space is completed. The target cycles are read-write cycles in which continuous accesses are switched between different spaces. 00: 1 idle cycle inserted 01: 1 idle cycle inserted 10: 2 idle cycles inserted 11: 4 idle cycles inserted Note: In actual operation, an idle cycle or cycles may be inserted by factors other than specification of these bits.
24	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
23, 22	IWRWS[1:0]	11	R/W	Specification for Idle Cycles between Read-Write Cycles in the Same Space Specify the number of idle cycles to be inserted after access to memory that is connected to the space is completed. The target cycles are read-write cycles in which continuous accesses are performed for the same space. 00: 1 idle cycle inserted 01: 1 idle cycle inserted 10: 2 idle cycles inserted 11: 4 idle cycles inserted Note: In actual operation, an idle cycle or cycles may be inserted by factors other than specification of these bits.

Bit	Bit Name	Initial Value	R/W	Description
21	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
20, 19	IWRRD[1:0]	11	R/W	Specification for Idle Cycles between Read-Read Cycles in Different Spaces Specify the number of idle cycles to be inserted after access to memory that is connected to the space is completed. The target cycles are read-read cycles in which continuous accesses are switched between different spaces. 00: No idle cycle inserted 01: 1 idle cycle inserted 10: 2 idle cycles inserted 11: 4 idle cycles inserted Note: In actual operation, an idle cycle or cycles may be inserted by factors other than specification of these bits.
18	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
17, 16	IWRRS[1:0]	11	R/W	Specification for Idle Cycles between Read-Read Cycles in the Same Space Specify the number of idle cycles to be inserted after access to memory that is connected to the space is completed. The target cycles are read-read cycles in which continuous accesses are performed for the same space. 00: No idle cycle inserted 01: 1 idle cycle inserted 10: 2 idle cycles inserted 11: 4 idle cycles inserted Note: In actual operation, an idle cycle or cycles may be inserted by factors other than specification of these bits.

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 12	TYPE[2:0]	000	R/W	Memory Type Specification Specify the type of memory connected to the space. 000: Normal space 001: Burst ROM 011: SRAM with byte selection Other than above: Setting prohibited Note: Burst ROM can be set in areas 0, 2, and 4 only.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10, 9	BSZ[1:0]	10	R/W	Data Bus Size Specification Specify the data bus sizes of spaces. Either 8-bit size or 16-bit size can be specified for CS2, CS4, CS5A, CS5B, CS6A. CS0 can be specified to 16-bit size only. 00: Setting prohibited 01: 8-bit size 10: 16-bit size 11: 32-bit size
8 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CKOSTP	0	R/W	CKO stop enable bit 0: When access a pertinent area, CKO is output. 1: When access a pertinent area, CKO is not output.
3		0	R	Reserved These bits are always read as 0. The write value should always be 0.

2	BUSYEN	0/1	R/W	Busy Wait Enable The initial value of CS0 is 1 and that of other signals are 0. 0: Access inhibition that is specified by the BUSY control register is disabled. 1: Access inhibition that is specified by the BUSY control register is enabled.
1	PH1RD	0	R/W	Data Sampling Timing Specification 0: Data is sampled on the falling edge of the operation clock ZBϕ of the BSC. The RD_N output timing is the falling edge of ZBϕ. 1: Data is sampled on the rising edge of the operation clock ZBϕ of the BSC. The RD_N output timing is the rising edge of ZBϕ.
0	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

6.4.3 CSn Space Wait Control Register (CSnWCR) (n = 0, 2, 4, 5A, 5B, 6A)

CSnWCR specifies various wait cycles for memory accesses. The bit configuration of this register varies as shown below according to the memory type specified by the TYPE bits in the CSn space bus control register (CSnBCR). Specify CSnWCR before accessing the target area. Specify CSnBCR first, then specify CSnWCR.

CSnWCR is initialized to H'0000 0540 by a power-on reset. However, CSnWCR is not initialized but retains the previous value in standby mode.

(1) Normal Space, SRAM with Byte Selection

- CS0WCR, CS4WCR, CS5AWCR, CS5BWCR, CS6AWCR

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	WSHWEN	0	R/W	0: Access is made according to SW[1:0] and HW[1:0] during the write cycle. 1: Access is made according to WSW[1:0] and WHW[1:0] during the write cycle.
27, 26	WSW[1:0]	00	R/W	Number of Delay Cycles from Address, CSn_N Assertion to RD_N, WEn_N Assertion Specify the number of delay cycles from address and CSn_N assertion to RD_N and WEn_N assertion during write cycles. When the WSHWEN bit is set to 1, the setting for this bit is enabled. 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles
25, 24	WHW[1:0]	00	R/W	Number of Delay Cycles from RD_N, WEn_N Negation to Address, CSn_N Negation Specify the number of delay cycles from RD_N and WEn_N negation to address and CSn_N negation during write cycles. When the WSHWEN bit is set to 1, the setting for this bit is enabled. 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	BAS	0	R/W	Byte Access Selection when SRAM with Byte Selection is Used Specifies the WEn_N and RDWR signal timing when SRAM interface with byte selection is used. 0: Asserts the WEn _N signal at the read/write timing and asserts the RDWR signal during the write access cycle 1: Asserts the WEn_N signal during the read/write access cycle and asserts the RDWR signal at the write timing
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	WW[2:0]	000	R/W	Number of Wait Cycles in Write Access Specify the number of cycles necessary for write access. 000: The same cycles as WR[3:0] settings (read access wait) 001: 0 cycle 010: 1 cycle 011: 2 cycles 100: 3 cycles 101: 4 cycles 110: 5 cycles 111: 6 cycles

Bit	Bit Name	Initial Value	R/W	Description
15	ADRSFIX	0	R/W	Address Updating Inhibited (only valid for CS6A) 0: Outputs address normally 1: Inhibits address updating of the second and subsequent burst access.
14, 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12, 11	SW[1:0]	00/11*1	R/W	Number of Delay Cycles from Address, CSn_N Assertion to RD_N, WEn_N Assertion Specify the number of delay cycles from address and CSn_N assertion to RD_N and WEn_N assertion. WEn_N and RD_N in case with CSnBCR.PH1RD=0 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles RD_N in case with CSnBCR.PH1RD=1 00: 1 cycle 01: 2 cycles 10: 3 cycles 11: 4 cycles Note: In the case with CSnBCR.PH1RD=1 and CSnWCR.ADMUX=1,RD_N assertion delay cycle becomes 3 cycle.
10 to 7	WR[3:0]	1010	R/W	Number of Access Wait Cycles Specify the number of wait cycles necessary for read/write access.

				0000: 0 cycle	1000: 10 cycles
				0001: 1 cycle	1001: 12 cycles
				0010: 2 cycles	1010: 14 cycles
				0011: 3 cycles	1011: 18 cycles
				0100: 4 cycles	1100: 24 cycles
				0101: 5 cycles	1101: 32 cycles
				0110: 6 cycles	1110: 38 cycles
				0111: 8 cycles	1111: 52 cycles
6	WM	1	R/W	External Wait Mask Specification Specifies whether or not the external wait input is valid. The specification by this bit is valid even when the number of access wait cycles is 0. 0: External wait is valid 1: External wait is ignored	
5, 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.	
3	ADMUX	0/1*	R/W	Address Data Multiplex Mode Specification 0: Normal memory 1: AD-MUX memory At BS_N assert of the AD-MUX interface, address bits A27 to A17 are output from pins A11 to A1 and address bits A16 to A1 are output from pins D15 to D0.	

Bit	Bit Name	Initial Value	R/W	Description
2	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	HW[1:0]	00	R/W	Delay Cycles from RD_N, WEn_N Negation to Address, CSn_N Negation Specify the number of delay cycles from RD_N and WEn_N negation to address and CSn_N negation. WEn_N and RD_N in case with CSnBCR.PH1RD=0 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles RD_N in case with CSnBCR.PH1RD=1 00: 0 cycle 01: 1 cycles 10: 2 cycles 11: 3 cycles

Notes: 1. The initial value of the CS0 space differs according to the setting value of the BSCMD pin. When the BSCMD level is high, the SW bits become 11.
2. The initial value of the CS0 space differs according to the setting value of the BSCMD pin. When the BSCMD level is high, the ADMUX bit becomes 1.

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	WSHWEN	0	R/W	0: Access is made according to SW[1:0] and HW[1:0] during the write cycle. 1: Access is made according to WSW[1:0] and WHW[1:0] during the write cycle.
27, 26	WSW[1:0]	00	R/W	Number of Delay Cycles from Address, CSn_N Assertion to RD_N, WEn_N Assertion Specify the number of delay cycles from address and CSn_N assertion to RD_N and WEn_N assertion during write cycles. When the WSHWEN bit is set to 1, the setting for this bit is enabled. 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles
25, 24	WHW[1:0]	00	R/W	Number of Delay Cycles from RD_N, WEn_N Negation to Address, CSn_N Negation Specify the number of delay cycles from RD_N and WEn_N negation to address and CSn_N negation during write cycles. When the WSHWEN bit is set to 1, the setting for this bit is enabled. 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles
23, 22	BW[1:0]	00	R/W	Number of Burst Wait Cycles Specify the number of wait cycles to be inserted in the second and later access cycles in burst access. 00: 0 cycle 01: 1 cycle 10: 2 cycles 11: 3 cycles Note: The bit positions are different from the burst ROM.

Bit	Bit Name	Initial Value	R/W	Description
21	PMD	0	R/W	Page Mode Specification when SRAM with Byte Selection is Used Specifies the page mode of SRAM with byte selection. 0: Non-page mode access 1: Page mode access
20	BAS	0	R/W	Byte Access Selection when SRAM with Byte Selection is Used Specifies the WEn_N and RDWR signal timing when SRAM interface with byte selection is used. 0: Asserts the WEn_N signal at the read/write timing and asserts the RDWR signal during the write access cycle 1: Asserts the WEn_N signal during the read/write access cycle and asserts the RDWR signal at the write timing
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	WW[2:0]	000	R/W	Number of Wait Cycles in Write Access Specify the number of cycles necessary for write access. 000: The same cycles as WR[3:0] settings (read access wait) 001: 0 cycle 010: 1 cycle 011: 2 cycles 100: 3 cycles 101: 4 cycles 110: 5 cycles 111: 6 cycles
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
12, 11	SW[1:0]	00	R/W	Number of Delay Cycles from Address, CSn_N Assertion to RD_N, WEn_N Assertion Specify the number of delay cycles from address and CSn_N assertion to RD_N and WEn_N assertion. WEn_N and RD_N in case with CSnBCR.PH1RD=0 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles RD_N in case with CSnBCR.PH1RD=1 00: 1 cycle 01: 2 cycles 10: 3 cycles 11: 4 cycles Note: In the case with CSnBCR.PH1RD=1 and CSnWCR.ADMUX=1,RD_N assertion delay cycle becomes 3 cycle.
10 to 7	WR[3:0]	1010	R/W	Number of Access Wait Cycles Specify the number of cycles necessary for read/write access. 0000: 0 cycle 0001: 1 cycle 0010: 2 cycles 0011: 3 cycles 0100: 4 cycles 0101: 5 cycles 0110: 6 cycles 0111: 8 cycles 1000: 10 cycles 1001: 12 cycles 1010: 14 cycles 1011: 18 cycles 1100: 24 cycles 1101: Setting prohibited 1110: Setting prohibited 1111: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
6	WM	1	R/W	External Wait Mask Specification Specifies whether or not the external wait input is valid. The specification by this bit is valid even when the number of access wait cycles is 0. 0: External wait input is valid 1: External wait input is ignored
5, 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	ADMUX	0/1*	R/W	Address Data Multiplex Mode Specification 0: Normal memory 1: AD-MUX memory At BS_N assert of the AD-MUX interface, address bits A27 to A17 are output from pins A11 to A1 and address bits A16 to A1 are output from pins D15 to D0.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	HW[1:0]	00	R/W	Delay Cycles from RD_N, WEn_N Negation to Address, CSn_N Negation Specify the number of delay cycles from RD_N and WEn_N negation to address and CSn_N negation. 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles

Note: * The initial value of the CS0 space differs according to the setting value of the BSCMD pin. When the BSCMD level is high, the ADMUX bit becomes 1.

31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	WSHWEN	0	R/W	0: Access is made according to SW[1:0] and HW[1:0] during the write cycle. 1: Access is made according to WSW[1:0] and WHW[1:0] during the write cycle.
27, 26	WSW[1:0]	00	R/W	Number of Delay Cycles from address, CSn_N assertion to RD_N, WEn_N assertion Specify the number of delay cycles from address and CSn_N assertion to RD_N and WEn_N assertion during write cycles. When the WSHWEN bit is set to 1, the setting for this bit is enabled. 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles

Bit	Bit Name	Initial Value	R/W	Description
25, 24	WHW[1:0]	00	R/W	Number of Delay Cycles from address, CSn_N assertion to RD_N, WEn_N assertion Specify the number of delay cycles from address and CSn_N assertion to RD_N and WEn_N assertion during write cycles. When the WSHWEN bit is set to 1, the setting for this bit is enabled. 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles
23, 22	BSTMD[1:0]	00	R/W	Burst Mode Specification 00: 8-burst mode 01: 4-burst mode 10: 16-burst mode 11: Prohibition
21	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	BAS	0	R/W	Byte access selection of Burst ROM When Burst ROM is selected, this bit specify the timing of WEn_N and RDWR. 0: WEn_N is asserted according to the timing of reading and writing. RDWR is asserted while writing access. 1: WEn_N is asserted while writing access. RDWR is s asserted according to the timing of reading and writing.
19, 18	BSW[1:0]	00	R/W	Number of BS_N Assert Cycles Specify the number of cycles for the BS_N assert period. 00: 1 cycle 01: 2 cycles 10: 3 cycles 11: 4 cycles

Bit	Bit Name	Initial Value	R/W	Description
17, 16	BW[1:0]	00	R/W	Number of Burst Wait Cycles Specify the number of wait cycles to be inserted in the second and later access cycles in burst read access. 00: 0 cycle 01: 1 cycle 10: 2 cycles 11: 3 cycles
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12, 11	SW[1:0]	00/11*1	R/W	Number of Delay Cycles from Address, CSn_N Assertion to RD_N, WEn_N Assertion Specify the number of delay cycles from address and CSn_N assertion to RD and WEn_N assertion. WEn_N and RD_N in case with CSnBCR.PH1RD=0 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles RD_N in case with CSnBCR.PH1RD=1 00: 1 cycle 01: 2 cycles 10: 3 cycles 11: 4 cycles Note: In the case with CSnBCR.PH1RD=1 and CSnWCR .ADMUX=1,RD_N assertion delay cycle becomes 3 cycle.
10 to 7	W[3:0]	1010	R/W	Number of Access Wait Cycles Specify the number of wait cycles to be inserted in the write and first read access cycles. 0000: 0 cycle 1000: 10 cycles 0001: 1 cycle 1001: 12 cycles 0010: 2 cycles 1010: 14 cycles 0011: 3 cycles 1011: 18 cycles 0100: 4 cycles 1100: 24 cycles 0101: 5 cycles 1101: Setting prohibited 0110: 6 cycles 1110: Setting prohibited 0111: 8 cycles 1111: Setting prohibited

6	WM	1	R/W	External Wait Mask Specification Specify whether or not the external wait input is valid. The specification by this bit is valid even when the number of access wait cycles is 0. 0: External wait input is valid 1: External wait input is ignored
5, 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	ADMUX	0/1*2	R/W	Address Data Multiplex Mode Specification 0: Normal memory 1: AD-MUX memory At BS_N assert of the AD-MUX interface, address bits A27 to A17 are output from pins A11 to A1 and address bits A16 to A1 are output from pins D15 to D0.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	HW[1:0]	00	R/W	Delay Cycles from RD_N, WEn_N Negation to Address, CSn_N Negation Specify the number of delay cycles from RD_N and WEn _N negation to address and CSn_N negation. WEn_N and RD_N in case with CSnBCR.PH1RD=0 00: 0.5 cycle 01: 1.5 cycles 10: 2.5 cycles 11: 3.5 cycles RD_N in case with CSnBCR.PH1RD=1 00: 0 cycle 01: 1 cycles 10: 2 cycles 11: 3 cycles

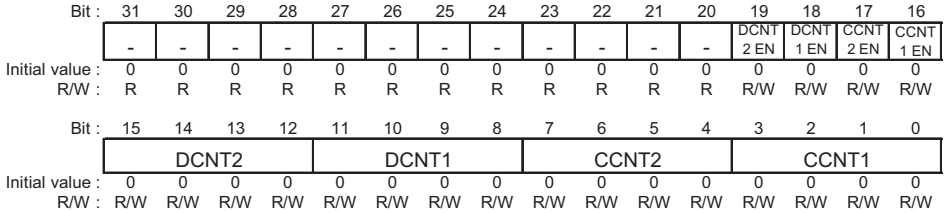
Notes: 1. The initial value of the CS0 space differs according to the setting value of the BSCMD pin. When the BSCMD level is high, the SW bits become 11.
2. The initial value of the CS0 space differs according to the setting value of the BSCMD pin. When the BSCMD level is high, the ADMUX bit becomes 1.

6.4.4 Reset Bus Wait Counter (RBWTCNT)

RBWTCNT is a 7-bit counter. This counter starts to decrement in synchronization with the CKO pin after a power-on reset is cleared, and stops when the value reaches H'00. External bus access is suspended while the counter is operating. This counter is provided to assure the minimum time from clearing a reset for flash memory and the like to the first access.

6.4.5 Busy Control Register (BUSYCR)

BUSYCR specifies the time period until access is started after BUSY is negated.



Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	BUSY SETE	-	BUSYWAIT						
Initial value :	0	0	0	0	0	0	0	1	0	0	0	0	0	1	0	0
R/W :	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	BUSYSETEN	1	R/W	Counts down the value that is specified by the BUSYWAIT bits after BUSY is negated. When an access to the BUSY_EN setting area of BCR occurs, an access is inhibited until counting down is completed. This bit is also used to enable the NBRST input. 0: BUSYWAIT bits are not set after BUSY is negated. NBRST input is invalid. 1: BUSYWAIT bits are set after BUSY is negated. NBRST input is valid.
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	BUSYWAIT[7:0]	H'04	R/W	Specify the wait period after BUSY is negated.

6.4.7 Burst ROM Timing Control Register (BROMTIMCR)

BROMTIMCR adjusts the data pin input timing and the CKO pin output timing.

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19	DCNT2EN	0	R/W	Enables the DCNT2 bit setting. In the case to set busrt write mode of CSnWCR2, and when CKO2 of CSnWCR2 is set to 1, the setting of this bit is selected. 0: Disabled 1: Enabled
18	DCNT1EN	0	R/W	Enables the DCNT1 bit setting. 0: Disabled 1: Enabled
17	CCNT2EN	0	R/W	Enables the CCNT2 bit setting. In the case to set busrt write mode of CSnWCR2, and when CKO2 of CSnWCR2 is set to 1, the setting of this bit is selected. 0: Disabled 1: Enabled
16	CCNT1EN	0	R/W	Enables the CCNT1 bit setting. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	DCNT2[3:0]	0000	R/W	The timing input from the data signal pin is set. In the case to set busrt write mode of CSnWCR2, and when CKO2 of CSnWCR2 is set to 1, the setting of this bit is selected. 1111: Long delay ~ 0000: Short delay
11 to 8	DCNT1[3:0]	0000	R/W	The timing input from the data signal pin is set. 1111: Long delay ~ 0000: Short delay
7 to 4	CCNT2[3:0]	0	R/W	Sets the timing of output from the CKO pin. In the case to set busrt write mode of CSnWCR2, and when CKO2 of CSnWCR2 is set to 1, the setting of this bit is selected. 1111: Long delay ~ 0000: Short delay
3 to 0	CCNT[3:0]	0	R/W	Sets the timing of output from the CKO pin. 1111: Long delay ~ 0000: Short delay

6.4.8 Memory Protection Area Settings Register (BPTCR00 to 31)

BPTCR is a 32-bit register that configures write protection for the external memory space.

Write-protection settings can be set in 64-bit increments for a designated 2-Gbit area starting at the initial address of each supported external memory space. This register has register write protection functions that disable setting changes from CPUs that do not have access privileges.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	CPUTYPE[1:0]		REG WP	-	-	-	-			RP_ RSP	WP_ RSP
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R/W	R/W

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	BB_ RP	AP_ RP	-	-	-	-	-	-	BB_ WP	AP_ WP
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26, 25	CPUTYPE[1:0]	00	R	These bits specify the type of CPU that has the privilege to change this register's settings. When setting the privilege to change settings in this register, also write 1 to the REGWP bit. The CPU set in this register is automatically designated as the CPU that has the privilege to change settings. When B'0 is written to the REGWP bit, these bits are cleared to B'00, allowing settings to be changed from all CPUs. 00: All CPUs have the privilege to change settings. 01: Only AP-SH has the privilege to change settings. 10: Only AP-ARM has the privilege to change settings.

Bit	Bit Name	Initial Value	R/W	Description
24	REGWP	0	R/W	Privilege to Change Register Setting This bit specifies whether the CPU that specified this register's settings permits the settings value to be changed by other CPUs. After 1 is written to this bit, the bit automatically becomes 0. When this bit is set to 1, the type of CPU that set this register is specified in CPUTYPE. After the register value changes, the register is read and this bit returns to 0. Accordingly, do not start a memory area access until first checking with software that CPUTYPE has been set. Also, write operations from CPUs that do not have the privilege to change settings, as specified by CPUTYPE, are disabled. 0: Enables all CPUs to change settings. 1: Only the CPU that set this register has the privilege to change settings.
23 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	RP_RSP	0	R/W	This bit specifies the BSC response method when a read access to the read protection area occurs. If a CPU that does not have the privilege to change this register's settings as specified in CPUTYPE attempts to write to this bit, the operation is ignored. 0: An error response is sent. 1: No error response is sent. About error responses when this bit is set to 0 When AP-SH accesses the protected area, BSC returns an error response, but AP-SH exception handling does not occur. When AP-ARM accesses the protected area, the error is treated as a data abort condition.

Bit	Bit Name	Initial Value	R/W	Description
16	WP_RSP	0	R/W	This bit specifies the BSC response method when a write access to the read protection area occurs. If a CPU that does not have the privilege to change this register's settings as specified in CPUTYPE attempts to write to this bit, the operation is ignored. 0: An error response is sent. 1: No error response is sent. About error responses when this bit is set to 0 When AP-SH accesses the protected area, BSC returns an error response, but AP-SH exception handling does not occur. When AP-ARM accesses the protected area, the error is treated as a data abort condition.
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	BB_RP	0	R/W	Privilege to Read BB Resource* Setting If a CPU that does not have the privilege to change this register's settings as specified in CPUTYPE attempts to write to this bit, the operation is ignored. When the read protection area is read, this bit is read as 0.
8	AP_RP	0	R/W	Privilege to Read AP Resource* Setting If a CPU that does not have the privilege to change this register's settings as specified in CPUTYPE attempts to write to this bit, the operation is ignored. 0: The read privilege for the corresponding BSC area exists. 1: No read privilege for the corresponding BSC area exists. When the read protection area is read, this bit is read as 0.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1	BB_WP	0	R/W	Privilege to Write to BB Resource* Setting If a CPU that does not have the privilege to change this register's settings as specified in CPUTYPE attempts to write to this bit, the operation is ignored. 0: The read privilege for the corresponding BSC area exists. 1: No read privilege for the corresponding BSC area exists.
0	AP_WP	0	R/W	AP Resource Write Authorization Settings If a CPU that does not have the privilege to change this register's settings as specified in CPUTYPE attempts to write to this bit, the operation is ignored. 0: The write privilege for the corresponding BSC area exists. 1: No write privilege for the corresponding BSC area exists.

BB resources: ACMFI

6.4.9 BS assert period Settings Register (BSWCR)

BSWCR is a 32-bit register that specifies the period of BS_N assert.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	BSCS6A[1:0]		BSCS5B[1:0]		BSCS5A[1:0]		BSCS4[1:0]		-	-	BSCS2[1:0]		BSCS0[1:0]	
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
13,12	BSCS6A[1:0]	00	R/W	BS_N assert cycle number of area CS6A specifies. 00: 1 cycle 01: 2 cycle 10: 3 cycle 11: Prohibition
11,10	BSCS5B[1:0]	00	R/W	BS_N assert cycle number of area CS5B specifies. 00: 1 cycle 01: 2 cycle 10: 3 cycle 11: Prohibition
9, 8	BSCS5A[1:0]	00	R/W	BS_N assert cycle number of area CS5A specifies. 00: 1 cycle 01: 2 cycle 10: 3 cycle 11: Prohibition
7, 6	BSCS4[1:0]	00	R/W	BS_N assert cycle number of area CS4 specifies. 00: 1 cycle 01: 2 cycle 10: 3 cycle 11: Prohibition [notes] When burst ROM is selected,these bits set 00 and BS_N assert cycle number is specifies by BSW bits of CS4WCR.
5, 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3, 2	BSCS2[1:0]	00	R/W	BS_N assert cycle number of area CS2 specifies. 00: 1 cycle 01: 2 cycle 10: 3 cycle 11: Prohibition [notes] When burst ROM is selected,these bits set 00 and BS_N assert cycle number is specifies by BSW bits of CS2WCR.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	BSCS0[1:0]	00	R/W	BS_N assert cycle number of area CS0 specifies. 00: 1 cycle 01: 2 cycle 10: 3 cycle 11: Prohibition [notes] When burst ROM is selected,these bits set 00 and BS_N assert cycle number is specifies by BSW bits of CS0WCR.

6.4.10 CSn Space Wait Control Register 2(CSnWCR2) (n = 0, 2, 4)

CSnWCR2 specifies various wait cycles for memory accesses. Specify CSnWCR2 before accessing the target area.

CSnWCR is initialized to H'0000 0000 by a power-on reset. However, CSnWCR is not initialized but retains the previous value in standby mode.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	–	–	–	BST16	–	RWAIT			–	WWAIT			–	CKO2	WAITMD	BWMD
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	BST16	0	R/W	Burst write setting 0: 8 burst write 1: 16 burst write
11	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	RWAIT[2:0]	000	R/W	After WAIT_N sampling, beginning of burst read is set. 000: 1cycle 001: 2cycle 010: 3cycle 100: 0cycle
7	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 4	WWAIT[2:0]	000	R/W	After WAIT_N sampling, beginning of burst write is set. 100: 1cycle 000: 2cycle 001: 3cycle Excluding the above-mentioned : reserve
3	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	CKO2	0	R/W	In the Case of BWMD bit is 1 0: Feedback CKO is selected 1: Feedback CKO2 is selected
1	WAITMD	0	R/W	WAIT mode is set. This bit sets the method of WAIT_N sampling. 0: WAIT_N signal is not sampling by CKO. 1: WAIT_N signal is sampling by CKO.
0	BWMD	0	R/W	Burst Write mode specifies. 0: Single Write mode Write cycle is asynchronous single write. BST16 , RWAIT[1:0] and WWAIT[1:0] are invalid. 1: Burst Write mode Write cycle is burst write. BST16 , RWAIT[1:0] and WWAIT[1:0] are valid.

6.5 Operation

6.5.1 Endian/Access Size and Data Alignment

This LSI supports little endian, in which the 0 address is the least significant byte (LSByte) in the byte data. Two data bus widths (8 bits and 16 bits) are available for normal memory and SRAM with byte selection. Data alignment is performed in accordance with the data bus width of the device and endian. This also means that when longword data is read from an 8-bit width device, the read operation must be done four times. In this LSI, data alignment and conversion of the data length are performed automatically between the respective interfaces.

Tables 6.8 and 6.9 show the relationship between endian, device data width, and access unit.

Table 6.8 16-Bit External Device/Little Endian Access and Data Alignment

6.5.2 Normal Space Interface

(1) Basic Timing

For access to a normal space, this LSI uses strobe signal output in consideration of the fact that mainly SRAM without a byte-selection pin will be directly connected. When using SRAM with a byte-selection pin, see section 6.5.6, SRAM Interface with Byte Selection. Figure 6.2 shows the basic timing of normal space access. A no-wait normal access is completed in two cycles. The BS_N signal indicates that the bus cycle has started, and is asserted one clock cycle.

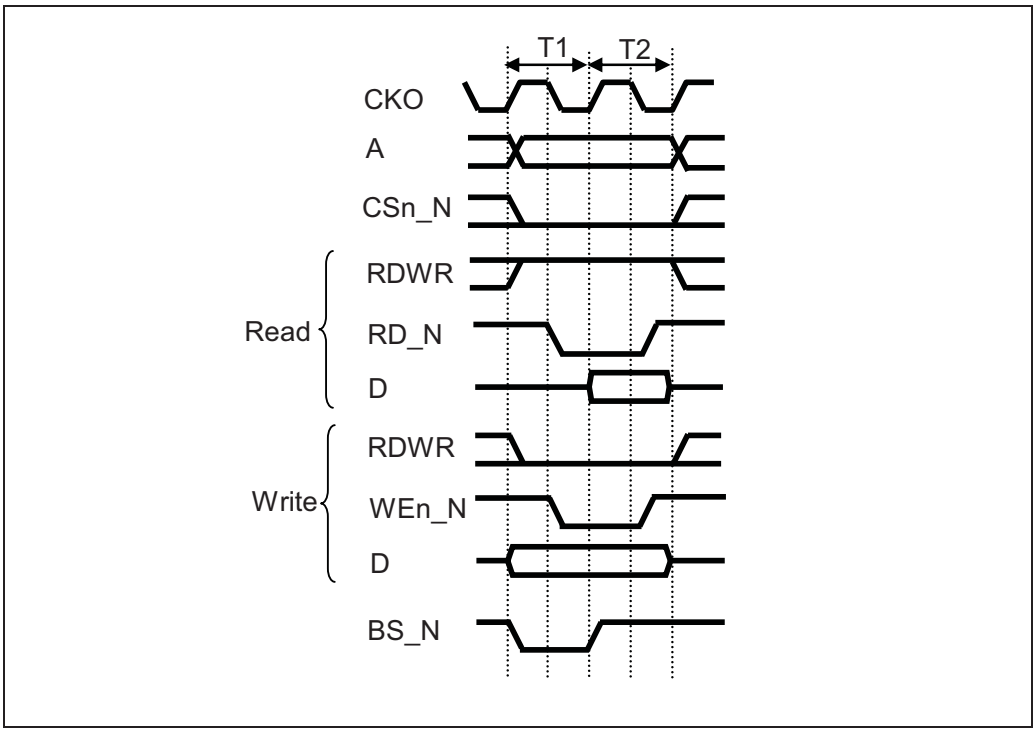

Figure 6.2 Normal Space Basic Access Timing (Access Wait = 0 (WW[2:0] = B'000, W/WR[3:0] = B'0000, SW[1:0] = B'00, HW[1:0] = B'00))

There is no access size specification when reading from the external bus. The correct access start address is output in the least significant bit of the address, but since there is no access size specification, 16 bits are always read in case of a 16-bit device. When writing, only the WEn_N signal for the byte to be written is asserted.

It is necessary to output the data that has been read using the RD_N signal when a buffer is provided in the data bus. The RDWR signal is in a read state (high output) when no access has been carried out. Therefore, care must be taken to avoid collision when controlling the external data buffer using RDWR signal.

Figures 6.3 and 6.4 show the basic timings of continuous accesses to a normal space. If the WM bit in CSnWCR is cleared to 0, a Tnop cycle is inserted to evaluate the external wait (figure 6.3). However, if the WM bit is set to 1, external waits are ignored and no Tnop cycle is inserted (figure 6.4).

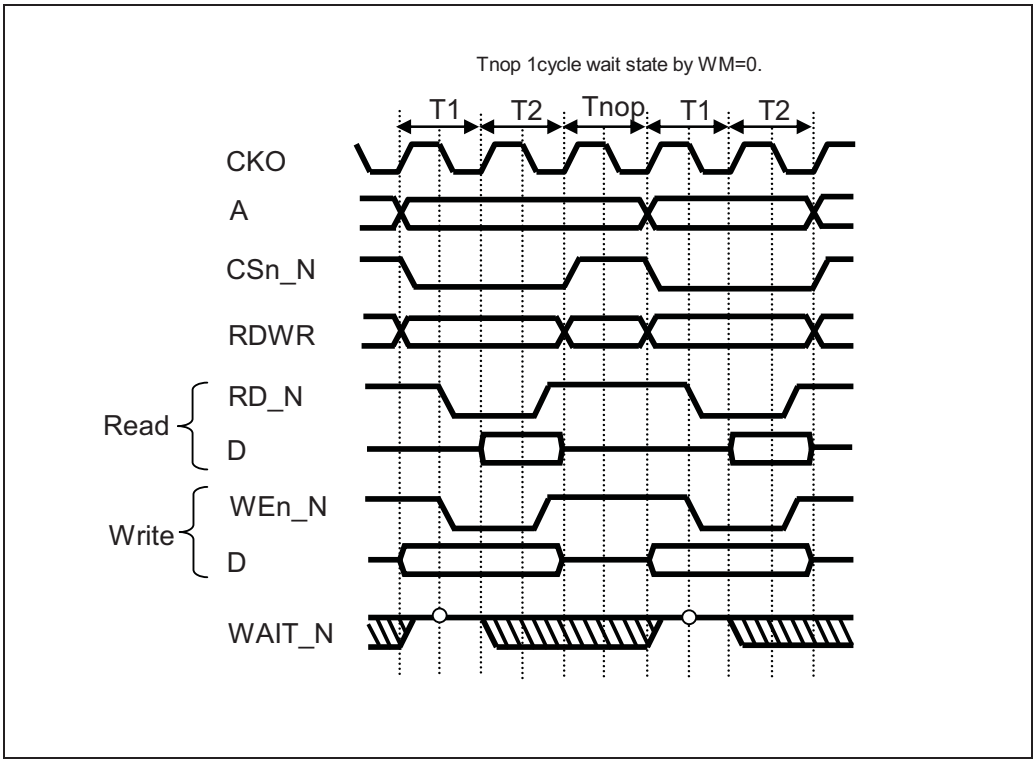

Figure 6.3 Continuous Access for Normal Space 1
Bus Width = 16 Bits, Longword Access, WM Bit in CSnWCR = 0
(Access Wait = 0 (WW[2:0] = B'000, W/WR[3:0] = B'0000, SW[1:0] = B'00,
HW[1:0] = B'00), Cycle Wait = 0 (IWW[1:0] = B'00, IWRWD[1:0] = B'00,
IWRWS[1:0] = B'00, IWRRD[1:0] = B'00, IWRRS[1:0] = B'00))

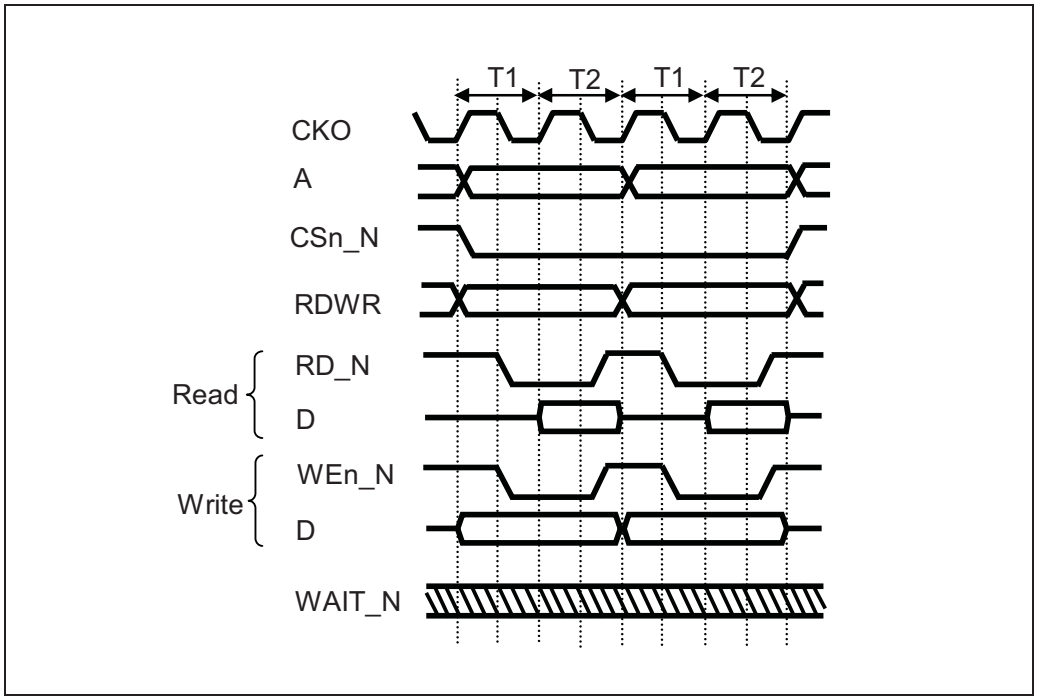

Figure 6.4 Continuous Access for Normal Space 2
Bus Width = 16 Bits, Longword Access, WM Bit in CSnWCR = 1
(Access Wait = 0 (WW[2:0] = B'000, W/WR[3:0] = B'0000, SW[1:0] = B'00, HW[1:0] = B'00), Cycle Wait = 0 (IWW[1:0] = B'00, IWRWD[1:0] = B'00, IWRWS[1:0] = B'00, IWRRD[1:0] = B'00, IWRRS[1:0] = B'00))

Figure 6.5 shows an example of connection to 16-bit data-width SRAM.

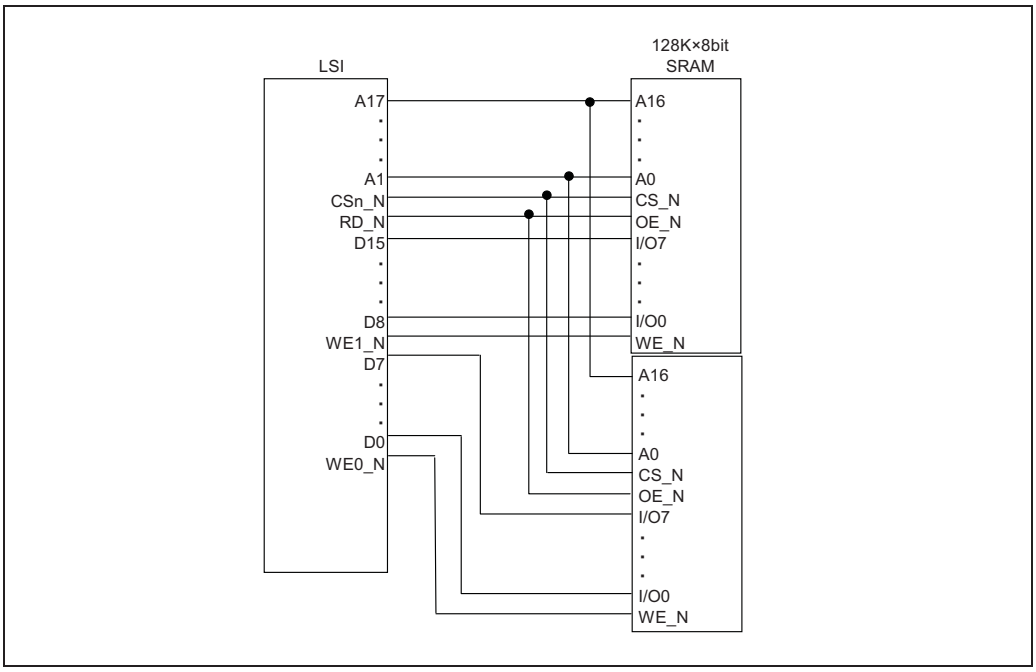

Figure 6.5 Example of 16-Bit Data-Width SRAM Connection

Figure 6.6 shows an example of connection to 8-bit data-width SRAM.

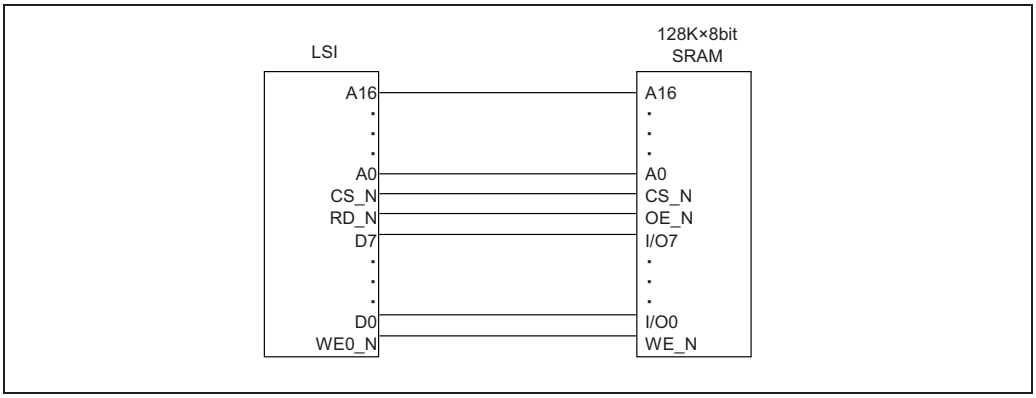

Figure 6.6 Example of 8-Bit Data-Width SRAM Connection

6.5.3 Access Wait Control

Wait cycle insertion on a normal space access can be controlled by setting the WR bits in CSnWCR. Setting the WW bits can insert wait cycles independently in read access and in write access. The specified number of Tw cycles are inserted as wait cycles in a normal space access shown in figure 6.7.

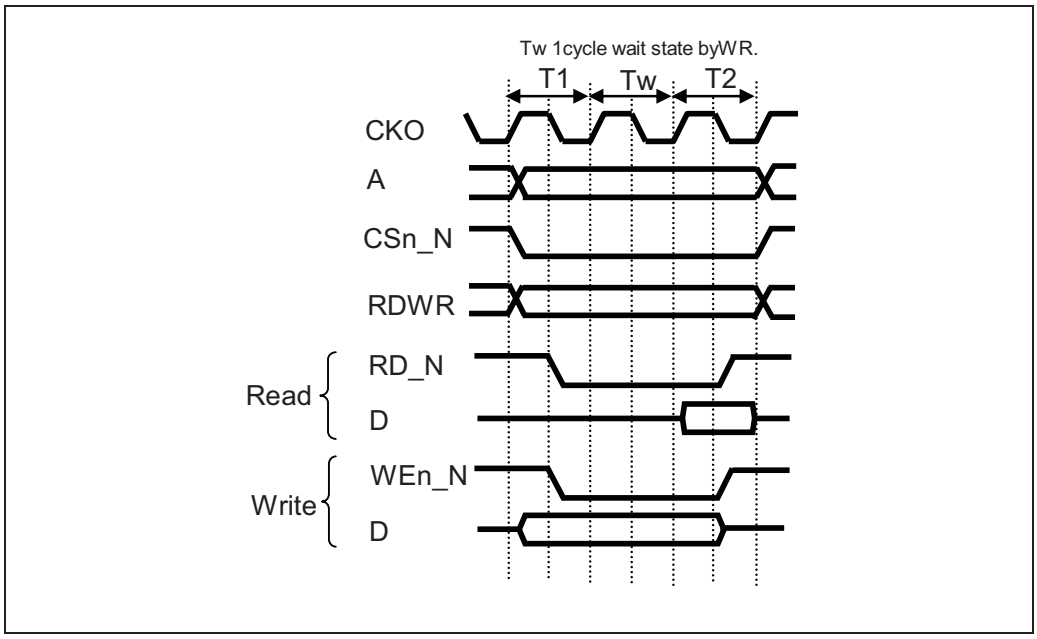

Figure 6.7 Wait Timing for Normal Space Access (Software Wait Only)
(Setting Example in Figure: Access Wait = 1 (WW[2:0] = B'000, W/WR[3:0] = B'0001, SW[1:0] = B'00, HW[1:0] = B'00))

When the WM bit in CSnWCR is cleared to 0, the external wait input WAIT_N signal is also sampled. WAIT_N pin sampling is shown in figure 6.8. A 2-cycle wait is specified as a software wait. The WAIT_N signal is sampled at the falling edge of CKO at the transition from the T1 or Tw cycle to the T2 cycle.

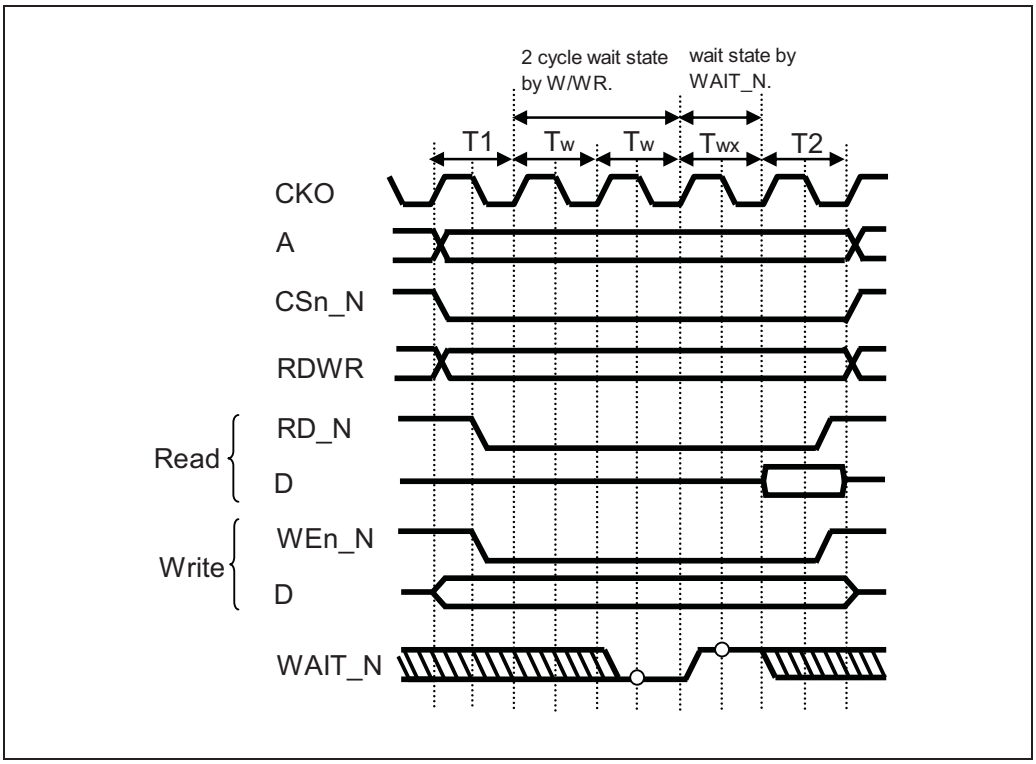

Figure 6.8 Wait Cycle Timing for Normal Space Access (Wait Cycle Insertion Using WAIT_N Signal) (Setting Example in Figure: Access Wait = 2 (WW[2:0] = B'000, W/WR[3:0] = B'0010, SW[1:0] = B'00, HW[1:0] = B'00), External Wait Valid (WM = 0))

6.5.4 CSn_N Assert Period Extension

The number of cycles from CSn_N assertion to RD_N, WEn_N assertion can be specified by setting the SW bits in CSnWCR. The number of cycles from RD_N, WEn_N negation to CSn_N negation can be specified by setting the HW bits. Therefore, a flexible interface to an external device can be obtained.

Figure 6.9 shows an example.

A Th cycle and a Tf cycle are added before and after an ordinary cycle, respectively. In these cycles, RD_N and WEn_N are not asserted, while other signals are asserted. The data output is prolonged to the Tf cycle, and this prolongation is useful for devices with slow write operations.

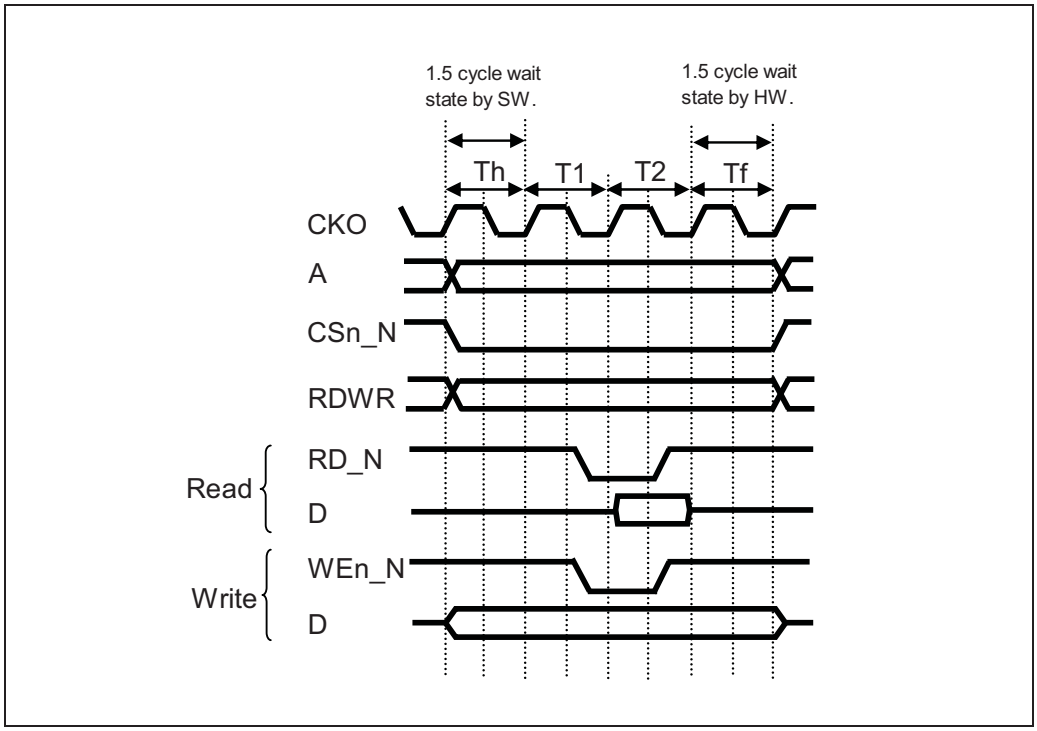

Figure 6.9 CSn_N Assert Period Extension
(Setting Example in Figure: Access Wait = 0, Setup Wait = 1, Hold Wait = 1
(WW[2:0] = B'000, W/WR[3:0] = B'0000, SW[1:0] = B'01, HW[1:0] = B'01))

6.5.5 Burst ROM Interface

(1) Page Mode

The burst ROM interface is used to access a memory with a high-speed read function using a method of address switching called burst mode or page mode. In the burst ROM interface, basically the same access as the normal space is performed, but the second and subsequent accesses are performed by changing only the address, without negating the RD_N signal at the end of the first cycle. In the second and subsequent accesses, addresses are changed at the falling edge of CKO.

For the first access cycle, the number of wait cycles specified by the W bits in CSnWCR is inserted. For the second and subsequent access cycles, the number of wait cycles specified by the BW bits in CSnWCR is inserted.

In the burst ROM access, the BS_N signal is asserted only in the first access cycle. Also, an external wait input is valid only in the first access cycle.

In the single access or write access that does not perform the burst operation in the burst ROM interface, access timing is the same as a normal space.

Table 6.10 lists a relationship between the bus width, access size, and number of bursts. Figure 6.10 shows a timing chart.

Table 6.10 Relationship between Bus Width, Access Size, and Number of Bursts

Bus Width	Access Size	Number of Bursts	Number of Accesses
8 bits	8 bits	1	1
	16 bits	2	1
	32 bits	4	1
	16 bytes	16	1
	32 bytes	16	2
16 bits 4-burst mode BSTMD = 1	8 bits	1	1
	16 bits	1	1
	32 bits	2	1
	16 bytes	4	2
	32 bytes	4	4
16 bits 8-burst mode BSTMD = 0	8 bits	1	1
	16 bits	1	1
	32 bits	2	1
	16 bytes	8	1
	32 bytes	8	2

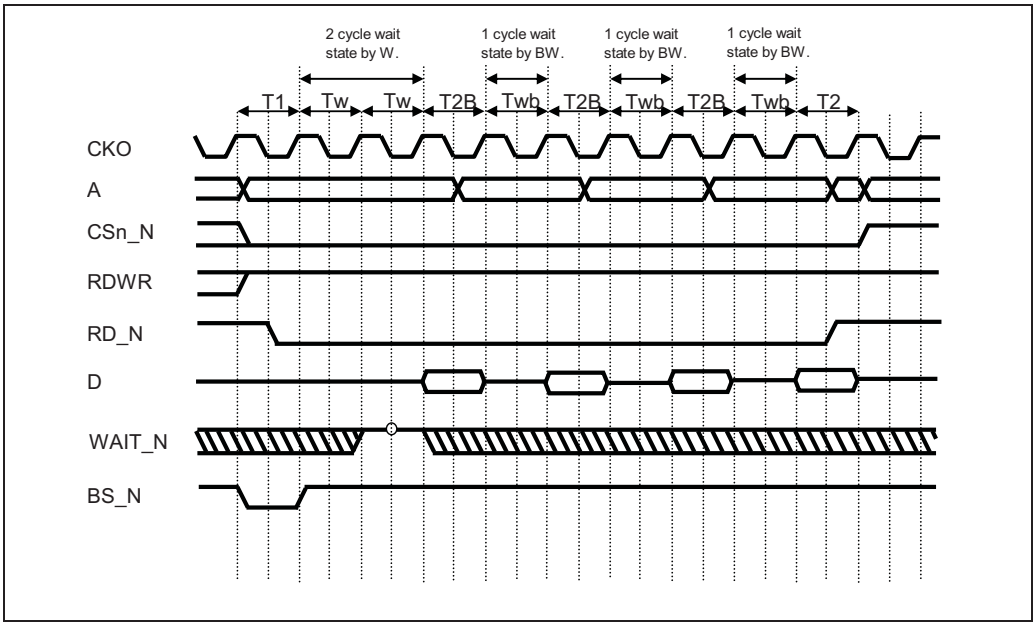

Figure 6.10 Burst ROM Access
(Bus Width = 16 Bits, 8-Byte Transfer (Number of Bursts = 4)
(Setting Example in Figure: Access Wait for 1st Time = 2, Access Wait for 2nd Time and After = 1, Setup Wait = 0, Hold Wait = 0 (BW[1:0] = B'01, W[3:0] = B'0010, SW[1:0] = B'00,
HW[1:0] = B'00, PH1RD = B'0, BROMMD = B'00))

(2) Clock Synchronous Burst Mode

This LSI can be interfaced with the memory having a clock-synchronous burst mode. To form the interface with memory of this type, connect the BS_N pin of this LSI to the address valid pin of the memory.

To assure the hold time for the clock that is supplied to the memory, set the BROMMD0 bit in CMNCR to 1. In addition, set the PH1RD bit in CSnBCR to 1 to assure the read data setup time for this LSI. Set the memory to wrap around with a burst length of 8.

Figures 6.11 and 6.12 show burst ROM (AD-MUX) access timings.

When the ADMUX bit in CSnWCR is set to 1 in the normal space interface or the burst ROM interface, the AD-MUX interface is specified for the CS0, CS2, and CS4 spaces. When the BSCMD external pin is reset to the high level, the ADMUX bit in CS0WCR is

set to its initial value of 1 and the AD-MUX interface is specified. In the AD-MUX interface, the lower 16 bits of the address, A16 to A1, are output from the data pins D15 to D0 and address bits A27 to A17 are output from address pins A11 to A1. In asynchronous mode, while BS_N is low, these outputs are loaded into memory and used as the address. In clock synchronous mode, these outputs are loaded into memory on the rising edge of CKO while BS_N is low and used as the address.

The BS_N assert period can be set by the BSW bits in CSnWCR. The access after BS_N negate is similar to an access in an interface other than the AD-MUX interface.

The WR3 to WR0 bits in CSnWCR control the wait period from negation of the RD_N signal to initial data loading. Figure 6.11 shows the timing chart when 3 cycles are specified by the WR3 to WR0 bits in CSnWCR. Initial data is loaded on the third CKO rising edge (Tck3) after the RD_N signal falls.

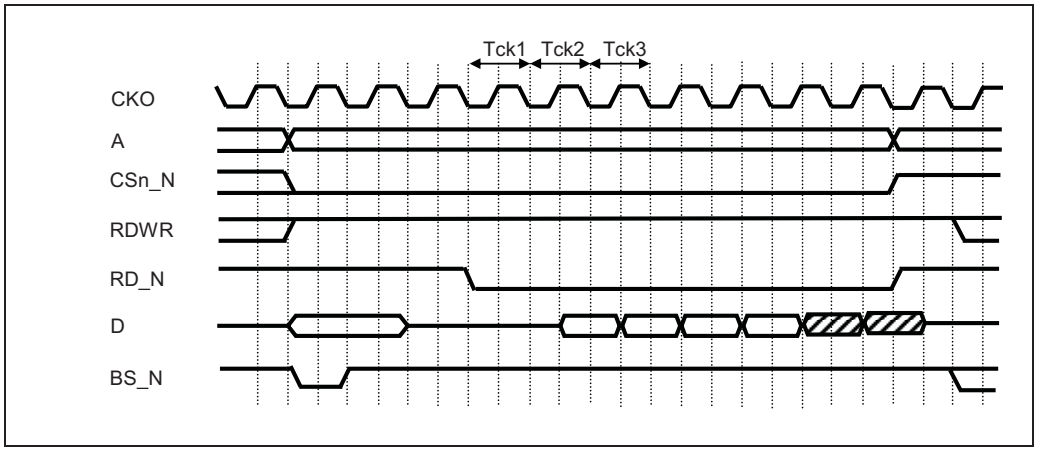

Figure 6.11 Burst ROM Access, 8-Byte Read
(Setting Example in Figure: Access Wait for 1st Time = 1, Access Wait for 2nd Time and After = 0, Setup Wait = 0, Hold Wait = 0 (BW[1:0] = B'00, W[3:0] = B'0011, SW[1:0] = B'10,
HW[1:0] = B'00), ADMUX = B'1, PH1RD = B'1, BROMMD = B'11, BSW = B'00)

HW[1:0] = B'00), ADMUX = B'1, PH1RD = B'1, BROMMD = B'11, BSW = B'01)

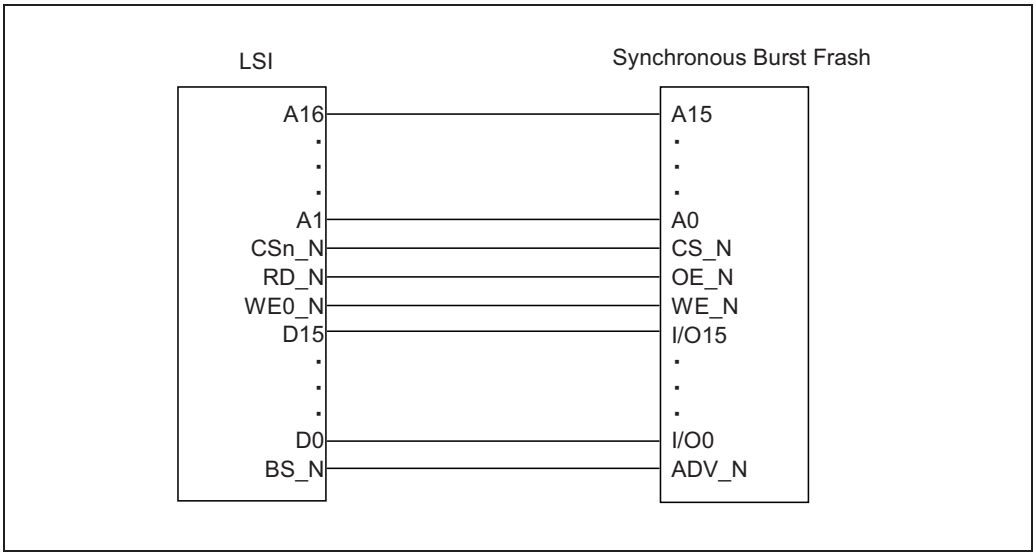

Figure 6.13 Synchronous Burst Flash Connection Example

6.5.6 SRAM Interface with Byte Selection

(1) Basic Access Timing

The SRAM interface with byte selection is a memory interface which outputs a byte-selection pin (WEn_N) in a read/write bus cycle. This interface has 16-bit data pins and accesses SRAMs having upper and lower byte-selection pins, such as UB and LB.

When the BAS bit in CSnWCR is cleared to 0 (initial value), the write access timing of the SRAM interface with byte selection is the same as that for the normal space interface. While in read access of the SRAM interface with byte selection, the byte-selection signal is output from the WEn_N pin, which is different from that for the normal space interface. The basic access timing is shown in figure 6.13. In write access, data is written to memory according to the timing of the byte-selection pin (WEn_N). For details, refer to the data sheet for the corresponding memory.

If the BAS bit is set to 1, the WEn_N pin and RDWR pin timings change. Figure 6.14 shows the basic access timing. In write access, data is written to memory according to the timing of the write enable pin (RDWR).

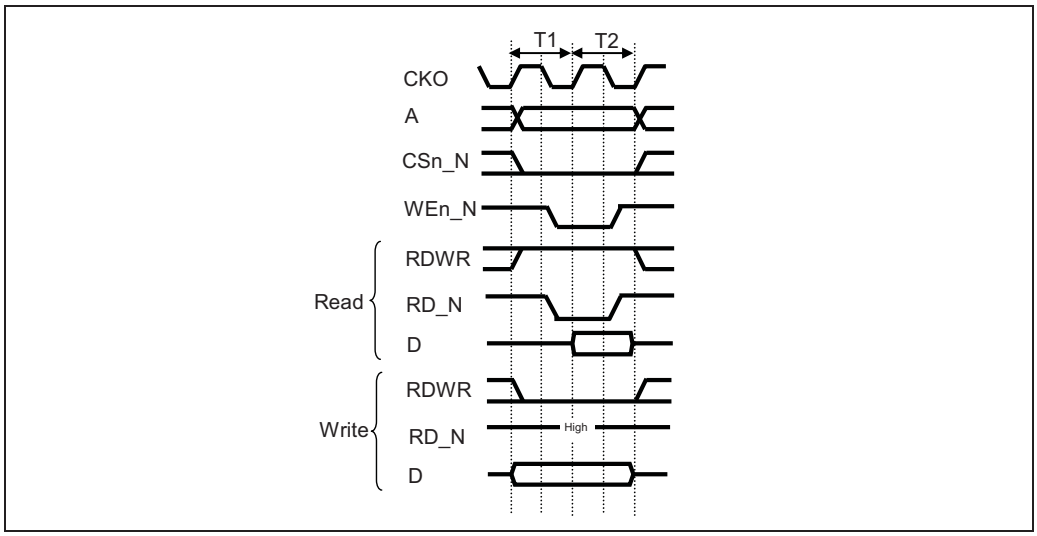

Figure 6.14 Basic Access Timing for SRAM with Byte Selection (BAS = 0) (Access Wait = 0 (WW[2:0] = B'000, W/WR[3:0] = B'0000, SW[1:0] = B'00, HW[1:0] = B'00))

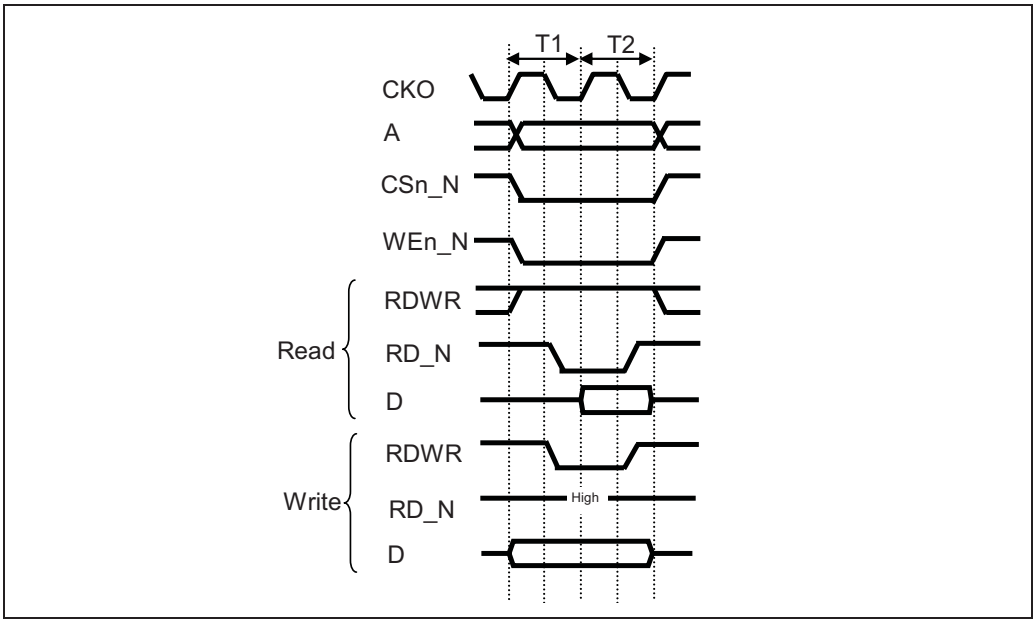

Figure 6.15 Basic Access Timing for SRAM with Byte Selection (BAS = 1) (Access Wait = 0 (WW[2:0] = B'000, W/WR[3:0] = B'0000, SW[1:0] = B'00, HW[1:0] = B'00))

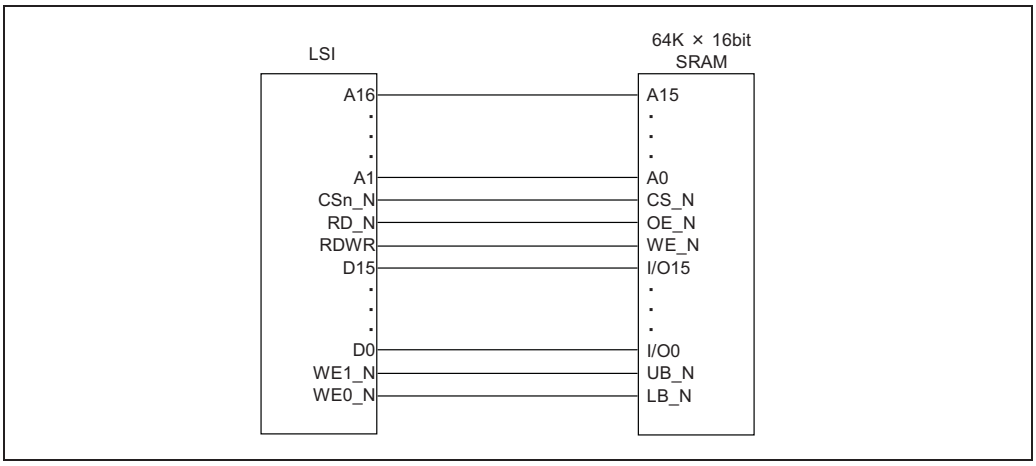

Figure 6.16 Example of Connection with SRAM with Byte Selection (16-Bit Data Bus)

(2) Page Mode of SRAM with Byte Selection

The page mode of SRAM with byte selection is used to access a memory with a high-speed read function using a method of address switching called burst mode or page mode. In page mode of SRAM with byte selection, basically the same access as the normal space is performed, but the 2nd and subsequent accesses are performed by changing only the address, without negating the RD_N signal at the end of the first cycle. In the second and subsequent accesses, addresses are changed at the falling edge of CKO*.

For the first access cycle, the number of wait cycles specified by the WR bits in CSnWCR is inserted. For the second and subsequent access cycles, the number of wait cycles specified by the BW bits in CSnWCR is inserted.

During the period of read in page mode, the BS_N signal is asserted only in the first access cycle. Also, an external wait input is valid only in the first access cycle.

The signal access or write access that does not perform the burst operation in page mode of SRAM with byte selection has the same access timing as an non-page mode access.

Table 6.11 lists a relationship between the bus width, access size, and number of bursts. Figures 6.16 and 6.17 show timing charts.

Note: * This description relates to a case where the CKO output and the BSC operation clock ZBCK are output in the same phase.

Bus Width	Access Size	Number of Bursts	Number of Accesses
8 bits	8 bits	1	1
	16 bits	2	1
	32 bits	4	1
	16 bytes	16	1
	32 bytes	16	2
16 bits	8 bits	1	1
	16 bits	1	1
	32 bits	2	1
	16 bytes	8	1
	32 bytes	8	2

Table 6.11 Relationship between Bus Width, Access Size, and Number of Bursts

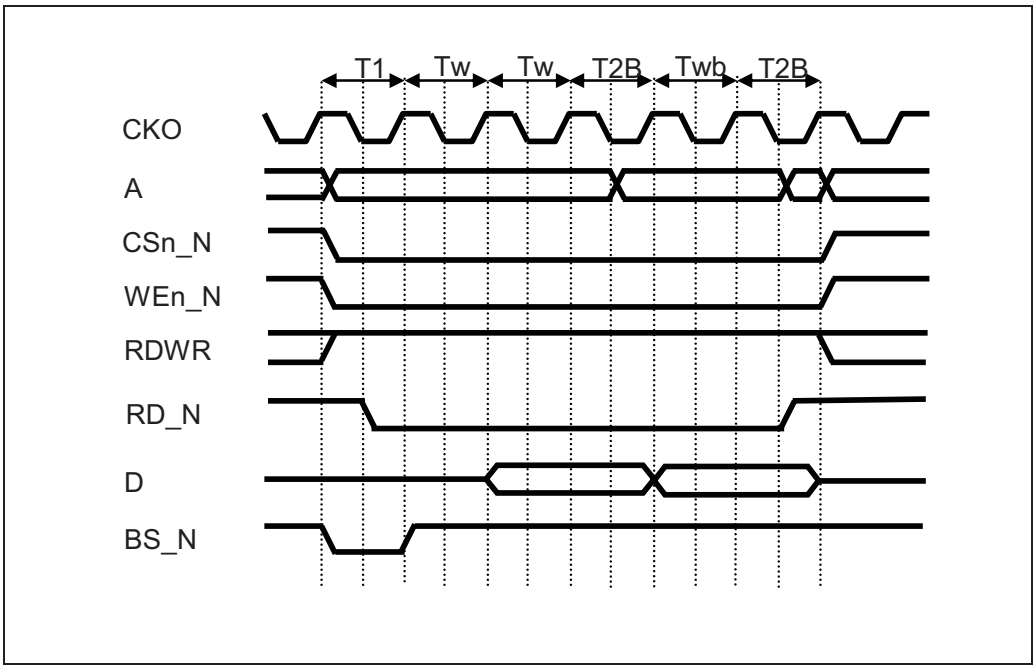

Figure 6.17 Page Mode Read for SRAM with Byte Selection (PMD = 1, BAS = 1) (Bus Width = 16 Bits, Longword Transfer (Number of Bursts = 2), Access Wait for 1st Time = 2, Access Wait for 2nd Time and After = 1) (BW[1:0] = B'01, WW[2:0] = B'000, WR[3:0] = B'0010, SW[1:0] = B'00, HW[1:0] = B'00)

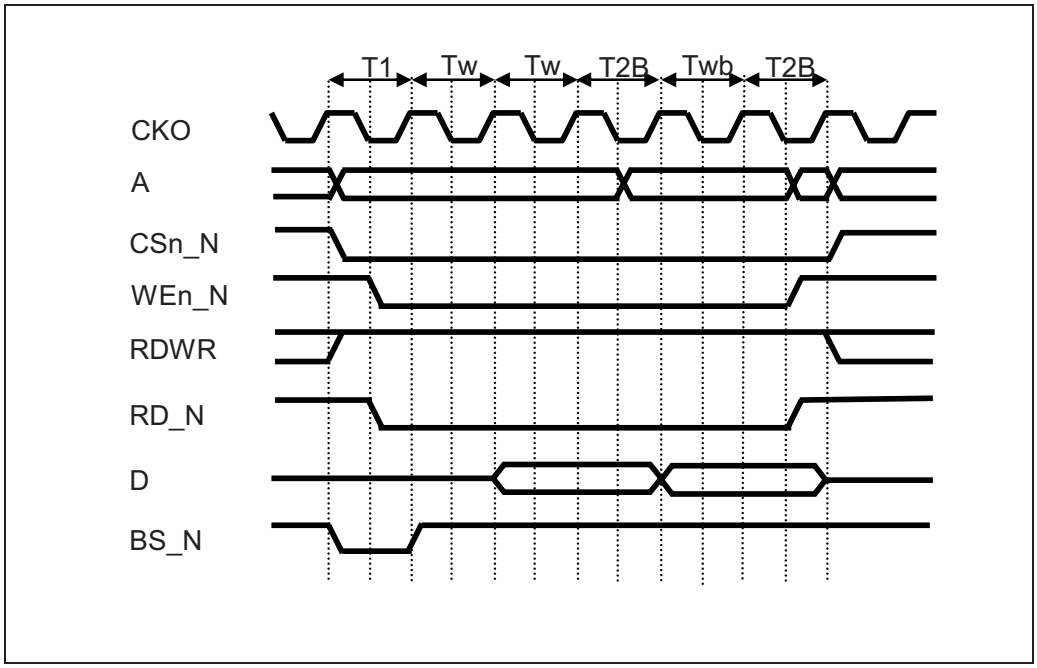

Figure 6.18 Page Mode Read for SRAM with Byte Selection (PMD = 1, BAS = 0) (Bus Width = 16 Bits, Longword Transfer (Number of Bursts = 2), Access Wait for 1st Time = 2, Access Wait for 2nd Time and After = 1) (BW[1:0] = B'01, WW[2:0] = B'000, WR[3:0] = B'0010, SW[1:0] = B'00, HW[1:0] = B'00)

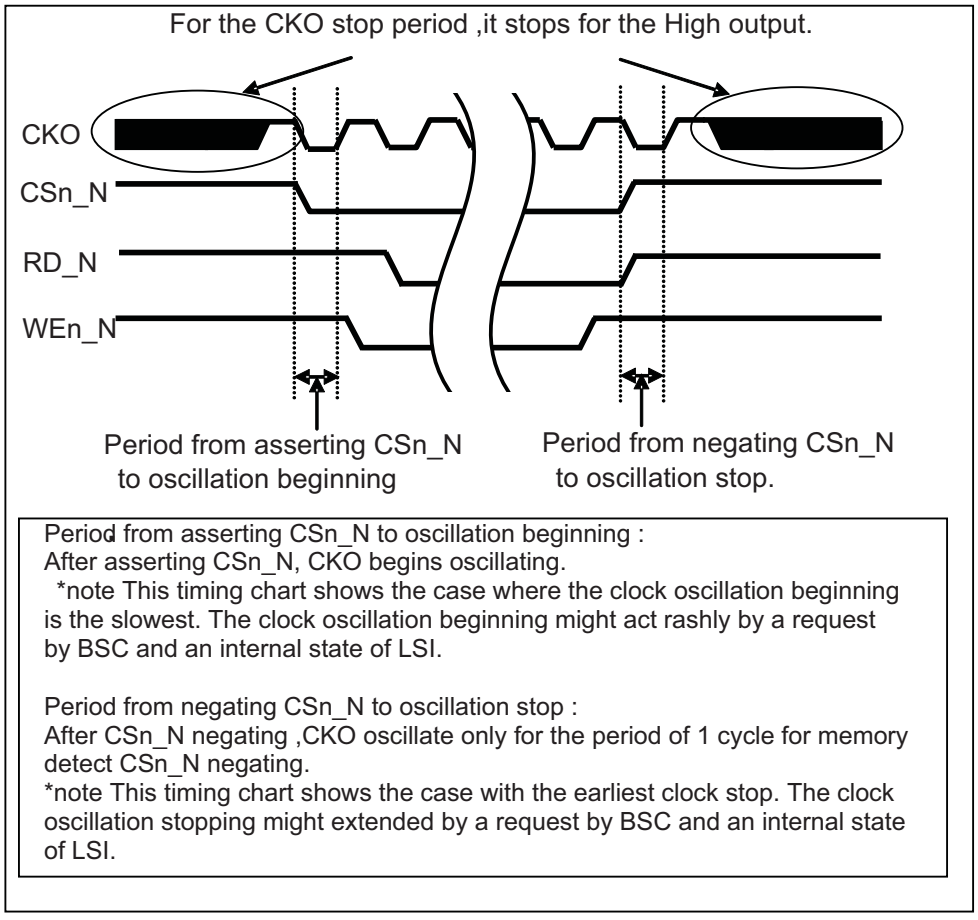
6.5.7 Wait between Access Cycles



As the operating frequency of LSIs becomes higher, the off-operation of the data buffer often collides with the next data output when the data output from devices with slow access speed is completed. As a result of these collisions, the reliability of the device is low and malfunctions may occur. A function that avoids data collisions by inserting wait cycles between continuous access cycles has been newly added.

The number of wait cycles between access cycles can be set by the IWW, IWRWD, IWRWS, IWRRD, and IWRRS bits in CSnBCR. The conditions for inserting the wait cycles (idle cycles) between access cycles are shown below.

1. Continuous accesses are write-read or write-write
2. Continuous accesses are read-write for different spaces
3. Continuous accesses are read-write for the same space
4. Continuous accesses are read-read for different spaces
5. Continuous accesses are read-read for the same space

6.5.8 CKO automatic stop function in case where output is not needed.

The control of the selection of the output of CKO is added in each area. This control is controlled by CSnBCR.CKOSTP bit . When the asynchronization memory that doesn't need the CKO output is connected, the output of CKO is controlled by setting CSnBCR.CKOSTP to 1. The CKO output start and stop timing are shown.

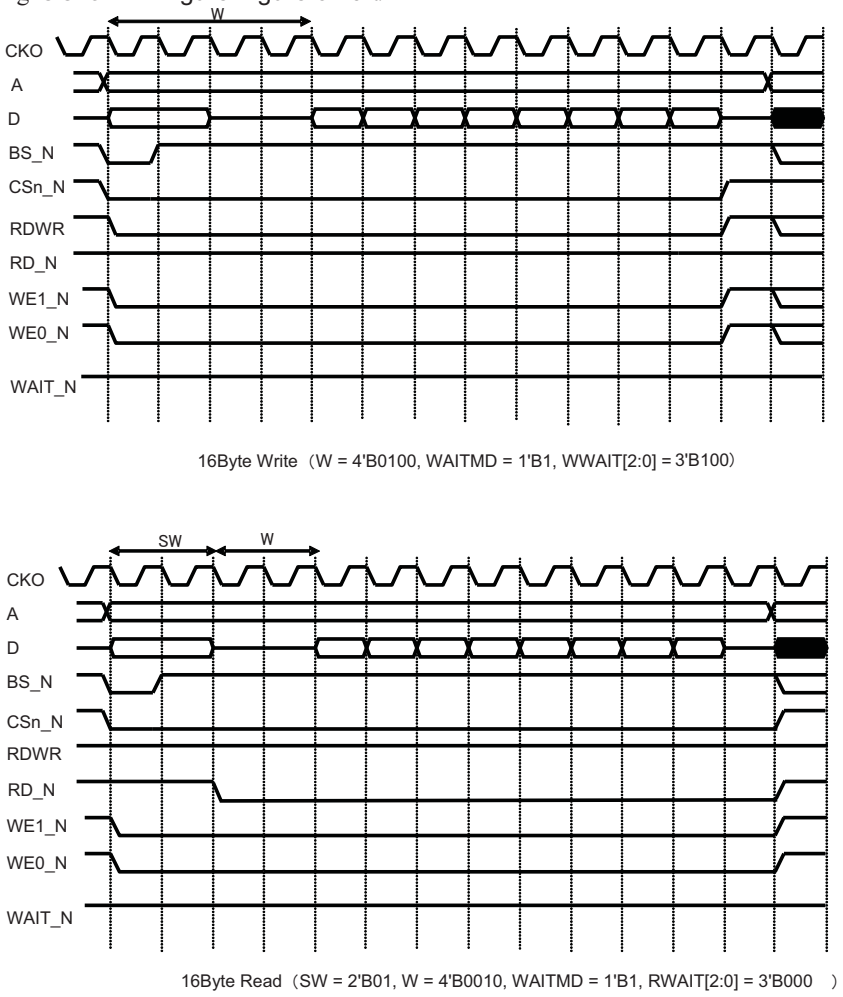
Period from asserting CSn_N to oscillation beginning :
After asserting CSn_N, CKO begins oscillating.
*note This timing chart shows the case where the clock oscillation beginning is the slowest. The clock oscillation beginning might act rashly by a request by BSC and an internal state of LSI.

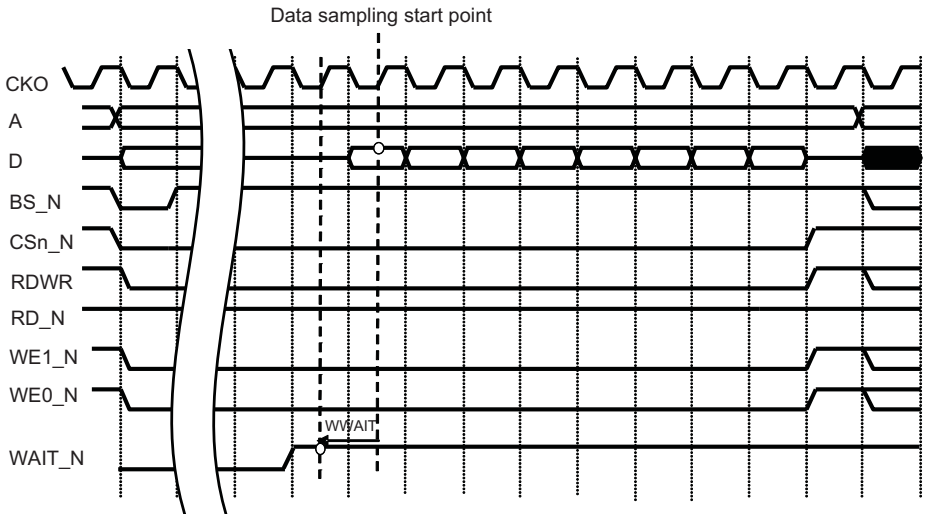
Period from negating CSn_N to oscillation stop :
After CSn_N negating ,CKO oscillate only for the period of 1 cycle for memory detect CSn_N negating.
*note This timing chart shows the case with the earliest clock stop. The clock oscillation stopping might extended by a request by BSC and an internal state of LSI.

Figure 6.19 CKO output start and stop timing

6.5.9 Burst Write mode.

Burst Write mode is used to access the memory in which the rapid access is possible and Burst Write mode function is provided. The write/read access timing without WAIT is shown in Figure 6.20.a, with WAIT is shown in Figure 6.20.b.The Write access timing with WWAIT Setting is shown in figure Figure 6.20.c. The Read access timing with RWAIT Setting is shown in figure Figure 6.20.d.





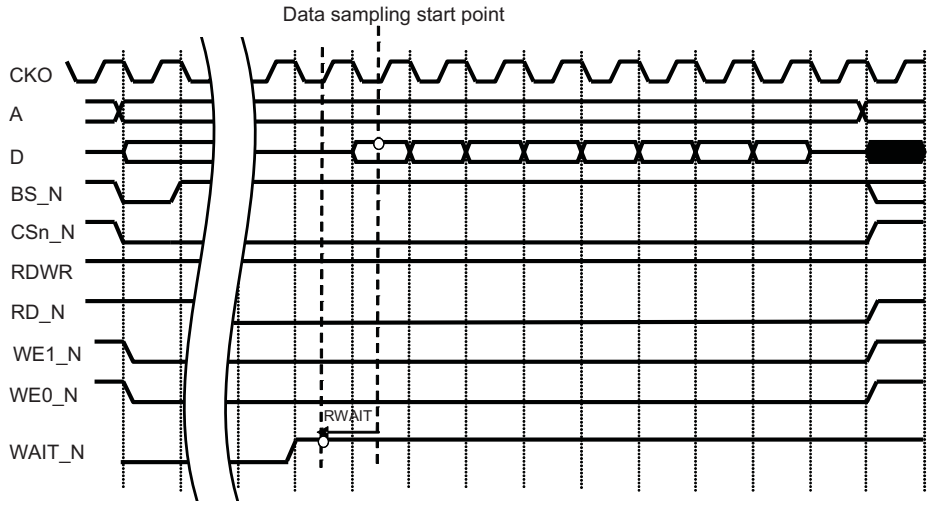


Figure 6.20.a Burst write/read timing (Without WAIT)

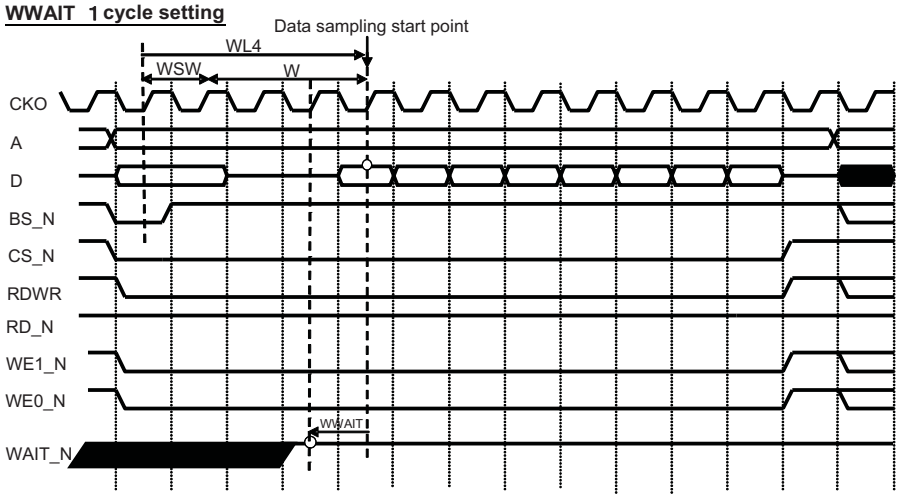

16Byte Write（WAITMD = 1'B1, WWAIT[2:0] = 3'B100）

Table 6.14 : **Burst Write Register Setting**

Register Setting				WL	RL
WSHWEN	WSW[1:0]	SW[1:0]	W[1:0]		
1	10	11	0001	3*	4
1	11	11	0001	4	4
1	10	11	0010	4	5
1	10	11	0011	5	6
1	11	11	0010	5	5
1	10	11	0100	6	7
1	11	11	0100	7	7

Please do not change to the settings other than the following.

CMNCR.BROMMD = 2'b11, CMNCR.TYPE = 3'B001

CSnBCR.PH1RD = 1'B1

CSnWCR.BSTMD = 2'B10, CSnWCR.BAS = 1'B1, CSnWCR.ADMUX = 1'B1

CSnWCR.WM = 1'B0, CSnWCR.HW = 2'B00

Note: * If set WL=3 and use external WAIT, Please set CSnWCR2.WWAIT = 3'B000 or 3'B100.

6.6 Others

6.6.1 Reset

The BSC can be initialized completely only by a power-on reset. At a power-on reset, all signals are negated and output buffers are turned off immediately regardless of the bus cycle state. All control registers are initialized. When power supply is intercepted,excluding C5 area, control registers of the BSC are not initialized.

Some flash memories may specify a minimum time from reset cancel to the first access. To ensure this minimum time, the BSC supports a 7-bit counter (RBWTCNT). At a power-on reset, RBWTCNT is set to H'7F. After clearing a power-on reset, RBWTCNT is counted down synchronized with CKO and an external access will not be generated until RBWTCNT is counted up to H'00.

6.6.2 On-Chip Peripheral Module Access

To access an on-chip peripheral module register, two or more peripheral clock (Pϕ) cycles are required. Care must be taken in system design.

6.6.3 Releasing the External Bus

The external bus of this LSI is shared by the BSC and FLCTL of the AP block (see figure 6.19).

When the FLCTL requires access to the external bus, the FLCTL issues a request to the BSC, and the BSC performs arbitration. BSC access is kept waiting while there is a request from the FLCTL block.

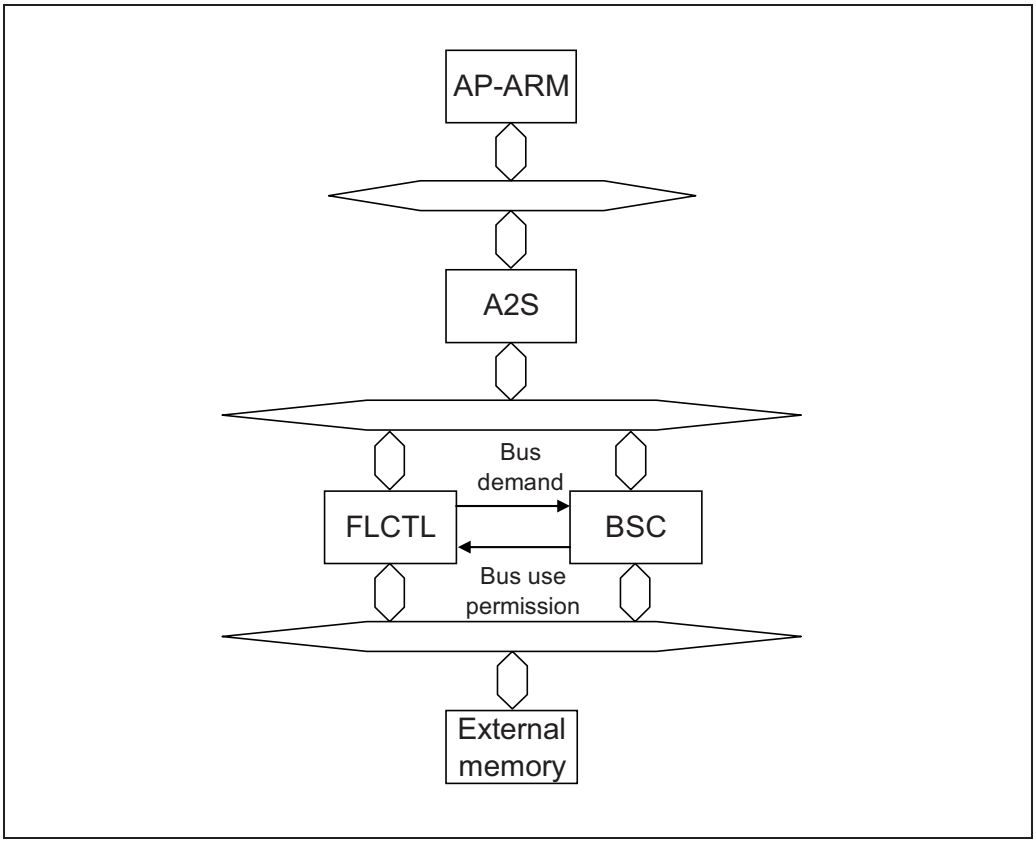

Figure 6.19 Relationship of Permissions and Bus Release Requests

6.6.4 Memory Protection Area Settings Registers and Handling of the Address Space

By setting BPTCR 00 to 31, this LSI can set write and read privileges for every 64 Mbits of the BSC area. Table 6.15 shows BPTCR 00 to 31 and the corresponding address space.

Table 6.14 Memory Protection Area Settings Registers and Handling of the Address Space

Space	Area Name	Settings Register Name	Start Address	End Address	Size

Area 0	Protection area 0	BPTCR 00	H'0000_0000	H'007F_FFFF	64 Mbits

6.6.5 Wait Control Using External Pins

BSC uses the WAIT_N pins for wait control based on external pins. Figure 6.21 shows the control circuit from these pins to the BSC wait control block.

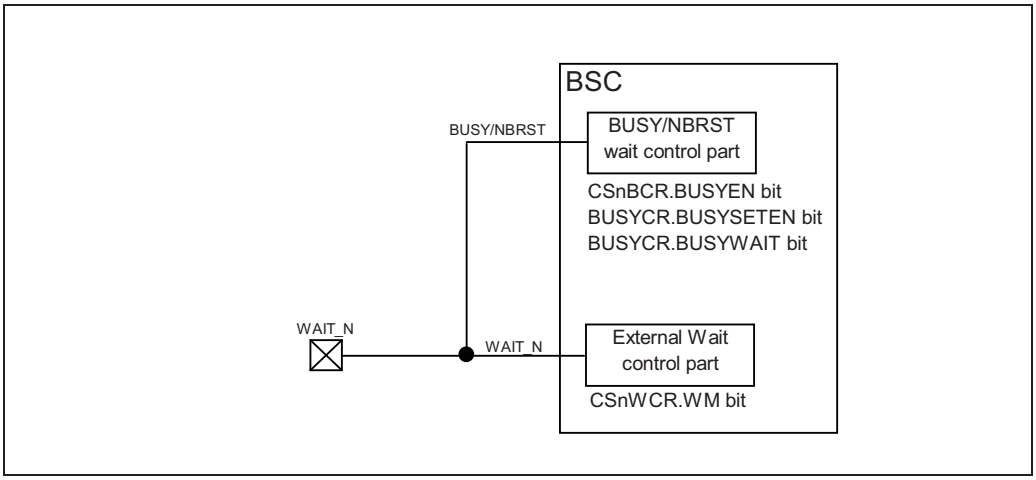

Figure 6.21 Wait Control Using External Pins

6.6.6 CKO Output, D-pin Input Control

The CKO pin and D pin of this LSI are controlled by the BSC bit and CPGA bit shown in table 16.6. These control bits must be set when clock asynchronous burst mode of the burst Rom interface is used.

Table 6.15: Relationship between Memory Protection Area Settings Registers and Address Space

Bit Name	Settings When Clock Asynchronous Burst Mode of the Burst Rom Interface Used
BSC.CSnBCR.PH1RD	Must be set to 1.
BSC.CMNCR.BROMMD0	Must be set to 1.
BSC.CMNCR.BROMMD1	Must be set to 1.
BSC.CMNCR.CKODSTP	For low power consumption, set to 1.
BSC. CMNCR.CKOSTP	Must be set to 0.
BSC.BROMTIMCR.CCNT[3:0]	Renesas will provide this information separately.
BSC.BROMTIMCR.DCNT[3:0]	Renesas will provide this information separately.
CPGA.PLLC1CR.CKODIVSTP	For low power consumption, set to 1.

Figure 6.22 shows the concept of CKO pin control and D pin control, both of which are controlled by the bits listed in the above table.

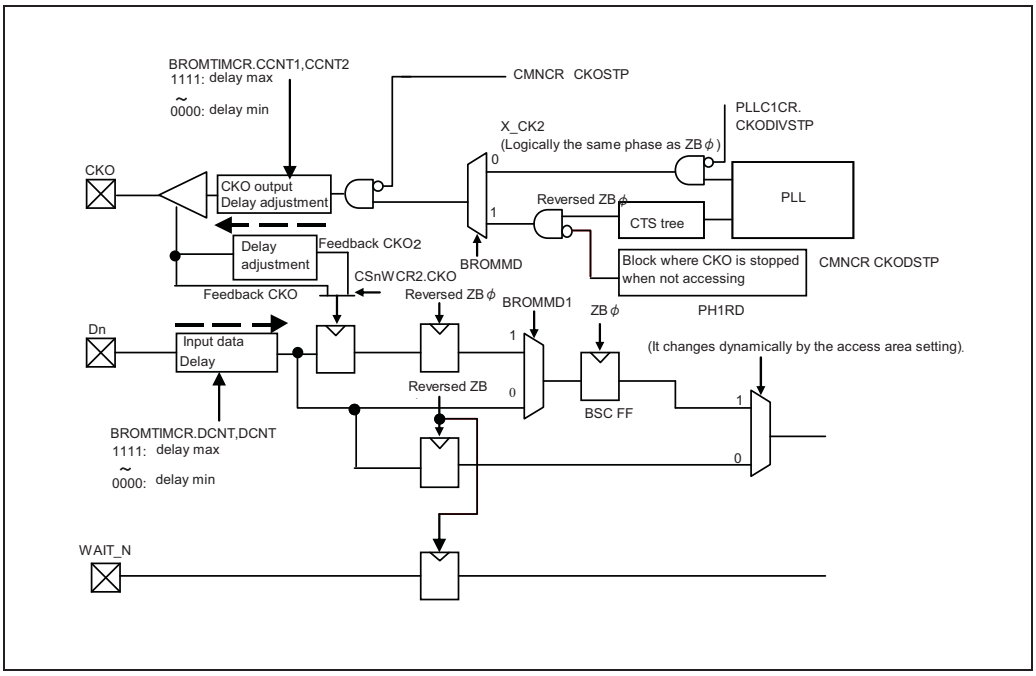

Figure 6.22 Concept of CKO Pin Control and C Pin Control

Section 7. Bus State Controller for SDRAM (SBSC)

The bus state controller for SDRAM (SBSC) outputs control signals for SDRAM that is connected to the external address space. The SBSC functions enable this LSI to connect directly with SDRAM.

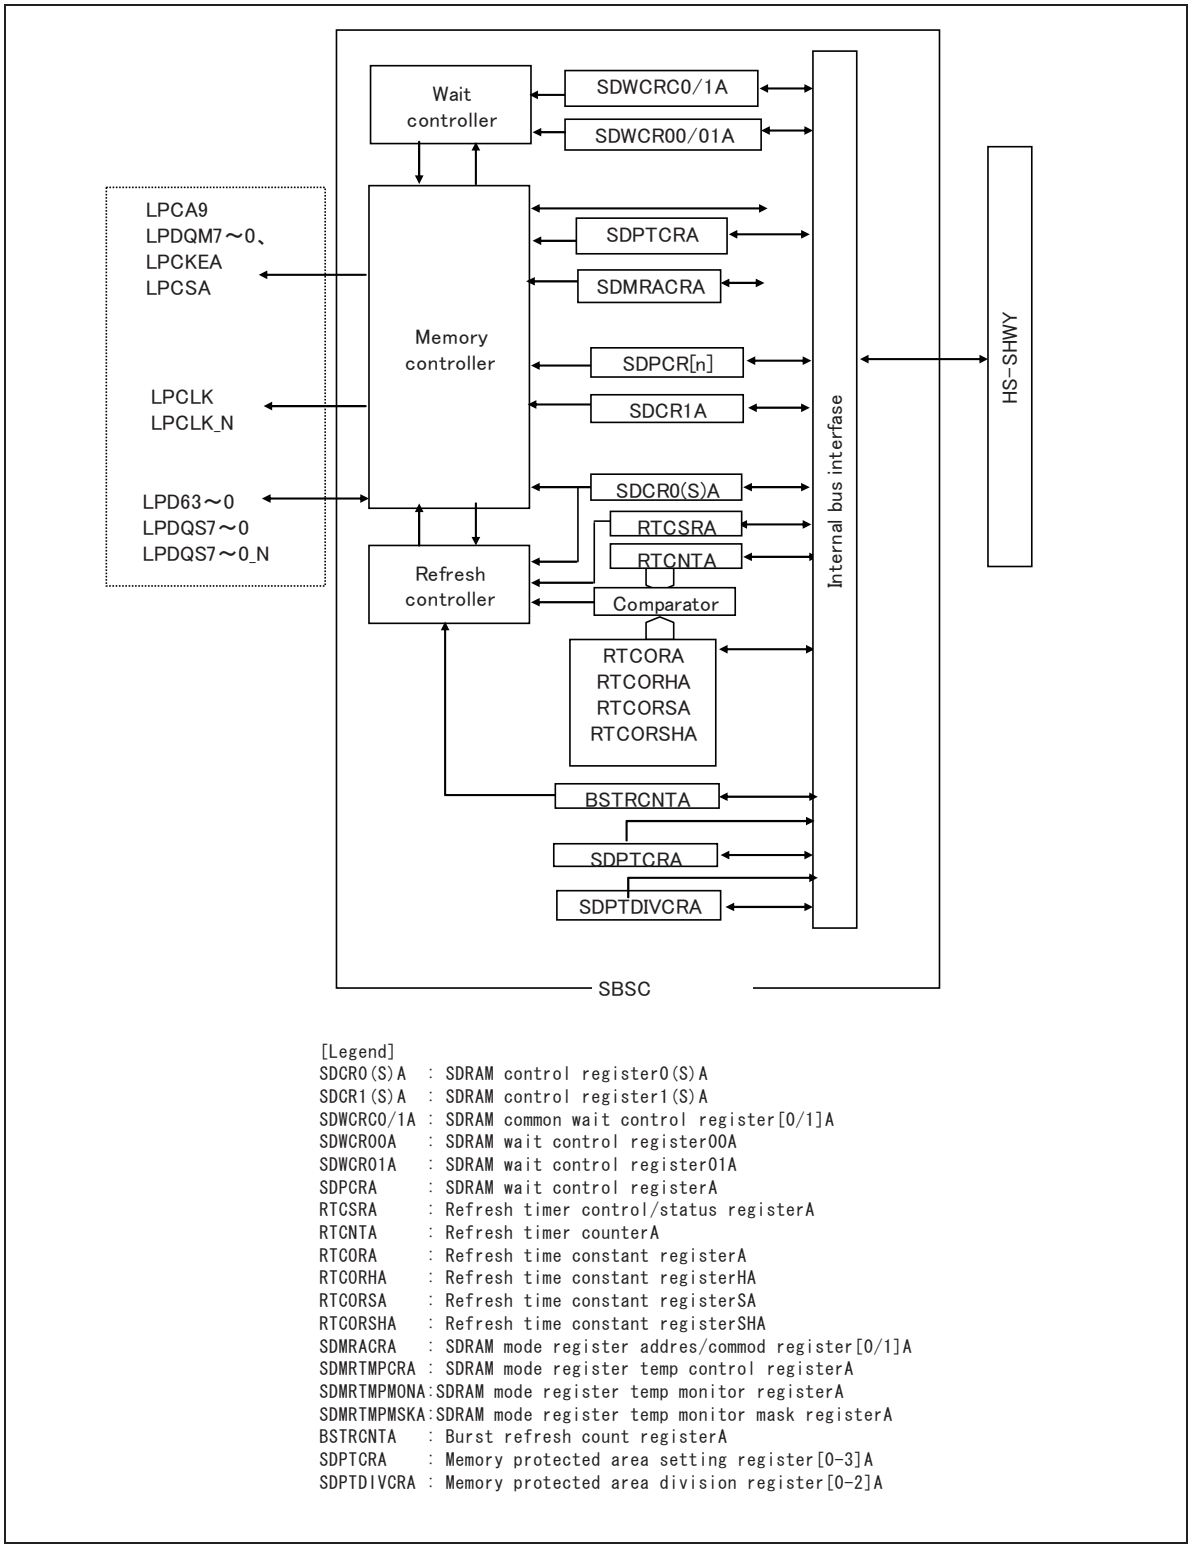
7.1 Features

The SBSC has the following features:

- Module configuration
  The SBSC controls the LP bus, and has one chip select signal.

- External address space
  The SBSC has a maximum 4 Gbits of external address space.
  The SBSC controls the one area of LPCSA.

- Operational mode
  SBSC has two operational modes (DDR600, DDR400)
  (DDR600 mode and DDR400 mode are selected with CPGA.FRQCRD.ZB3D2SEL bit)
  DDR600 mode
  Frequency : 20 to 300 MHz (ZBCLK3)
  Bus Width : 32 bits
  RL/WL/BL : 5/2/4
  DDR400 mode
  Frequency : 20 to 200 MHz(ZBCLK3)
  Bus Width : 32 bits / 64 bits
  RL/WL/BL : 3/1/4



- Controllable insertion of wait cycles according to the LPDDR2-S4 specifications

- LPDDR2-S4, interface
  Multiplexed output for command/row address/column address
  High-speed access by bank-active mode.
  Supports auto-refresh and self-refresh.
  Supports a low-power function.

- Memory protection function
  Can set the privilege to write to and read from the AP module or BB module (ACMFI).
  The area is divided into four, and a minimum unit of each area is 1 Mbits.

- Refresh function
  Supports auto-refresh and self-refresh.
  Specifies the refresh interval using the refresh counter and clock selection.
  Can execute concentrated refresh by specifying the refresh count (1, 2, 4, 6, or 8).
  Has a function to automatically switch the refresh rate based on the automatic determination of the temperature sensor in LPDDR-S4 MR#4 register.

Figure 7.1 shows a block diagram of the SBSC.

7.2 Input/Output Pins

Table 7.1 lists the SBSC pin configurations.

The SBSC controls the LP bus.

Table 7.1 SBSC Pin Configuration (LP Bus)

Name	Function	I/O	Description
LPCA9 to LPCA0	Command/Address bus	Output	Command / Address output
LPD63 to LPD0	Data bus	I/O	32-bit or 64-bit bidirectional bus
LPCSA	Chip select	Output	Chip select signal for connection to memory in DRAM area 0
LPDQM7	UUU-side data mask	Output	Byte-selection signal corresponding to D63 to D55 of LPDDR2-S4 Only 64-bit bus is used
LPDQM6	UUL-side data mask	Output	Byte-selection signal corresponding to D54 to D48 of LPDDR2-S4 Only 64-bit bus is used
LPDQM5	ULU-side data mask	Output	Byte-selection signal corresponding to D47 to D40 of LPDDR2-S4 Only 64-bit bus is used
LPDQM4	ULL-side data mask	Output	Byte-selection signal corresponding to D39 to D32 of LPDDR2-S4 Only 64-bit bus is used
LPDQM3	LUU-side data mask	Output	Byte-selection signal corresponding to D31 to D24 of LPDDR2-S4.
LPDQM2	LUL-side data mask	Output	Byte-selection signal corresponding to D23 to D16 of LPDDR2-S4.
LPDQM1	LLU-side data mask	Output	Byte-selection signal corresponding to D15 to D8 of LPDDR2-S4.
LPDQM0	LLL-side data mask	Output	Byte-selection signal corresponding to D7 to D0 of LPDDR2-S4.
LPCKEA	Clock enable	Output	SDRAM clock enable signal. Connected to the CKE pin of SDRAM.
LPCLK	Synchronous clock	Output	Synchronous clock output
LPCLK_N	Synchronous clock	Output	Inverted LPCLK clock output for LPDDR2-S4
LPDQS7/ LPDQS7_N	Data strobe	I/O	Data strobe signal corresponding to D63 to D56 of LPDDR2-S4 Only 64-bit bus is used
LPDQS6/ LPDQS6_N	Data strobe	I/O	Data strobe signal corresponding to D55 to D48 of LPDDR2-S4 Only 64-bit bus is used

Name	Function	I/O	Description
LPDQS5/ LPDQS5_N	Data strobe	I/O	Data strobe signal corresponding to D47 to D40 of LPDDR2-S4 Only 64-bit bus is used
LPDQS4/ LPDQS4_N	Data strobe	I/O	Data strobe signal corresponding to D39 to D32 of LPDDR2-S4 Only 64-bit bus is used
LPDQS3/ LPDQS3_N	Data strobe	I/O	Data strobe signal corresponding to D31 to D24 of LPDDR2-S4
LPDQS2/ LPDQS2_N	Data strobe	I/O	Data strobe signal corresponding to D23 to D16 of LPDDR2-S4
LPDQS1/ LPDQS1_N	Data strobe	I/O	Data strobe signal corresponding to D15 to D8 of LPDDR2-S4
LPDQS0/ LPDQS0_N	Data strobe	I/O	Data strobe signal corresponding to D7 to D0 of LPDDR2-S4

7.3 Area Overview

7.3.1 Address Map

This LSI has 4 Gbits for the external address space only for LPDDR2-S4. The external address space is divided into up to eight partial spaces according to the maximum size of the connected memory. Among these partial spaces, the SBSC controls DRAM area 0.

Tables 7.2 show the address maps of the external address space.

Table 7.2 Address Map

Address	Area	Memory to be Connected	Capacity
H'4000 0000 to H'5FFF FFFF	DRAM area 0 (SBSC)	LPDDR2-SDRAM(S4 only)	4-Gbit
-	DRAM area 1 (SBSC)	Not support.	-

7.3.2 Memory Bus Width

The memory bus width of this LSI can be set as 32 bits or 64 bits by the SZ bit in the SDRAM control registers 0A (SDCR0A).

7.3.3 Data Alignment

This LSI supports only the little endian method for data alignment.

7.4 Register Descriptions of SBSC1

Table 7.3 shows the SBSC1 register configuration. Table 7.4 shows the register states in each operating mode. Do not access DRAM area 0 or DRAM area 1 until the memory interface settings have been made.

Table 7.3 SBSC1 Register Configuration

Register	Abbreviation	R/W	Address	Access Size
SDRAM control register 0A	SDCR0A	R/W	H'FE40 0008	32

Notes: 1. To prevent the erroneous writing, 32-bit write operations only are performed when the upper 16 bits of the write data are H'A55A. Otherwise, write operations are not performed. The upper 16 bits of the data are read as H'0000.

2. The entity of this register is in SDRAM. Data is written to the register in the SDRAM by accessing the register space for it. For details, refer to section 7.6.2 (3),LPDDR2-S4 internal register access function.

Notes: 1. Bits OVF and CMF in RTCSRA are not retained.

7.4.1 SDRAM Control Register 0 A (SDCR0A)

SDCR0A specifies the method to refresh and access SDRAM connected to DRAM area 0, and the types and bus width of SDRAM to be connected.

SDCR0A is initialized to H'B0CA0109 by a power-on reset, but is not initialized and retains the contents in standby mode. Bits other than PDSELF, SRF_PRE, RFSH, RMODE, PDOWN, and DEEP should be set before accessing SDRAM connected to DRAM area 0, and should not be modified during SDRAM access. When writing to the PDSELF, SRF_PRE, RFSH, RMODE, PDOWN, and DEEP bits, the same value should be written to the other bits so that they remain unchanged.

bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	SDSZ[1:0]		PDSELF	PLLCNT	–	–	MEMTYPE[1:0]		–	–	BL	SRF_PRE	SZ[1:0]	
Initial value	1	0	1	1	0	0	0	0	1	1	0	0	1	0	1	0
R/W:	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W

bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PDOWN1	PDOWN0	DEEP	–	RFSH	RMODE	–	BACTV	–	BANK	ROW[2:0]			–	COL[1:0]

R/W:	R/W	R/W	R/W	R	R/W	R/W	R	R/W	R	R/W	R/W	R/W	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
30	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
29, 28	—	11	R	Reserved This bit is always read as 1. The write value should always be 1.
27	PDSELF	0	R/W	Selects whether to transit to self-refresh mode when the ZBCK3 frequency has been changed and SBSC power (A4S) is turned off. 0: Does not enter self-refresh mode 1: Enters self-refresh mode Note: The DEEP bit in SDCR0A must be cleared to 0 when this bit is set to 1. Even though partial refreshing has been specified when setting MR10 of the SDRAM, care is required for using this bit because memory contents cannot be saved in some areas. When a frequency is changed, this bit must be set to 1 in order to avoid refresh shortage.
26	PLLCNT	0	R/W	DRAM control at PLLC1 off period is specified. 0:SDRAM in the SBSC1 area in off PLLC1 continues an auto refreshing. 1:SDRAM in the SBSC1 area in off PLLC1 is assumed to be self-refresh. For details of settings, refer refer to "7.6.2(5) (f) Control of Automatic Transition to Self-Refresh Mode while PLLC1 is Off"

Bit	Bit Name	Initial Value	R/W	Description
25 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23,22	MEMTYPE	11	R/W	Memory Type Select 11:LPDDR2-S4 is connected to DRAM area 0. Others: Setting prohibited
21 to 20	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
19	BL	1	R/W	Burst Length Select When selecting the burst length of 4, the BACTV bit should be set to 1 to select bank active mode. 1: Burst length is 4 for LPDDR2-S4 access Others: Setting prohibited
18	SRF_PRE	0	R/W	All Bank Precharge Select Selects whether to issue the all-bank precharge command (PALL) before the burst refreshing that is performed on clearing of self-refresh mode. This bit is valid only when the SRFCNT bits in the BSTRCNTA register are set to a value greater than or equal to 1. 0: PALL is not issued before the burst refreshing is started 1: PALL is issued before the burst refreshing is started
17 to 16	SZ	10	R/W	Data Bus Width Specifies the data bus width of SDRAM. 01: 32 bits 10:64 bits Others: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
15, 14	PDOWN1 PDOWN0	All 0	R/W	These bits select the power-down mode. When the PDOWNSEL bit in SDPDCR0A is 1, the setting of these bits is compared with the power-down mode set by the PDOWN bits in SDCRA1, and the power-down mode with the smaller access latency is selected. 00: Normal operation 10: Power-down mode 1 If there is no access to the SBSC during the ZB3ϕ cycles specified by the PDWAIT bits in SDPDCR0A, the LPCKEA and LPCKEB pins are pulled to low and the SDRAM is placed in power-down mode. 01: Power-down mode 2 If there is no access to the SBSC during the ZB3ϕ cycles specified by the PDWAIT bits in SDPDCR0A, the LPCKEA and LPCKEB pins are pulled to low and the SDRAM is placed in power-down mode. At this time, the clock to the internal bus interface block in the SBSC is stopped. If there is a new access to the SBSC, a latency of one ZSϕ clock cycle is added compared to power-down mode 1 to start clock supply to the internal bus interface block. 11: Power-down mode 3 If there is no access to the SBSC during the ZB3ϕ cycles specified by the PDWAIT bits in SDPDCR0A, the self-refresh command is issued for the SDRAM and the SDRAM is placed in self-refresh mode. At this time, the clock (ZSϕ) to the internal bus interface block in the SBSC and the SBSC operation clock (ZB3ϕ) are stopped. If there is a new access to the SBSC, a latency of three ZSϕ clock cycles is added compared to power-down mode 1 to start clock supply.

Bit	Bit Name	Initial Value	R/W	Description
13	DEEP	0	R/W	Deep Power-Down Mode This bit is valid only for low-power SDRAM. If the RFSH and RMODE bits in SDCR0A are both set to 1 when the DEEPSEL0 bit in SDPDCR0A is 0 and this bit is set to 1, the deep power-down entry command is issued for the low-power SDRAM connected to DRAM area 0 and the low-power SDRAM enters deep power-down mode. When the DEEPSEL0 bit in SDPDCR0A is 1, whether to enter self-refresh mode or deep power-down mode is determined by ANDing this bit and the DEEP bit in SDCRA0S. Transition to self-refresh mode or deep power-down mode occurs at the timing specified when the RFSH bit in SDCR0 A is 1 and the RMODE bit in SDCR0(S) A is 1. The target mode is determined by the following setting. • When the DEEPSEL0 bit in SDPDCR0A is 0 0: DRAM area 0 enters self-refresh mode 1: DRAM area 0 enters deep power-down mode When the DEEPSEL0 bit in SDPDCR0A is 1 SDCR0A DEEP / SDCRA0S DEEP / Description 0 / 0 / DRAM area 0 enters self-refresh mode 1 / 0 / DRAM area 0 enters self-refresh mode 0 / 1 / DRAM area 0 enters self-refresh mode 1 / 1 / DRAM area 0 enters deep power-down mode
12	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
11	RFSH	0	R/W	Refresh Control Specifies whether or not the refresh operation of SDRAM is performed. 0: No refresh 1: Refresh

Bit	Bit Name	Initial Value	R/W	Description
10	RMODE	0	R/W	Refresh Mode Specifies whether to perform auto-refresh or self-refresh for the low-power SDRAM connected to DRAM area 0 when the RFSH bit in SDCRA0 is 1. When the RFSH bit is 1 and this bit is 1, self-refresh starts immediately. When the RFSH bit is 1 and this bit is 0, auto-refresh starts according to the settings in RTCSRA, RTCNTA, and RTCORA. When the RMODESEL0 bit in SDPDCR0A is 0, auto-refresh or self-refresh is selected by only this bit. However, when the RMODESEL0 bit in SDPDCR0A is 1, auto-refresh or self-refresh is determined by ANDing this bit and the RMODE bit in SDCRA0S. • When the RMODESEL0 bit in SDPDCR0A is 0 0: Auto-refresh is performed 1: Self-refresh is performed • When the RMODESEL0 bit in SDPDCR0A is 1 SDCR0A .RMODE / SDCR0SA .RMODE / Description 0 / 0 / DRAM area 0 enters auto-refresh mode 1 / 0 / DRAM area 0 enters auto-refresh mode 0 / 1 / DRAM area 0 enters auto-refresh mode 1 / 1 / DRAM area 0 enters self-refresh mode
9	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
8	BACTV	1	R/W	Bank Active Mode Specifies whether to access in auto-precharge mode (using READA and WRITA commands) or in bank active mode (using READ and WRIT commands). 0: Auto-precharge mode (using READA and WRITA commands) 1: Bank active mode (using READ and WRIT commands)
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	BANK	0	R/W	Number of Bits of Bank Address These bits specify the number of bits of bank address for DRAM area 0. 0: 2 bits (4-banks) 1: 3 bits (8-banks)

Bit	Bit Name	Initial Value	R/W	Description
5 to 3	ROW[2:0]	011	R/W	Number of Bits of Row Address These bits specify the number of bits of row address for DRAM area 0. 000: 11 bits 001: 12 bits 010: 13 bits 011: 14 bits 100: 15 bits Others: Setting prohibited
2	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	COL[1:0]	00	R/W	Number of Bits of Column Address These bits specify the number of bits of column address for DRAM area 0. 00: 8 bits 01: 9 bits 10: 10 bits 11: Setting prohibited

7.4.2 SDRAM Control Register 1 A (SDCR1A)

SDCR1A specifies the method to refresh and access SDRAM connected to DRAM area 0, and the types and bus width of SDRAM to be connected.

SDCR1A is initialized to H'00020409 by a power-on reset, but is not initialized and retains the contents in standby mode.

bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Initial value:	0	0	0	0	0	1	0	0	0	0	0	0	1	0	0	1

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved This bit is always read as 1. The write value should always be 1.
17	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
16	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
15, 14	PDOWN1 PDOWN0	All 0	R/W	These bits select the power-down mode. These bits are valid only when the PDOWNSEL bit in SDPDCR0A is 1. When the PDOWNSEL bit in SDPDCR0A is 1, the setting of these bits is compared with the power-down mode set by the PDOWN bits in SDCR0A, and the power-down mode with the smaller access latency is selected. 00: Normal operation 10: Power-down mode 1 01: Power-down mode 2 11: Power-down mode 3 Note:The latency order is as follows: Normal operation < Power-down mode 1 < Power-down mode 2 < Power-down mode 3
13 to 11	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
10	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
9 to 4	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
3	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
2 ,1	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

7.4.3 SDRAM Control Register 0S A (SDCR0SA)

SDCR0SA specifies power-down control for the SDRAM connected to DRAM area 0. SDCR0SA is initialized to H'0000 0000 by a power-on reset, but is not initialized and retains the contents in standby mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	DEEP	—	—	RMODE	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R	R	R/W	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	DEEP	0	R/W	Deep Power-Down Mode This bit is valid only when the DEEPSEL0 bit in SDPDCR0A is 1. When the DEEPSEL0 bit in SDPDCR0A is 1, whether DRAM area 0 enters self-refresh mode or deep power-down mode is determined by ANDing this bit and the DEEP bit in SDCRA0. For details about transition to self-refresh mode or deep power-down mode, see the bit description for the DEEP bit in SDCRA0. • When the DEEPSEL0 bit in SDPDCR0A is 0 0: Invalid setting 1: Invalid setting When the DEEPSEL0 bit in SDPDCR0A is 1 SDCRA0. DEEP / SDCRA0S DEEP / Description 0 / 0 / DRAM area 0 enters self-refresh mode 1 / 0 / DRAM area 0 enters self-refresh mode 0 / 1 / DRAM area 0 enters self-refresh mode 1 / 1 / DRAM area 0 enters deep power-down mode

Bit	Bit Name	Initial Value	R/W	Description
12, 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	RMODE	0	R/W	Refresh Mode This bit is valid only when the RMODESEL0 bit in SDPDCR0A is 1. When the RMODESEL0 bit in SDPDCR0A is 1, auto-refresh or self-refresh is determined for the SDRAM connected to DRAM area 0 by ANDing this bit and the RMODE bit in SDCRA0. • When the RMODESEL0 bit in SDPDCR0A is 0 0: Invalid setting 1: Invalid setting When the RMODESEL0 bit in SDPDCR0A is 1 SDCRA1. SDCRA1S. RMODE RMODE Description 0 0 DRAM area 0 enters auto-refresh mode 1 0 DRAM area 0 enters auto-refresh mode 0 1 DRAM area 0 enters auto-refresh mode 1 1 DRAM area 0 enters self-refresh mode
9 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

7.4.4 SDRAM Common Wait Control Register C0A(SDWCRC0A)

SDWCRC0A specifies various wait cycles for SDRAM access. Set SDWCRC0A before accessing SDRAM.SDWCRC0A is initialized to H'20562111 by a power-on reset, but is not initialized and retains the contents in standby mode. The bits should be set before accessing SDRAM, and should not be modified during SDRAM access.

27 to 26	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25, 24	WL[1:0]	All 0	R/W	WL (Write laytency) 00: 1 cycle 01: 2 cycles Other than above: Setting prohibited
23	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	TWTR[2:0]	101	R/W	tWTR , Write to Read Time These bits specify the minimum number of cycles from issuing of an WRIT(A) command to to issuing of the READ(A) command. The specification of cycle number becomes this bit setting value +1. 000: 1 cycle 001: 2 cycles : 111: 8 cycles

Bit	Bit Name	Initial Value	R/W	Description
19	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	TRTW[2:0]	110	R/W	tRTW , Read to Write Time These bits specify the minimum number of cycles from issuing of an READ(A) command to to issuing of the WRIT(A) commond. The specification of cycle number becomes this bit setting value +1. 000: 1 cycle 001: 2 cycles : 111: 8 cycles
15	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 12	TMRW[2:0]	010	R/W	tMRW These bits specify the minimum number of cycles from issuing of an MRW(Mode Register Write) command to to issuing of the any command. 000: 1 cycle 001: 2 cycles : 111: 8 cycles
11, 10	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	TMRR[2:0]	01	R/W	tMRR These bits specify the minimum number of cycles from issuing of an MRR(Mode Register Read) command to to issuing of the any command. 00: 1 cycle 01: 2 cycles 10: 3 cycles 11: 4 cycles
7, 6	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	TCKE[1:0]	01	R/W	tCKE These bits specify the minimum number of CKE pulse width during power-down mode. 00: 2 cycles 01: 3 cycles 10: 4 cycles 11: 5 cycles

Bit	Bit Name	Initial Value	R/W	Description
3	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2 to 0	TCKESR [2:0]	001	R/W	tCKESR These bits specify the minimum number of CKE pulse width during Self-refresh or Deep power-down mode. The specification of cycle number becomes this bit setting value +2. 000: 2 cycles 001: 3 cycles : 111: 9 cycles

7.4.5 SDRAM Common Wait Control Register C1A(SDWCRC1A)

SDWCRC1A specifies various wait cycles for SDRAM access. Set SDWCRC1A before accessing SDRAM.SDWCRC0A is initialized to H'20090120 by a power-on reset, but is not initialized and retains the contents in standby mode. The bits should be set before accessing SDRAM, and should not be modified during SDRAM access.

29 to 24	TRFC[5:0]	100000	R/W	tRFC These bits specify the minimum number of cycles from issuing of the REF command to issuing of the next REF command, the minimum number of cycles from issuing of the REF command to issuing of the ACTV command. The specification of cycle number becomes this bit setting value +1. 000000: 1 cycles 000001: 2 cycles : 111111: 64 cycles
23 to 21	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20 to 16	TRCAB[4:0]	01001	R/W	tRC(AB) These bits specify the minimum number of cycles from issuing of the ACTV command to issuing of the (REF/SELF/DEEP) command. The specification of cycle number becomes this bit setting value +1. 00000: 1 cycles 00001: 2 cycles : 11111: 32 cycles

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	TFAW	All 0	R/W	tFAW These bits specify four Bank Active window(tFAW) The specification of cycle number becomes this bit setting value +1. 0000: 1 cycles 0001: 2 cycles : 1111: 16 cycles
11 to 8	TXP[3:0]	0001	R/W	tXR These bits specify the minimum number of cycles from exit power-down to next valid command. The specification of cycle number becomes this bit setting value +1. 0000: 1 cycles 0001: 2 cycles : 1111: 16 cycles
7,6	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	TSREX[5:0]	100000	R/W	tSREX(tXSR) These bits specify the minimum number of cycles from exit self-refresh to next valid command. The specification of cycle number becomes this bit setting value +1. 000000: 1 cycles 000001: 2 cycles : 111111: 64 cycles

7.4.6 SDRAM Wait Control Register 00A(SDWCR00A)

SDWCR00A specifies various wait cycles for SDRAM access. Set SDWCR00A before accessing SDRAM.SDWCR00A is initialized to H'10608203 by a power-on reset, but is not initialized and retains the contents in standby mode. The bits should be set before accessing SDRAM, and should not be modified during SDRAM access.

Bit	Bit Name	Initial Value	R/W	Description
31	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30 to 28	TRRD[2:0]	001	R/W	t_{RRD}, Delay Time for RAS to RAS Assertion These bits specify the minimum number of cycles from issuing of an ACTV command to issuing of the next ACTV command for a different bank. The specification of cycle number becomes this bit setting value +1. 000: 1 cycle 001: 2 cycles : 111: 8 cycles
27 to 25	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24 to 20	TRAS[4:0]	00110	R/W	t_{RAS}, RAS Active Time These bits specify the minimum number of cycles from issuing of an ACTV command to issuing of the PRE command for the same bank. The specification of cycle number becomes this bit setting value +1. 00000 : 1cycles 00001 : 2 cycles : 11111 : 32 cycles
19,18	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17 to 14	TPRAB[3:0]	0010	R/W	$t_{RP(Ab)}$, Delay Time for All Bank Precharge to ACTV Command These bits specify the minimum number of cycles from issuing of the PALL command to issuing of the ACTV command. The specification of cycle number becomes this bit setting value +1. 0000 : 1 cycle 0001 : 2 cycles : 1111 : 16 cycles
13,12	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	TPRPB[3:0]	0010	R/W	$t_{RP(PB)}$, Delay Time for Precharge to ACTV Command These bits specify the minimum number of cycles from the start of auto-precharge or issuing of the PRE command to issuing of the ACTV command for the same bank. The specification of cycle number becomes this bit setting value +1. 0000 : 1 cycle 0001 : 2 cycles : 1111 : 16 cycles
7,6	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	TRCD[5:0]	000011	R/W	tRCD, Number of Cycles from ACTV Command to READ(A)/WRIT(A) Command These bits specify the minimum number of cycles from issuing of the ACTV command to issuing of the READ(A)/WRIT(A) command. The specification of cycle number becomes this bit setting value +1. 000000 : 1 cycle 000001 : 2 cycles : 111111 : 64 cycles

7.4.7 SDRAM Wait Control Register 01A(SDWCR01A)

SDWCR01A specifies various wait cycles for SDRAM access. Set SDWCR01A before accessing SDRAM. SDWCR01A is initialized to H'00090106 by a power-on reset, but is not initialized and retains the contents in standby mode. The bits should be set before accessing SDRAM, and should not be modified during SDRAM access.

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20 to 16	TRCPB[4:0]	01001	R/W	t_{RC} Number of t_{RC}, RAS Cycles These bits specify the minimum number of cycles the from issuing of the ACTV command to issuing of the REF command or ACTV command for the same bank. The specification of cycle number becomes this bit setting value +1. 00000 : 1cycles 00001 : 2 cycles : 11111 : 32 cycles
15 to 11	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	TRTP[2:0]	001	R/W	tRTP Number of Cycles from READ(A) Command to PALL / PRE Command These bits specify the minimum number of cycles the from issuing of the READ(A) command to issuing of the PALL command or PRE command for the same bank. The specification of cycle number becomes this bit setting value +1. 000 : 1cycles 001 : 2 cycles : 111 : 8 cycles
7 to 4	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	TWTP[3:0]	0110	R/W	tWTP, Number of Cycles from WRIT(A) Command to PALL / PRE Command These bits specify the minimum number of cycles the from issuing of the WRIT(A) command to issuing of the PALL command or PRE command for the same bank. The specification of cycle number becomes this bit setting value +1. 0000 : 1cycles 0001 : 2 cycles : 1111 : 16 cycles

7.4.8 SDRAM Pin Control Register A (SDPCRA)

SDPCRA specifies the SDRAM pin states in standby mode. Set SDPCRA before accessing SDRAM. SDPCRA is initialized to H'0030 0087 by a power-on reset, but is not initialized and retains the contents in standby mode. Before changing the LPCLKFIX, CKEFIXA, and CKEFIXB bit values, confirm that the SDRAM is not being accessed.

bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	CKELV	–	–	–	–	–	–	–
Initial value	0	0	0	0	0	0	0	0	*	0	0	0	0	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	LPCLKFIX	0	R/W	LPCLK/LPCLK_N Pin Control bit 0: Normal oscillation for LPCLK and LPCLK_N after entering self-refresh mode or deep power-down mode (automatically stops when power-down mode is selected) 1: Fixed low-level output from LPCLK and LPCLK_N
23, 22	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	MONCKEA	1	R	LPCKEA Status Monitor 0: External pin LPCKEA is low 1: External pin LPCKEA is high
20	MONCKEB	1	R	LPCKEB Status Monitor 0: External pin LPCKEB is low 1: External pin LPCKEB is high
19, 18	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	CKEFIXA	0	R/W	LPCKEA Pin Fixed Output 0: Normal operation 1: External pin LPCKEA is fixed to low
16	CKEFIXB	0	R/W	LPCKEB Pin Fixed Output 0: Normal operation 1: External pin LPCKEB is fixed to low
15 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	CKELV	*	R/W	LPCKEA/LPCKEB Pin Level Control at Reset In a power-on reset or A4S area reset, the value of the CKEMD10 bit in reset control register 2 (RESCNT2) of the SYSC is sampled and set in this bit. If the chip is started with the CKEMD10 bit cleared to 0, the LPCKEA/LPCKEB pin will initially be at the low level. The LPCKEA/LPCKEB pin can then be driven high by writing 1 to this bit. This bit is automatically cleared when self-refresh mode is entered with both the RFSH and RMODE bits in the SDCRA0 register set to 1. This bit is readable and writable, but the only valid value for writing is 1. When the chip has been started up with the CKEMD10 bit cleared to 0, drive the LPCKEA/LPCKEB pin back to the high level by writing 1 to this bit. 0: The CKEMD10 bit, which sets the initial level of LPCKEA/LPCKEB, was 0 at the time of a power-on reset or A4S area reset, so the LPCKEA/LPCKEB pin is at the low level during the power-on reset or A4S area reset and after the reset has been canceled. 1: The CKEMD10 bit, which sets the initial level of LPCKEA/LPCKEB, was 1 at the time of a power-on reset or A4S area reset, so the LPCKEA/LPCKEB pin is at the high level during the power-on reset or A4S area reset and after the reset has been canceled.
6 to 3	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	-	111	R	Reserved These bits are always read as 1. The write value should always be 1.

Note: * At a power-on reset or A4S area reset, the value of the CKEMD10 bit in reset control register 2 of the SYSC, which sets the initial level of LPCKEA/LPCKEB, is sampled and set in the CKELV bit.

7.4.9 Power-Down Control Register (SDPDCR0A)

SDPDCR0A is used to make settings related to power-down modes.

SDPDCR0A is initialized to H'08000000 by a power-on reset, but is not initialized and retains the contents in standby mode. The values of the bits should not be modified during SDRAM access.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PDWAIT								—	PDOWNSEL	—	—	—	—	—	—

R/W:	R	R	R/W	R/W	R	R/W	R/W	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	PDWAIT	H'08	R/W	These bits specify the number of cycles (ZBCK3) it takes to enter power-down mode. When power-down mode 0 or 1 is selected by the PDWON bits in SDCRA0/SDCRA1, the number of cycles between issuance of the last command to the SDRAM and the CKE pin pulled down to low is specified. When power-down mode 2 is selected by the PDWON bits in SDCRA0/SDCRA1, the number of cycles between issuance of the last command to the SDRAM and issuance of the self-refresh command is specified. H'00 to H'07: Setting prohibited H'08 to H'FF: Enters power-down mode after the specified number of cycles (ZBCK3) has passed
23	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22	PDOWNSEL	0	R/W	Specifies the condition for entering power-down mode. 0: Selects the power-down mode specified by the PDWON bits in SDCRA0 1: Compares the power-down mode specified by the PDWON bits in SDCRA0 with the power-down mode specified by the PDWON bits in SDCRA1, and selects the power-down mode with the smaller access latency
21 to 14	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	RMODESEL0	0	R/W	RMODE Select Bit 0 Specifies the condition for making the SDRAM connected to DRAM area 0 enter self-refresh mode. Whether to AND the RMODE bit in SDCRA0 and the RMODE bit in SDCRA0S is specified. 0: Self-refresh mode is controlled only by the RMODE bit in SDCRA0 1: Self-refresh mode is controlled by ANDing the RMODE bit in SDCRA0 and the RMODE bit in SDCRA0S (self-refresh mode is entered only when both bits are 1)
12	RMODESEL1	0	R/W	RMODE Select Bit 1 Specifies the condition for making the SDRAM connected to DRAM area 1 enter self-refresh mode. Whether to AND the RMODE bit in SDCRA1 and the RMODE bit in SDCRA1S is specified. 0: Self-refresh mode is controlled only by the RMODE bit in SDCRA1 1: Self-refresh mode is controlled by ANDing the RMODE bit in SDCRA1 and the RMODE bit in SDCRA1S (self-refresh mode is entered only when both bits are 1)
11	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	DEEPSEL0	0	R/W	DEEP Select Bit 0 Specifies the condition for making the SDRAM connected to DRAM area 0 enter deep power-down mode. Whether to AND the DEEP bit in SDCRA0 and the DEEP bit in SDCRA0S is specified. 0: Deep power-down mode is controlled only by the DEEP bit in SDCRA0 1: Deep power-down mode is controlled by ANDing the DEEP bit in SDCRA0 and the DEEP bit in SDCRA0S (deep power-down mode is entered only when both bits are 1)
9	DEEPSEL1	0	R/W	DEEP Select Bit 1 Specifies the condition for making the SDRAM connected to DRAM area 1 enter deep power-down mode. Whether to AND the DEEP bit in SDCRA1 and the DEEP bit in SDCRA1S is specified. 0: Deep power-down mode is controlled only by the DEEP bit in SDCRA1 1: Deep power-down mode is controlled by ANDing the DEEP bit in SDCRA1 and the DEEP bit in SDCRA1S (deep power-down mode is entered only when both bits are 1)
8 to 0	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

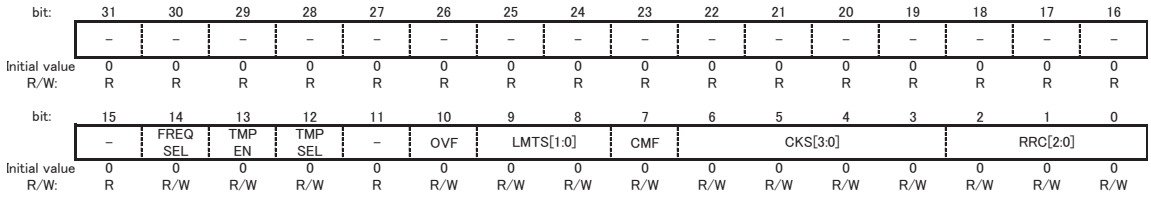
7.4.10 Extend bank mode Register (EBMCRA)

EBMCRA is a register that controls the bank address.

EBMCRA is initialized to H'00000000 by a power-on reset, but is not initialized and retains the contents in standby mode.

The values of the bits should not be modified during SDRAM access.

bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R



bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	BAA[1:0]	
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1 to 0	BAA[1:0]	00	R/W	Bank adders control(DRAM0) BANK(BA2 to 0), ROW, and the COL address position of the memory connected with the DRAM0 area are controlled. 00: BA2,BA1,BA0,ROW,COL 01: BA2,BA1, ROW, BA0,COL 10: BA2, ROW, BA1,BA0,COL 11: ROW, BA2,BA1,BA0,COL [notes] The high rank of an internal address doesn't correspond to the memory bank address when this bit is set excluding 00. Therefore, the bank position in which the memory by partial self-refresh is maintained doesn't become linear. When the BANK bit of SDCR0A is 0(four banks memory), this bit cannot be set to 11.

7.4.11 Refresh Timer Control/Status Register A (RTCSRA)

RTCSRA specifies various items about refresh for SDRAM.

When setting RTCSRA, write H'A55A to the upper 16 bits and the data to be written to the lower 16 bits in longwords.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be H'A55A.
15	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14	FRQSEL	0	R/W	Frequency(ZBCK3) synchronization control bit of auto refreshing 0:OFF 1:ON
13	TMPEN	0	R/W	Temperature Sensor Refresh Control Enable 0: Disabled 1: Enabled
12	TMPSEL	0	R/W	Temperature Sensor Signal Polarity Select 0: Normal temperature when the temperature control signal is 0 and high temperature when it is 1 1: Normal temperature when the temperature control signal is 1 and high temperature when it is 0
11	OVF	0	R/W	Refresh Count Overflow Flag 0: Clearing condition: When 0 is written to the OVF bit after reading out RTCSRA during OVF = 1. 1: Setting condition: When the RFCRA counter overflows, that is, exceeds the count limit value indicated by bits LMTS[1:0].
10	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9, 8	LMTS[1:0]	00	R/W	Refresh Count Overflow Limit Indicate the count limit value to be compared with the refresh count indicated by the RFCRA counter. When the RFCRA counter exceeds the value shown by these bits and overflows, the OVF flag is set. 00: Count limit value is 2048 01: Count limit value is 4096 10: Count limit value is 8192 11: Setting prohibited
7	CMF	0	R/W	Compare Match Flag 0: Clearing condition: When 0 is written to the CMF bit after reading out RTCSRA during CMF = 1. 1: Setting condition: When the condition RTCNTA = RTCORA is satisfied.
6 to 3	CKS[3:0]	0000	R/W	Clock Select Select the clock input to count up RTCNTA. 0000: Stop the counting-up 0001: ZB3ϕ/4 0010: ZB3ϕ/16 0011: ZB3ϕ/64 0100: ZB3ϕ/256 0101: ZB3ϕ/1024 0110: ZB3ϕ/2048 1001: EXTAL1ϕ/2 Other: Setting prohibited
2 to 0	RRC[2:0]	000	R/W	Refresh Count Specify the number of continuous refresh cycles, when the refresh request occurs after the coincidence of the values of RTCNTA and RTCORA. These bits can make the period of occurrence of refresh long. 000: Once 001: Twice 010: 4 times 011: 6 times 100: 8 times 101: Setting prohibited 110: Setting prohibited 111: Setting prohibited

7.4.12 Refresh Timer Counter A (RTCNTA)

RTCNTA is an 8-bit counter that increments using the clock selected by the CKS bits in RTCSRA. When RTCNTA matches RTCORA, RTCNTA is cleared to 0. The value in RTCNTA returns to 0 after counting up to 255.

When setting RTCNTA , write H'A55A00 to the upper 24 bits and the data to be written to the lower eight bits in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be H'A55A00.
7 to 0		H'00	R/W	8-Bit Counter

7.4.13 Refresh Time Constant Register A (RTCORA)

RTCORA is referenced when the TMPEN bit in RTCSRA is 0 or 1 with the SDRAM temperature sensor indicating normal temperature. When the RTCORA value matches the RTCNTA value, the CMF bit in RTCSRA is set to 1 and RTCNTA is cleared to 0.

When the RFSH bit in SDCRA0 is set to 1, a refresh request is issued by this matching signal. This refresh request is retained until the refresh operation is performed. If the refresh request is not processed when the next matching occurs, the previous refresh request is ignored.

When setting RTCORA, write H'A55A00 to the upper 24 bits and the data to be written to the lower eight bits in longwords

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be H'A55A00.
7 to 0	-	H'00	R/W	Counter Upper Limit Value

7.4.14 Refresh Time Constant Register HA (RTCORHA)

RTCORHA is referenced instead of RTCORA when the TMPEN bit in RTCSRA is 1 with the SDRAM temperature sensor indicating high temperature. When the RTCORHA value matches the RTCNTA value, the CMF bit in RTCSRA is set to 1 and RTCNTA is cleared to 0.

When the RFSH bit in SDCRA0 is set to 1, a refresh request is issued by this matching signal. This refresh request is retained until the refresh operation is performed. If the refresh request is not processed when the next matching occurs, the previous refresh request is ignored.

When setting RTCORHA, write H'A55A00 to the upper 24 bits and the data to be written to the lower eight bits in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be H'A55A00.
7 to 0	-	H'00	R/W	Counter Upper Limit Value

7.4.15 Refresh Time Constant Register SA (RTCORSA)

RTCORSA is referenced when the FREQSEL bit in RTCSRA is 1 with ZBCLK3 is slow frequency and when the TMPEN bit in RTCSRA is 0 or 1 with the SDRAM temperature sensor indicating normal temperature. When the RTCORSA value matches the RTCNTA value, the CMF bit in RTCSRA is set to 1 and RTCNTA is cleared to 0.

When the RFSH bit in SDCRA0 is set to 1, a refresh request is issued by this matching signal. This refresh request is retained until the refresh operation is performed. If the refresh request is not processed when the next matching occurs, the previous refresh request is ignored.

When setting RTCORSA, write H'A55A00 to the upper 24 bits and the data to be written to the lower eight bits in longwords

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be H'A55A00.
7 to 0	-	H'00	R/W	Counter Upper Limit Value

7.4.16 Refresh Time Constant Register SHA (RTCORSHA)

RTCORSHA is referenced when the FREQSEL bit in RTCSRA is 1 with ZBCLK3 is high frequency and when the TMPEN bit in RTCSRA is 0 or 1 with the SDRAM temperature sensor indicating normal temperature. When the RTCORSHA value matches the RTCNTA value, the CMF bit in RTCSRA is set to 1 and RTCNTA is cleared to 0.

When the RFSH bit in SDCRA0 is set to 1, a refresh request is issued by this matching signal. This refresh request is retained until the refresh operation is performed. If the refresh request is not processed when the next matching occurs, the previous refresh request is ignored.

When setting RTCORSHA, write H'A55A00 to the upper 24 bits and the data to be written to the lower eight bits in longwords

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be H'A55A00.
7 to 0	-	H'00	R/W	Counter Upper Limit Value

7.4.17 Refresh Count Register A (RFCRA)

RFCRA is a readable/writable 13-bit counter that counts the number of refreshing. The count is incremented each time RTCORA and RTCNTA match. When the count exceeds the count limit value specified by the LMTS bit in RTCSRA, the OVF flag in RTCSRA is set and RFCRA is cleared.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

12 to 0	-	H'0000	R/W	13-Bit Counter

7.4.18 SDRAM Mode Register Addres/Commod Register0/1A (SDMRACR0/1A)

SDMRACR0/1A is 32-bit registers that control the mode register access. SDMRACR0/1A is initialized to H'00000000 by a power-on reset, but is not initialized and retains the contents in standby mode.

SDMRACCR0A is referred to when SDMR.REGSEL=0 and SDMRACCR1A is referred to when SDMR.REGSEL=1.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	RDSEL3[3:0]	All 0	R/W	These bits controls the position where the data read by the MRR command is stored. (R[31:24] of CPU). 1xxx : 8'h00 is returned to R[31:24] of CPU 0000 : LPD[7:0] is returned to R[31:24] of CPU 0001 : LPD[15:8] is returned to R[31:24] of CPU 0010 : LPD[23:16] is returned to R[31:24] of CPU 0011 : LPD[31:24] is returned to R[31:24] of CPU. 0100 : LPD[39:32] is returned to R[31:24] of CPU 0101 : LPD[47:40] is returned to R[31:24] of CPU 0110 : LPD[55:48] is returned to R[31:24] of CPU 0111 : LPD[63:56] is returned to R[31:24] of CPU A set value of this bit depends on the connection of this LSI and LPDDR2-SDRAM.

Bit	Bit Name	Initial Value	R/W	Description
27 to 24	RDSEL2[3:0]	0000	R/W	These bits controls the position where the data read by the MRR command is stored. (R[23:16] of CPU). 1xxx : 8'h00 is returned to R[23:16] of CPU 0000 : LPD[7:0] is returned to R[23:16] of CPU 0001 : LPD[15:8] is returned to R[23:16] of CPU 0010 : LPD[23:16] is returned to R[23:16] of CPU 0011 : LPD[31:24] is returned to R[23:16] of CPU. 0100 : LPD[39:32] is returned to R[23:16] of CPU 0101 : LPD[47:40] is returned to R[23:16] of CPU 0110 : LPD[55:48] is returned to R[23:16] of CPU 0111 : LPD[63:56] is returned to R[23:16] of CPU A set value of this bit depends on the connection of this LSI and LPDDR2-SDRAM.
23 to 20	RDSEL1[3:0]	0000	R/W	These bits controls the position where the data read by the MRR command is stored. (R[15:8] of CPU). 1xxx : 8'h00 is returned to R[15:8] of CPU 0000 : LPD[7:0] is returned to R[15:8] of CPU 0001 : LPD[15:8] is returned to R[15:8] of CPU 0010 : LPD[23:16] is returned to R[15:8] of CPU 0011 : LPD[31:24] is returned to R[15:8] of CPU. 0100 : LPD[39:32] is returned to R[15:8] of CPU 0101 : LPD[47:40] is returned to R[15:8] of CPU 0110 : LPD[55:48] is returned to R[15:8] of CPU 0111 : LPD[63:56] is returned to R[15:8] of CPU A set value of this bit depends on the connection of this LSI and LPDDR2-SDRAM.
19 to 16	RDSEL0[3:0]	0000	R/W	These bits controls the position where the data read by the MRR command is stored. (R[7:0] of CPU). 1xxx : 8'h00 is returned to R[7:0] of CPU 0000 : LPD[7:0] is returned to R[7:0] of CPU 0001 : LPD[15:8] is returned to R[7:0] of CPU 0010 : LPD[23:16] is returned to R[7:0] of CPU 0011 : LPD[31:24] is returned to R[7:0] of CPU. 0100 : LPD[39:32] is returned to R[7:0] of CPU 0101 : LPD[47:40] is returned to R[7:0] of CPU 0110 : LPD[55:48] is returned to R[7:0] of CPU 0111 : LPD[63:56] is returned to R[7:0] of CPU A set value of this bit depends on the connection of this LSI and LPDDR2-SDRAM.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	OP[7:0]	All 0	R/W	Specifies value set in mode register (OP).
7 to 0	MA[7:0]	All 0	R/W	Specifies mode register address (MA).

7.4.19 SDRAM Mode Register Temp Control RegisterA (SDMRTMPCRA)

SDMRTMPCRA controls the automatic refresh rate switch function. SDMRTMPCRA is initialized to H'00000000 by a power-on reset, but is not initialized and retains the contents in standby mode.

bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

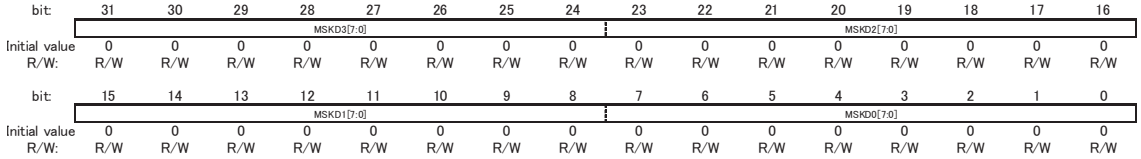
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 20	RDSEL1[3:0]	0000	R/W	When automatic refresh rate switch function is used, the reading data from mode register specified in the MA bit of this register is stored in SDMRTMPMONA. These bits controls the position where the data read by the MRR command is stored. (SDMRTMPMONA[15:8]). These bits controls the reading value from the memory connected with DRAM area 0. 1xxx : 0 is returned to SDMRTMPMONA[15:8]. 0000 : LPD[7:0] is returned to SDMRTMPMONA[15:8] 0001 : LPD[15:8] is returned to SDMRTMPMONA[15:8] 0010 : LPD[23:16] is returned to SDMRTMPMONA[15:8] 0011 : LPD[31:24] is returned to SDMRTMPMONA[15:8] 0100 : LPD[39:32] is returned to SDMRTMPMONA[15:8] 0101 : LPD[47:40] is returned to SDMRTMPMONA[15:8] 0110 : LPD[55:48] is returned to SDMRTMPMONA[15:8] 0111 : LPD[63:56] is returned to SDMRTMPMONA[15:8] A set value of this bit depends on the connection of this LSI and LPDDR2-SDRAM.

Bit	Bit Name	Initial Value	R/W	Description
19 to 16	RDSEL0 [3:0]	0000	R/W	When automatic refresh rate switch function is used, the reading data from mode register specified in the MA bit of this register is stored in SDMRTMPMONA. These bits controls the position where the data read by the MRR command is stored. (SDMRTMPMONA[7:0]). These bits controls the reading value from the memory connected with DRAM area 0. 1xxx : 0 is returned to SDMRTMPMONA[7:0]. 0000 : LPD[7:0] is returned to SDMRTMPMONA[7:0] 0001 : LPD[15:8] is returned to SDMRTMPMONA[7:0] 0010 : LPD[23:16] is returned to SDMRTMPMONA[7:0] 0011 : LPD[31:24] is returned to SDMRTMPMONA[7:0] 0100 : LPD[39:32] is returned to SDMRTMPMONA[7:0] 0101 : LPD[47:40] is returned to SDMRTMPMONA[7:0] 0110 : LPD[55:48] is returned to SDMRTMPMONA[7:0] 0111 : LPD[63:56] is returned to SDMRTMPMONA[7:0] A set value of this bit depends on the connection of this LSI and LPDDR2-SDRAM.
15 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	MA[7:0]	All 0	R/W	Specifies mode register address (MA).

7.4.20 SDRAM Mode Register Temp Monitor Mask RegisterA (SDMRTMPMONA)



SDMRTMPMONA is a register that stores the reading value from a memory internal register when the automatic refresh rate switch function is used. SDMRTMPMONA is initialized to H'00000000 by a power-on reset, but is not initialized and retains the contents in standby mode.

bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MOND3[7:0]								MOND2[7:0]

bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MOND1[7:0]								MOND0[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

7.4.21 SDRAM Mode Register Temp Monitor Mask RegisterA (SDMRTMPMSKA)

SDMRTMPMSKA selects the bit value used from the reading value taken into the SDMRTMPMONA for high temperature/normal temperature judgment, when the automatic refresh rate switch function is used.

SDMRTMPMSKA is initialized to H'00000000 by a power-on reset, but is not initialized and retains the contents in standby mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	MOND3[7:0]	All 0	R/W	The data read according to the setting of the MA bit and the RDSEL3 bit of the SDMRTMPCRA is stored.
23 to 16	MOND2[7:0]	All 0	R/W	The data read according to the setting of the MA bit and the RDSEL2 bit of the SDMRTMPCRA is stored.
15 to 8	MOND1[7:0]	All 0	R/W	The data read according to the setting of the MA bit and the RDSEL1 bit of the SDMRTMPCRA is stored.
7 to 0	MOND0[7:0]	All 0	R/W	The data read according to the setting of the MA bit and the RDSEL0 bit of the SDMRTMPCRA is stored.

7.4.22 SDRAM General-purpose Down Counter A (SDGENCNTA)

SDGENCNTA is a general-purpose down counter. SDGENCNTA can be used when waiting for a fixed time as execute the initialization sequence of the memory. The countdown begins immediately when the value of 1 or more is written in this register. And, it stops when becoming 0. SDGENCNTA is a 32-bit counter that decrements using ZB3D2CLK.

SDGENCNTA is initialized to H'00000000 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CNT[31:0]	All 0	R/W	These bits set the count value. The countdown begins immediately when the value of 1 or more is written in this register. And, it stops when becoming 0 [note] There is a possibility that the SBSC internal clock stops when Power-down mode3 has been selected. Therefore, this counter operation stops, too.

7.4.23 Burst Refresh Count Register A (BSTRCNTA)

BSTRCNTA specifies the number of refresh operations in burst refreshing performed after the SDRAM has been taken out of self-refresh mode. This function should be used when the SDRAM in use requires a specified number of auto-refresh operations after leaving self-refresh mode.

BSTRCNTA is initialized to H'00000000 by a power-on reset, but is not initialized and retains its contents when the chip enters standby mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	SREFCNT [15:0]	H'0000	R/W	Specifies the number of refresh commands (REF) to be inserted after self-refresh mode is exited. The refresh command will be issued the number of times specified in this part of the register.*

Note: * With this register set to 0, burst refreshing will not be performed after self-refresh mode is exited.

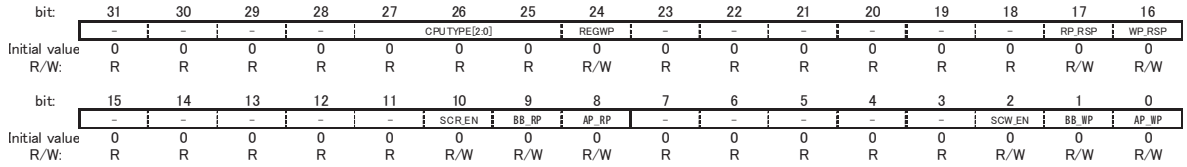
7.4.24 Memory Protected Area Division Register 0 to 2 A (SDPTDIVCR0 to 2A)

SDPTDIVCRA is a 32-bit register that sets the division in the protection location of the external memory space. This register has the register write protection function.

These registers which have the register write protect function cannot be changed by a CPU that does not have the privilege to access.

bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	CPUTYPE[2:0]			REGWP	REGWP2	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R

bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DIVADDR[14:0]															-
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R



Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
27 to 25	CPUTYPE[2:0]	000	R	These bits indicate the CPU that has the privilege to change this register setting. When specifying the CPU that will have the privilege to change this register setting, write 1 to the REGWP bit or the REGWP2 at the same time. When REGWP2 is set 1, no CPUs have the privilege to change this register setting. When REGWP2 is set 0 and REGWP is set 1, the CPU that has written to this register is automatically set as the CPU with the privilege to change this register setting. When B'0 is written to the REGWP bit, these bits are cleared to B'000 and all CPUs are allowed to change this register setting. 000: All CPUs have the privilege to change this register setting 001: Only AP-SH has the privilege to change this register setting 010: Only AP-ARM (non-secure mode) has the privilege to change this register setting 110: Only AP-ARM (secure mode) has the privilege to change this register setting 111: No CPUs has the privilege to change this register setting No values other than the above can be read.
24	REGWP	0	R/W	Register Write Privilege Setting Specifies whether the CPU that has set this register allows other CPUs to change the register setting. After 1 is written to this bit, this bit is automatically cleared to 0. When this bit is set to 1, the CPU that has set this register is set to the CPUTYPE bits. After this register value has been changed, read from this register to confirm through software that this bit has returned to 0 and the CPUTYPE bit setting has been updated. After that, start access to the memory area. A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated. 0: All CPUs can change this register setting 1: Only the CPU that has set this register has the privilege to change this register setting

Bit	Bit Name	Initial Value	R/W	Description
23	REGWP2	0	R/W	Register Write Privilege Setting2 Specifies whether to prohibit the setting change of this register since this register was set. After 1 is written to this bit, this bit is automatically cleared to 0. When this bit is set to 1, the CPU that has set this register is set to the CPUTYPE bits. When REGWP2 is set to 1, 3'b111 is set to CPUTYPE. After this register value has been changed, read from this register to confirm through software that this bit has returned to 0 and the CPUTYPE bit setting has been updated. After that, start access to the memory area. A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated. 0: The privilege that changes this register setting depends on the REGWP bit. 1: No CPU have the privilege that changes this register setting even in power-on reset.
23 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 1	DIVADR	All 0	R/W	The memory protection division address is set. The physical address[31:17] of this LSI is set. [note] SDPTCR0A to 3A register is not set until this register is set. A set value of the DIVADR bit should fill the relation between the following. (SBSC top address (0x40000000) >> 17) < SDPTDIVCR0.DIVADR < SDPTDIVCR1.DIVADR < SDPTDIVCR2.DIVADR < (SBSC top address (0x5FFFFFFF) >> 17) Operation when violating it is outside the guarantee as for the restriction.
0	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.

7.4.25 Memory Protected Area Setting Registers 0A to 3A (SDPTCR0A to SDPTCR3A)

The SDPTCRA registers are 32-bit registers that specify write protection for the external memory spaces.
Protection can be set within 4 Gbits from the start address of each supported external memory space, and the access inhibit to four each area divided by the SDPTDIVCR0Ato2A register is set.
These registers which have the register write protect function cannot be changed by a CPU that does not have the privilege to access.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 25	CPUTYPE [2:0]	000	R	These bits indicate the CPU that has the privilege to change this register setting. When specifying the CPU that will have the privilege to change this register setting, write 1 to the REGWP bit at the same time. The CPU that has written to this register is automatically set as the CPU with the privilege to change this register setting. When B'0 is written to the REGWP bit, these bits are cleared to B'000 and all CPUs are allowed to change this register setting. 000: All CPUs have the privilege to change this register setting 001: Only AP-SH has the privilege to change this register setting 010: Only AP-ARM (non-secure mode) has the privilege to change this register setting 110: Only AP-ARM (secure mode) has the privilege to change this register setting Nothing other than the above will be read.
24	REGWP	0	R/W	Register Write Privilege Setting Specifies whether the CPU that has set this register allows other CPUs to change the register setting. After 1 is written to this bit, this bit is automatically cleared to 0. When this bit is set to 1, the CPU that has set this register is set to the CPUTYPE bits. After this register value has been changed, read from this register to confirm through software that this bit has returned to 0 and the CPUTYPE bit setting has been updated. After that, start access to the memory area. A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated. 0: All CPUs can change this register setting 1: Only the CPU that has set this register has the privilege to change this register setting
23 to 18	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
17	RP_RSP	0	R/W	Specifies the SBSC1 response method used when a read-protected area was accessed for read. A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated. 0: Error response 1: No error response Note:Error response when this bit is 0: When the AP-SH accesses a write-protected area, the SBSC returns an error response but the AP-SH does not initiate exception handling. When the AP-ARM accesses a write-protected area, data is aborted.
16	WP_RSP	0	R/W	Specifies the SBSC1 response method when a write-protected area was accessed for write. A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated. 0: Error response 1: No error response Note:Error response when this bit is 0: When the AP-SH accesses a write-protected area, the SBSC returns an error response but the AP-SH does not initiate exception handling. When the AP-ARM accesses a write-protected area, data is aborted.
15 to 11	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	SCR_EN	0	R/W	Secure area specification. (Read Privilege Setting) A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated . 0: The relevant SBSC area is Non-Secure area 1: The relevant SBSC area is Secure area When this bit is set to1, only the initiator of the secure mode can be read, and it doesn't depend on the setting of the BB_RP/AP_RP bit . When reading from initiators other than the secure mode , all 0 is read.
9	BB_RP	0	R/W	BB Resource* Read Privilege Setting A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated. 0: Has the privilege to read the appropriate SBSC area 1: Does not have the privilege to read the appropriate SBSC area A value read from a read-protected area is always 0.

Bit	Bit Name	Initial Value	R/W	Description
8	AP_RP	0	R/W	AP Resource* Read Privilege Setting A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated. 0: Has the privilege to read the appropriate SBSC area 1: Does not have the privilege to read the appropriate SBSC area A value read from a read-protected area is always 0.
7 to 3	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	SCW_EN	0	R/W	Secure area specification. (Write Privilege Setting) A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated . 0: The relevant SBSC area is Non-Secure area 1: The relevant SBSC area is Secure area When this bit is set to1, Only the initiator of the secure mode can be write, and it doesn't depend on the setting of the BB_WP/AP_WP bits .
1	BB_WP	0	R/W	BB Resource* Write Privilege Setting A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated. 0: Has the privilege to write to the relevant SBSC area 1: Does not have the privilege to write to the relevant SBSC area
0	AP_WP	0	R/W	AP Resource* Write Privilege Setting A write to this register from a CPU that does not have the privilege to change this register setting as shown by the CPUTYPE bits is invalidated. 0: Has the privilege to write to the relevant SBSC area 1: Does not have the privilege to write to the relevant SBSC area

Note: * AP resources: AP-SH, AP-ARM, AP-DMAC (RT-DMAC, SYS-DMAC), AP-JTAG, and others (image IP, USBDMAC)
BB resources: ACMFI

7.4.26 SDRAM Drivability Control Register 0A (SDDRVCR0A)

SDDRVCR0A controls the drivability of the LP bus. SDDRVCR0A is initialized to H'0FFFFFFF at a power-on reset. In standby mode, however, SDDRVCR0A is not initialized and retains its content. Do not change the value of any bit during access to SDRAM.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved
16	-	x	R	Reserved The reading value of this bit is not decided.
15	DLLMON	0	R	The state of DLL oscillation 0: DLL oscillation is not steady. 1: DLL oscillation is steady.
14 to 5	-	All 0	R	Reserved These bits are always read as 0.

Bit	Bit Name	Initial Value	R/W	Description
4	PLLC1MON	1	R	The state of PLLC1. SDCR0A.PLLCNT is 0 : This bit is always read as 1. SDCR0A.PLLCNT is 1 : 0 : PLLC1 OFF 1 : PLLC1 ON
3	-	0		Reserved These bits are always read as 0.
2	-	x	R	Reserved The reading value of this bit is not decided.
1		0		Reserved These bits are always read as 0.
0	DDRMODE	0	R	The state of CPGA.FRQCRD.ZB3D2SEL 0: ZB3D2SEL = 0 (DDR400 mode is selected) 1: ZB3D2SEL = 1 (DDR600 mode is selected)

7.5 Operation

This section describes the SBSC1 operation.

Replace the register names and pin names shown below when reading if not specified otherwise.

- Register names to be replaced when reading

  SBSC1: XXXXA → Notation in section 7.5: XXXX

  Example: SDCR0A (SDRAM control register 0A of SBSC1) → Notation in section 7.5: SDCR0

This LSI supports only 32-bits / 64-bits width SDRAM.

7.5.1 Access Size and Data Alignment

This LSI supports little endian, in which address 0 is the least significant byte (LSByte) in the byte data. Two data bus widths are available; 32 bits and 64 bits in the SBSC1. Data alignment is performed in accordance with the data bus width. This also means that when longword data is read from a 16-bit width SDRAM, the read operation must be done twice. In this LSI, data alignment and conversion of the data length are performed automatically through the interface with SDRAM.

Tables 7.5 to 7.7 show the relationship between the SDRAM data width and access unit.

Table 7.5 16-Bit External Bus Access and Data Alignment

Operation		Data bus				Strobe Signals

7.5.2 LPDDR2-SDRAM (S4 Standard) Interface

(1) LPDDR2-SDRAM (S4 Standard) Interface

The LPDDR2-S4 device that can be connected to this LSI is a product that has 11/12/13/14/15 bits of row address, 8/9/10/11 bits of column address, and 4/8 banks, and conforms to the JEDEC standard.

The control signals for direct connection of LPDDR2-S4 are LPCLK, /LPCLK, $\overline{\text{LPCSA}}$, LPCA, LPCKEA, and LPCKEB. Signals, except for LPCKEA and LPCKEB, are only valid while $\overline{\text{LPCSA}}$ or $\overline{\text{LPCSB}}$ is asserted. The data bus width of the area that is connected to LPDDR2-S4 can be set as 16 bits, 32 bits, or 64 bits. Depending on the data bus width, part of or all of LPDQM7 to LPDQM0, LPDQS7 to LPDQS0, /LPDQS7 to /LPDQS0, and LPD64 to LPD0 are used.

Commands for LPDDR2-S4 can be specified by the LPCA, LPCKEA, and LPCKEB signals. This LSI issues the following commands to the LPDDR2-S4.

No operation (NOP)

All banks auto-refresh (REFAB)

Self-refresh (SELF)

Deep power-down (DEEP)

All banks precharge (PALL)

Specified bank precharge (PRE)

Bank active (ACTV)

Read (READ)

Read with precharge (READA)

Write (WRIT)

Write with precharge (WRITA)

Write to mode register (MRW)

Read from mode register (MRR)

Table 7.8 Commands for LPDDR2-S4

Command	Description	LPCKE[n]		LPCS[n]	LPCA0	LPCA1	LPCA2	LPCA3	LPCA4	LPCA5	LPCA6	LPCA7	LPCA8	LPCA9	LPCLK EDGE

The byte to be accessed is specified by LPDQM7 to LPDQM0. Read or write access is performed for a byte whose corresponding LPDQMn is low. For details on the relationship between LPDQM7 to LPDQM0 and the byte to be accessed, refer to section 7.5.1, Access Size and Data Alignment.

Figures 7.2 to 74 show connection examples through the 16-bit, 32-bit, and 64-bit buses, respectively.

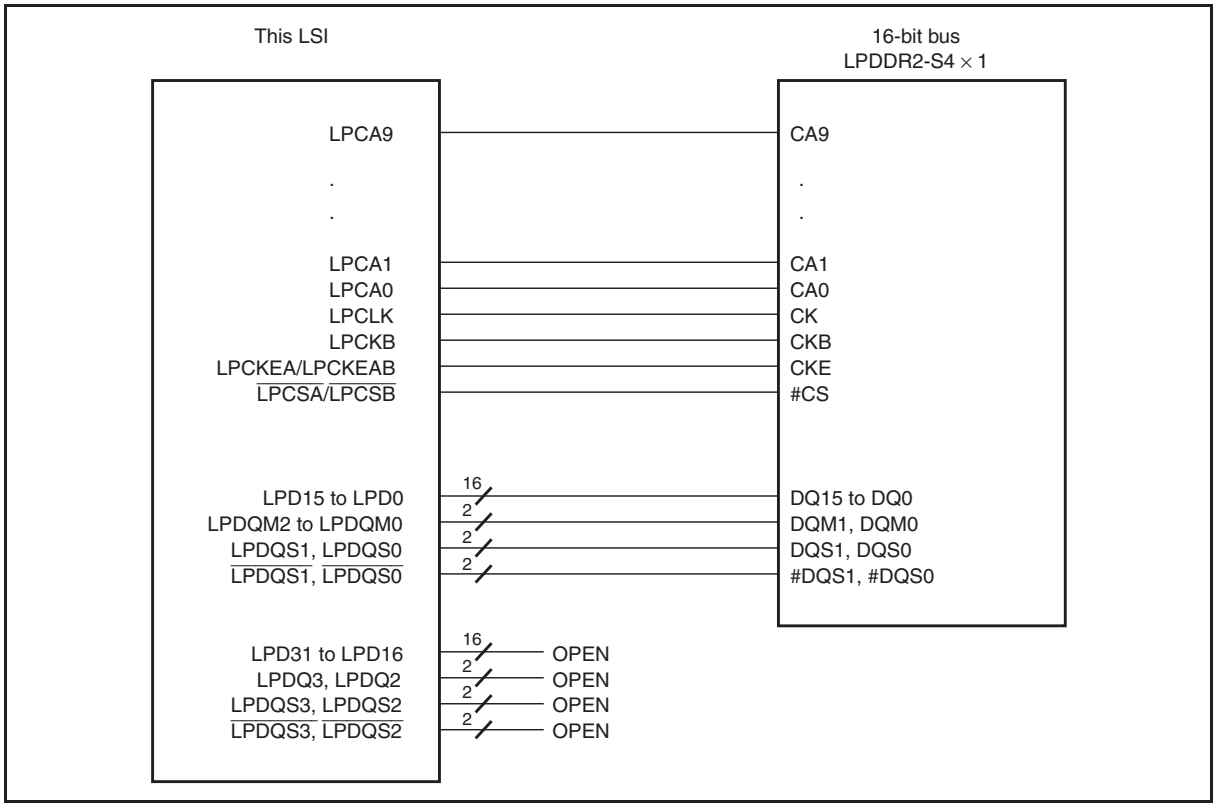

Figure 7.2 Example of Connection with LPDDR2-S4 (16-Bit Data Bus)

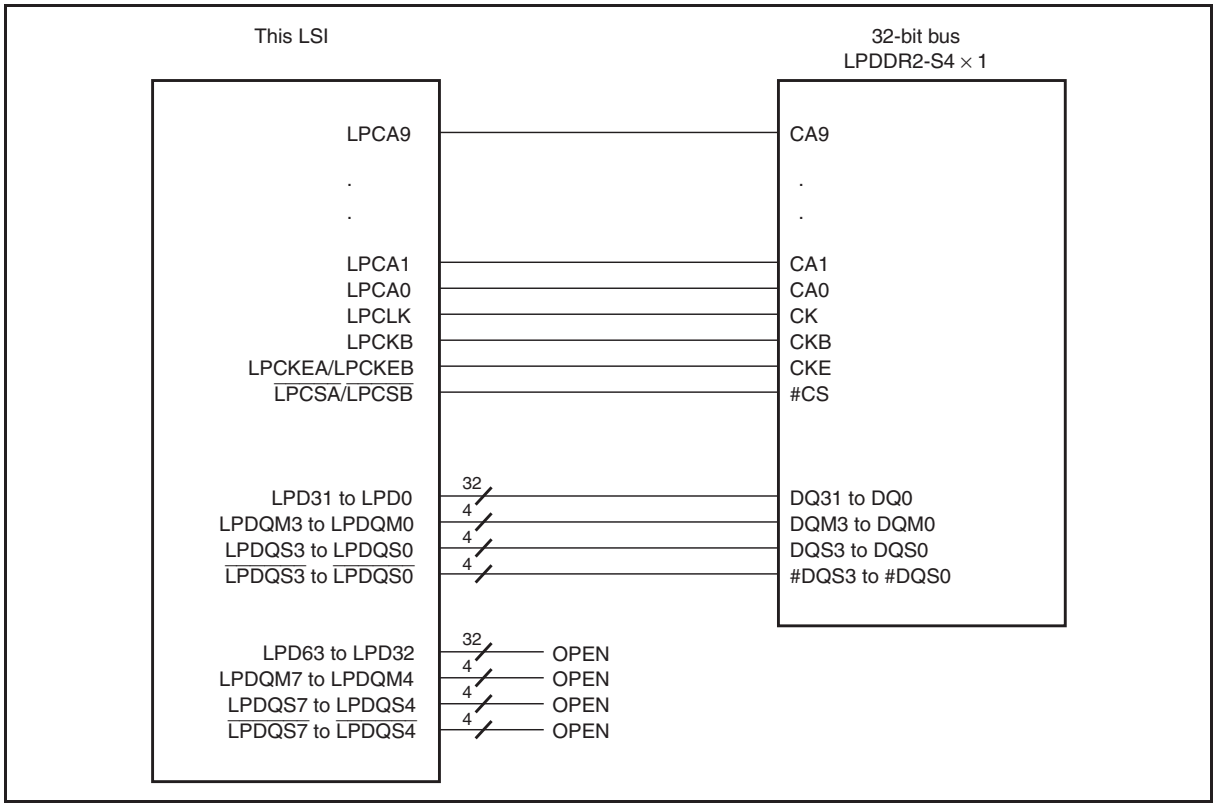

Figure 7.3 Example of Connection with LPDDR2-S4 (32-Bit Data Bus)

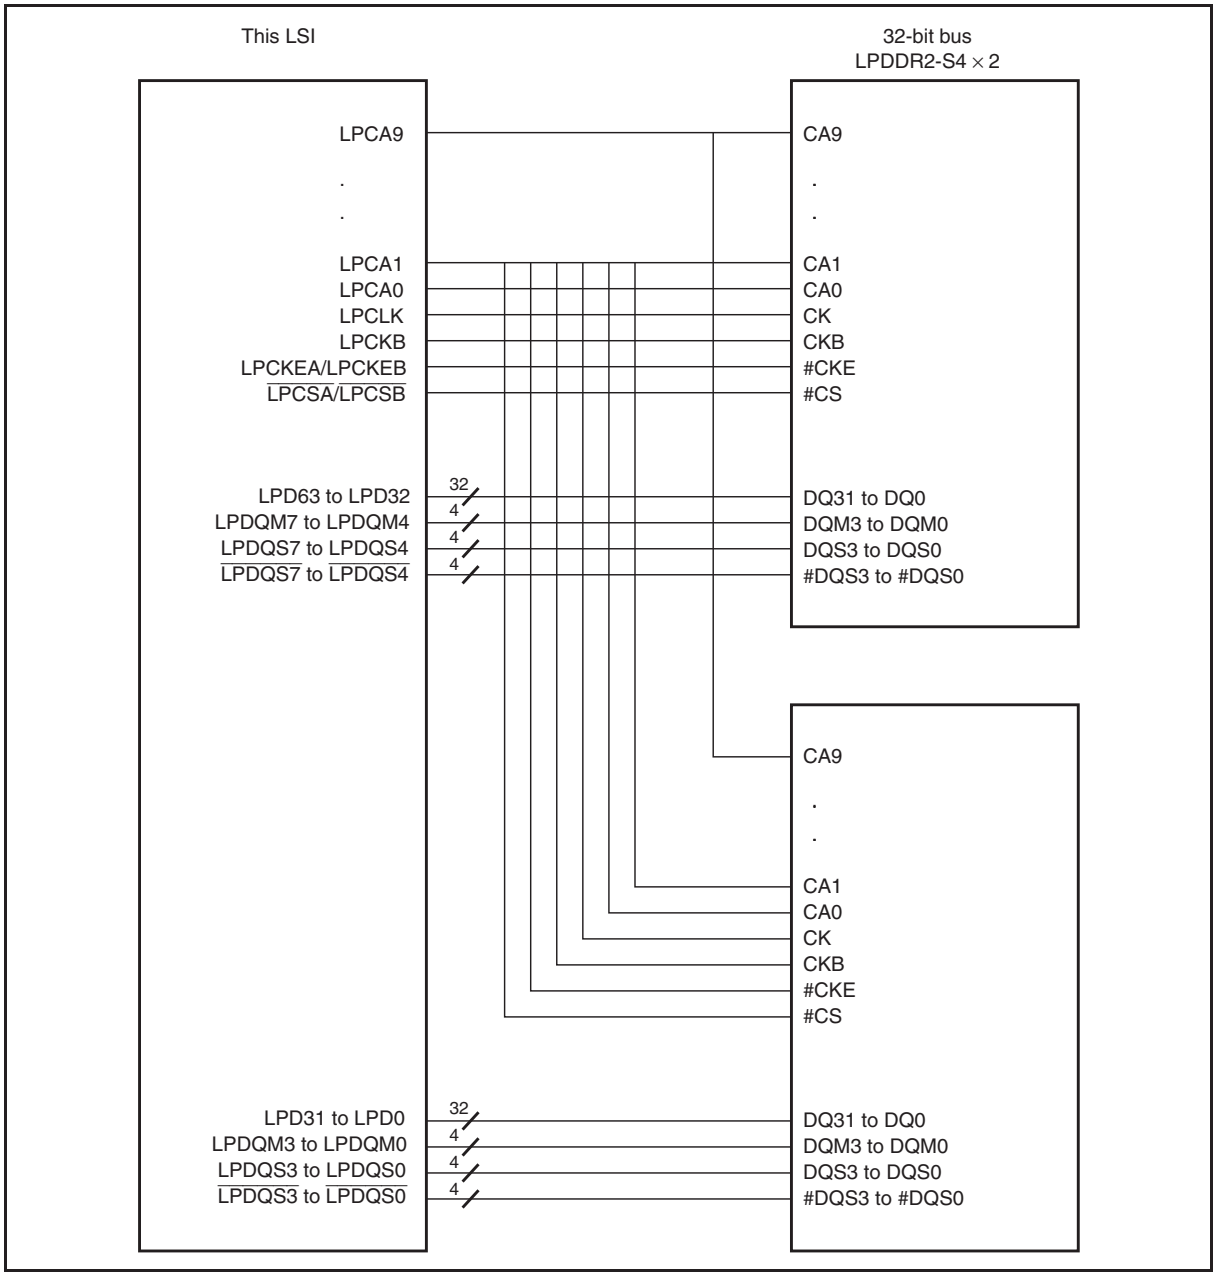

Figure 7.4 Example of Connection with LPDDR2-S4 (64-Bit Data Bus)

(2) Address Multiplexing

Address multiplexing is specified so that the LPDDR2-S4 device can be connected without external address multiplexing circuitry according to the settings of the SZ, BANK, ROW, and COL bits in SDCR0 and SDCR1 and the BAA bits in EBMCR. Tables 7.16 to 7.19 show the relationship between the settings of the SZ, BANK, ROW, COL and BAA bits, the LPDDR2-S4 memory address, and the physical address (Ax) in this LSI.

Connect the CA0 pin of the LPDDR2-S4 to the LPCA0 pin of this LSI, then the CA1 pin to the LPCA1 pin, and so on,

regardless of the data bus width.

(3) LPDDR2-S4 Internal Register Access Function

The LPDDR2-S4 device has registers (MR registers) in memory. The SBSC provides an interface for accessing these MR registers. Use the SDMR access function to access the MR registers.

a) Writing to MR Registers

An MR register can be written to through longword or byte write to the 32-bit address (32 {MRSKET11 to MRSKET0, REF_SEL, PADINI, AREASELEN, AREASEL, PALLMSK, 4'b0, TMRWSEL, 8'b0}} shown in table 7.20. According to each bit setting through the write access, an MRW command is issued to the LPDDR2-S4 device and the MR register is written to. The MR register address (MA) and setting data (OP) should be written to SDMRACR0 or SDMRACR1 in advance.

Table 7.13 Writing to MR Register

Bit	Bit Name	Bit Count	Description
31 to 20	MRSKET11 to MRSKET0	12	When setting SBSC1: H'FE5
19	REF_SEL	1	0: Refreshing is not inserted between the PALL and MRW/MRR commands 1: Refreshing is inserted between the PALL and MRW/MRR commands (two times)
18	PADINI	1	Specifies whether to initialize the PAD. 0: An MR register write (MRW) command is issued 1: PAD is initialized When SDMR is written to with this bit set to 1, the MRW command is not issued. To perform a dummy read from the LPDDR2-S4 device to initialize the PAD, the LPDDR2-S4 device should be reset in advance. The PAD should be initialized only after step 9) described in section 7.5.2 (4), Power-On Sequence.
17	AREASELEN	1	MRW Command Issue Area Select Enable For SBSC1: 0: MRW command is issued for both DRAM areas 0 and 1 1: MRW command is issued for the DRAM area selected through the AREASEL bit
16	AREASEL	1	MRW Command Issue Area Select For SBSC1: 0: MRW command is issued for DRAM area 0 1: MRW command is issued for DRAM area 1

Bit	Bit Name	Bit Count	Description
15	REGSEL	1	Specifies the address (MA) and data (OP) for the MRW command to be issued. 0: MA and OP of SDMRACR0 are specified 1: MA and OP of SDMRACR1 are specified
14	PALLMSK	1	PALL Command Issue Select before MRW Command 0: Before the MRW command is issued, the PALL command is issued (PALL -> MRW) 1: Only the MRW command is issued Note: When issuing a RESET command to initialize the LPDDR2, set this bit to 1. In other cases, clear this bit to 0. When setting this bit to 1, be sure to clear the REF_SEL and PADINI bits to 0.
13 to 10	—	2	Reserved These bits should always be 0.
9 to 8	TMRWSEL	2	TMRW Specification Setting These bits should be used only when selecting the tMRW bits that specify the minimum number of cycles between an MRW command for writing to an MR register and the next valid command. These bits are provided assuming the case where the ZQ calibration function of the LPDDR2 memory is used. A different wait cycle setting should be specified in each of the tMRW1 to tMRW3 bits separately for each ZQ calibration type and the register bits to be referenced should be switched through these TMRWSEL bits according to the target ZQ calibration type. 00: tMRW bits in SDWCRC0 are referenced 01: tMRW1 bits in SDWCRC2 are referenced 10: tMRW2 bits in SDWCRC2 are referenced 11: tMRW3 bits in SDWCRC2 are referenced
7 to 0	—	1	Reserved These bits should always be 0.

The following shows some examples of command processing.

To issue a reset command for the LPDDR2-S4 device in DRAM areas 0 and 1 (no PALL command):

1) Write 8'h3F to the MA bits in SDMRACR0.
2) Execute a byte or longword write to address 0xFE500000 (REF_SEL = 0, PADINI = 0, AREASELEN = 0, AREASEL = x, REFSEL = 0, ALLMSK = 1).

To write 0x42 to MR1 of the LPDDR2-S4 device in DRAM area 3
(no refreshing is inserted between PALL and MRW commands and the PAD is not initialized):

1) Write 0x01 to the MA bits and 0x42 to the OP bits in SDMRACR1.
2) Execute a byte or longword write to address 0xFB538000 (REF_SEL = 0, PADINI = 0, AREASELEN = 1, AREASEL = 1, REFSEL = 1, PALLMSK = 0).

To write 0x03 to MR2 of the LPDDR2-S4 device in DRAM areas 2 and 3
(refreshing is inserted between PALL and MRW commands and the PAD is initialized at the same time):

1) Write 0x02 to the MA bits and 0x03 to the OP bits in SDMRACR1.
2) Execute a byte or longword write to address 0xFB5C8000 (REF_SEL = 1, PADINI = 1, AREASELEN = 0, AREASEL = 0, REFSEL = 1, PALLMSK = 0).

When an MRW issue request is generated, the SBSC waits for the end of precharging that is in progress in any bank, and then issues a PALL command to move all banks from active state to precharged state. After that, the SBSC inserts a wait for the number of cycles specified through the TRPAB bits and then issues an MRW command or an REFA command. When the REF_SEL bit is 1, the wait cycles specified through the TRFC bits are inserted after the last REFA command and then an MRW command is issued. The period between the MRW command and the next valid command is determined by the TMRW bit setting.

Figure 7.5 is a waveform when REF_SEL = 0 and PALLMSK = 0, figure 7.6 is a waveform when REF_SEL = 1 and PALLMSK = 0, and figure 7.7 is a waveform when REF_SEL = 0 and PALLMSK = 1.

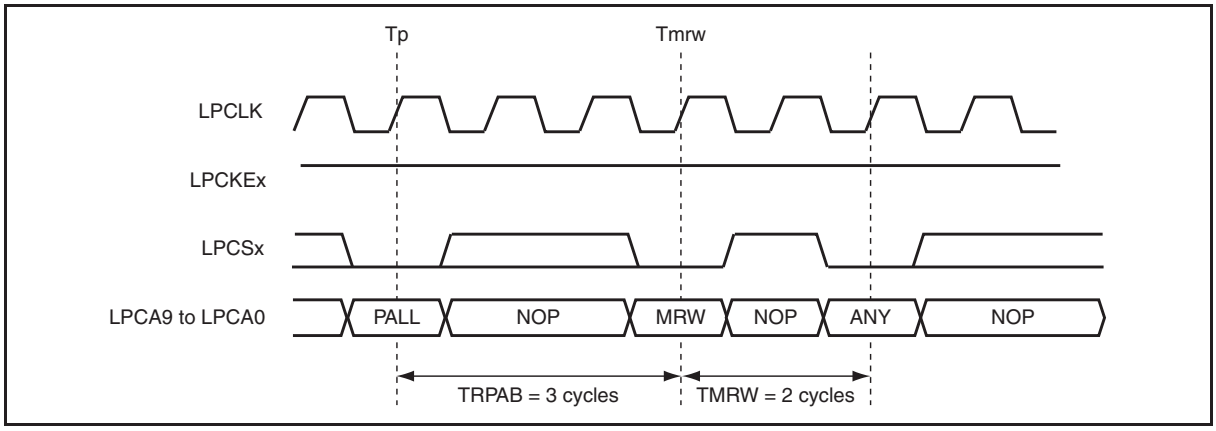

Figure 7.5 Timing Chart of MRW Command Issuing (REF_SEL = 0 and PALLMSK = 0)

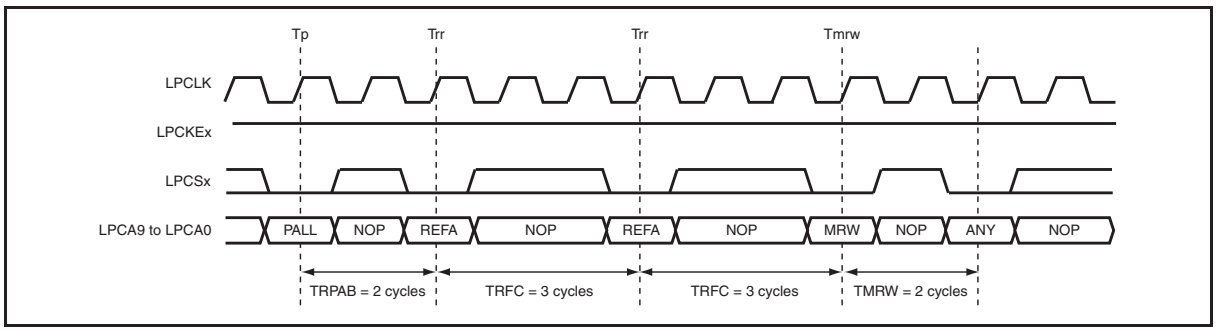

Figure 7.6 Timing Chart of MRW Command Issuing (REF_SEL = 1 and PALLMSK = 0)

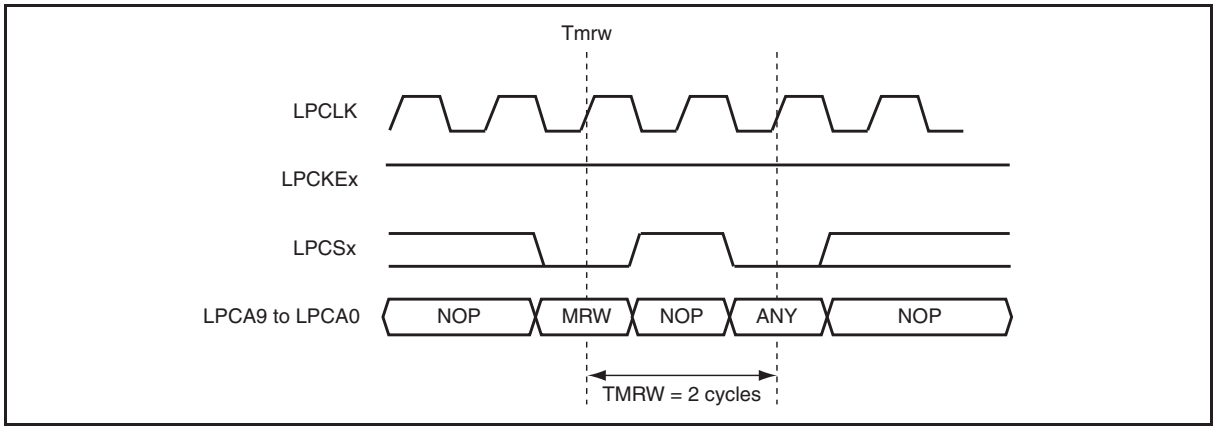

Figure 7.7 Timing Chart of MRW Command Issuing (REF_SEL = 0 and PALLMSK = 1)

b) Reading from MR Registers

An MR register can be read through longword read from the 32-bit address (32{MRSKET11 to MRSKET0, 3'b000, AREASEL, REGSEL, 15'b0}) shown in table 7.14. According to each bit setting through the read access, an

MRR command is issued to the MR register in the LPDDR2-S4 device. The MR register address (MA) and setting data (OP) should be written to SDMRACR0 or SDMRACR1 in advance.

Table 7.14 Reading from MR Register

Bit	Bit Name	Bit Count	Description
31 to 20	MRSKET11 to MRSKET0	12	When setting SBSC1: H'FE5
19 to 17	—	3	These bits should be 0 when the MR register is read.
16	AREASEL	1	MRR Command Issue Area Select For SBSC1: 0: MRR command is issued for DRAM area 0 to read the MR register 1: MRR command is issued for DRAM area 1 to read the MR register
15	REGSEL	1	Specifies the address (MA) and data (OP) for MRW command to be issued. 0: MA and OP of SDMRACR0 are specified 1: MA and OP of SDMRACR1 are specified
14 to 0	—	15	Reserved These bits should always be 0.

Figure 7.8 shows a timing chart of MRR command issuing. When an MRR command issue request is generated, the SBSC waits for the end of precharging that is in progress in any bank, and then issues a PALL command to move all banks from active state to precharged state. After that, the SBSC inserts a wait for the number of cycles specified through the TRPAB bits and then issues an MRR command. The period between the MRR command and data reading from the LPD bus is determined by the RL bit setting. The period between the MRR command and the next valid command is determined by the TMRR bit setting.

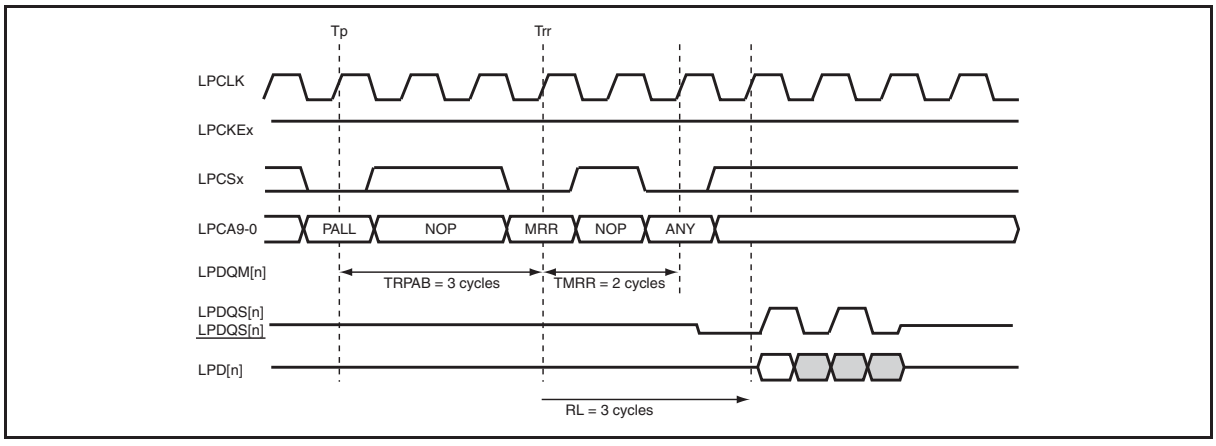

Figure 7.8 Timing Chart of MRR Command Issuing

The LPDDR2-S4 device outputs data read from a register to DQ7 to DQ0. When two x32-bit LPDDR2-S4 devices are

used with 64-bit bus width, data is read from the first LPDDR2-S4 device through LPD7 to LPD0 and from the second LPDDR2-S4 device through LPD39 to LPD32. As the bit position on the LPD bus to be read depends on the memory configuration, the correspondence between the LPD bus bits and the 32-bit read value is specified through the RDSEL3 to RDSEL0 bits in SDMRACR0 or SDMRACR1.

For example, to store 0 in general register bits R[31:16] in the CPU, the value read from the first LPDDR2-S4 device (lower data) in R[7:0], and the value read from the second LPDDR2-S4 device (upper data) in R[15:8], specify RDSEL3 = 0x8, RDSEL2 = 0x8, RDSEL1 = 0x4, and RDSEL0 =0x0 in SDMRACR0 or SDMRACR1. Figure 7.9 shows a schematic diagram of this example.

Table 7.15 shows the correspondence between the SBSC bus width, SDMRACR setting for each memory configuration, and the value read from the CPU when the connected memory provides an MR register read function conforming to the JEDEC LPDDR2-S4 device standard.

Table 7.15 SDMRACR Setting and Value Read from CPU

Memory Configuration			SDMRACR					Value Read from CPU			
Bus Width	DRAM0	DRAM1	RDSEL0	RDSEL1	RDSEL2	RDSEL3	Register Value	R[31:24]	R[23:16]	R[15:8]	R[7:0]
64	64 bits x 1	None	0x0	0x8	0x8	0x8	0x8880XXXX	0x00	0x00	0x00	Valid
	None	64 bits x 1	0x0	0x8	0x8	0x8	0x8880XXXX	0x00	0x00	0x00	Valid
	32 bits x 2	None	0x0	0x4	0x8	0x8	0x8840XXXX	0x00	0x00	Valid	Valid
	None	32 bits x 2	0x0	0x4	0x8	0x8	0x8840XXXX	0x00	0x00	Valid	Valid
32	32 bits x 1	32 bits x 1	0x0	0x8	0x8	0x8	0x8880XXXX	0x00	0x00	0x00	Valid

(4) Power-On Sequence

To use the LPDDR2-S4 device, reset and mode setting must first be done for the LPDDR2-S4 device after powering on. The following shows an example of this procedure. For details of settings, refer to the data sheet of the target LPDDR2-S4 device.

1) Keep CKE low until power is supplied to all LPDDR2 devices.
   (Refer to the power-supply sequence in the data sheet of the LPDDR2-S4 device.)
2) Set the SBSC1 operating frequency (ZB3ϕ) to a value from 10 MHz to 55 MHz.
3) Enable DLL oscillation in the DDRPHY.
   This setting is unnecessary, if only DDR400 mode is used.
   3.1) Set the DLL operating frequency (DDRPCLKϕ) to a value 300MHz.
   3.2) Set the DLLCYC bit in DLLCNT0A to 0x01AD.
   3.3) Set the DLLMODE[1:0] bit in DLLCNT0A to b01 (DLL oscillation ON always).

4) After specifying the frequency, wait at least 100 ns.
   Insert wait cycles by software, or write the number of cycles corresponding to 100 ns at ZB3ϕ to SDGENCNT and wait until this number becomes 0.
5) Make necessary settings in SBSC1 control registers according to the target LPDDR2 device. Do not specify auto-refreshing, power-down mode, or self-refreshing at this time.
   Note: When the LPDDR2 device to be connected may be changed:
   - Among the memory parameters set in SDCR, the SDSZ, BANK, ROW, and COL bit settings do not need to match the actually-connected memory for a correct power-on sequence.
   - For each wait parameter, the longest wait cycles among the memory devices that may be connected should be specified.
6) Set the CKELV bit in SDPCR to 1 to drive CKE high.
   Before proceeding to the next step, read the CKELV bit to confirm that the bit is set to 1.
7) Wait at least 200 μs by software.
   Insert wait cycles by software, or write the number of cycles corresponding to 200 μs at ZB3ϕ or ZB3Sϕ to SDGENCNT and wait until this number becomes 0.
8) Issue a RESET command to the LPDDR2 device; that is,
   8.1) Write SDMRACRA0 = 0x0000003F.
   8.2) Access SDMR (byte or longword write to address 0xFE500000 consisting of REF_SEL = 0, PADINI = 0, AREALSEEN = 0, AREASEL = 0, REGSEL = 0, and PALLMSK = 1).
9) Wait at least 10 μs(tINIT5) after the end of step 8) before proceeding to step 10).
   Insert wait cycles by software, or write the number of cycles corresponding to 1 μs at ZB3ϕ to SDGENCNT and wait until this number becomes 0.
10) An MRW ZS lnitialzation Calibration commond is issued to the LPDDR2.
   10.1) Write SDMRACRA0 = 0x0000FF0A.
   10.2) Access SDMR (byte or longword write to address 0xFE500000 consisting of REF_SEL = 0, PADINI = 0, AREALSEEN = 0, AREASEL = 0, REGSEL = 0, and PALLMSK = 1).
11) Wait at least 1 μs(tZQINIT) after the end of step 10) before proceeding to step 12).
   Insert wait cycles by software, or write the number of cycles corresponding to 1 μs at ZB3ϕ to SDGENCNT and wait until this number becomes 0.
12) Specify the operating mode through MR registers in the LPDDR2. The following shows an example of MR1/2 setting.
   12.1) Write SDMRACRA0 = 0x00002201 (nWR = 3'b001, WC = 1'b0, BT = 1'b0, and BL = 3'b010)
   12.2) Access SDMR (byte or longword write to address 0xFE500000 consisting of REF_SEL = 0, PADINI = 0, AREALSEEN = 0, AREASEL = x, REGSEL = 0, and PALLMSK = 0).
   12.3) Write SDMRACRA0 = 0x00000302(DDR600mode) or 0x00000102(DDR400mode).
   (RL&WL=RL3/WL1(DDR400mode)orRL5/WL2(DDR600mode)
   12.4) Access SDMR (byte or longword write to address 0xFE500000 consisting of REF_SEL = 0, PADINI = 0, AREALSEEN = 0, AREASEL = x, REGSEL = 0, and PALLMSK = 0).
13) Initialize the DDR I/F section of this LSI.
   Access SDMR (byte or longword write to address 0xFE5C0000 consisting of REF_SEL = 1, PADINI = 1, AREALSEEN = 0, AREASEL = x, REGSEL = 0, and PALLMSK = 0).
14) Initialization of the LPDDR2 device is completed.
15) Specify the following through SBSC registers.
   15.1) Temperature sensor control
   15.2) Auto-refreshing control
   15.3) Memory protection settings
   15.4) Power-down mode control

16) Select DLL mode.
This setting is unnecessary, if only DDR400 mode is used.

17) Set the SBSC1 operating frequency to a desired value.

(5) Refreshing

The SBSC has a function for controlling LPDDR2-S4 refreshing. Auto-refreshing can be performed by clearing the RMODE bit to 0 and setting the RFSH bit to 1 in SDCR0. A continuous refreshing can be performed by setting the RRC bits in RTCSR. If SDR-SDRAM is not accessed for a long period, self-refresh mode, in which power consumption is low, can be activated by setting both the RMODE bit and RFSH bit to 1.

(a) Auto-Refreshing

The number of times of refreshing set by the RRC bits in RTCSR is performed at intervals determined by the input clock selected by the CKS bits in RTCSR and the value set in RTCOR. Register settings should be made so as to satisfy the refresh interval stipulation for the LPDDR2-S4 used. First make the settings for RTCOR, RTCNT, and the RMODE and RFSH bits in SDCR0, then make the settings for the CKS and RRC bits in RTCSR. When the input clock is selected by the CKS bits, RTCNT starts counting up from the value at that time. The RTCNT value is constantly compared with the RTCOR value, and when the two values become the same, a refresh request is generated and auto-refreshing is performed for the number of times specified by the RRC bits. At the same time, RTCNT is cleared to 0 and restarts count-up.

Figure 7.10 shows the auto-refresh cycle timing. After starting auto-refreshing, the PALL command is issued in the Tp cycle to move all banks from the active state to the precharged state after completion of precharging that is in progress in any bank. The REFA command is then issued in the Trr cycle after inserting idle cycles of which number is specified by the TRP bits. A new command is not issued for the duration of the number of cycles specified by the TRFC bits after the Trr cycle. The TRFC bits must be set so as to satisfy the LPDDR2-S4 refreshing cycle time stipulation (t_{RFC}). An NOP cycle is inserted between the Tp cycle and Trr cycle when the value set in the TRP bits is two or more cycles.

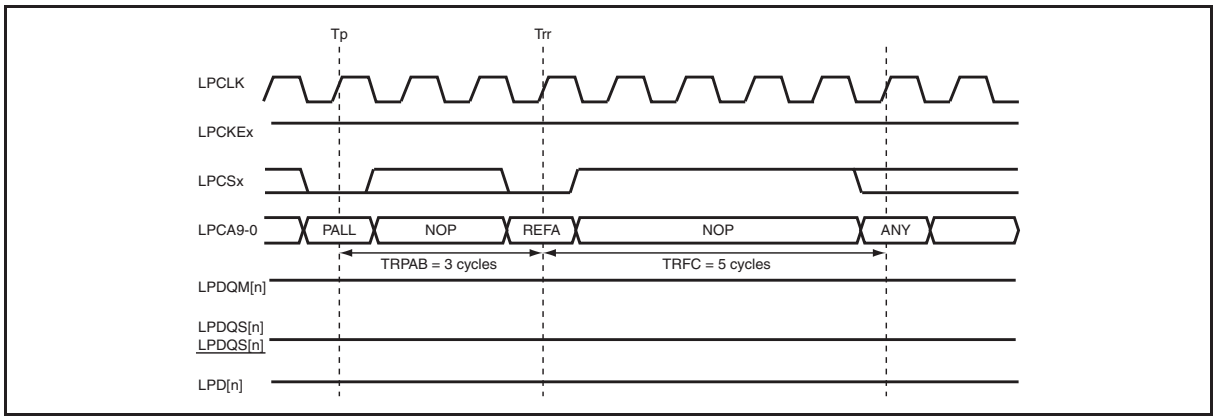

Figure 7.10 Auto-Refresh Timing (SDCR0.RMODE = 0, RFSH = 1, TRPAB= 2 (3 cycles), TRFC = 4 (5 cycles))

(b) Automatic Switching of Auto-Refresh Rate

The SBSC has a function for selecting one of four RTCORx registers to be referenced to determine the refresh rate

according to the SBSC operation clock frequency (ZB3φ) and the LPDDR2-S4 internal temperature. Four RTCOR registers are used for the following purposes.

RTCOR: Referenced when the SBSC clock is set to high-speed clock mode and the temperature sensor indicates a normal temperature

RTCORH: Referenced when the SBSC clock is set to high-speed clock mode and the temperature sensor indicates a high temperature

RTCOSR: Referenced when the SBSC clock is set to low-speed clock mode and the temperature sensor indicates a normal temperature

RTCOSRH: Referenced when the SBSC clock is set to low-speed clock mode and the temperature sensor indicates a high temperature

The frequency synchronization control function is enabled by setting the FRQSEL bit to 1 in RTCSR. There are two clock modes, high-speed mode and low-speed clock mode, and the mode is determined by the division ratio of the SBSC operation clock frequency specified in the CPG and the PLLC1 status. Table 7.16 shows the clock mode conditions. When FRQSEL = 0, RTCOR or RTCORH (selected according to the temperature) is referenced. When FRQSEL = 1, RTCOR or RTCORH (selected according to the temperature) is referenced in high-speed clock mode, and RTCORS or RTCORSH (selected according to the temperature) is referenced in low-speed clock mode.

Table 7.16 SBSC Operation Clock Modes

SBSC1	Mode	Condition
SBSC1	High-speed clock mode	ZB3φ = 1/6 division (or higher) and PLLC1 is enabled
	Low-speed clock mode	ZB3φ = 1/8 division (or lower) or PLLC1 is disabled

The following describes the refresh rate switching control function according to the LPDDR2-S4 internal temperature.

This function is enabled by setting the TMPEN bit to 1 in RTCSR. When TMPEN = 0, RTCOR or RTCORS (selected according to the operation clock mode) is referenced. When TMPEN = 1, RTCORH or RTCORSH (selected according to the operation clock mode) is referenced at a high temperature, and RTCOR or RTCORS (selected according to the operation clock mode) is referenced at a normal temperature.

The LPDDR2-S4 internal temperature is indicated in the Device Temperature register (MR4) in the LPDDR2-S4. The SBSC reads the temperature from MR4 with the same timing as auto-refreshing. The SBSC then stores the read data in SDMRTMPMON, masks the data with the value specified in SDMRTMPMSK in bit units, and ORs all bits of the obtained data into a value to determine whether the LPDDR2-S4 internal temperature is normal (all-ORed value is 0) or high (all-ORed value is 1).

The temperature synchronization control function should be specified as follows.

1) Specify in the MA bits in SDMRTMPCR the address of the register that indicates the LPDDR2-S4 internal temperature.
2) Specify in the RDSEL0 and RDSEL1 bits in SDMRTMPCR the LPD bus bits where the MR register value read from the LPDDR2-S4 connected to DRAM area 0 or 2 is output. When no LPDDR2-S4 is connected to DRAM area 0 or 2, set both RDSEL0 and RDSEL1 to 0x8, or when only one memory is connected to either DRAM area 0 or 2, set RDSEL1 to 0x8, so that 0x00 is always stored in the corresponding bits.
3) Likewise, specify in the RDSEL2 and RDSEL3 bits in SDMRTMPCR the LPD bus bits where the MR register value read from the LPDDR2-S4 connected to DRAM area 1 or 3 is output. When no LPDDR2-S4 is connected to DRAM area 1 or 3, set both RDSEL2 and RDSEL3 to 0x8, or when only one memory is connected to either DRAM area 1 or 3, set RDSEL1 to 0x8, so that 0x00 is always stored in the corresponding bits. SDMRTMPMSK is a register that selects the bits used to determine whether the temperature is high or normal. Only the bits used for judgment should be set to 1.

Figure 7.11 gives an overview of sample setting and operation when an LPDDR2-S4 device with a 32-bit bus width is connected to DRAM area 2 through the LPB bus and an LPDDR2-S4 device with a 32-bit bus width is connected to DRAM area 3.

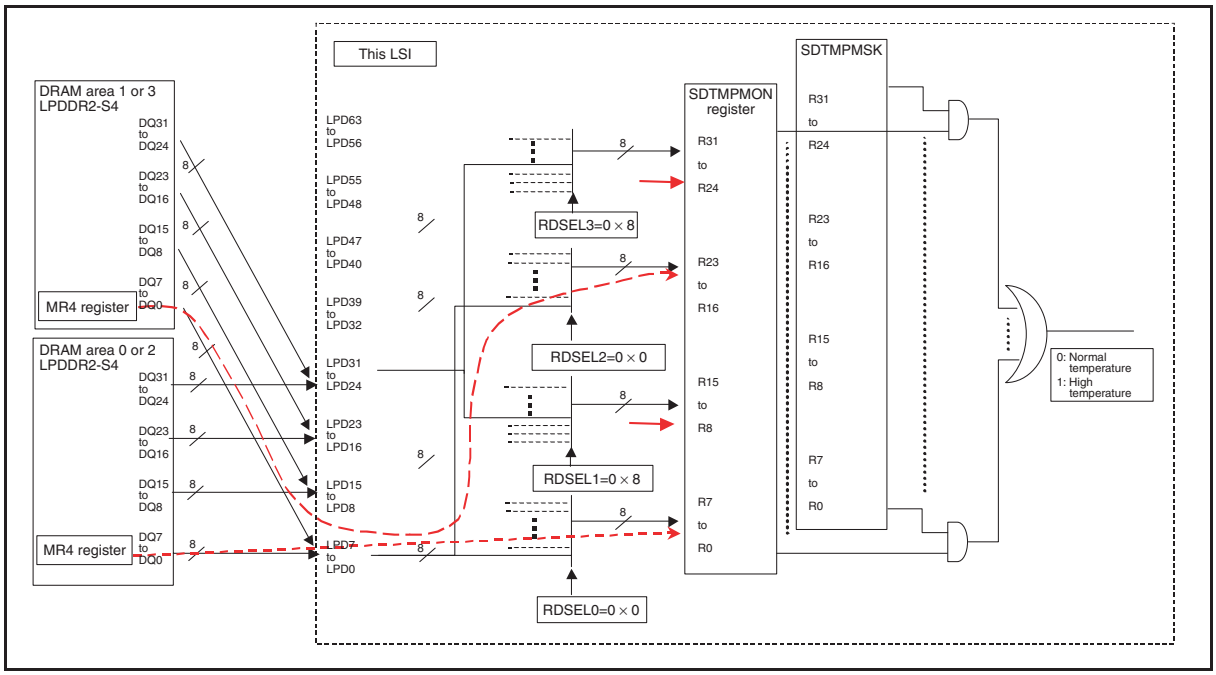

Figure 7.11 Temperature Control Operation Overview

Table 7.24 shows examples of SDTMPCR and SDTMPMSK register settings corresponding to the SBSC bus width and

memory configuration for the Device Temperature register (MR4) conforming to the JEDEC LPDDR2-S4 device standard.

Table 7.17 SDTMPCR and SDTMPMSK Setting Examples

Memory Configuration			SDMRTMPCR						SDMRTMPMSK
Bus Width	DRAM0	DRAM1	MA	RDSEL0	RDSEL1	RDSEL2	RDSEL3	Register Value	Register Value

	None	16 bits x 1	0x04	0x8	0x8	0x0	0x8	0x80880004	0x00040000

(c) Self-Refreshing

Self-refresh mode is a kind of standby mode in which the refresh timing and refresh addresses are generated within the LPDDR2-S4. Self-refreshing is activated by setting both the RMODE bit and RFSH bit in SDCR0 to 1. After starting self-refreshing, the PALL command is issued in the Tp cycle after completion of precharging that is in progress in any bank. The SELF command is then issued in the Tsr cycle after inserting idle cycles of which number is specified by the TRPAB bits. The LPDDR2-S4 cannot be accessed in the self-refresh state. Self-refresh mode is canceled by clearing the RMODE bit to 0. After self-refresh mode has been canceled, command issuance is disabled for the number of cycles specified by the TSREX bits.

Self-refresh timing is shown in figure 7.12. After self-refreshing is canceled, settings must be made so that auto-refreshing is performed immediately at the correct intervals. When self-refreshing is activated from the state in which auto-refreshing is set, auto-refreshing is restarted if the RFSH bit is set to 1 and the RMODE bit is cleared to 0 when self-refresh mode is cleared. If the transition from clearing of self-refresh mode to the start of auto-refreshing takes time, making the RTCNT value 1 less than the RTCOR value will enable auto-refreshing to be started immediately.

The SBSC stops LPCLK and /LPCLK in self-refresh mode to reduce the I/O current of this LSI. The stop timing is one clock cycle after the SELF command is issued (Tsr) and the start timing is five clock cycles before self-refresh mode is cleared (Tsrexit).

After self-refreshing has been set, the self-refresh state continues even if this LSI enters the standby state and is maintained even after wakeup from standby state due to an interrupt. After a power-on reset, the LPCKEA and LPCKEB pins need to be driven low to continue self-refreshing (see section 7.5.2 (10), Initial Value of LPCKEA/LPCKEB Pin Level).

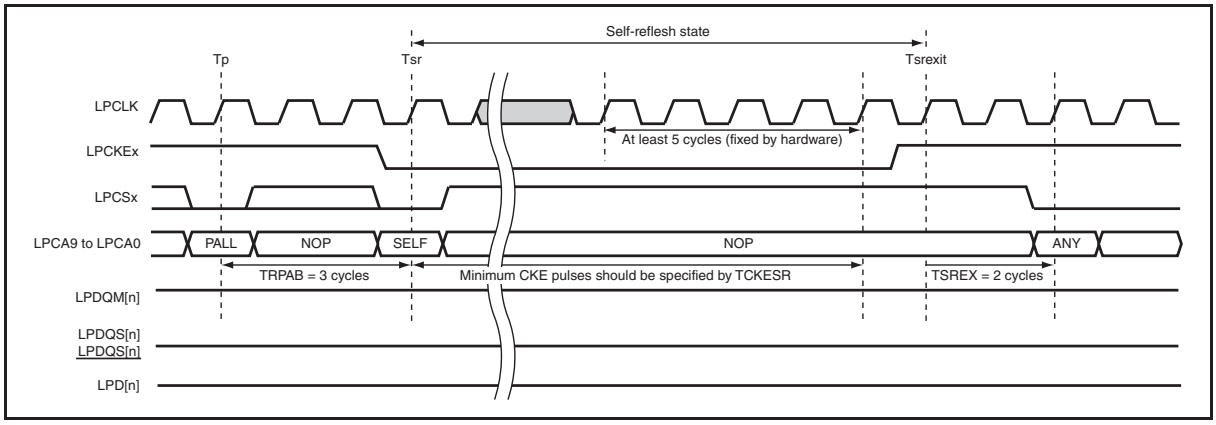

Figure 7.12 Self-Refresh Timing
(SDCR0.RMODE = 1, RFSH = 1, TRPAB = 2 (3 cycles), TSREX = 1 (2 cycles))

(d) Burst-Refreshing after Exit from Self-Refreshing

Some LPDDR2-S4 devices require that auto-refreshing be performed a specified number of times after they are taken out of self-refresh mode. To support such devices, this LSI has a function for issuing a specified number of consecutive refresh commands after the LPDDR2-S4 has been taken out of self-refresh mode. This is called "burst refreshing". No other commands are issued while burst refreshing is in progress.

Setting SREFCNT to 1 or a greater value before the LPDDR2-S4 is placed in self-refresh mode selects auto-refreshing the specified number of times after the LPDDR2-S4 is taken out of self-refresh mode. Furthermore, setting the SREF_PRE bit in SDCR0 to 1 selects issuing of the precharge command (PALL) before the issuance of REF commands the number of times set in SREFCNT.

Figure 7.13 shows the timing when the LPDDR2-S4 is taken out of self-refresh mode when SREFCNT has been set to a value greater than or equal to 1 and the SREF_PRE bit has been cleared to 0. Figure 7.14 shows the timing when the LPDDR2-S4 is taken out of self-refresh mode when SREFCNT has been set to a value greater than or equal to 1 and the SREF_PRE bit has been set to 1. Note that no refresh commands will be issued if SREFCNT is set to 0. For the operation in this case, see section 7.5.2 (5) (c), Self-Refreshing.

With the SREF_PRE bit cleared to 0, the LPDDR2-S4 leaves self-refresh mode in the Tsrexit cycle where LPCKEA/LPCKEB is driven high. After that, the number of idle cycles specified by the TSREX bits are inserted, and the first REFA command is issued in the Trr cycle. The number of idle cycles specified by the TRFC bits are then inserted before all subsequently issued REFA commands. After the last REFA command has been issued, no further commands are issued for the number of cycles specified by the TRFC bits. With the SREF_PRE bit set to 1, the LPDDR2-S4 leaves self-refresh mode in the Tsrexit cycle, the number of idle cycles specified by the TSREX bits are inserted, and the all-bank precharge command (PALL) is issued in the Tp cycle. After that, the number of idle cycles specified by the TRFC bits are inserted, and the first REFA command is issued in the Trr cycle. The number of idle cycles specified by the TRFC bits are then inserted before all subsequently issued REFA commands. After the last REFA command has been issued, no further commands are issued for the number of cycles specified by the TRFC bits.

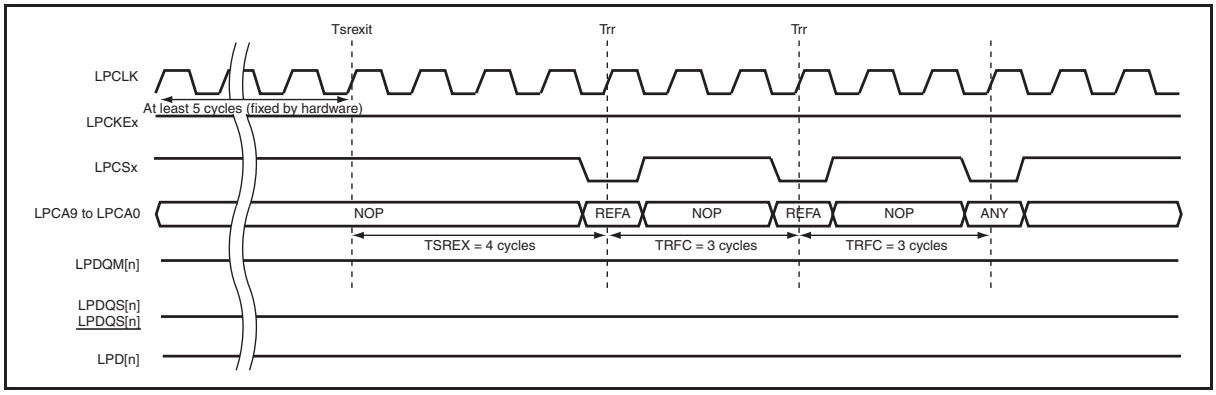

Figure 7.13 Burst-Refreshing after Exit from Self-Refresh Mode (1)
(SREFCNT = 2 (twice), SDCR0.SREF_PRE = 0, TSREX = 3 (4 cycles), TRFC = 2 (3 cycles))

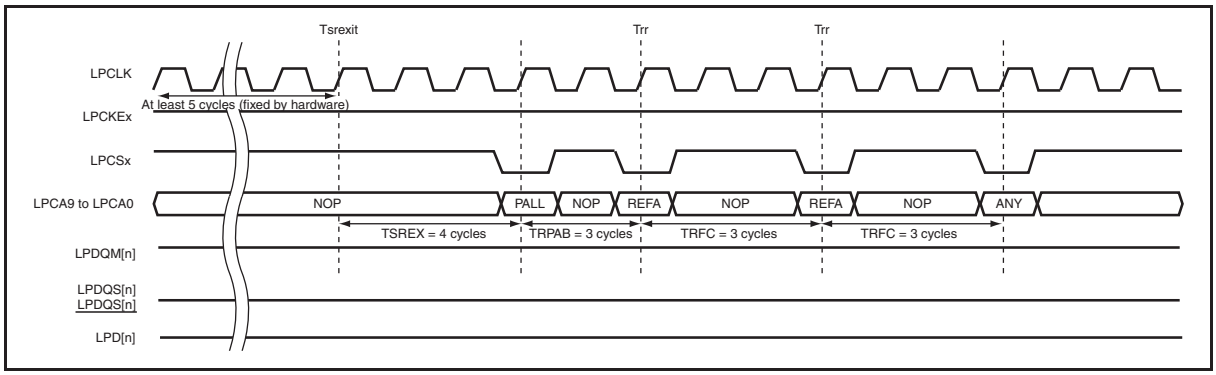

Figure 7.14 Burst-Refreshing after Exit from Self-Refresh Mode (2)
(SREFCNT = 2 (twice), SDCR0.SREF_PRE = 1, TSREX = 3 (4 cycles), TRPAB = 1 (2 cycles), TRFC = 2 (3 cycles))

Precautions:

1. Settings of SREFCNT and the SREF_PRE bit in SDCR0 should be made before the LPDDR2-S4 is placed in self-refresh mode.
2. The LPDDR2-S4 can be taken out of self-refresh mode by writing 1 to the RMODE bit in SDCR0. When writing to this bit, be careful not to change the value of bit SREF_PRE.

(e) Procedures for Controlling Transition to or Exit from Self-Refresh Mode

The following gives restrictions and notes on control of the SBSC and connected LPDDR2-S4 at transition to or exit from self-refresh mode. Use the control procedures given below. When stopping the clock supply (stopping the source clock) to the SBSC after transition to self-refresh mode, specify self-refreshing through the RMODE bit in SDCR0 or cut the power supply to the SBSC area by setting PDSEFL = 1 and RFSH = 1 in SDCR0 so that the LPDDR2-S4 is in self-refresh state. This section describes the procedures for using the RMODE bit in SDCRx for self-refresh control.

- Procedure for controlling transition to self-refresh mode
  1. Stop access to the LPDDR2-S4 in the target memory space to be set to self-refresh mode. This must be controlled by software. If an access is made to the memory space that is in self-refresh mode, the SBSC will return an error.
  2. Write 1 to the RMODE and RFSH bits in SDCR0 that controls the target memory space to set it to self-refresh mode.

     Note: If 1 is written to the DEEP bit before or at the same time as 1 is written to the RMODE bit, the LPDDR2-S4 in the corresponding memory space is moved to deep power-down mode.

     To specify partial self-refreshing of the LPDDR2-S4, use the registers in the LPDDR2-S4. For details, refer to the data sheet of the LPDDR2-S4 device.

- Procedure for controlling exit from self-refresh mode
  1. Check that the power is turned on in the SBSC power-supply area (SBSC1: A4S).
  2. Write 0 to the RMODE bit in SDCRx that controls the target memory space to clear self-refresh mode for the memory space.
  3. Restart access to the LPDDR2-S4.

(f) Control of Automatic Transition to Self-Refresh Mode while PLLC1 is Off

While the PLLC1 in this LSI is turned off, the frequency of the SBSC clock (ZB3ϕ or ZB3Sϕ) is low (the frequency depends on the input clock and frequency division ratio) and auto-refreshing is not performed at the necessary rate. To avoid this, self-refresh mode should be specified through the RMODE bit in SDCRx, but in some systems self-refreshing cannot be correctly controlled by software. Assuming such a case, the SBSC provides a function for controlling self-refreshing in synchronization with the PLLC1 status (on or off). This function is enabled by setting the PLLCNT bit to 1 in SDCR0.

- Operation when PLLCNT == 0:

  Auto-refreshing continues while the PLLC1 is turned off. During the period in which the PLLC1 might be turned off, the memory should be placed in self-refresh mode through the RMODE bit setting in SDCRx to avoid data loss due to an insufficient refreshing rate.

- Operation when PLLCNT==1:

  The SDRAM is placed in self-refresh mode while the PLLC1 is turned off. Upon detecting the processing that turns off the PLLC1, the SBSC automatically moves the SDRAM to self-refresh mode. Upon detecting the processing that turns on the PLLC1, the SBSC automatically releases the SDRAM from self-refresh mode.

  Note that when the SDRAM has been moved to self-refresh mode through the RMODE bit setting in SDCRx, self-refreshing continues regardless of PLLC1 transition to the on or off state.

If the SBSC memory space is accessed (including the registers in the SDRAM) while this automatic transition function is enabled and the PLLC1 is off, the SBSC will return an access error and an abort is generated in the CPU.

Figure 7.15 shows the relationship between PLLC1 state transition (on or off) and self-refreshing when PLLCNT = 1.

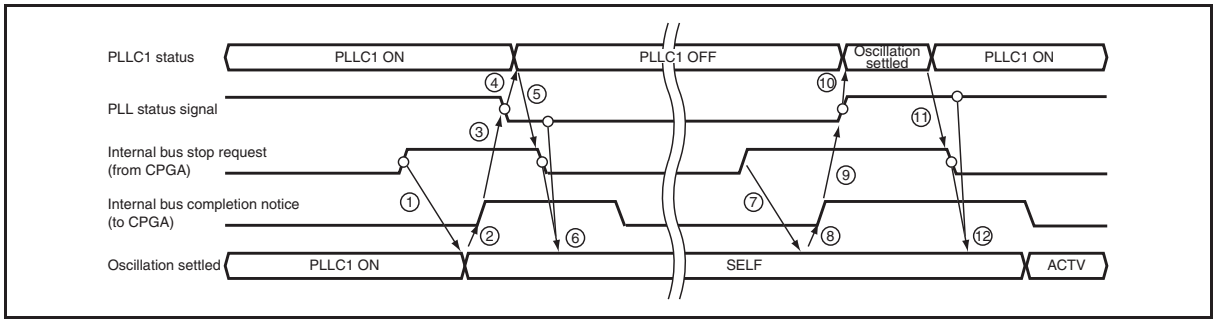

Figure 7.15 Relationship between PLLC1 State Transition (On or Off) and Self-Refreshing

Description:

1. Upon detecting a turn-off request for the PLLC1, the CPGA sends an internal bus stop request to each module.
2. Upon receiving the internal bus stop request from the CPGA, the SBSC moves to self-refresh mode. After completion of transition to self-refresh mode, the SBSC returns an internal bus stop completion notice to the CPGA.
3. After all modules have returned an internal bus stop completion notice, the CPGA instructs the PLLC1 to stop oscillation.
4. Upon receiving the instruction, the PLLC1 stops oscillation.
5. After the PLLC1 has stopped, the CPGA negates the internal bus stop request to each module.
6. When the internal bus stop request is negated, the SBSC checks the PLL status signal. Here, the PLLC1 status signal indicates the off state and the SBSC continues self-refreshing.
7. Upon detecting a turn-on request for the PLLC1, the CPGA sends an internal bus stop request to each module.
8. Upon receiving the internal bus stop request form the CPGA, the SBSC checks its state. When the SBSC state is self-refresh mode, the SBSC returns an internal bus stop completion notice to the CPGA immediately.
9. After all modules have returned an internal bus stop completion notice, the CPGA instructs the PLLC1 to start oscillation.
10. Upon receiving the instruction, the PLLC1 starts oscillation.
11. After checking that the PLLC1 has started oscillation, the CPGA negates the internal bus stop request to each module.
12. When the internal bus stop request is negated, the SBSC checks the PLL status signal. Here, the PLL status signal indicates the on state, and the SBSC clears self-refreshing mode.

(6) Relationship between Refresh Requests and Bus Cycles

If a refresh request occurs during bus cycle execution, the refresh cycle must wait for the bus cycle to be completed.

If a new refresh request occurs while waiting for the previous refresh request, the previous refresh request is deleted. To perform refreshing correctly, a bus cycle longer than the refresh interval or the bus mastership occupation must be prevented from occurring.

(7) Power-Down Modes

This LSI has three types of power-down modes that can be selected by the PDOWN bits in SDCR0. When the PDOWNSEL bit in SDPDCR0 is set to 1, the PDOWN bit setting of SDCR0 is compared with the PDOWN bit setting of SDCR1, and the power-down mode with the smaller access latency is selected.

The access latency order for power-down modes is as follows:

Normal operation < Power-down mode 1 < Power-down mode 2 < Power-down mode 3

Power-down mode 3 has the largest access latency.

Refer to section 7.5.2 (9), Power-Down Control Using LPCKEA/LPCKEB Pin, for operation with the PDOWNSEL bit in SDPDCR0 set to 1.

The SBSC stops the LPCLK and /LPCLK clock output in power-down mode or self-refresh mode to reduce the current flowing in the I/O section of the SBSC. The earliest oscillation stop timing is one clock cycle after transition to power-down mode or self-refresh mode (CKE is driven low) and the latest oscillation start timing is five clock cycles before power-down mode or self-refresh mode is cleared (CKE is driven high).

Note on Power-Down Mode Switching:

When the connected SDRAM is set to self-refresh mode through the RMODE and RFSH bit settings in SDCRx, do not change power-down mode through the PDMODE bit (when the SDRAM is not actually in self-refresh state, the power-down mode can be switched because of register arbitration).

When only one of DRAM areas 0 and 1 in the SBSC1 is in self-refresh state, the power-down mode can be switched.

(a) Power-Down Mode 1

If the PDOWN1 and PDOWN0 bits in SDCR0 are set to B'10, the LPDDR2-S4 is placed in power-down mode by setting the LPCKEA/LPCKEB signal to the low level in a non-access cycle. The period it takes to enter power-down mode is specified by the PDWAIT bits in SDPDCR0. After issuance of the last command to the LPDDR2-S4, if there is no new transfer request during the period of ZB3ϕ cycles specified by the PDWAIT bits, the LPDDR2-S4 enters power-down mode. This power-down mode can effectively lower power consumption in non-access cycles. However, note that if an access occurs in power-down mode, one cycle for driving LPCKEA/LPCKEB high to cancel LPDDR2-S4 power-down mode and wait cycles to satisfy the tXR specification of the LPDDR2-S4 are inserted. Figure 7.17 shows the access timing in power-down mode 1.

(b) Power-Down Mode 2

If the PDOWN1 and PDOWN0 bits in SDCR0 are set to B'01, the LPDDR2-S4 is placed in power-down mode by setting the LPCKEA/LPCKEB signal to the low level in a non-access cycle. At this time, the clock (ZSϕ for SBSC1) to the internal

bus interface block in the SBSC is stopped. The period it takes to enter power-down mode is specified by the PDWAIT bits in SDPDCR0. After issuance of the last command to the LPDDR2-S4, if there is no new transfer request during the period of ZB3ϕ cycles specified by the PDWAIT bits, the LPDDR2-S4 enters power-down mode. This power-down mode can effectively lower power consumption in non-access cycles. However, note that if an access occurs in power-down mode, one cycle for supplying the clock to the internal bus I/F section, one cycle driving the LPCKEA/LPCKEB signal high to cancel LPDDR2-S4 power-down mode, and wait cycles to satisfy the tXR specification of the LPDDR2-S4 are inserted. Figure 7.16 shows the access timing in power-down mode 2.

(c) Power-Down Mode 3

If the PDOWN1 and PDOWN0 bits in SDCR0 are set to B'11, the LPDDR2-S4 is placed in self-refresh mode by issuing the self-refresh command for the LPDDR2-S4 in a non-access cycle. At this time, the clock (ZSϕ for SBSC1) to the internal bus interface block in the SBSC and the SBSC operation clock (ZB3ϕ) are stopped. The period it takes to issue the self-refresh command is specified by the PDWAIT bits in SDPDCR0. After issuance of the last command to the LPDDR2-S4, if there is no new transfer request during the period of ZB3ϕ cycles specified by the PDWAIT bits, the LPDDR2-S4 enters self-refresh mode. This power-down mode can effectively lower power consumption in non-access cycles. However, note that if an access occurs in self-refresh mode, an overhead equal to the number of wait cycles occurring between SDR-SDRAM self-refresh mode cancellation and ACTV command issuance occurs in order to cancel LPDDR2-S4 self-refresh mode. Figure 7.16 shows the access timing in power-down mode 3.

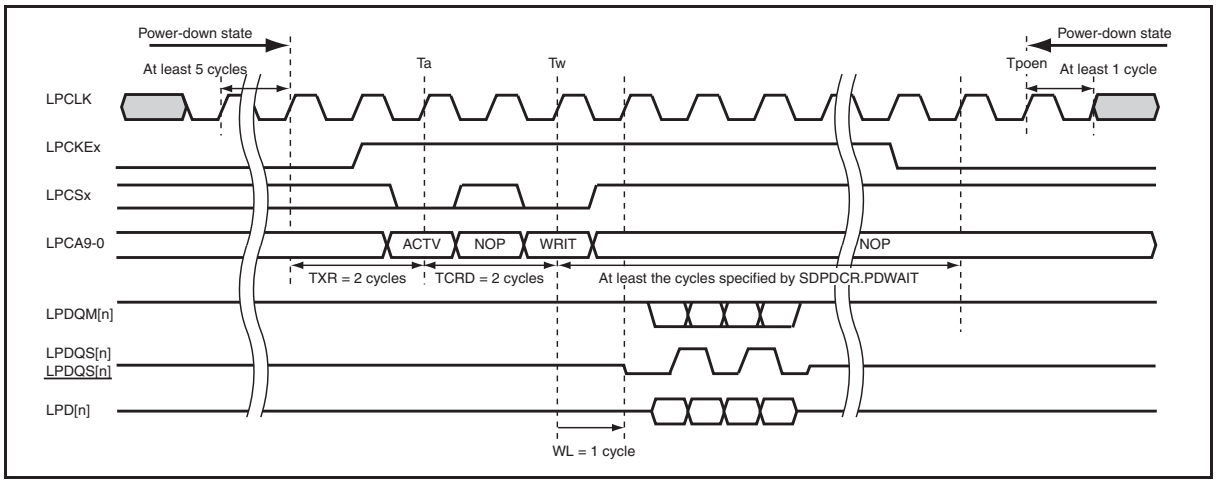

Figure 7.16 Access Timing in Power Down Mode 1 or 2 (SDCR0.PDOWN10 = 10/01, TXR = 1 (2 cycles), TRCD = 1 (2 cycles))

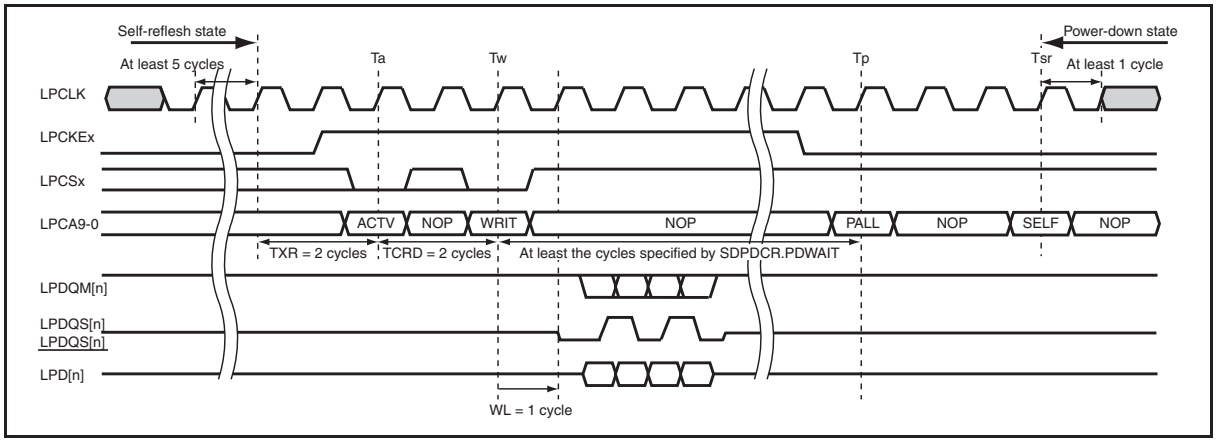

Figure 7.17 Access Timing in Power Down Mode 3
(SDCR0.PDOWN10 = 10/01, TSREX = 1 (2 cycles), TRCD = 1 (2 cycles), TRPAB = 2 (3 cycles))

(8) Deep Power-Down Mode

The LPDDR2-S4 supporting the low-power function provides deep power-down mode as a power-down mode.

With the partial self-refresh function, self-refreshing is performed on a specific area. In deep power-down mode, self-refreshing will not be performed on any memory area. This mode is effective in systems where all of the system memory areas are used as work areas.

If the value of 1 is written to the RMODE bit while the DEEP bit in SDCR0/SDCR1 and the RFSH bit are both set to 1, the LPDDR2-S4 supporting the low-power function enters deep power-down mode. If the RMODE bit is cleared to 0, the LPCKEA/LPCKEB signal is pulled high to cancel deep power-down mode. Before executing an access after canceling deep power-down mode, the power-on sequence must be re-executed.

Note that some LPDDR2-S4 devices require specific cycles of idle time after cancellation of deep power-down mode. For information on this idle time, see the manual of the LPDDR2-S4 to be used.

When shifting the LPDDR2-S4 from self-refresh state to deep power-down mode, write 0 to the RMODE bit to clear self-refresh mode before setting deep power-down mode. Likewise, when shifting from deep power-down mode to self-refresh mode, clear deep power-down mode before setting self-refresh mode.

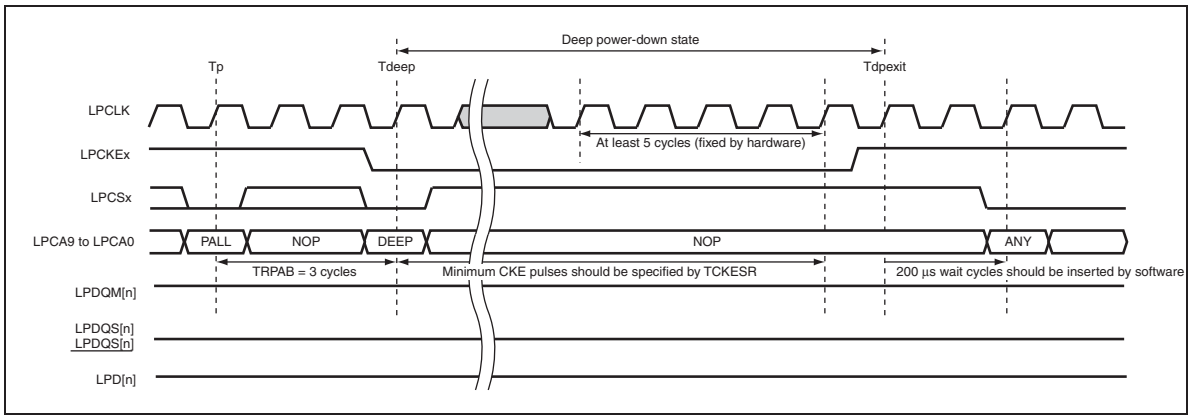

Figure 7.18 Deep Power-Down Mode Transition Timing (SDCR0.DEEP = 1, RMODE = 1, RFSH = 1, SDWCR0/1.TRP = 2)

(9) Power-Down Control Using LPCKEA/LPCKEB Pin

In this LSI, a different CKE pin can be connected to each LPDDR2-S4. This enables power-down modes, such as self-refresh mode and deep power-down mode, to be selected separately for each LPDDR2-S4 to reduce power consumption. In power-down mode 1, 2, or 3, only the DRAM area that is accessed is activated.

(10) Initial Value of LPCKEA/LPCKEB Pin Level

In this LSI, the initial value of the LPACKEA/LPACKEB pin during a power-on reset and after cancellation of a reset can be selected with the CKEMD10 (SBSC1) bit in reset control register 2 (RESCNT2) of the SYSC. The correspondence between the CKEMD10 bit and the LPACKEA/LPACKEB pin level is shown in table 7.18.

If the low level is selected as the initial value of the LPACKEA/LPACKEB pin, drive the LPACKEA/LPACKEB pin back to the high level by writing 1 to the CKELV bit in SDPCR before access to LPDDR2-S4 is restarted.

Table 7.18 Correspondence between CKEMD10 Bit in Reset Control Register 2 of SYSC and LPACKEA/LPACKEB Pin Level

CKEMD10 Bit in Reset Control Register 2	Description
0	LPACKEA/LPACKEB pin outputs low level as initial state
1	LPACKEA/LPACKEB pin outputs high level as initial state

(11) Control during Power Cutoff

The SBSC is allocated in the area where the power cutoff function works.

SBSC1: Power-supply area A4S

The SBSC has a function for register backup during power cutoff; after power-supply is restarted, the register contents can be restored to the state before power cutoff. (For the registers whose contents are saved, refer to table 7.3, SBSC1 Register States in Each Operating Mode.)

The following shows the procedures for SBSC power cutoff.

a) Power Cutoff while the SBSC is in Self-Refresh Mode

a-1) Stop memory access to the SBSC. It should be guaranteed by software that the SBSC area is never accessed during power cutoff. If the memory space or register space in the SBSC is accessed while the power to the SBSC is stopped, the SHWY module returns an error.

a-2) Set the SBSC to self-refresh mode through the RMODE bit in SDCRx.

a-3) Turn off the power to the corresponding power-supply area. *

a-4) Power cutoff state *

a-5) Turn on the power to the corresponding power-supply area. *

a-6) Check the status bit that indicates the power-supply state to confirm that the power has been turned on. *

a-7) Clear self-refresh mode. (Write 1 to the RMODE bit in SDCRx.)

a-8) Read the RMODE bit to confirm that 1 has been written to it.

a-9) Restart memory access.

Note: * For details of power control, refer to the section describing the SYSC.

b) Power Cutoff while the SBSC is in Auto-Refresh Mode

When power is cut off while the SBSC is in auto-refresh mode without being shifted to self-refresh mode, the SBSC detects the power cutoff sequence and automatically moves to self-refresh mode. Therefore, correct memory contents are retained after the power supply is stopped and then restarted.

b-1) Stop memory access to the SBSC. It should be guaranteed by software that the SBSC area is never accessed

during power cutoff. If the memory space or register space in the SBSC is accessed while the power to the SBSC is stopped, the SHWY module returns an error.

b-2) Turn off the power to the corresponding power-supply area. *

b-3) Power cutoff state *

(When PDSELF = 1 and RFSH = 1 in SDCR0, the SBSC sets the LPDDR2-S4 to self-refresh state in synchronization with power cutoff in the SBSC area.)

b-4) Turn on the power to the corresponding power-supply area. *

Upon detecting the power-on sequence, the SBSC clears self-refresh mode and restarts auto-refreshing (if self-refresh mode was specified through the RMODE bit before power cutoff, the SBSC continues self-refresh mode).

b-5) Check the status bit that indicates the power-supply state to confirm that the power has been turned on. *

b-6) Restart memory access.

Note: * For details of power control, refer to the section describing the SYSC.

(12) Memory Protected Area Function

In this LSI, each SBSC area is divided into four areas through the setting in the memory protected area division register and an access privilege can be assigned for each area. The memory protection function of this LSI has the following features.

a) Ability to specify a privilege to change the memory protected area setting register (SDPTCR)

Once a CPU writes to SDPTCR with the REGWP bit set to 1, only that CPU subsequently has the privilege to change the SDPTCR setting.

The BB-CPU, AP-CPU, AP secure CPU, and RT-CPU can have this privilege.

b) Ability to specify a privilege to access (change) the memory protected area division register (SDPTDIVCR)

Once a CPU writes to SDPTDIVCR with the REGWP bit set to 1, only that CPU subsequently has the privilege to change the SDPTDIVCR setting. The BB-CPU, AP-CPU, AP secure CPU, and RT-CPU can have this privilege. In addition, once a CPU writes to SDPTDIVCR with the REGWP2 bit set to 1, no CPU can subsequently change the SDPTDIVCR setting. In this case, the SDPTDIVCR setting cannot be modified until a power-on reset is applied.

c) Ability to specify secure-mode areas

Writing 1 to the SCR_EN or SRW_EN bit in SDPTDIVCR specifies the corresponding area as a secure-mode area; that is, the area can be accessed only from a secure initiator. When SCR_EN = 1, the area can be read only from a secure initiator, and when SCR_EN = 1, the area can be written to only from a secure initiator. The AP-ARM, BB-ARM, CC5, or CoreSight in secure mode can be a secure initiator.

d) Ability to specify a privilege of access from the BB and AP to an area set to non-secure mode

For an area that is used in non-secure mode, the privilege of access from the AP-domain modules and BB-domain modules can be specified separately for read access and write access.

Figure 7.19 gives an overview of the SBSC memory protection function.

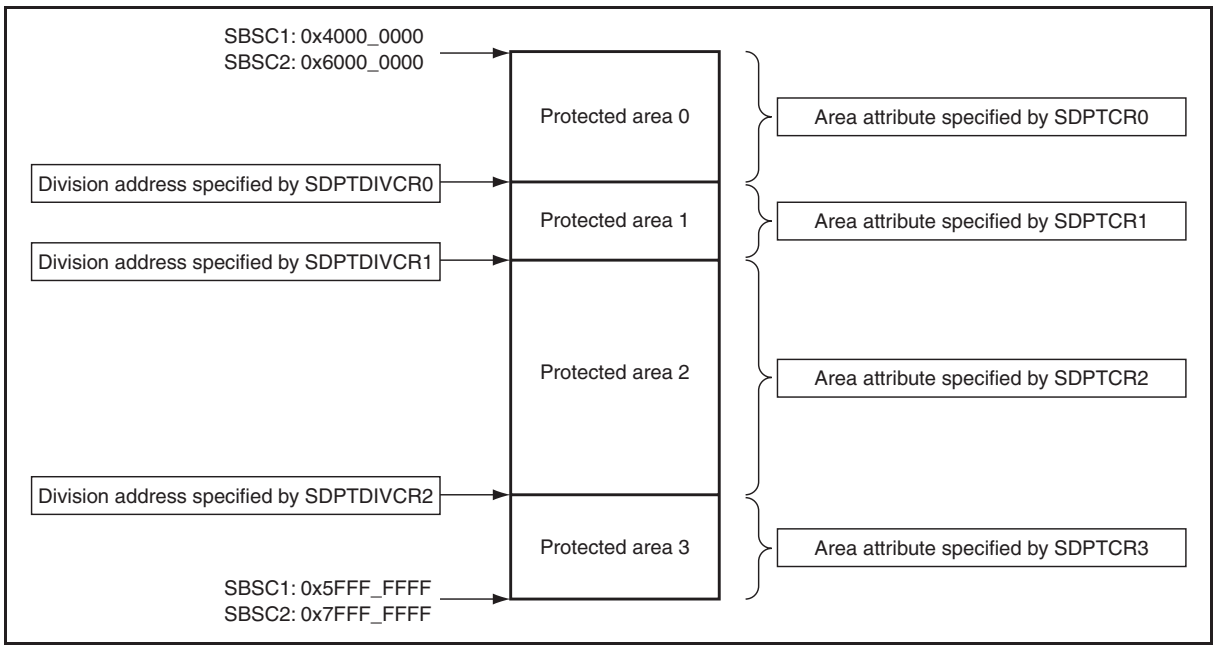

Figure 7.19 Overview of SBSC Memory Protection Function

Use the following procedure for memory protection setting.

1) Specify area division addresses through SDPTDIVCR0 to SDPTDIVCR2 to satisfy the following restrictions.

   Restrictions on SBSC1 memory protection setting

   Bits 31 to 17 of SBSC1 start address (0x40000000)

   < SDPTDIVCR0A.DIVADR < SDPTDIVCR1A.DIVADR < SDPTDIVCR2A.DIVADR

   < Bits 31 to 17 of SBSC1 end address (0x5FFFFFFF)

2) Check that desired values are read from the CPUTYPE bits in SDPTDIVCR0 to SDPTDIVCR2 and both the REGWP and REGWP2 bits are cleared to 0.

3) Make necessary memory protection settings for each area through SDPTCR0 to SDPTCR3.

4) Check that desired values are read from the CPUTYPE bits in SDPTCR0 to SDPTCR3 and the REGWP bit is cleared to 0.

Notes:

1) The SDPTDIVCR0 to SDPTDIVCR2 values must satisfy the above restrictions. Until SDPTDIVCR settings are completed and satisfy the above restrictions, do not make memory protection settings for each area through SDPTCR0 to SDPTCR3; otherwise, the memory protection function will work unexpectedly.

2) SDPTDIVCR0 to SDPTDIVCR2 and SDPTCR0 to SDPTCR3 can be modified from a program in the SBSC external memory space including the target area of a memory protection setting modification, but make sure that the area does not become the target of access protection during or after setting modification.

7.6 Others

7.6.1 Reset

The SBSC1 can be initialized completely only by a power-on reset. At a power-on reset, all signals are negated and output buffers are turned off immediately regardless of the bus cycle state. All control registers are initialized.

The SBSC1 has a function to retain the control register values when the power to the power supply area (A4S) where the SBSC1 is allocated is cut off. The control registers whose values are to be retained are shown in tables 7.9 and 7.11. The backup registers for retaining control register values are allocated in area C5. Control register values will not be retained if the power to area C5 is cut off.

7.6.2 Access Error

The SBSC may return an access error according to its state.

When the SBSC returns an access error, a prefetch abort or a data abort occurs in the CPU.

In cases 1) to 7) below, the SBSC returns an access error.

1) After a power-on reset is canceled, memory is accessed while the CKELV bit in SDPTCR is 0.
2) Access is done for a memory area that has been set to self-refresh or deep power-down state through the RMODE bit setting in SDCRx.
3) A memory area is accessed by a CPU that is not assigned a privilege of access to that memory area through the memory protection function.
4) Access is done for a DRAM area whose memory parameter setting exceeds the memory capacity specified through the SDSZ bits (memory space per DRAM area) in SDCR0.

   Example: Case 4) applies to when DRAM area 0 is accessed while the SDCRA0.SDSZ bits are set to 2'b00 (512 Mbits per area) and parameters for 1-Gbit memory (SZ = 2'b01, BANK = 0 (4-bank configuration), ROW = 3'b100 (15 bits), and COL = 2'b00 (8 bits)) are specified in SDCR0.
5) Access is done at an address exceeding the memory capacity in the DRAM area whose memory parameter setting does not reach the memory capacity specified through the SDSZ bits (memory space per DRAM area) in SDCR0.

   Example: When the SDCRA0.SDSZ bits are set to 2'b01 (1 Gbits per area) and parameters for 512-Mbit memory are specified in SDCR0:

   DRAM area 0: 1 G bits from 0x50000000 to 0x57FFFFFF

   Memory parameter setting: 512 Mbits from 0x50000000 to 0x53FFFFFF

   Case 5) applies to access to an address from 0x54000000 to 0x57FFFFFF under the above conditions.
6) An SBSC register or memory area is accessed while the power-supply area where the SBSC is allocated is turned off.
7) The memory area (including the registers in the memory) is accessed while the PLLCNT bit in SDCR0 is 1 and the PLLC1 is turned off.

7.6.3 SBSC1 Performance Monitor

This LSI has an SBSC access monitor function. For details, refer to the section describing the TDBG.

The module stop setting through the CPGA is applied to this monitor block. In the initial state, this block is in module stop state; to use the monitor function, cancel module stop state.

When the SBSC1 performance monitor function is used, signals are output in the mobileDDR (single data rate) protocol for each output command because if the LPDDR2 protocol is used instead, addresses and commands are output at double data rate and cannot be monitored correctly from outside.

Table 7.20 shows the correspondence between the LPDDR-S4 protocol and monitor output protocol.

Table 7.20 Correspondence between LPDDR-S4 Protocol and Monitor Output Protocol

LPDDR2-S4 Command		Monitor Output									
Command	Command Description	CKE		CS	RAS	CAS	RDWR	AP (ADR10)	BA 2 to 0	ADR 14 to 0	Remarks
		CLK(n-1)	CLK(n)

Section 8 Direct Memory Access Controller (DMAC)

This LSI includes three sets of direct memory access controllers (DMAC1, DMAC2 and DMAC3 which are collectively called the DMAC).

The DMAC can be used in place of the CPU to perform high-speed transfers between external memory, on-chip memory, memory-mapped external devices, and on-chip peripheral modules.

8.1 Features

- Six channels
- 4-Gbyte physical address space
- Data transfer unit is selectable: Byte, word (2 bytes), longword (4 bytes), 8 bytes, 16 bytes, 32 bytes, and 64 bytes
- Maximum transfer count: 16,777,216 transfers
- Address mode: Dual address mode
- Transfer requests:

  On-chip peripheral module request, or auto request can be selected.

  The following modules can issue an on-chip peripheral module request.

  — CMT1, SCIFA0/1/2/3/4/5, SCIFB, MSIOF0/1/2, BBIF1/2, IIC0/1/2/3/4, FLCTL0/1, FSI, SDHI0/1/2, TPU0, TSIF0/1, IRDA, DSI0/1, HSI, MFI, MMC, SHWYSTAT
- Bus mode: Cycle steal mode (normal mode and intermittent mode)
- Selectable channel priority levels:

  The channel priority levels are selectable between fixed mode and round-robin mode.
- Interrupt request: An interrupt request can be generated to the CPU after half of the transfers ended, all transfers ended, or an address error occurred.
- Gathering buffer function: Transfer data of 256 bytes or less can be collectively transmitted.

Figure 8.1 shows the block diagram of the DMAC.

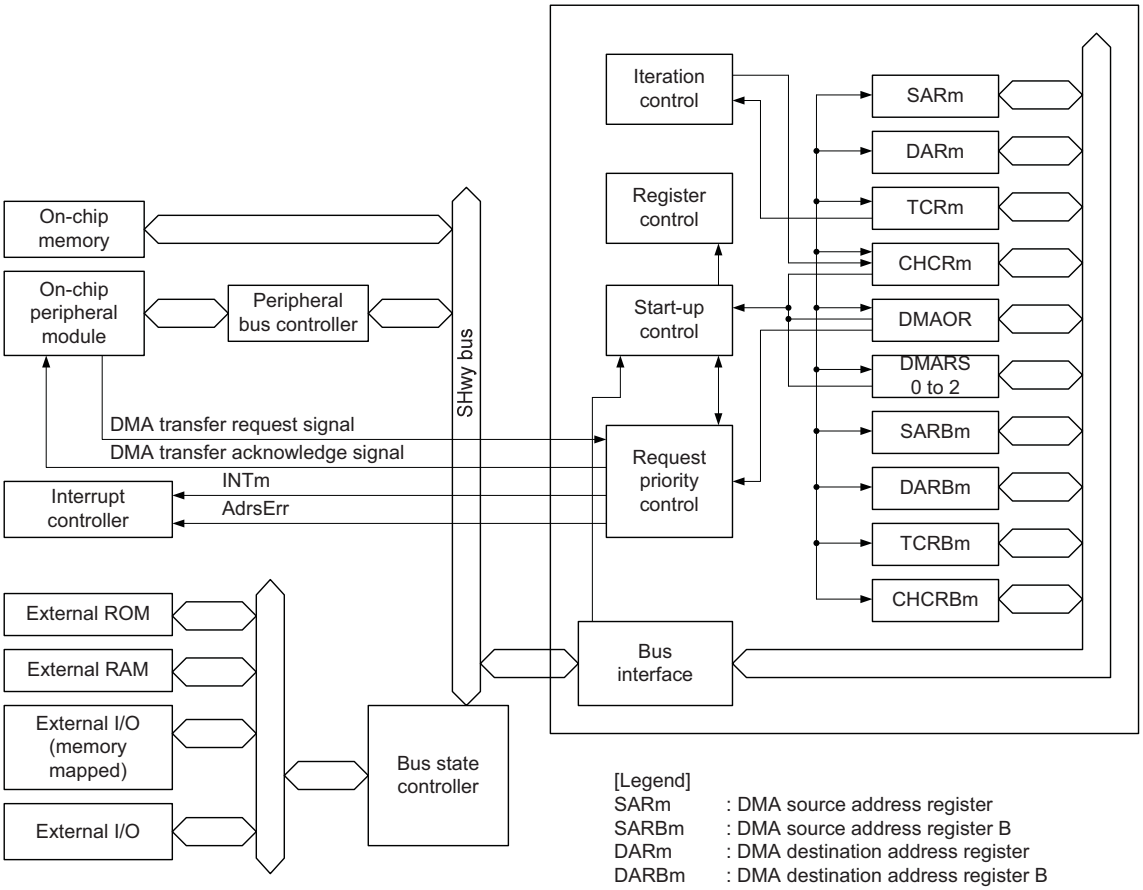

Figure 8.1 Block Diagram of DMAC

8.2 Input/Output Pins

There are no external pins relevant to the DMAC.

8.3 Register Descriptions

Table 8.1, Table 8.3, and Table 8.5 show the configuration of registers of the DMAC1, DMAC2, and DMAC3, respectively. Table 8.2, Table 8.4, and Table 8.6 show the state of the registers in each processing mode.

The DMASAR for channel 0 in the DMAC1 is expressed as DMA1SAR_0 and the DMAOR for channel 2 in the DMAC2 is expressed as DMA2OR.

Table 8.1 Register Configuration of DMAC1

Name	Abbreviation	R/W	Address	Access Size

8.3.1 DMA Source Address Registers 0 to 5 (DMASAR_0 to DMASAR_5)

The DMASAR registers are 32-bit readable/writable registers that specify the source address of a DMA transfer. During a DMA transfer, these registers indicate the next source address.

To transfer data in word or in longword units, specify a word or longword boundary address. When transferring data in 8-byte, 16-byte, 32-byte, or 64-byte units, an 8-byte, 16-byte, 32-byte, or 64-byte boundary must be set for the source address value. However, if the address mode in the DMA channel control register is set as fixed (SM[1:0] = B'11) even when transferring data in 32-byte or 64-byte, a value can be specified in 16-byte boundary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SAR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

8.3.2 DMA Source Address Registers B_0 to 5 (DMASARB_0 to DMASARB_5)

The DMASARB registers are 32-bit readable/writable registers that specify the source address of a DMA transfer that is to be set in DMASAR in repeat/reload mode. Data to be written from the CPU to DMASAR is also written to DMASARB. To set a DMASARB address that differs from the DMASAR address, write data to DMASARB after DMASAR.

To transfer data in word or in longword units, specify a word or longword boundary address. When transferring data in 8-byte, 16-byte, 32-byte, or 64-byte units, an 8-byte, 16-byte, 32-byte, or 64-byte boundary must be set for the source address value. However, if the address mode in the DMA channel control register is set as fixed (SM[1:0] = B'11) even when transferring data in 32-byte or 64-byte, a value can be specified in 16-byte boundary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.3.3 DMA Destination Address Registers 0 to 5 (DMADAR_0 to DMADAR_5)

The DMADAR registers are 32-bit readable/writable registers that specify the destination address of a DMA transfer. During a DMA transfer, these registers indicate the next destination address.

To transfer data in word or in longword units, specify a word or longword boundary address. When transferring data in 8-byte, 16-byte, 32-byte, or 64-byte units, an 8-byte, 16-byte, 32-byte, or 64-byte boundary must be set for the destination address value. However, if the address mode in the DMA channel control register is set as fixed (SM[1:0] = B'11) even when transferring data in 32-byte or 64-byte, a value can be specified in 16-byte boundary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DAR															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

8.3.4 DMA Destination Address Registers B_0 to 5 (DMADARB_0 to DMADARB_5)

The DMADARB registers are 32-bit readable/writable registers that specify the destination address of a DMA transfer that is to be set in DMADAR in repeat/reload mode. Data to be written from the CPU to DMADAR is also written to DMADARB. To set a DMADARB address that differs from the DMADAR address, write data to DMADARB after DMADAR.

To transfer data in word or in longword units, specify a word or longword boundary address. When transferring data in 8-byte, 16-byte, 32-byte, or 64-byte units, an 8-byte, 16-byte, 32-byte, or 64-byte boundary must be set for the destination address value. However, if the address mode in the DMA channel control register is set as fixed (SM[1:0] = B'11) even when transferring data in 32-byte or 64-byte, a value can be specified in 16-byte boundary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DARB															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DARB

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

8.3.5 DMA Transfer Count Registers 0 to 5 (DMATCR_0 to DMATCR_5)

The DMATCR registers are 32-bit readable/writable registers that specify the DMA transfer count. The number of transfers is 1 when the setting is H'00000001, 16,777,215 when H'00FFFFFF is set, and 16,777,216 (the maximum) when H'00000000 is set. During a DMA transfer, these registers indicate the remaining transfer count.

The upper eight bits of DMATCR are always read as 0, and the write value should always be 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.3.6 DMA Transfer Count Registers B_0 to 5 (DMATCRB_0 to DMATCRB_5)

The DMATCRB registers are 32-bit readable/writable registers. Data to be written from the CPU to DMATCR is also written to DMATCRB. To set a DMATCRB address that differs from the DMATCR address, write data to DMATCRB after DMATCR. While the HE function is used, DMATCRB is used to hold the initial value for detecting HE. DMATCRB specifies the number of DMA transfers which are set in DMATCR in repeat mode. DMATCRB specifies the number of DMA transfers and are used as a transfer counter in reload mode.

In reload mode, the lower 16 bits operate as a transfer counter; the values of DMASAR and DMADAR are updated after the value of the lower 16 bits became 0, and the value of the upper 16 bits of DMATCRB is loaded to the lower 16 bits. In the upper 16 bits, set the number of transfers that should be executed before the transfer count is reloaded. In reload mode, the same number of transfers should be set in both upper and lower 16 bits. In addition, set the HIE bit in DMACHCR to 0 and do not use the HE function.

8.3.7 DMA Channel Control Registers 0 to 5 (DMACHCR_0 to DMACHCR_5)

The DMACHCR registers are 32-bit readable/writable registers that control the DMA transfer mode.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CAE	CAIE	HEE[1:0]		RPT[2:0]			-	-	-	TS[3:2]		HE	HIE	-	–

R/W :	R/(W)*	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/(W)*	R/W	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DM[1:0]		SM[1:0]		RS[3:0]				-	-	-	TS[1:0]		IE	TE	DE
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/(W)*	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	CAE	0	R/(W)*	Address Error Flag Indicates that an address error interrupt occurred during DMA transfer. This bit is set under following conditions: • The value set in DMASAR or DMADAR does not match the transfer size boundary. • The transfer source or transfer destination is invalid space. • The transfer source or transfer destination is in module stop mode If this bit is set, DMA transfer is not enabled for the channel even if the DE bit is set to 1. To clear the CAE bit, write 0 to the CAE bit after reading 1 from the bit or clear the AE bit in DMAOR. (Clearing the AE bit clears the channel address errors for all channels.) 0: No DMAC address error interrupt [Clearing condition] Writing CAE = 0 after reading CAE = 1 1: DMAC address error interrupt occurs during DMA transfer
30	CAIE	0	R/W	Channel Address Error Interrupt Enable Specifies whether to request the CPU of an interrupt when an address error occurs. If the CAIE bit is set to 1, setting the CAE bit requests the CPU of an interrupt (DEI0 to DEI 5) for each channel. Note: An address error interrupt (DADERR) is asserted simultaneously. For interrupts, see section 5, Interrupt Controller (INTC). 0: Interrupt request disabled 1: Interrupt request enabled

Bit	Bit Name	Initial Value	R/W	Descriptions
29, 28	HEE[1:0]	00	R/W	HE Interrupt Function Extension This bit is meaningful only when the HIE bit is set to 1. 00: HE interrupt occurs when the transfer count reaches about a half of DMATCR which is set before transfer (same as before). 01: HE interrupt occurs every time the transfer count reaches about n/4 (n=1, 2, or 3) of DMATCR which is set before transfer. 10: HE interrupt occurs every time the transfer count reaches about n/8 (n=1 to 7) of DMATCR which is set before transfer. 11: HE interrupt occurs every time the transfer count reaches about n/16 (n=1 to 15) of DMATCR which is set before transfer.
27 to 25	RPT[2:0]	000	R/W	DMA Setting Renewal Specify 000: Normal mode (DMAC operation) 001: Repeat mode DMASAR/DMADAR used as repeat area 010: Repeat mode DMADAR used as repeat area 011: Repeat mode DMASAR used as repeat area 100: Setting prohibited 101: Reload mode DMASAR/DMADAR used as reload area 110: Reload mode DMADAR used as reload area 111: Reload mode DMASAR used as reload area
24 to 22	—	000	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
21, 20	TS[3:2]	00	R/W	DMA Transfer Size Specify With TS[1:0], these bits specify the DMA transfer size. When the transfer source or transfer destination is a register of an on-chip peripheral module with a transfer size set, a proper transfer size for the register should be set. In 2-division transfer mode, 16/32-byte data is halved and transferred in two operations. For the transfer source or destination address specified by DMASAR or DMADAR, an appropriate boundary address should be set according to the transfer data size. TS[3:2] + TS[1:0] 0000: Byte units transfer 0001: Word (2-byte) units transfer 0010: Longword (4-byte) units transfer 0011: 16-byte units transfer 0100: 32-byte units transfer 0101: 64-byte units transfer 0111: 8-byte units transfer Other than above: Setting prohibited
19	HE	0	R/(W)*	Half End Flag After HIE (bit 18) is set to 1 and the number of transfers become half of DMATCR (1 bit shift to right) which is set before transfer starts, HE becomes 1. The HE bit is not set when transfers are ended by an address error or by clearing the DE bit and the DME bit in DMAOR before the number of transfers is decreased to half of the DMATCR value set preceding the transfer. The HE bit is kept set when the transfer ends by an address error, or clearing the DE bit (bit 0) or the DME bit in DMAOR after the HE bit is set to 1. To clear the HE bit, write 0 after reading 1 in the HE bit. 0: During the DMA transfer or DMA transfer has been interrupted DMATCR > (DMATCR set before transfer)/2 [Clearing condition] Writing 0 after reading HE = 1. 1: DMATCR ≤ (DMATCR set before transfer)/2
18	HIE	0	R/W	Half End Interrupt Enable Specifies whether an interrupt request is generated to the CPU when the number of transfers is decreased to half of the DMATCR value set preceding the transfer. When the HIE bit is set to 1 and the HE bit is set, an interrupt request is generated to the CPU. Set this bit to 0 while reload mode is set. 0: Interrupt request is disabled when DMATCR = (DMATCR set before transfer)/2 1: Interrupt request is enabled when DMATCR = (DMATCR set before transfer)/2
17, 16	—	000	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	DM[1:0]	00	R/W	Destination Address Mode Specify whether the DMA destination address is incremented, decremented, or left fixed. 00: Fixed destination address 01: Destination address is incremented +1 in byte units transfer +2 in word units transfer +4 in longword units transfer +8 in 8-byte units transfer +16 in 16-byte units transfer +32 in 32-byte units transfer +64 in 64-byte units transfer 10: Destination address is decremented –1 in byte units transfer –2 in word units transfer –4 in longword units transfer Setting prohibited in 8/16/32-byte units transfer 11: Fixed destination address Set to prevent an address from being changed in the objective modules. Example: When specifying FIFOs in the peripheral modules.
13, 12	SM[1:0]	00	R/W	Source Address Mode Specify whether the DMA source address is incremented, decremented, or left fixed. 00: Fixed source address 01: Source address is incremented +1 in byte units transfer +2 in word units transfer +4 in longword units transfer +8 in 8-byte units transfer +16 in 16-byte units transfer +32 in 32-byte units transfer +64 in 64-byte units transfer 10: Source address is decremented –1 in byte units transfer –2 in word units transfer –4 in longword units transfer Setting prohibited in 8/16/32-byte units transfer 11: Fixed source address Set to prevent an address from being changed in the objective modules. Example: When specifying FIFOs in the peripheral modules.
11 to 8	RS[3:0]	0000	R/W	Resource Select Specify which transfer requests will be sent to the DMAC. The changing of transfer request source should be done in the state that the DMA enable bit (DE) is set to 0. 0100: Auto request 1000: Selected by DMA extended resource selector Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Descriptions
7 to 5	—	000	R	Reserved This bit is always read as 0. The write value should always be 0.
4, 3	TS[1:0]	00	R/W	DMA Transfer Size Specify See the description of TS[3:2] (bits 21 and 20).
2	IE	0	R/W	Interrupt Enable Specifies whether or not an interrupt request is generated to the CPU at the end of the DMA transfer. Setting this bit to 1 generates an interrupt request (DEI) to the CPU when the TE bit is set to 1. 0: Interrupt request is disabled. 1: Interrupt request is enabled.
1	TE	0	R/(W)*	Transfer End Flag The TE bit is set to 1 when data transfer ends when DMATCR becomes 0. The TE bit is not set to 1 in the following cases. • DMA transfer ends due to a DMA address error before DMATCR becomes 0. • DMA transfer is ended by clearing the DE bit and DME bit in DMAOR. To clear the TE bit, the TE bit should be written to 0 after reading 1. Even if the DE bit is set to 1 while this bit is set to 1, transfer is not enabled. 0: During the DMA transfer or DMA transfer has been interrupted [Clearing condition] Writing 0 after reading TE = 1 1: DMA transfer ends by the specified count (TCR = 0)
0	DE	0	R/W	DMA Enable Enables or disables the DMA transfer. In auto request mode, DMA transfer starts by setting the DE bit and DME bit in DMAOR to 1. At this time, both of the AE bit in DMAOR and the TE bit must be 0. In an peripheral module request, DMA transfer starts if DMA transfer request is generated by the devices or peripheral modules after setting the DE and DME bits to 1. In this case, however, both of the TE and AE bits must be 0, which is the same as in the case of auto request mode. Clearing the DE bit to 0 can terminate the DMA transfer. 0: DMA transfer disabled 1: DMA transfer enabled

Note: * Writing 0 is possible to clear the flag.

8.3.8 DMA Channel Control Register B_0 to 5 (DMACHCRB_0 to DMACHCRB_5)

The DMACHCRB registers are 32-bit readable/writable registers that control the DMA transfer mode.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	GS	GL	GCNT[3:0]				-	-	-	-	-	-	-	–
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	PRI[3:0]			
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
29	GS	0	R/W	Gathering Buffer Enable (Writing side) Data is transmitted collectively to the transfer destination. 0: disabled 1: enabled
28	GL	0	R/W	Gathering Buffer Enable (Reading side) Data is received collectively from the transfer source. 0: disabled 1: enabled
27 to 24	GCNT[3:0]	0000	R/W	Number of data gathering ability in gathering buffer Specify the number of data collectively transmitted with GCNT+1. The number of data transmits the transfer unit specified for the TS bits in DMACHCR. However, when the transfer size exceeds 256 bytes, the transfer size becomes 256 bytes.
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	PRI[3:0]	0000	R/W	Bus Request Priority Setting These bits set the priority of the bus request that is output by the DMAC. 1111: Highest priority : 0000: Lowest priority Note: For details of the PRI signal, see section 1-F Bus Functions.

8.3.9 DMA Operation Register (DMAOR)

DMAOR is a 16-bit readable/writable register that specifies the priority level of channels for the DMA transfer. This register also shows the DMA transfer status.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMS[3:0]				-	-	PR[1:0]		PPRI	-	-	-	-	AE	-	DME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R	R	R	R	R/(W)*	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	CMS[3:0]	0000	R/W	Cycle Steal Mode Select Select either normal mode or intermittent mode in cycle steal mode. It is necessary that all channel's bus modes are set to cycle steal mode to make valid intermittent mode. 0000: Normal mode 0010: Intermittent mode 16 Executes one DMA transfer in each of 16 cycles of the external bus clock. 0011: Intermittent mode 64 Executes one DMA transfer in each of 64 cycles of the external bus clock. 0100: Intermittent mode 256 Executes one DMA transfer in each of 256 cycles of the external bus clock. Other than above: Setting prohibited
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	PR[1:0]	00	R/W	Priority Mode Select the priority level between channels when there are transfer requests for multiple channels simultaneously. 00: CH0 > CH1 > CH2 > CH3 > CH4 > CH5 01: CH0 > CH2 > CH3 > CH1 > CH4 > CH5 10: Round-robin mode with top priority placed on CH0 11: Round-robin mode
7	PPRI	0	R/W	Bus Request Priority Push out Assigns the highest DMA bus request priority setting for channels performing DMA transfer as the value of bus request priority being currently output to the SHWY. 0: Normal mode 1: Bus request priority push out
6 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

2	AE	0	R/(W)*	Address Error Flag Indicates that an address error interrupt occurred during DMA transfer. This bit is set under following conditions: • The value set in DMASAR or DMADAR does not match the transfer size boundary. • The transfer source or transfer destination is invalid space. • The transfer source or transfer destination is in module stop mode If this bit is set, DMA transfer is not enabled for the channel even if the DE bit is set to 1. To clear the AE bit, write 0 to the AE bit after reading 1 from the bit or clear the CAE bit for each channel. (Clearing the AE bit clears the channel address errors for all channels.) 0: No DMAC address error interrupt [Clearing condition] Writing CAE = 0 after reading CAE = 1 1: DMAC address error interrupt occurs during DMA transfer
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	DME	0	R/W	DMA Master Enable Enables or disables DMA transfers on all channels. If the DME bit and the DE bit in DMACHCR are set to 1, DMA transfer is enabled. At this time, the TE bits in DMACHCR and the AE bits in DMAOR must be all 0. If this bit is cleared during transfer, transfers in all channels are terminated. 0: Disables DMA transfers on all channels 1: Enables DMA transfers on all channels

Note: * Writing 0 is possible to clear the flag.

8.3.10 DMA Channel Clear Register 0 to 5 (CHCLR_0 to CHCLR_5)

The CHCLR registers are 32-bit readable/writable registers that clear the buffer of each channel.

Bit	:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
		—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value	:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
		—	—	—	—	—	—	—	RP[4:0]					—	—	—	CLR
Initial value	:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 4	RP[4:0]	All 0	R	Number of data in buffer of channel The number of data that remains in the buffer of the channel is read. Units of the number of data are the DMA transfer size.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CLR	0	W	Channel Clear Bit When writing 0 to the bit, the buffer of channel to be cleared. Writing is prohibited during DMA operating.

8.3.11 DMA Extended Resource Selectors 0 to 2 (DMARS_0 to DMARS_2)

The DMARS registers are 16-bit readable/writable registers that specify the peripheral module as the source of the DMA transfer request for each channel. DMARS_0 specifies for channels 0 and 1, DMARS_1 specifies for channels 2 and 3, and DMARS_2 specifies for channels 4 and 5.

When MID/RID is set to a value other than the values listed in Table 8.7, the operation of this LSI is not guaranteed. The transfer request from DMARS is valid only when the resource select bits (RS[3:0]) have been set to B'1000 for DMACHCR_0 to DMACHCR_5. Otherwise, even if DMARS has been set, transfer request source is not accepted.

DMARS_0

8.4 Operation

When there is a DMA transfer request, the DMAC starts the transfer according to the predetermined channel priority; when the transfer end conditions are satisfied, it ends the transfer. Transfers can be requested in two modes: auto request, and on-chip peripheral module request. As bus mode, cycle steal mode (normal mode and intermittent mode) is used.

8.4.1 DMA Transfer Requests

DMA transfer requests are basically generated in either the data transfer source or destination, but they can also be generated by on-chip peripheral modules that are neither the source nor the destination. Transfers can be requested in two modes: auto request, and on-chip peripheral module request. The request mode is selected for each channel in the RS[3:0] bits in DMACHCR, DMARS0 to DMARS2.

(1) Auto-Request Mode

When there is no transfer request signal from an external source, as in a memory-to-memory transfer or a transfer between memory and an on-chip peripheral module unable to request a transfer, auto-request mode allows the DMAC to automatically generate a transfer request signal internally. When the DE bit in DMACHCR and the DME bit in DMAOR are set to 1 for the target channel, the transfer begins so long as the CAE bit in DMACHCRR is 0.

(2) On-Chip Peripheral Module Request Mode

In this mode, a transfer is performed at the transfer request signal of an on-chip peripheral module. The source (peripheral module) of the DMA transfer request is specified by the DMARS_0/1/2 register.

When this mode is selected, if the DMA transfer is enabled (DE = 1, DME = 1, TE = 0, CAE = 0), a transfer is performed upon the input of a transfer request signal.

When a transmit data empty transfer request of the SCIF is set as the transfer request, the transfer destination must be the SCIF's transmit data register. Likewise, when receive data full transfer request of the SCIF is set as the transfer request, the transfer source must be the SCIF's receive data register. These conditions also apply to the other on-chip peripheral modules.

The number of the receive FIFO triggers can be set as a transfer request depending on an on-chip peripheral module. Data needs to be read after the DMA transfer is ended, because data may be left in the receive FIFO when the receive FIFO trigger condition is not satisfied.

Table 8.8 Selecting On-Chip Peripheral Module Request Modes with Bits RS3 to RS0 (T.B.D.)

8.4.2 Channel Priority

When the DMAC receives simultaneous transfer requests on two or more channels, it transfers data according to a predetermined priority. Two modes (fixed mode and round-robin mode) are selected by the PR[1:0] bits in DMAOR.

(1) Fixed Mode

In this mode, the priority levels among the channels remain fixed. There are two kinds of fixed modes as follows:

- CH0 > CH1 > CH2 > CH3 > CH4 > CH5
- CH0 > CH2 > CH3 > CH1 > CH4 > CH5

These are selected by the PR[1:0] bits in DMAOR.

(2) Round-Robin Mode

In round-robin mode each time data of one transfer unit (byte, word, longword, 8-byte, 16-byte, or 32-byte unit) is transferred on one channel, the priority is rotated. The channel on which the transfer was just finished rotates to the bottom of the priority. The round-robin mode operation is shown in Figure 8.2. The priority of round-robin mode is CH0 > CH1 > CH2 > CH3 > CH4 > CH5 immediately after reset.

(3) CH0 Top Priority Round-Robin Mode

In this mode, the round-robin mode function is enabled for the channels from CH1 to CH5, with CH0 being always transferred at top priority. Once the transfer of CH0 is completed, the priority order will be the same as that applicable before the transfer.

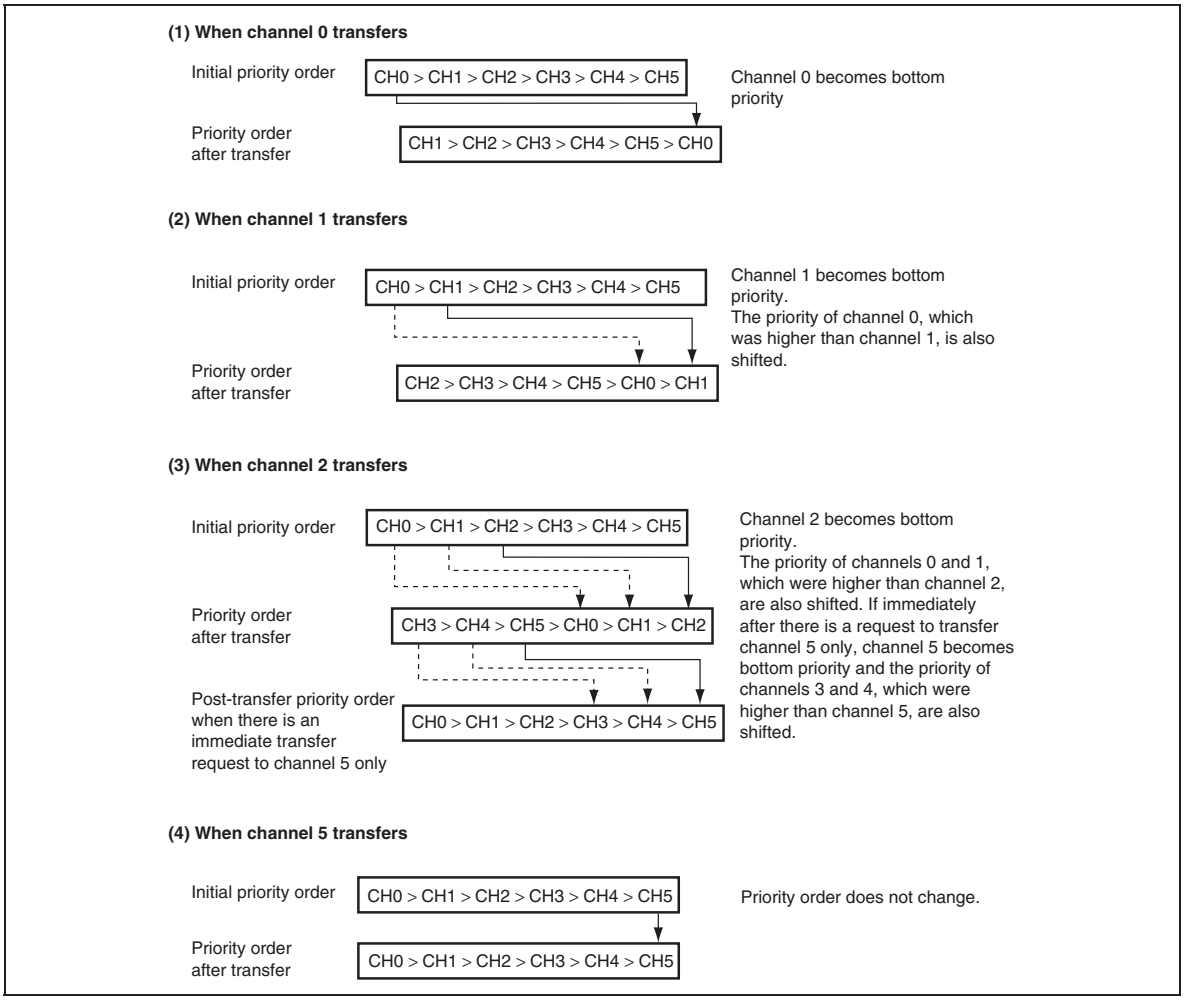

Figure 8.2 Round-Robin Mode

Figure 8.3 shows how the priority changes when channel 0 and channel 3 transfers are requested simultaneously and a channel 1 transfer is requested during the channel 0 transfer. The DMAC operates as follows:

1. Transfer requests are generated simultaneously to channels 0 and 3.
2. Channel 0 has a higher priority, so the channel 0 transfer begins first (channel 3 waits for transfer).
3. A channel 1 transfer request occurs during the channel 0 transfer (channels 1 and 3 are both waiting)
4. When the channel 0 transfer ends, channel 0 becomes lowest priority.
5. At this point, channel 1 has a higher priority than channel 3, so the channel 1 transfer begins (channel 3 waits for transfer).
6. When the channel 1 transfer ends, channel 1 becomes lowest priority.
7. The channel 3 transfer begins.
8. When the channel 3 transfer ends, channels 3 and 2 shift downward in priority so that channel 3 becomes the lowest priority.

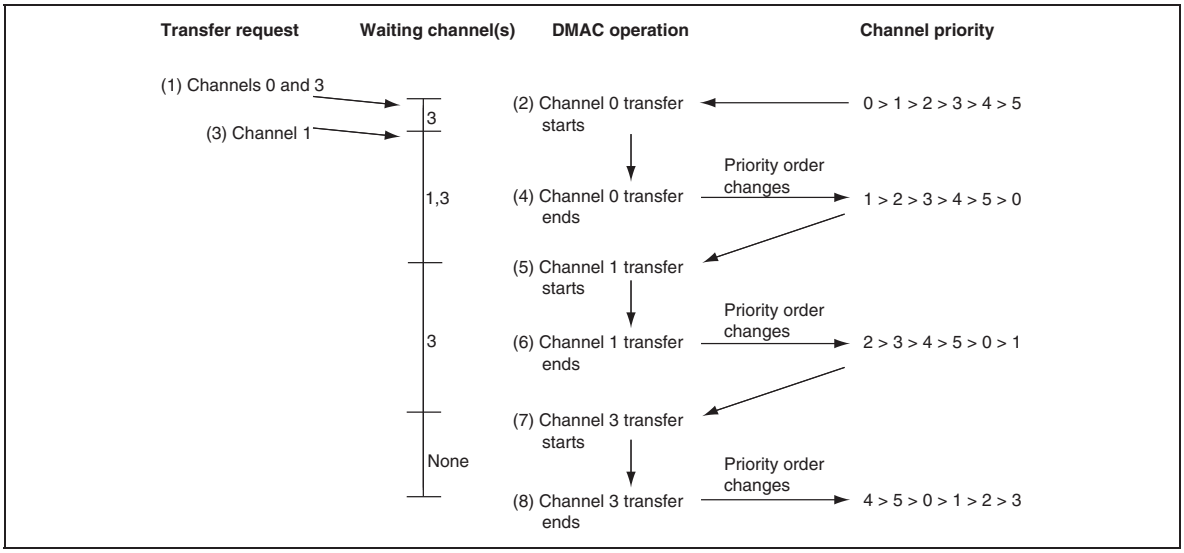

Figure 8.3 Changes in Channel Priority in Round-Robin Mode

8.4.3 Bus Request Priority Push out

The bus request priority push out is a function that assigns the highest value of the bus request priority setting bit in the DMA channel control register B among the output-enabled channels (channels in auto-request mode or channels that accepted a request) as the value of bus request priority being currently output to the SHWY.

Enabling this function prevents the processing of channels with higher bus request priority from being delayed by the presence of channels with lower bus request priority.

Figure 8.4 shows an example in which the bus request priority push out function is enabled.

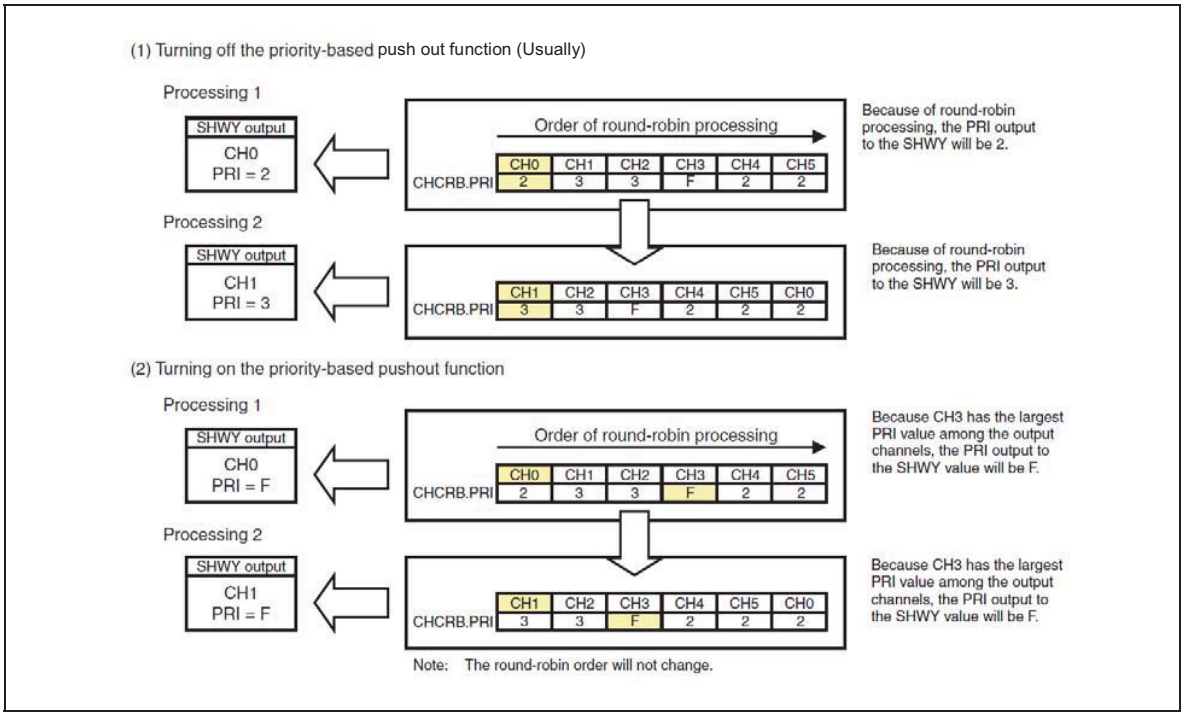

Figure 8.4 Example of Using the Bus Request Priority Push out Function

Note: For details of the PRI signal, see section 1-F Bus Functions.

8.4.4 DMA Transfer Types

DMA transfer is done in dual address mode. As bus mode, cycle steal mode (normal mode and intermittent mode) is used. The DMAC supports the transfers shown in Table 8.9.

Table 8.9 Supported DMA Transfers

	Destination			
Source	**External Memory**	**Memory-Mapped External Device**	**On-Chip Peripheral Module**	**X/Y Memory**
External device with DACK	Dual	Dual	Not available	Not available
External memory	Dual	Dual	Dual	Dual
Memory-mapped external device	Dual	Dual	Dual	Dual
On-chip peripheral module	Dual	Dual	Dual	Dual
X/Y memory	Dual	Dual	Dual	Dual

Note: 1. Dual: Dual address mode

(1) Address Mode

(a) Dual Address Mode

In dual address mode, both the transfer source and destination are accessed by addresses. The source and destination can be located externally or internally.

DMA transfer requires two bus cycles because data is read from the transfer source in a data read cycle and written to the transfer destination in a data write cycle. At this time, transfer data is temporarily stored in the DMAC. In the transfer between external memories as shown in Figure 8.5, data is read to the DMAC from one external memory in a data read cycle, and then that data is written to the other external memory in a write cycle.

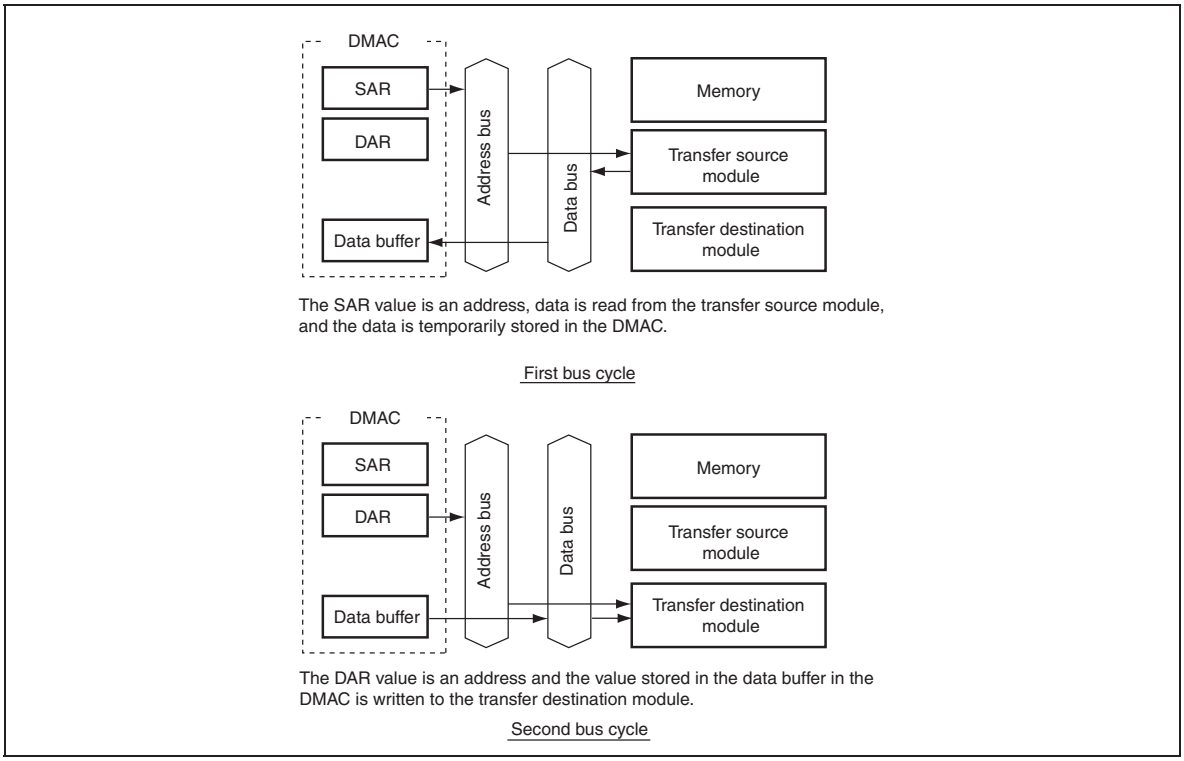

Figure 8.5 Data Flow of Dual Address Mode

Auto request, and on-chip peripheral module request are available for the transfer request.

(2) Bus Modes

Cycle steal mode is used as bus mode.

(a) Cycle-Steal Mode

- Normal mode

  In cycle-steal normal mode, the DMAC gives the bus mastership to another bus master every time a unit of transfer (byte, word, longword, 8-byte, 16-byte, 32-byte, or 64-byte unit) is complete. When another transfer request occurs after that, the DMAC gets the bus mastership from the other bus master and performs a transfer for one transfer unit. When that transfer ends, the DMAC returns the bus mastership to the other bus master. This is repeated until the transfer end conditions are satisfied.

  In cycle-steal normal mode, all transfer areas are available for the transfer request source, transfer source, and transfer destination.

  Figure 8.6 shows an example of DMA transfer timing in cycle-steal normal mode. Transfer conditions shown in the figure are:

  — Condition 1: Dual address mode

  — Condition 2: DREQ low level detection

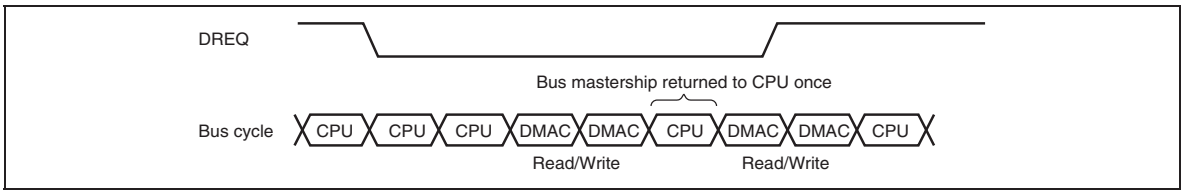

Figure 8.6 DMA Transfer Example in Cycle-Steal Normal Mode (Dual Address, DREQ Low Level Detection)

- Intermittent mode

  In intermittent mode of cycle steal, the DMAC gives the bus mastership to another bus master every time a unit of transfer (byte, word, longword, 8-byte, 16-byte, 32-byte or 64-byte unit) is complete. When another transfer request occurs after that, the DMAC gets the bus mastership from the other bus master after waiting for 16, 64, or 256 clock cycles in ZSϕ count. The DMAC then transfers data of one unit and returns the bus mastership to the other bus master. This is repeated until the transfer end conditions are satisfied. It is thus possible to make lower the ratio of bus occupation by DMA transfer than cycle-steal normal mode.

  When the DMAC gets again the bus mastership, DMA transfer can be postponed in case of entry updating due to cache miss.

  In intermittent mode, all transfer areas are available for the transfer request source, transfer source, and transfer destination. The bus modes, however, must be cycle steal mode in all channels.

  Figure 8.7 shows an example of DMA transfer timing in cycle steal intermittent mode. Transfer conditions shown in the figure are:

  — Condition 1: Dual address mode

  — Condition 2: DREQ low level detection

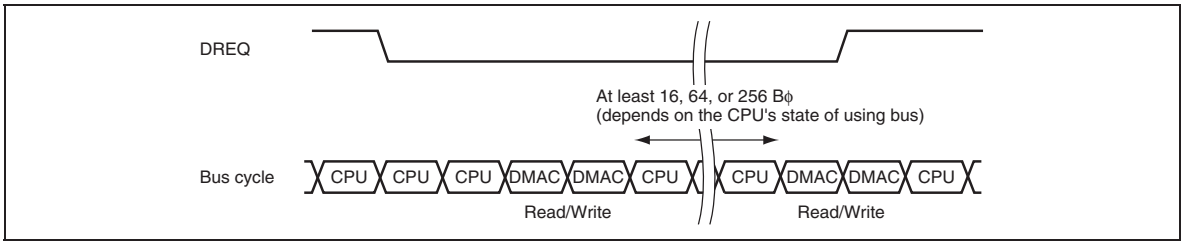

Figure 8.7 Example of DMA Transfer in Cycle Steal Intermittent Mode (Dual Address, DREQ Low Level Detection)

(3) Relationship between Request Modes and Bus Modes by DMA Transfer Category

Table 8.10 shows the relationship between request modes and bus modes by DMA transfer category.

Table 8.10 Relationship between Request Modes and Bus Modes by DMA Transfer Category

Address Mode	Transfer Category	Request Mode	Bus Mode	Transfer Size (Bits)	Usable Channels
Dual	External memory and external memory	External, auto	C	1/2/4/8/16/32/64	0 to 5
	External memory and memory-mapped external device	External, auto	C	1/2/4/8/16/32/64	0 to 5
	Memory-mapped external device and memory-mapped external device	External, auto	C	1/2/4/8/16/32/64	0 to 5
	External memory and on-chip peripheral module	All*[1]	C	1/2/4/8/16/32/64*[2]	0 to 5
	Memory-mapped external device and on-chip peripheral module	All*[1]	C	1/2/4/8/16/32/64*[2]	0 to 5
	On-chip peripheral module and on-chip peripheral module	All*[1]	C	1/2/4/8/16/32/64*[2]	0 to 5
	X/Y memory and X/Y memory	External, auto	C	1/2/4/8/16/32/64	0 to 5
	X/Y memory and memory-mapped external device	External, auto	C	1/2/4/8/16/32/64	0 to 5
	X/Y memory and on-chip peripheral module	All*[1]	C	1/2/4/8/16/32/64*[2]	0 to 5
	X/Y memory and external memory	External, auto	C	1/2/4/8/16/32/64	0 to 5

[Legend]

C: Cycle steal mode

Notes: 1. Auto requests, and on-chip peripheral module requests are all available. However the request source register must be designated as the transfer source or the transfer destination.

2. Access size permitted for the on-chip peripheral module register functioning as the transfer source or transfer destination.

Table 8.11 DMA transfer size according to module

notes : * Never transmits directly to CMT1.

8.4.5 DMA Transfer Flow

After the DMA source address registers (DMASAR), DMA destination address registers (DMADAR), DMA transfer count registers (DMATCR), DMA channel control registers (DMACHCR), DMA operation register (DMAOR), and DMA extended resource selectors (DMARS) are set, the DMAC transfers data according to the following procedure:

1. Checks to see if transfer is enabled (DE = 1, DME = 1, TE = 0, CAE = 0)
2. When a transfer request occurs while transfer is enabled, the DMAC transfers one transfer unit of data (depending on the setting of the TS3 to TS0 bits). In auto request mode, the transfer begins automatically when the DE bit and DME bit are set to 1. The DMATCR value will be decremented for each transfer. The actual transfer flows vary by address mode and bus mode.
3. When the specified number of transfers have been completed (when DMATCR reaches 0), the transfer ends normally. If the IE bit in DMACHCR is set to 1 at this time, a DEI interrupt is sent to the CPU.
4. When an address error is generated, the transfer is aborted. Transfers are also aborted when the DE bit in DMACHCR or the DME bit in DMAOR is changed to 0.

Figure 8.8 shows a flowchart of this procedure.

Notes:
1. In repeat mode, a transfer request is acceptted with TE =1 when HIE = 1 and HE = 0.
2. In auto-request mode, transfer starts when bits NMIF, AE, and TE are all 0 or bits TE and HIE are 1 and HE is 0 (in repeat mode), and bits DE and DME are set to 1.
3. Internal peripheral module request.
4. Auto request.
5. Loading to SAR and DAR differs according to the operating conditions in each mode.
6. TCRBH represents bits TCRB[13:16] and TCRBL represents bits TCRB [15 to 0].

Figure 8.8 DMA Transfer Flowchart

8.4.6 Repeat Mode Transfer

In a repeat mode transfer, a DMA transfer is repeated without making the transfer settings every time before executing a transfer.

Using a repeat mode transfer with the half end function allows a double buffer transfer executed virtually. The following procedures can be executed effectively by using a repeat mode transfer. As an example, operation of receiving voice data from the VOICE CODEC and compressing it is explained.

In the following example, processing of compressing 40-word voice data for every data reception is explained. In this case, it is assumed that voice data is received by means of MSIOF.

1. DMAC settings
- Set address of the MSIOF receive data register in DMASAR
- Set address of an internal memory data store area in DMADAR
- Set DMATCR to 80 (H'50)
- Make the following settings of DMACHCR
  Bits RPT[2:0] = B'010: Repeat mode (use DAR as a repeat area)
  Bit HIE = B'1: TCR/2 interrupt generated
  Bits DM[1:0] = B'01: DAR incremented
  Bits SM[1:0] = B'00: SAR fixed
  Bit IE = B'1: Interrupt enabled
  Bit DE = B'1: DMA transfer enabled
- Set such as bits TB and TS[2:0] according to use conditions
- Set bits CMS[3:0] and PR[1:0] in DMAOR according to use conditions and set the DME bit to B'1

2. Voice data is received and then transferred by MSIOF/DMAC
3. DMATCR is decreased to half of its initial value and an interrupt is generated
   Read DMACHCR to confirm that the HE bit is set to 1 by an interrupt processing, and compress 40-word voice data from the address set in DMADAR.
4. DMATCR is cleared to 0 and an interrupt is generated
   Read DMACHCR to confirm that the TE bit is set to 1 by an interrupt processing, and compress 40-word voice data from the address set in DMADAR + 40. After this operation, the value of DMADARB is copied to DMADAR in DMAC and initialized, and the value of DMATCRB is copied to DMATCR and initialized to 80.
5. Hereafter, steps 2 and 3 are repeated until bit DME or DE is set to B'0.

As explained above, a repeat mode transfer enables sequential voice compression by switching a buffer for storing data received consequentially and a data buffer for processing signals alternately.

8.4.7 Reload Mode Transfer

In a reload mode transfer, according to the settings of bits RPT[2:0] in DMACHCR, the value set in DMASARB/DMADARB is set to DMASAR/DMADAR and the value of bits DMATCRB[31:16] is set in bits DMATCRB[15:0] every time the number of transfers specified in the DMATCRB[15:0] bits are completed, and the transfer is repeated until DMATCR becomes 0 without specifying the transfer settings again. A reload mode transfer is effective when repeating data transfer with specific areas. Figure 8.9 shows the operation of reload mode transfer.

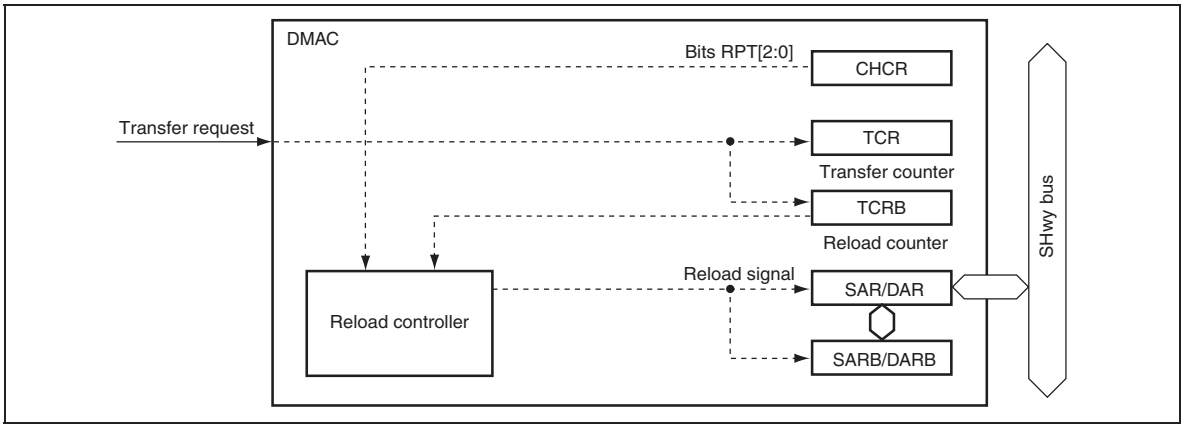

Figure 8.9 Reload Mode Transfer

When a reload mode transfer is executed, DMATCRB is used as a reload counter. Set DMATCRB as described in section 8.3.7, DMA Transfer Count Registers B_0 to 5 (DMATCRB_0 to DMATCRB_5).

8.4.8 Gathering Buffer Function

When the gathering buffer function is made effective, receive data or the transmission data is transmitted collectively in 256 bytes or less. The penalty by the row address mistake of a different bank is reduced to SDRAM by collectively transmitting, and the performance of the transmission improves.

Write 0 to the GL bits in DMACHCRB when you make this function effective on the receiving side. Write 0 to the GS bits in DMACHCRB when you make this function effective at the transmitting side. And, set the GCNT bits in DMACHCRB. After, begin the DMA transfer. This function transmits the size specified for the TS bits in DMACHCR data GCNT+1 collectively. However, when the transfer size exceeds 256 bytes, the transfer size becomes 256 bytes.

When the RS bits in DMACHCR is DMA Extended Resource Selector (B'1000), On-chip peripheral module side can not enable the gathering buffer function.

When the RS bits in DMACHCR is DMA Extended Resource Selector (B'1000), the data that remains in the buffer is output to the memory when writing 0 to the DE bit in DMACHCR while receive data is being collected from the On-chip peripheral module.

The number of packets that remains in the buffer can be confirmed by reading RP bits in DMACHCLR.

Figure 8.10 shows the example of timing when the gathering buffer function is used.

Table 8.12 shows the correspondence table of the gathering buffer function.

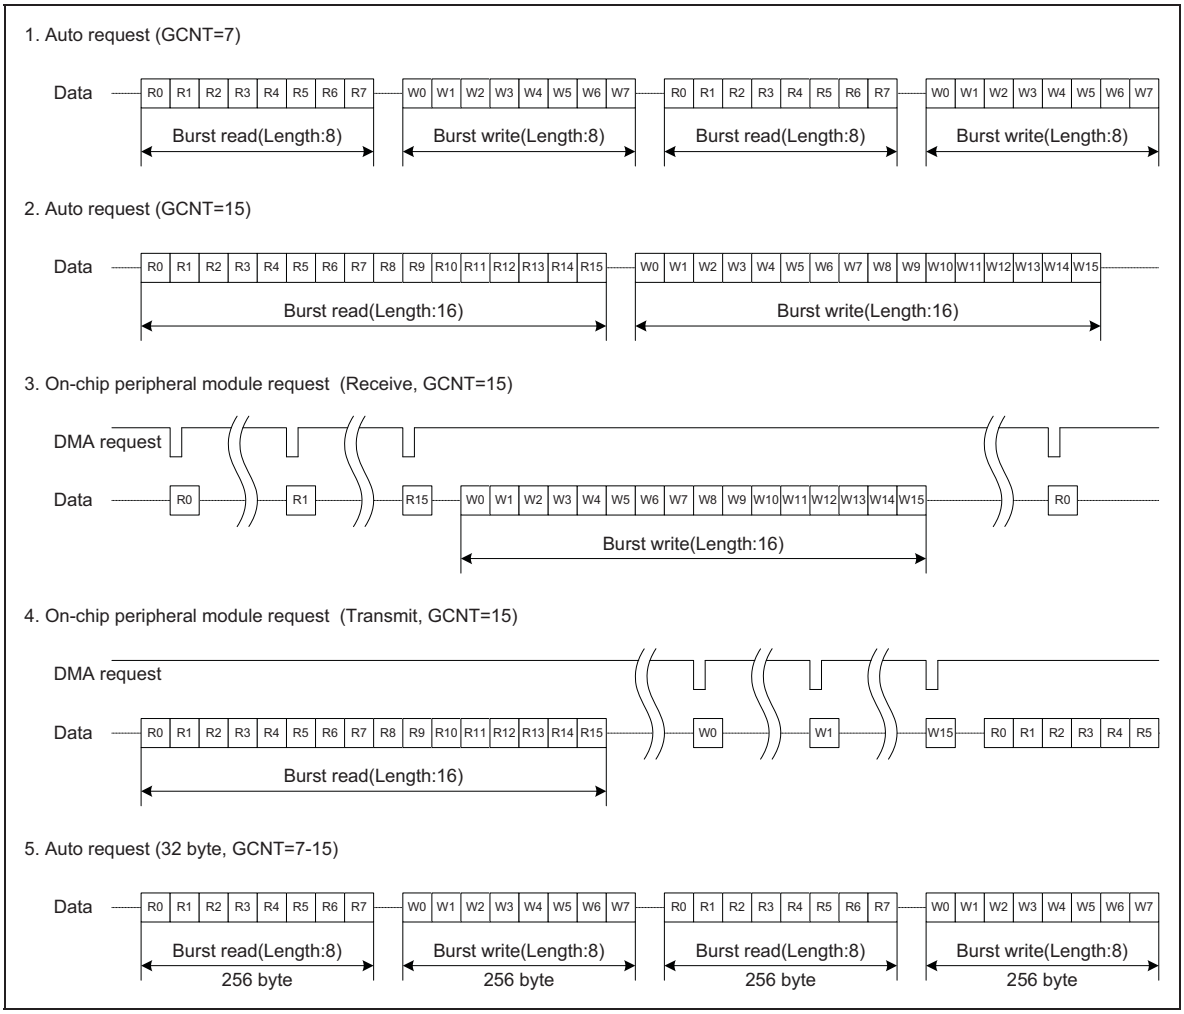

Figure 8.10 Example of Timing when the Gathering Buffer Function is Used

Table 8.12 The Correspondence Table of the Gathering Buffer Function.

Module	Function	Source	Destination
Memory-to-memory	—	Yes	Yes
External device	Transmit and receive	No	No
BBIF1/2	Transmit	Yes	No
	Receive	No	Yes

notes : As for the transfer to on-chip peripheral module side, the gathering buffer function is compulsorily invalidated.

8.5 Usage Notes

Pay attentions to the following notes when the DMAC is used.

(1) DMA Transfer for Peripheral Modules

When executing a DMA transfer for peripheral modules, an appropriate boundary address should be set for the transfer source or destination address according to the transfer data size. Otherwise, an address error may occur.

(2) Module Stop

While the DMAC is in operation, the DMAC should not be stopped by the module stop register (MSTPCR0) setting. When the DMAC is stopped, transfer contents cannot be guaranteed.

(3) Address Error

Clear the buffer by writing 0 to the CLR bit in DMA channel clear register (DMACHCLR) when the DMA address error occurs. When a DMA address error is generated, set the register of the error-ridden channel again and then start a transfer.

(4) DMA Transfer Stop

Wait for the RP bits in CHCLR to become 0 after writing 0 to the DE bit in CHCR about the stop of the DMA transfer.

(5) DMA Transfer Interruption

When make the DMA transfer interrupted, the interruption disable should be set and set the DE bit in DMA channel control register (DMACHCR) as the DMA transfer disable. If the TE is generated during the DMA transfer interruption, the TE should be initialized. The generation timing after the transfer interruption for an asynchronous assumed following three cases.

1. A case that after setting for the interruption disable, TE is changed to 1 before the CHCR initialization. The TE is initialized by the processing DMA transfer initialization.
2. A case that after setting for the interruption disable, the TE is changed to 1 by ignoring the transfer interruption. After the DMA transfer initialization and the CHCR dummy read, check the TE bit. If the TE bit is 1, the DMA transfer initialization process should be performed.
3. A case that after setting for the interruption disable, the TE is not changed to 0 even though the transfer interruption is occurred.
   After the DMA transfer interruption, the TE is not generated because the transfer data is still remained.

Note: In a case that the DMA transfer initialization is performed while the last transfer is executing, causes TE generation delay. So the dummy read should be performed.

Figure 8.11 shows the processing example when DMA transfer interruption (Data is guaranteed).

Figure 8.12 shows the processing example when DMA transfer interruption (Compulsion interruption).

Section 9 Realtime Direct Memory Access Controller (RTDMAC)

This LSI includes three sets of direct memory access controllers (RTDMAC1 and RTDMAC2 which are collectively called the RTDMAC).

The RTDMAC can be used in place of the CPU to perform high-speed transfers between external memory, on-chip memory, memory-mapped external devices, and on-chip peripheral modules.

9.1 Features

- Six channels
- 4-Gbyte physical address space
- Data transfer unit is selectable: Byte, word (2 bytes), longword (4 bytes), 8 bytes, 16 bytes, 32 bytes, and 64 bytes
- Maximum transfer count: 16,777,216 transfers
- Address mode: Dual address mode
- Transfer requests:

  On-chip peripheral module request, or auto request can be selected.

  The following modules can issue an on-chip peripheral module request.

  — CMT1, SCIFA0/1/2/3/4/5, SCIFB, MSIOF0/1/2, BBIF1/2, IIC0/1/2/3/4, FLCTL0/1, FSI, SDHI0/1/2, TPU0, TSIF0/1, IRDA, DSI0/1, HSI, MFI, MMC, SHWYSTAT
- Bus mode: Cycle steal mode (normal mode and intermittent mode)
- Selectable channel priority levels:

  The channel priority levels are selectable between fixed mode and round-robin mode.
- Interrupt request: An interrupt request can be generated to the CPU after half of the transfers ended, all transfers ended, or an address error occurred.
- Gathering buffer function: Transfer data of 256 bytes or less can be collectively transmitted.

Figure 9.1 shows the block diagram of the RTDMAC.

[Legend]
SARm : DMA source address register
SARBm : DMA source address register B
DARm : DMA destination address register
DARBm : DMA destination address register B

INTm : DMA transfer end/half-end interrupt request
AdrsErr : Address error interrupt request
m : 0,1,2,3,4,5

Figure 9.1 Block Diagram of RTDMAC

9.2 Input/Output Pins

There are no external pins relevant to the RTDMAC.

9.3 Register Descriptions

Table 9.1, and Table 9.3 show the configuration of registers of the RTDMAC, and RTDMAC2 respectively. Table 9.2, and Table 9.4 show the state of the registers in each processing mode.

The DMASAR for channel 0 in the RTDMAC is expressed as RDM1SAR_0 and the DMAOR for channel 2 in the RTDMAC2 is expressed as RDM2OR.

9.3.1 DMA Source Address Registers 0 to 5 (DMASAR_0 to DMASAR_5)

The DMASAR registers are 32-bit readable/writable registers that specify the source address of a DMA transfer. During a DMA transfer, these registers indicate the next source address.

To transfer data in word or in longword units, specify a word or longword boundary address. When transferring data in 8-byte, 16-byte, 32-byte, or 64-byte units, an 8-byte, 16-byte, 32-byte, or 64-byte boundary must be set for the source address value. However, if the address mode in the DMA channel control register is set as fixed (SM[1:0] = B'11) even when transferring data in 32-byte or 64-byte, a value can be specified in 16-byte boundary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SAR

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

9.3.2 DMA Source Address Registers B_0 to 5 (DMASARB_0 to DMASARB_5)

The DMASARB registers are 32-bit readable/writable registers that specify the source address of a DMA transfer that is to be set in DMASAR in repeat/reload mode. Data to be written from the CPU to DMASAR is also written to DMASARB. To set a DMASARB address that differs from the DMASAR address, write data to DMASARB after DMASAR.

To transfer data in word or in longword units, specify a word or longword boundary address. When transferring data in 8-byte, 16-byte, 32-byte, or 64-byte units, an 8-byte, 16-byte, 32-byte, or 64-byte boundary must be set for the source address value. However, if the address mode in the DMA channel control register is set as fixed (SM[1:0] = B'11) even when transferring data in 32-byte or 64-byte, a value can be specified in 16-byte boundary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

9.3.3 DMA Destination Address Registers 0 to 5 (DMADAR_0 to DMADAR_5)

The DMADAR registers are 32-bit readable/writable registers that specify the destination address of a DMA transfer. During a DMA transfer, these registers indicate the next destination address.

To transfer data in word or in longword units, specify a word or longword boundary address. When transferring data in 8-byte, 16-byte, 32-byte, or 64-byte units, an 8-byte, 16-byte, 32-byte, or 64-byte boundary must be set for the destination address value. However, if the address mode in the DMA channel control register is set as fixed (SM[1:0] = B'11) even when transferring data in 32-byte or 64-byte, a value can be specified in 16-byte boundary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

9.3.4 DMA Destination Address Registers B_0 to 5 (DMADARB_0 to DMADARB_5)

The DMADARB registers are 32-bit readable/writable registers that specify the destination address of a DMA transfer that is to be set in DMADAR in repeat/reload mode. Data to be written from the CPU to DMADAR is also written to DMADARB. To set a DMADARB address that differs from the DMADAR address, write data to DMADARB after DMADAR.

To transfer data in word or in longword units, specify a word or longword boundary address. When transferring data in 8-byte, 16-byte, 32-byte, or 64-byte units, an 8-byte, 16-byte, 32-byte, or 64-byte boundary must be set for the destination address value. However, if the address mode in the DMA channel control register is set as fixed (SM[1:0] = B'11) even when transferring data in 32-byte or 64-byte, a value can be specified in 16-byte boundary.

9.3.5 DMA Transfer Count Registers 0 to 5 (DMATCR_0 to DMATCR_5)

The DMATCR registers are 32-bit readable/writable registers that specify the DMA transfer count. The number of transfers is 1 when the setting is H'00000001, 16,777,215 when H'00FFFFFF is set, and 16,777,216 (the maximum) when H'00000000 is set. During a DMA transfer, these registers indicate the remaining transfer count.

The upper eight bits of DMATCR are always read as 0, and the write value should always be 0.

9.3.6 DMA Transfer Count Registers B_0 to 5 (DMATCRB_0 to DMATCRB_5)

The DMATCRB registers are 32-bit readable/writable registers. Data to be written from the CPU to DMATCR is also written to DMATCRB. To set a DMATCRB address that differs from the DMATCR address, write data to DMATCRB after DMATCR. While the HE function is used, DMATCRB is used to hold the initial value for detecting HE. DMATCRB specifies the number of DMA transfers which are set in DMATCR in repeat mode. DMATCRB specifies the number of DMA transfers and are used as a transfer counter in reload mode.

In reload mode, the lower 16 bits operate as a transfer counter; the values of DMASAR and DMADAR are updated after the value of the lower 16 bits became 0, and the value of the upper 16 bits of DMATCRB is loaded to the lower 16 bits. In the upper 16 bits, set the number of transfers that should be executed before the transfer count is reloaded. In reload mode, the same number of transfers should be set in both upper and lower 16 bits. In addition, set the HIE bit in DMACHCR to 0 and do not use the HE function.

9.3.7 DMA Channel Control Registers 0 to 5 (DMACHCR_0 to DMACHCR_5)

The DMACHCR registers are 32-bit readable/writable registers that control the DMA transfer mode.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CAE	CAIE	HEE[1:0]		RPT[2:0]			-	-	-	TS[3:2]		HE	HIE	-	–

R/W :	R/(W)*	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/(W)*	R/W	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DM[1:0]		SM[1:0]		RS[3:0]				-	-	-	TS[1:0]		IE	TE	DE
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/(W)*	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	CAE	0	R/(W)*	Address Error Flag Indicates that an address error interrupt occurred during DMA transfer. This bit is set under following conditions: • The value set in DMASAR or DMADAR does not match the transfer size boundary. • The transfer source or transfer destination is invalid space. • The transfer source or transfer destination is in module stop mode If this bit is set, DMA transfer is not enabled for the channel even if the DE bit is set to 1. To clear the CAE bit, write 0 to the CAE bit after reading 1 from the bit or clear the AE bit in DMAOR. (Clearing the AE bit clears the channel address errors for all channels.) 0: No RTDMAC address error interrupt [Clearing condition] Writing CAE = 0 after reading CAE = 1 1: RTDMAC address error interrupt occurs during DMA transfer
30	CAIE	0	R/W	Channel Address Error Interrupt Enable Specifies whether to request the CPU of an interrupt when an address error occurs. If the CAIE bit is set to 1, setting the CAE bit requests the CPU of an interrupt (DEI0 to DEI 5) for each channel. Note: An address error interrupt (DADERR) is asserted simultaneously. For interrupts, see section 5, Interrupt Controller (INTC). 0: Interrupt request disabled 1: Interrupt request enabled

Bit	Bit Name	Initial Value	R/W	Descriptions
29, 28	HEE[1:0]	00	R/W	HE Interrupt Function Extension This bit is meaningful only when the HIE bit is set to 1. 00: HE interrupt occurs when the transfer count reaches about a half of DMATCR which is set before transfer (same as before). 01: HE interrupt occurs every time the transfer count reaches about n/4 (n=1, 2, or 3) of DMATCR which is set before transfer. 10: HE interrupt occurs every time the transfer count reaches about n/8 (n=1 to 7) of DMATCR which is set before transfer. 11: HE interrupt occurs every time the transfer count reaches about n/16 (n=1 to 15) of DMATCR which is set before transfer.
27 to 25	RPT[2:0]	000	R/W	DMA Setting Renewal Specify 000: Normal mode (RTDMAC operation) 001: Repeat mode DMASAR/DMADAR used as repeat area 010: Repeat mode DMADAR used as repeat area 011: Repeat mode DMASAR used as repeat area 100: Setting prohibited 101: Reload mode DMASAR/DMADAR used as reload area 110: Reload mode DMADAR used as reload area 111: Reload mode DMASAR used as reload area
24 to 22	—	000	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
21, 20	TS[3:2]	00	R/W	DMA Transfer Size Specify With TS[1:0], these bits specify the DMA transfer size. When the transfer source or transfer destination is a register of an on-chip peripheral module with a transfer size set, a proper transfer size for the register should be set. In 2-division transfer mode, 16/32-byte data is halved and transferred in two operations. For the transfer source or destination address specified by DMASAR or DMADAR, an appropriate boundary address should be set according to the transfer data size. TS[3:2] + TS[1:0] 0000: Byte units transfer 0001: Word (2-byte) units transfer 0010: Longword (4-byte) units transfer 0011: 16-byte units transfer 0100: 32-byte units transfer 0101: 64-byte units transfer 0111: 8-byte units transfer Other than above: Setting prohibited
19	HE	0	R/(W)*	Half End Flag After HIE (bit 18) is set to 1 and the number of transfers become half of DMATCR (1 bit shift to right) which is set before transfer starts, HE becomes 1. The HE bit is not set when transfers are ended by an address error or by clearing the DE bit and the DME bit in DMAOR before the number of transfers is decreased to half of the DMATCR value set preceding the transfer. The HE bit is kept set when the transfer ends by an address error, or clearing the DE bit (bit 0) or the DME bit in DMAOR after the HE bit is set to 1. To clear the HE bit, write 0 after reading 1 in the HE bit. 0: During the DMA transfer or DMA transfer has been interrupted DMATCR > (DMATCR set before transfer)/2 [Clearing condition] Writing 0 after reading HE = 1. 1: DMATCR ≤ (DMATCR set before transfer)/2
18	HIE	0	R/W	Half End Interrupt Enable Specifies whether an interrupt request is generated to the CPU when the number of transfers is decreased to half of the DMATCR value set preceding the transfer. When the HIE bit is set to 1 and the HE bit is set, an interrupt request is generated to the CPU. Set this bit to 0 while reload mode is set. 0: Interrupt request is disabled when DMATCR = (DMATCR set before transfer)/2 1: Interrupt request is enabled when DMATCR = (DMATCR set before transfer)/2
17, 16	—	000	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	DM[1:0]	00	R/W	Destination Address Mode Specify whether the DMA destination address is incremented, decremented, or left fixed. 00: Fixed destination address 01: Destination address is incremented +1 in byte units transfer +2 in word units transfer +4 in longword units transfer +8 in 8-byte units transfer +16 in 16-byte units transfer +32 in 32-byte units transfer +64 in 64-byte units transfer 10: Destination address is decremented –1 in byte units transfer –2 in word units transfer –4 in longword units transfer Setting prohibited in 8/16/32-byte units transfer 11: Fixed destination address Set to prevent an address from being changed in the objective modules. Example: When specifying FIFOs in the peripheral modules.
13, 12	SM[1:0]	00	R/W	Source Address Mode Specify whether the DMA source address is incremented, decremented, or left fixed. 00: Fixed source address 01: Source address is incremented +1 in byte units transfer +2 in word units transfer +4 in longword units transfer +8 in 8-byte units transfer +16 in 16-byte units transfer +32 in 32-byte units transfer +64 in 64-byte units transfer 10: Source address is decremented –1 in byte units transfer –2 in word units transfer –4 in longword units transfer Setting prohibited in 8/16/32-byte units transfer 11: Fixed source address Set to prevent an address from being changed in the objective modules. Example: When specifying FIFOs in the peripheral modules.
11 to 8	RS[3:0]	0000	R/W	Resource Select Specify which transfer requests will be sent to the RTDMAC. The changing of transfer request source should be done in the state that the DMA enable bit (DE) is set to 0. 0100: Auto request 1000: Selected by DMA extended resource selector Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Descriptions
7 to 5	—	000	R	Reserved This bit is always read as 0. The write value should always be 0.
4, 3	TS[1:0]	00	R/W	DMA Transfer Size Specify See the description of TS[3:2] (bits 21 and 20).
2	IE	0	R/W	Interrupt Enable Specifies whether or not an interrupt request is generated to the CPU at the end of the DMA transfer. Setting this bit to 1 generates an interrupt request (DEI) to the CPU when the TE bit is set to 1. 0: Interrupt request is disabled. 1: Interrupt request is enabled.
1	TE	0	R/(W)*	Transfer End Flag The TE bit is set to 1 when data transfer ends when DMATCR becomes 0. The TE bit is not set to 1 in the following cases. • DMA transfer ends due to a DMA address error before DMATCR becomes 0. • DMA transfer is ended by clearing the DE bit and DME bit in DMAOR. To clear the TE bit, the TE bit should be written to 0 after reading 1. Even if the DE bit is set to 1 while this bit is set to 1, transfer is not enabled. 0: During the DMA transfer or DMA transfer has been interrupted [Clearing condition] Writing 0 after reading TE = 1 1: DMA transfer ends by the specified count (TCR = 0)
0	DE	0	R/W	DMA Enable Enables or disables the DMA transfer. In auto request mode, DMA transfer starts by setting the DE bit and DME bit in DMAOR to 1. At this time, both of the AE bit in DMAOR and the TE bit must be 0. In an peripheral module request, DMA transfer starts if DMA transfer request is generated by the devices or peripheral modules after setting the DE and DME bits to 1. In this case, however, both of the TE and AE bits must be 0, which is the same as in the case of auto request mode. Clearing the DE bit to 0 can terminate the DMA transfer. 0: DMA transfer disabled 1: DMA transfer enabled

Note: * Writing 0 is possible to clear the flag.

9.3.8 DMA Channel Control Register B_0 to 5 (DMACHCRB_0 to DMACHCRB_5)

The DMACHCRB registers are 32-bit readable/writable registers that control the DMA transfer mode.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
29	GS	0	R/W	Gathering Buffer Enable (Writing side) Data is transmitted collectively to the transfer destination. 0: disabled 1: enabled
28	GL	0	R/W	Gathering Buffer Enable (Reading side) Data is received collectively from the transfer source. 0: disabled 1: enabled
27 to 24	GCNT[3:0]	0000	R/W	Number of data gathering ability in gathering buffer Specify the number of data collectively transmitted with GCNT+1. The number of data transmits the transfer unit specified for the TS bits in DMACHCR. However, when the transfer size exceeds 256 bytes, the transfer size becomes 256 bytes.
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	PRI[3:0]	0000	R/W	Bus Request Priority Setting These bits set the priority of the bus request that is output by the RTDMAC. 1111: Highest priority : 0000: Lowest priority Note: For details of the PRI signal, see section 1-F Bus Functions.

9.3.9 DMA Operation Register (DMAOR)

DMAOR is a 16-bit readable/writable register that specifies the priority level of channels for the DMA transfer. This register also shows the DMA transfer status.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMS[3:0]				-	-	PR[1:0]		PPRI	-	-	-	-	AE	-	DME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R	R	R	R	R/(W)*	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	CMS[3:0]	0000	R/W	Cycle Steal Mode Select Select either normal mode or intermittent mode in cycle steal mode. It is necessary that all channel's bus modes are set to cycle steal mode to make valid intermittent mode. 0000: Normal mode 0010: Intermittent mode 16 Executes one DMA transfer in each of 16 cycles of the external bus clock. 0011: Intermittent mode 64 Executes one DMA transfer in each of 64 cycles of the external bus clock. 0100: Intermittent mode 256 Executes one DMA transfer in each of 256 cycles of the external bus clock. Other than above: Setting prohibited
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	PR[1:0]	00	R/W	Priority Mode Select the priority level between channels when there are transfer requests for multiple channels simultaneously. 00: CH0 > CH1 > CH2 > CH3 > CH4 > CH5 01: CH0 > CH2 > CH3 > CH1 > CH4 > CH5 10: Round-robin mode with top priority placed on CH0 11: Round-robin mode
7	PPRI	0	R/W	Bus Request Priority Push out Assigns the highest DMA bus request priority setting for channels performing DMA transfer as the value of bus request priority being currently output to the SHWY. 0: Normal mode 1: Bus request priority push out
6 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

2	AE	0	R/(W)*	Address Error Flag Indicates that an address error interrupt occurred during DMA transfer. This bit is set under following conditions: • The value set in DMASAR or DMADAR does not match the transfer size boundary. • The transfer source or transfer destination is invalid space. • The transfer source or transfer destination is in module stop mode If this bit is set, DMA transfer is not enabled for the channel even if the DE bit is set to 1. To clear the AE bit, write 0 to the AE bit after reading 1 from the bit or clear the CAE bit for each channel. (Clearing the AE bit clears the channel address errors for all channels.) 0: No RTDMAC address error interrupt [Clearing condition] Writing CAE = 0 after reading CAE = 1 1: RTDMAC address error interrupt occurs during DMA transfer
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	DME	0	R/W	DMA Master Enable Enables or disables DMA transfers on all channels. If the DME bit and the DE bit in DMACHCR are set to 1, DMA transfer is enabled. At this time, the TE bits in DMACHCR and the AE bits in DMAOR must be all 0. If this bit is cleared during transfer, transfers in all channels are terminated. 0: Disables DMA transfers on all channels 1: Enables DMA transfers on all channels

Note: * Writing 0 is possible to clear the flag.

9.3.10 DMA Channel Clear Register 0 to 5 (CHCLR_0 to CHCLR_5)

The CHCLR registers are 32-bit readable/writable registers that clear the buffer of each channel.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	RP[4:0]					—	—	—	CLR
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 4	RP[4:0]	All 0	R	Number of data in buffer of channel The number of data that remains in the buffer of the channel is read. Units of the number of data are the DMA transfer size.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CLR	0	W	Channel Clear Bit When writing 0 to the bit, the buffer of channel to be cleared. Writing is prohibited during DMA operating.

9.3.11 DMA Extended Resource Selectors 0 to 2 (DMARS_0 to DMARS_2)

The DMARS registers are 16-bit readable/writable registers that specify the peripheral module as the source of the DMA transfer request for each channel. DMARS_0 specifies for channels 0 and 1, DMARS_1 specifies for channels 2 and 3, and DMARS_2 specifies for channels 4 and 5.

When MID/RID is set to a value other than the values listed in Table 9.5, the operation of this LSI is not guaranteed. The transfer request from DMARS is valid only when the resource select bits (RS[3:0]) have been set to B'1000 for DMACHCR_0 to DMACHCR_5. Otherwise, even if DMARS has been set, transfer request source is not accepted.

DMARS_0

9.4 Operation

When there is a DMA transfer request, the RTDMAC starts the transfer according to the predetermined channel priority; when the transfer end conditions are satisfied, it ends the transfer. Transfers can be requested in two modes: auto request, and on-chip peripheral module request. As bus mode, cycle steal mode (normal mode and intermittent mode) is used.

9.4.1 DMA Transfer Requests

DMA transfer requests are basically generated in either the data transfer source or destination, but they can also be generated by on-chip peripheral modules that are neither the source nor the destination. Transfers can be requested in two modes: auto request, and on-chip peripheral module request. The request mode is selected for each channel in the RS[3:0] bits in DMACHCR, DMARS0 to DMARS2.

(1) Auto-Request Mode

When there is no transfer request signal from an external source, as in a memory-to-memory transfer or a transfer between memory and an on-chip peripheral module unable to request a transfer, auto-request mode allows the RTDMAC to automatically generate a transfer request signal internally. When the DE bit in DMACHCR and the DME bit in DMAOR are set to 1 for the target channel, the transfer begins so long as the CAE bit in DMACHCRR is 0.

(2) On-Chip Peripheral Module Request Mode

In this mode, a transfer is performed at the transfer request signal of an on-chip peripheral module. The source (peripheral module) of the DMA transfer request is specified by the DMARS_0/1/2 register.

When this mode is selected, if the DMA transfer is enabled (DE = 1, DME = 1, TE = 0, CAE = 0), a transfer is performed upon the input of a transfer request signal.

When a transmit data empty transfer request of the SCIF is set as the transfer request, the transfer destination must be the SCIF's transmit data register. Likewise, when receive data full transfer request of the SCIF is set as the transfer request, the transfer source must be the SCIF's receive data register. These conditions also apply to the other on-chip peripheral modules.

The number of the receive FIFO triggers can be set as a transfer request depending on an on-chip peripheral module. Data needs to be read after the DMA transfer is ended, because data may be left in the receive FIFO when the receive FIFO trigger condition is not satisfied.

Table 9.6 Selecting On-Chip Peripheral Module Request Modes with Bits RS3 to RS0 (T.B.D.)

CHCR	DMARS		DMA Transfer Request Source	DMA Transfer Request Signal	Source	Destination	Bus Mode

9.4.2 Channel Priority

When the RTDMAC receives simultaneous transfer requests on two or more channels, it transfers data according to a predetermined priority. Two modes (fixed mode and round-robin mode) are selected by the PR[1:0] bits in DMAOR.

(1) Fixed Mode

In this mode, the priority levels among the channels remain fixed. There are two kinds of fixed modes as follows:

- CH0 > CH1 > CH2 > CH3 > CH4 > CH5
- CH0 > CH2 > CH3 > CH1 > CH4 > CH5

These are selected by the PR[1:0] bits in DMAOR.

(2) Round-Robin Mode

In round-robin mode each time data of one transfer unit (byte, word, longword, 8-byte, 16-byte, or 32-byte unit) is transferred on one channel, the priority is rotated. The channel on which the transfer was just finished rotates to the bottom of the priority. The round-robin mode operation is shown in Figure 9.2. The priority of round-robin mode is CH0 > CH1 > CH2 > CH3 > CH4 > CH5 immediately after reset.

(3) CH0 Top Priority Round-Robin Mode

In this mode, the round-robin mode function is enabled for the channels from CH1 to CH5, with CH0 being always transferred at top priority. Once the transfer of CH0 is completed, the priority order will be the same as that applicable before the transfer.

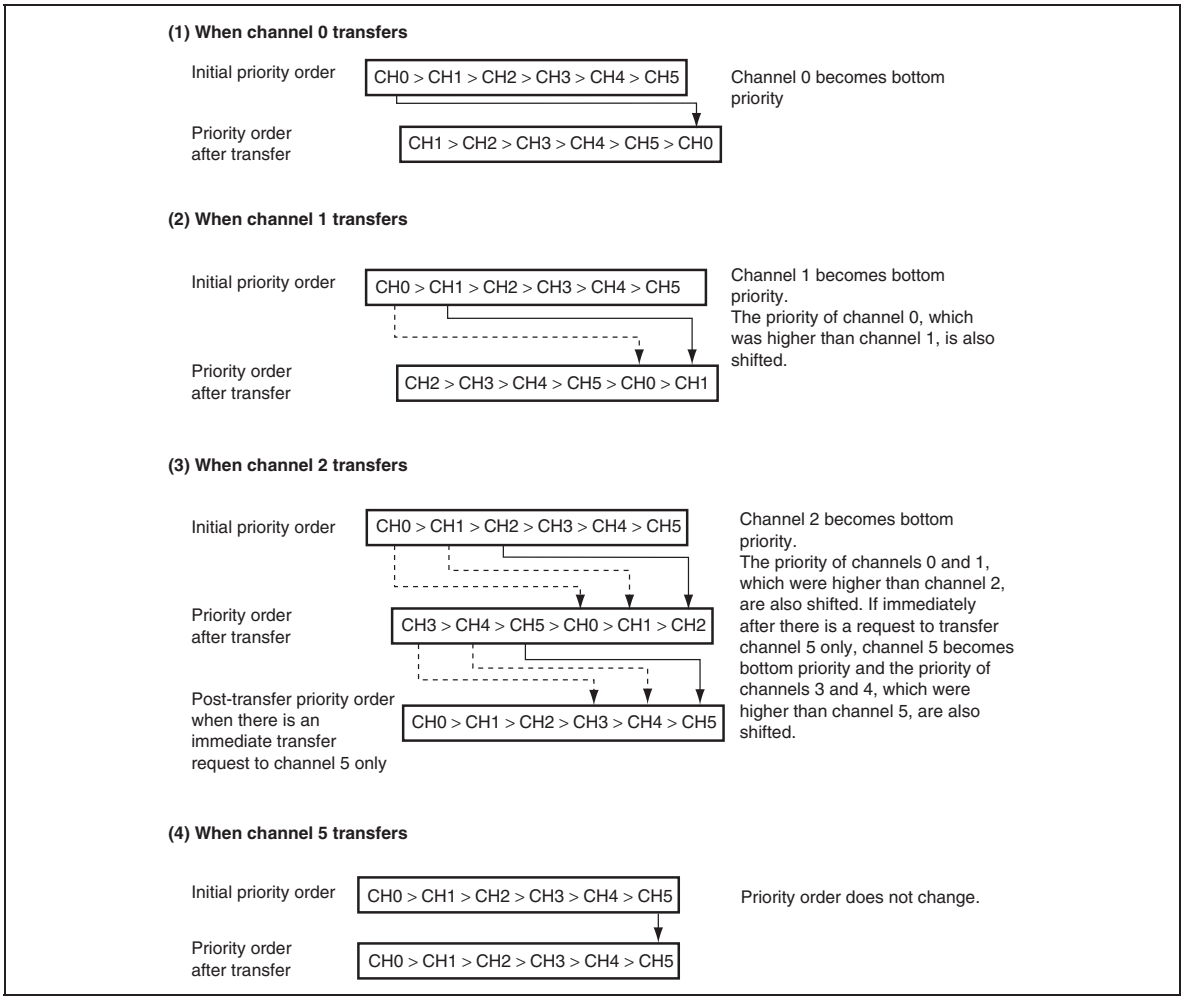

Figure 9.2 Round-Robin Mode

Figure 9.3 shows how the priority changes when channel 0 and channel 3 transfers are requested simultaneously and a channel 1 transfer is requested during the channel 0 transfer. The RTDMAC operates as follows:

1. Transfer requests are generated simultaneously to channels 0 and 3.
2. Channel 0 has a higher priority, so the channel 0 transfer begins first (channel 3 waits for transfer).
3. A channel 1 transfer request occurs during the channel 0 transfer (channels 1 and 3 are both waiting)
4. When the channel 0 transfer ends, channel 0 becomes lowest priority.
5. At this point, channel 1 has a higher priority than channel 3, so the channel 1 transfer begins (channel 3 waits for transfer).
6. When the channel 1 transfer ends, channel 1 becomes lowest priority.
7. The channel 3 transfer begins.
8. When the channel 3 transfer ends, channels 3 and 2 shift downward in priority so that channel 3 becomes the lowest priority.

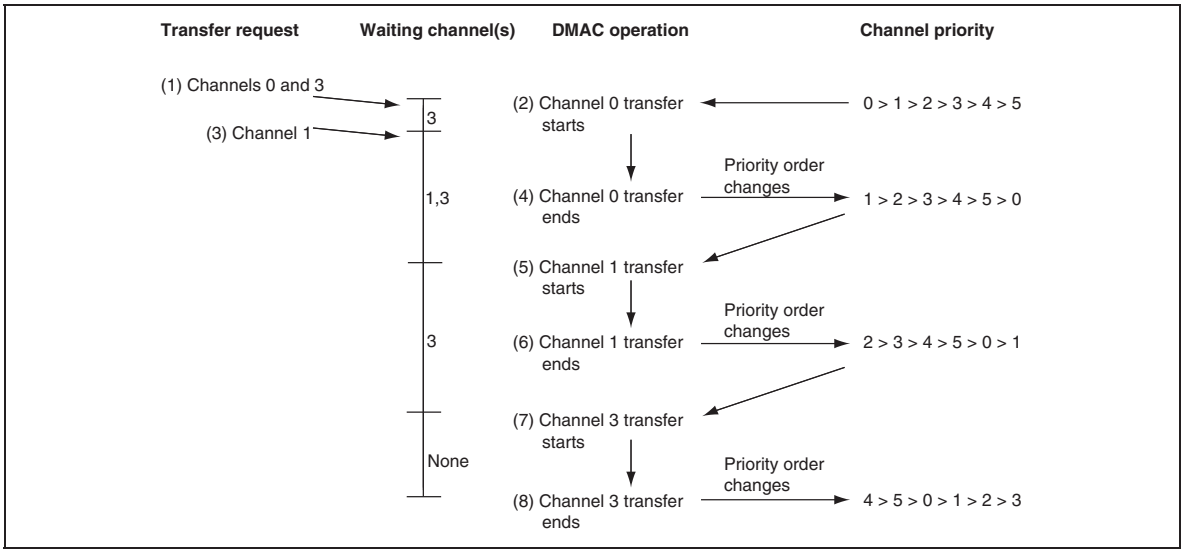

Figure 9.3 Changes in Channel Priority in Round-Robin Mode

9.4.3 Bus Request Priority Push out

The bus request priority push out is a function that assigns the highest value of the bus request priority setting bit in the DMA channel control register B among the output-enabled channels (channels in auto-request mode or channels that accepted a request) as the value of bus request priority being currently output to the SHWY.

Enabling this function prevents the processing of channels with higher bus request priority from being delayed by the presence of channels with lower bus request priority.

Figure 9.4 shows an example in which the bus request priority push out function is enabled.

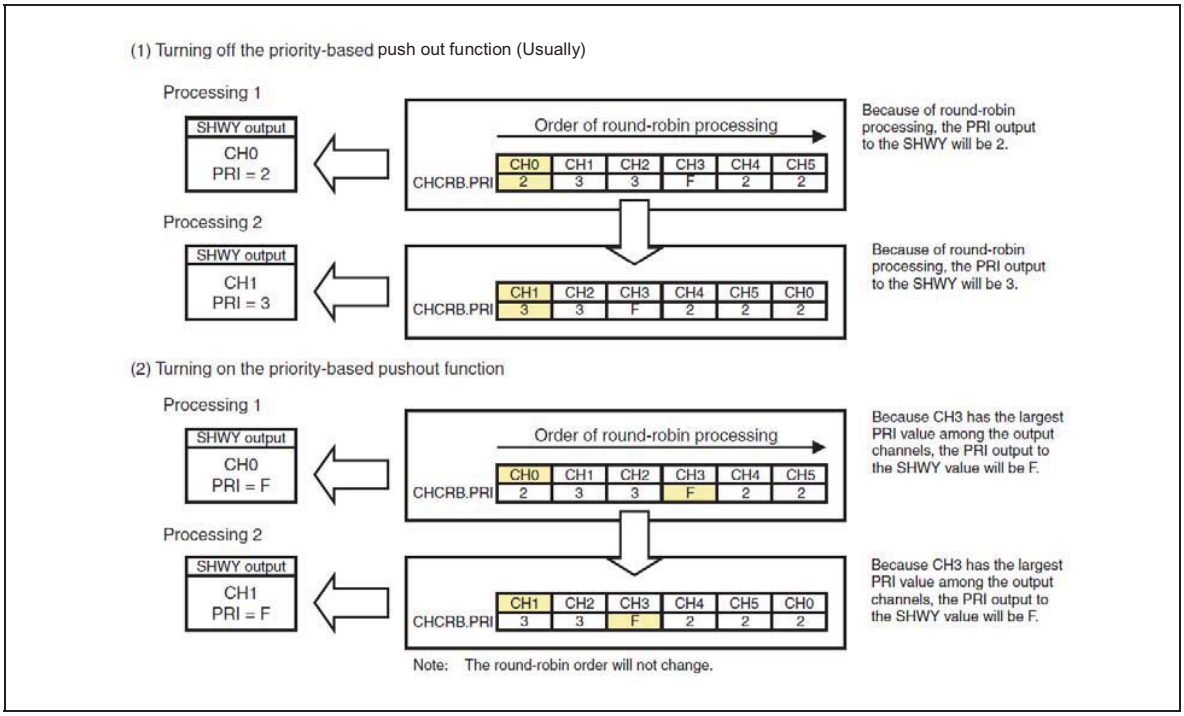

Figure 9.4 Example of Using the Bus Request Priority Push out Function

Note: For details of the PRI signal, see section 1-F Bus Functions.

9.4.4 DMA Transfer Types

DMA transfer is done in dual address mode. As bus mode, cycle steal mode (normal mode and intermittent mode) is used. The RTDMAC supports the transfers shown in Table 9.7.

Table 9.7 Supported DMA Transfers

	Destination			
Source	**External Memory**	**Memory-Mapped External Device**	**On-Chip Peripheral Module**	**X/Y Memory**
External device with DACK	Dual	Dual	Not available	Not available
External memory	Dual	Dual	Dual	Dual
Memory-mapped external device	Dual	Dual	Dual	Dual
On-chip peripheral module	Dual	Dual	Dual	Dual
X/Y memory	Dual	Dual	Dual	Dual

Note: 1. Dual: Dual address mode

(1) Address Mode

(a) Dual Address Mode

In dual address mode, both the transfer source and destination are accessed by addresses. The source and destination can be located externally or internally.

DMA transfer requires two bus cycles because data is read from the transfer source in a data read cycle and written to the transfer destination in a data write cycle. At this time, transfer data is temporarily stored in the RTDMAC. In the transfer between external memories as shown in Figure 9.5, data is read to the RTDMAC from one external memory in a data read cycle, and then that data is written to the other external memory in a write cycle.

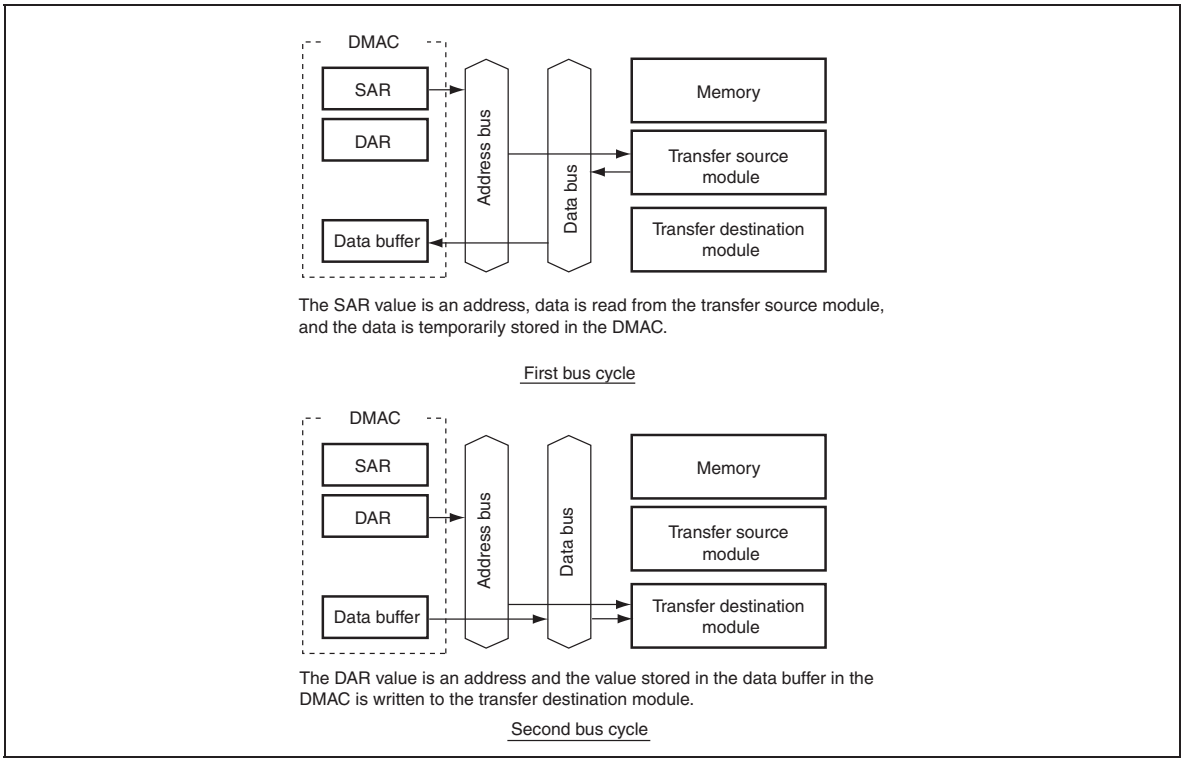

Figure 9.5 Data Flow of Dual Address Mode

Auto request, and on-chip peripheral module request are available for the transfer request.

(2) Bus Modes

Cycle steal mode is used as bus mode.

(a) Cycle-Steal Mode

- Normal mode

  In cycle-steal normal mode, the RTDMAC gives the bus mastership to another bus master every time a unit of transfer (byte, word, longword, 8-byte, 16-byte, 32-byte, or 64-byte unit) is complete. When another transfer request occurs after that, the RTDMAC gets the bus mastership from the other bus master and performs a transfer for one transfer unit. When that transfer ends, the RTDMAC returns the bus mastership to the other bus master. This is repeated until the transfer end conditions are satisfied.

  In cycle-steal normal mode, all transfer areas are available for the transfer request source, transfer source, and transfer destination.

  Figure 9.6 shows an example of DMA transfer timing in cycle-steal normal mode. Transfer conditions shown in the figure are:

  — Condition 1: Dual address mode

  — Condition 2: DREQ low level detection

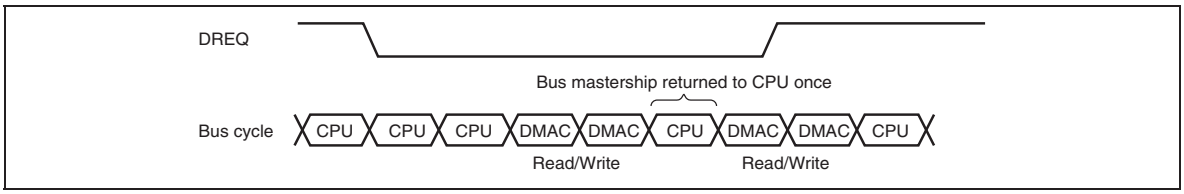

Figure 9.6 DMA Transfer Example in Cycle-Steal Normal Mode (Dual Address, DREQ Low Level Detection)

- Intermittent mode

  In intermittent mode of cycle steal, the RTDMAC gives the bus mastership to another bus master every time a unit of transfer (byte, word, longword, 8-byte, 16-byte, 32-byte or 64-byte unit) is complete. When another transfer request occurs after that, the RTDMAC gets the bus mastership from the other bus master after waiting for 16, 64, or 256 clock cycles in ZSϕ count. The RTDMAC then transfers data of one unit and returns the bus mastership to the other bus master. This is repeated until the transfer end conditions are satisfied. It is thus possible to make lower the ratio of bus occupation by DMA transfer than cycle-steal normal mode.

  When the RTDMAC gets again the bus mastership, DMA transfer can be postponed in case of entry updating due to cache miss.

  In intermittent mode, all transfer areas are available for the transfer request source, transfer source, and transfer destination. The bus modes, however, must be cycle steal mode in all channels.

  Figure 9.7 shows an example of DMA transfer timing in cycle steal intermittent mode. Transfer conditions shown in the figure are:

  — Condition 1: Dual address mode

  — Condition 2: DREQ low level detection

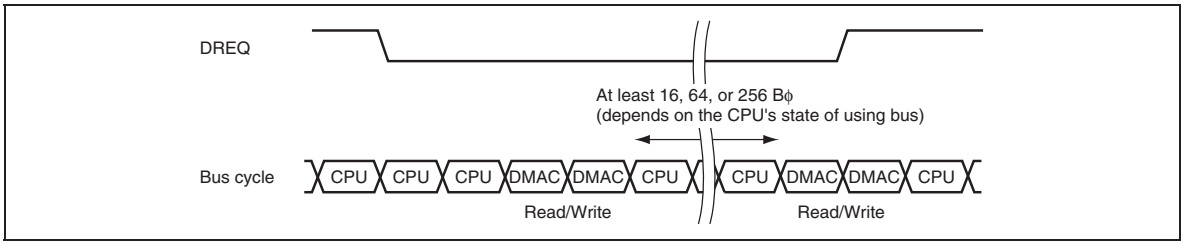

Figure 9.7 Example of DMA Transfer in Cycle Steal Intermittent Mode (Dual Address, DREQ Low Level Detection)

(3) Relationship between Request Modes and Bus Modes by DMA Transfer Category

Table 9.8 shows the relationship between request modes and bus modes by DMA transfer category.

Table 9.8 Relationship between Request Modes and Bus Modes by DMA Transfer Category

Address Mode	Transfer Category	Request Mode	Bus Mode	Transfer Size (Bits)	Usable Channels
Dual	External memory and external memory	External, auto	C	1/2/4/8/16/32/64	0 to 5
	External memory and memory-mapped external device	External, auto	C	1/2/4/8/16/32/64	0 to 5
	Memory-mapped external device and memory-mapped external device	External, auto	C	1/2/4/8/16/32/64	0 to 5
	External memory and on-chip peripheral module	All*[1]	C	1/2/4/8/16/32/64*[2]	0 to 5
	Memory-mapped external device and on-chip peripheral module	All*[1]	C	1/2/4/8/16/32/64*[2]	0 to 5
	On-chip peripheral module and on-chip peripheral module	All*[1]	C	1/2/4/8/16/32/64*[2]	0 to 5
	X/Y memory and X/Y memory	External, auto	C	1/2/4/8/16/32/64	0 to 5
	X/Y memory and memory-mapped external device	External, auto	C	1/2/4/8/16/32/64	0 to 5
	X/Y memory and on-chip peripheral module	All*[1]	C	1/2/4/8/16/32/64*[2]	0 to 5
	X/Y memory and external memory	External, auto	C	1/2/4/8/16/32/64	0 to 5

[Legend]

C: Cycle steal mode

Notes: 1. Auto requests, and on-chip peripheral module requests are all available. However the request source register must be designated as the transfer source or the transfer destination.

2. Access size permitted for the on-chip peripheral module register functioning as the transfer source or transfer destination.

notes : * Never transmits directly to CMT1.

9.4.5 DMA Transfer Flow

After the DMA source address registers (DMASAR), DMA destination address registers (DMADAR), DMA transfer count registers (DMATCR), DMA channel control registers (DMACHCR), DMA operation register (DMAOR), and DMA extended resource selectors (DMARS) are set, the RTDMAC transfers data according to the following procedure:

1. Checks to see if transfer is enabled (DE = 1, DME = 1, TE = 0, CAE = 0)
2. When a transfer request occurs while transfer is enabled, the RTDMAC transfers one transfer unit of data (depending on the setting of the TS3 to TS0 bits). In auto request mode, the transfer begins automatically when the DE bit and DME bit are set to 1. The DMATCR value will be decremented for each transfer. The actual transfer flows vary by address mode and bus mode.
3. When the specified number of transfers have been completed (when DMATCR reaches 0), the transfer ends normally. If the IE bit in DMACHCR is set to 1 at this time, a DEI interrupt is sent to the CPU.
4. When an address error is generated, the transfer is aborted. Transfers are also aborted when the DE bit in DMACHCR or the DME bit in DMAOR is changed to 0.

Figure 9.8 shows a flowchart of this procedure.

Notes:
1. In repeat mode, a transfer request is acceptted with TE =1 when HIE = 1 and HE = 0.
2. In auto-request mode, transfer starts when bits NMIF, AE, and TE are all 0 or bits TE and HIE are 1 and HE is 0 (in repeat mode), and bits DE and DME are set to 1.
3. Internal peripheral module request.
4. Auto request.
5. Loading to SAR and DAR differs according to the operating conditions in each mode.
6. TCRBH represents bits TCRB[13:16] and TCRBL represents bits TCRB [15 to 0].

Figure 9.8 DMA Transfer Flowchart

9.4.6 Repeat Mode Transfer

In a repeat mode transfer, a DMA transfer is repeated without making the transfer settings every time before executing a transfer.

Using a repeat mode transfer with the half end function allows a double buffer transfer executed virtually. The following procedures can be executed effectively by using a repeat mode transfer. As an example, operation of receiving voice data from the VOICE CODEC and compressing it is explained.

In the following example, processing of compressing 40-word voice data for every data reception is explained. In this case, it is assumed that voice data is received by means of MSIOF.

1. RTDMAC settings
- Set address of the MSIOF receive data register in DMASAR
- Set address of an internal memory data store area in DMADAR
- Set DMATCR to 80 (H'50)
- Make the following settings of DMACHCR
  Bits RPT[2:0] = B'010: Repeat mode (use DAR as a repeat area)
  Bit HIE = B'1: TCR/2 interrupt generated
  Bits DM[1:0] = B'01: DAR incremented
  Bits SM[1:0] = B'00: SAR fixed
  Bit IE = B'1: Interrupt enabled
  Bit DE = B'1: DMA transfer enabled
- Set such as bits TB and TS[2:0] according to use conditions
- Set bits CMS[3:0] and PR[1:0] in DMAOR according to use conditions and set the DME bit to B'1

2. Voice data is received and then transferred by MSIOF/RTDMAC
3. DMATCR is decreased to half of its initial value and an interrupt is generated
   Read DMACHCR to confirm that the HE bit is set to 1 by an interrupt processing, and compress 40-word voice data from the address set in DMADAR.
4. DMATCR is cleared to 0 and an interrupt is generated
   Read DMACHCR to confirm that the TE bit is set to 1 by an interrupt processing, and compress 40-word voice data from the address set in DMADAR + 40. After this operation, the value of DMADARB is copied to DMADAR in RTDMAC and initialized, and the value of DMATCRB is copied to DMATCR and initialized to 80.
5. Hereafter, steps 2 and 3 are repeated until bit DME or DE is set to B'0.

As explained above, a repeat mode transfer enables sequential voice compression by switching a buffer for storing data received consequentially and a data buffer for processing signals alternately.

9.4.7 Reload Mode Transfer

In a reload mode transfer, according to the settings of bits RPT[2:0] in DMACHCR, the value set in DMASARB/DMADARB is set to DMASAR/DMADAR and the value of bits DMATCRB[31:16] is set in bits DMATCRB[15:0] every time the number of transfers specified in the DMATCRB[15:0] bits are completed, and the transfer is repeated until DMATCR becomes 0 without specifying the transfer settings again. A reload mode transfer is effective when repeating data transfer with specific areas. Figure 9.9 shows the operation of reload mode transfer.

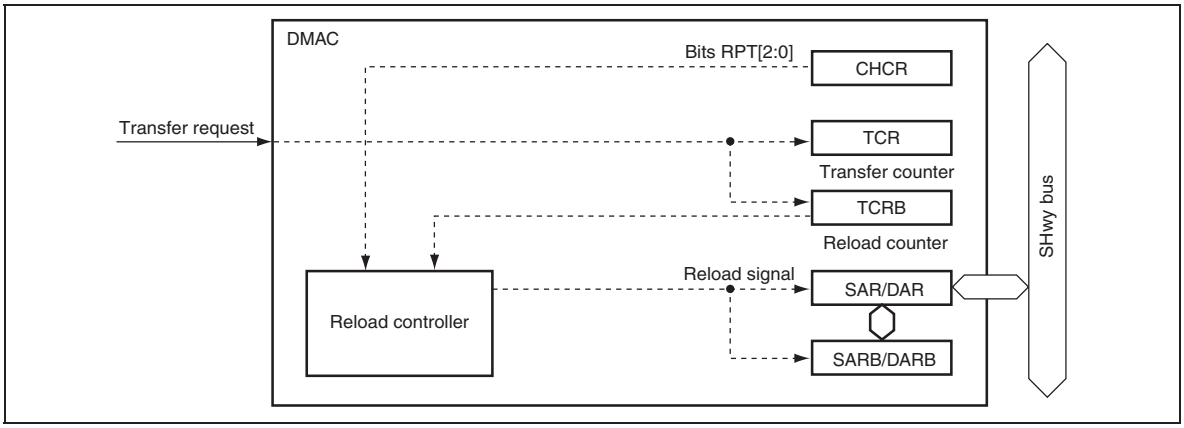

Figure 9.9 Reload Mode Transfer

When a reload mode transfer is executed, DMATCRB is used as a reload counter. Set DMATCRB as described in section 8.3.7, DMA Transfer Count Registers B_0 to 5 (DMATCRB_0 to DMATCRB_5).

9.4.8 Gathering Buffer Function

When the gathering buffer function is made effective, receive data or the transmission data is transmitted collectively in 256 bytes or less. The penalty by the row address mistake of a different bank is reduced to SDRAM by collectively transmitting, and the performance of the transmission improves.

Write 0 to the GL bits in DMACHCRB when you make this function effective on the receiving side. Write 0 to the GS bits in DMACHCRB when you make this function effective at the transmitting side. And, set the GCNT bits in DMACHCRB. After, begin the DMA transfer. This function transmits the size specified for the TS bits in DMACHCR data GCNT+1 collectively. However, when the transfer size exceeds 256 bytes, the transfer size becomes 256 bytes.

When the RS bits in DMACHCR is DMA Extended Resource Selector (B'1000), On-chip peripheral module side can not enable the gathering buffer function.

When the RS bits in DMACHCR is DMA Extended Resource Selector (B'1000), the data that remains in the buffer is output to the memory when writing 0 to the DE bit in DMACHCR while receive data is being collected from the On-chip peripheral module.

The number of packets that remains in the buffer can be confirmed by reading RP bits in DMACHCLR.

Figure 9.10 shows the example of timing when the gathering buffer function is used.

Table 9.10 shows the correspondence table of the gathering buffer function.

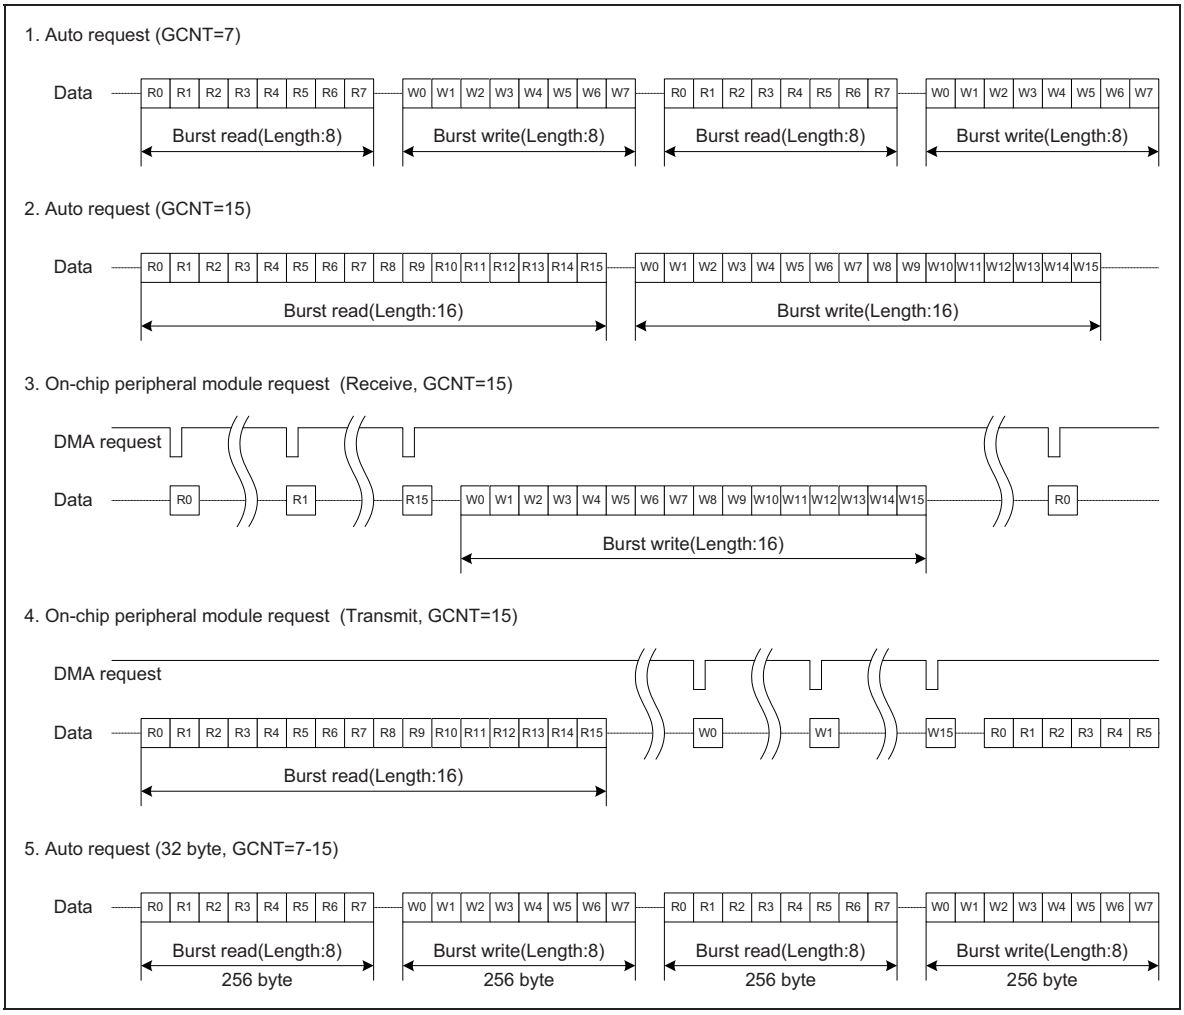

Figure 9.10 Example of Timing when the Gathering Buffer Function is Used

Table 9.10 The Correspondence Table of the Gathering Buffer Function.

Module	Function	Source	Destination
Memory-to-memory	—	Yes	Yes
External device	Transmit and receive	No	No
BBIF1/2	Transmit	Yes	No
	Receive	No	Yes
CMT1	Transmit and receive	No	No
FLCTL	Transmit and receive	No	No
IIC 0/1/2/3/4	Transmit	Yes	No
	Receive	No	Yes
MSIOF0/1/2	Transmit	Yes	No
	Receive	No	Yes
SCIF0/1/2/3/4/5,SCIFB	Transmit	Yes	No
	Receive	No	Yes
SDHI0/1/2	Transmit	Yes	No
	Receive	No	Yes
FSI	Transmit	Yes	No
	Receive	No	Yes

TSIF0/1	Receive	No	Yes
IRDA	Receive	No	Yes
DSI0/1	Receive	No	Yes
HSI	Transmit	Yes	No
	Receive	No	Yes
MMC	Transmit	Yes	No
	Receive	No	Yes
MFI	Transmit and receive	No	No
SHWYSTAT	Receive	No	Yes

notes : As for the transfer to on-chip peripheral module side, the gathering buffer function is compulsorily invalidated.

9.5 Usage Notes

Pay attentions to the following notes when the RTDMAC is used.

(1) DMA Transfer for Peripheral Modules

When executing a DMA transfer for peripheral modules, an appropriate boundary address should be set for the transfer source or destination address according to the transfer data size. Otherwise, an address error may occur.

(2) Module Stop

While the RTDMAC is in operation, the RTDMAC should not be stopped by the module stop register (MSTPCR0) setting. When the RTDMAC is stopped, transfer contents cannot be guaranteed.

(3) Address Error

Clear the buffer by writing 0 to the CLR bit in DMA channel clear register (DMACHCLR) when the DMA address error occurs. When a DMA address error is generated, set the register of the error-ridden channel again and then start a transfer.

(4) DMA Transfer Stop

Wait for the RP bits in CHCLR to become 0 after writing 0 to the DE bit in CHCR about the stop of the DMA transfer.

(5) DMA Transfer Interruption

When make the DMA transfer interrupted, the interruption disable should be set and set the DE bit in DMA channel control register (DMACHCR) as the DMA transfer disable. If the TE is generated during the DMA transfer interruption, the TE should be initialized. The generation timing after the transfer interruption for an asynchronous assumed following three cases.

1. A case that after setting for the interruption disable, TE is changed to 1 before the CHCR initialization. The TE is initialized by the processing DMA transfer initialization.
2. A case that after setting for the interruption disable, the TE is changed to 1 by ignoring the transfer interruption. After the DMA transfer initialization and the CHCR dummy read, check the TE bit. If the TE bit is 1, the DMA transfer initialization process should be performed.
3. A case that after setting for the interruption disable, the TE is not changed to 0 even though the transfer interruption is occurred.
   After the DMA transfer interruption, the TE is not generated because the transfer data is still remained.

Note: In a case that the DMA transfer initialization is performed while the last transfer is executing, causes TE generation delay. So the dummy read should be performed.

Figure 9.11 shows the processing example when DMA transfer interruption (Data is guaranteed).

Figure 9.12 shows the processing example when DMA transfer interruption (Compulsion interruption).

Section 10 DMAC Auxiliary Functions

10.1 DREQPAK

DREQPAK is a module that enables multiple pieces of DMA single data to be packed and transferred in burst mode to modules (e.g., SCIFA) that can select only small DMA transfer sizes such as bytes and words.

10.1.1 Overview

- Buffers send and receive 32 bytes. DMAC accesses the pack data register in address fixed mode.
- If the 32-byte transfer size contains a fraction, data is transferred in a 32-byte unit with garbage data.
- On the DMAC side, the transfer size is 32 bytes. The value obtained by dividing the transfer size by 32 and rounding up the result is set in the transfer count register. The total size of actual data is set in bytes in DRQPAK.
- Buffers are a ring buffer configuration that is one stage larger than the transfer size in consideration of occurrence of a DREQ from a peripheral module when data is transferred on the DMAC side. The next DREQ is output when near full or near empty is detected.

The following 15 modules are applicable.

SCIFA0, SCIFA1, SCIFA2, SCIFA3, SCIFA4, SCIFA5, SCIFB, MSIOF0, MSIOF1, MSIOF2, BBIF1, BBIF2, HSI, TSIF0, TSIF1

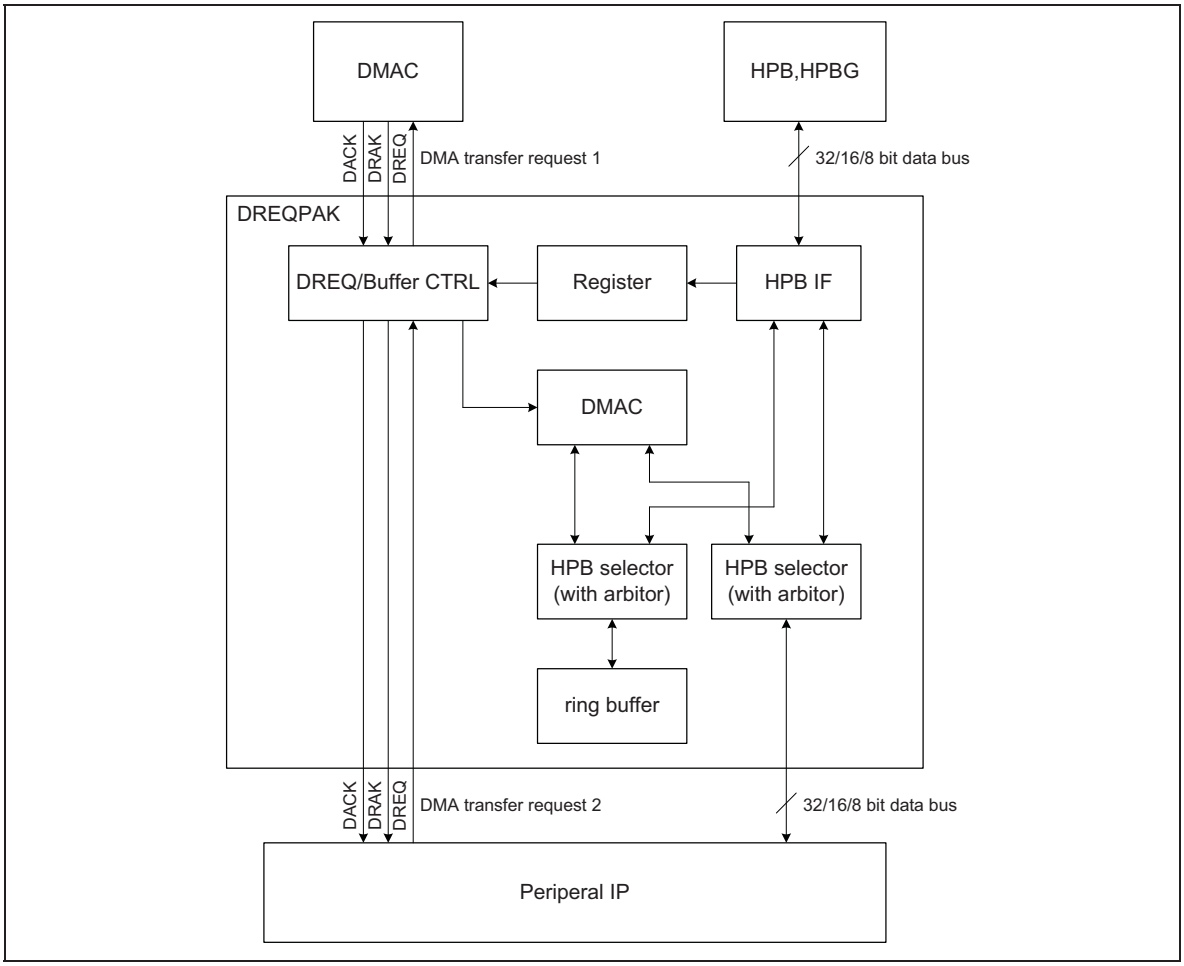

Figure 10.1 DREQPAK Internal Configuration

No access occurs in the upstream SHwy bus even if you use a peripheral module by using DREQPAK. This eliminates troublesome passes of accesses in small data units to the upstream SHwy bus.

An access latency occurs in a bus bridge but the total access time is shortened because the bus bridge reciprocation count becomes less.

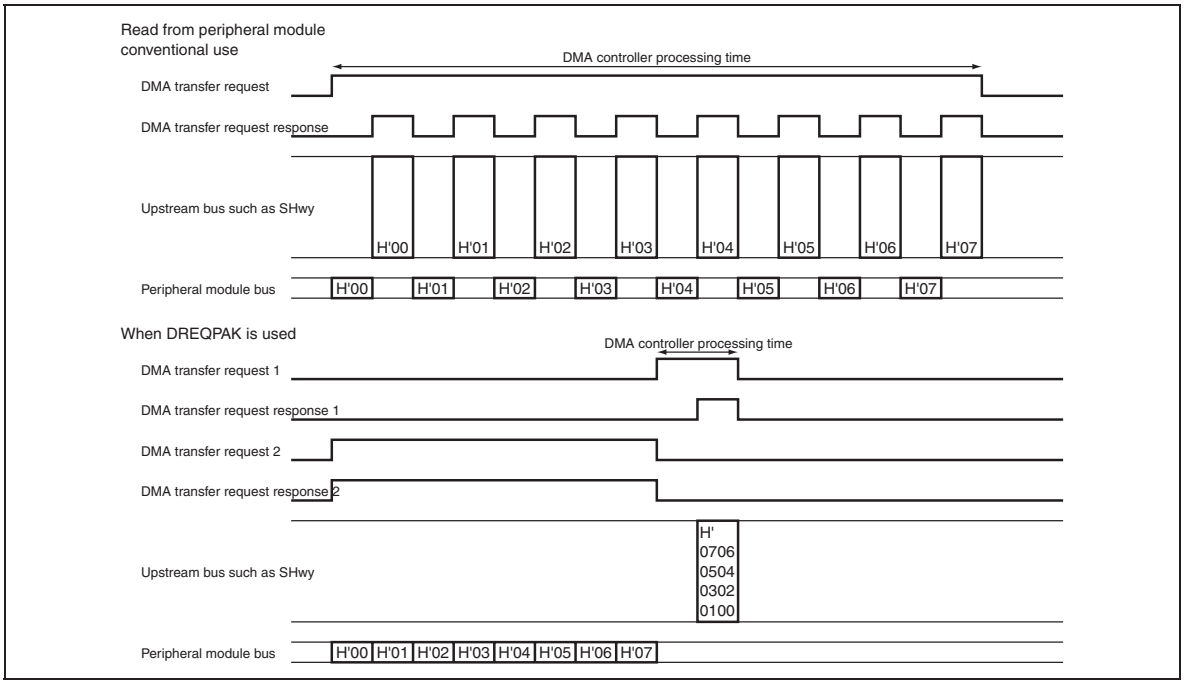

Figure 10.2 DMA Transfer Image When DREQPAK Is Used

10.1.2 DREQPAK Register Descriptions

Table 10.1 shows the DREQPAK register configuration. Table 10.2 shows the register states in each operating mode.

* For details, refer to section 1-D Overview of reset.

(Bit assignment is common to XXXX (SCIFA0, SCIFA1, SCIFA2, SCIFA3, SCIFA4, SCIFA5, SCIFB, TSIF0, and TSIF1) and YYYY (MSIOF0, MSIOF1, MSIOF2, BBIF0, BBIF1, and HSI).)

10.1.3 XXXX Target Address Register 0(,1)

XXXX Target Address Register 0(,1) specifies the lower 16-bit address of the register to be packed.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TGTADR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 0	TGTADR15 to TGTADR0	H'0000	R/W	Specify the lower 16-bit address of the XXXX register to be packed.

10.1.4 XXXX Pack Total Size Register 0L(,1L)

XXXX Pack Total Size Register 0L(,1L) specifies, in bytes, the total size (lower) of data to be transferred in a single DMAC start.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOTALSIZE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 0	TOTALSIZE15 to TOTALSIZE0	H'0000	R/W	Specify, in bytes, the total size of data to be transferred in a single DMAC start.

10.1.5 XXXX Pack Total Size Register 0H(,1H)

XXXX Pack Total Size Register 0H(,1H) specifies, in bytes, the total size (upper) of data to be transferred in a single DMAC start. For transmission, specify the total size with a multiple of 2.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOTALSIZE[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 0	TOTALSIZE31 to TOTALSIZE16	H'0000	R/W	Specify, in bytes, the total size of data to be transferred in a single DMAC start.

10.1.6 XXXX Pack Control Register 0(,1)

XXXX Pack Control Register 0(,1) specifies whether to use the DREQPAK function and settings when the function is used.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	FREE RUN	RW SIZE	—	RW SEL	RST	PKEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 6	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	FREERUN	0	R/W	Free Run Mode Setting 0: Normal mode 1: Free run mode
4	RWSIZE	0	R/W	Register Access Size Set in Target Address Register 0: Words 1: Bytes

3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	RWSEL	0	R/W	DMA Transfer Direction Select. Set this bit tailored to the target DMA request. 0: XXXX is the DMA transfer source. 1: XXXX is the DMA transfer destination.
1	RST	0	R/W	Buffer Reset 0: The buffer is not cleared. 1: The buffer is cleared.
0	PKEN	0	R/W	DREQPAK Use/Nonuse Select. This bit is cleared to 0 after data transfer is completed. 0: DREQPAK is not used. DMA transfer is performed in a single byte or word. 1: DREQPAK is used.

10.1.7 XXXX Pack Status Register 0L(,1L)

XXXX Pack Status Register 0L(,1L) indicates the status when the pack function is used.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TRANSDCOUNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 0	TRANSDCOUNT15 to TRANSDCOUNT0	H'0000	R	Indicate, in bytes, the amount of remaining DMA transfer data.

10.1.8 XXXX Pack Status Register 0H(,1H)

XXXX Pack Status Register 0H(,1H) indicates the status when the pack function is used.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERR FLG	TRANSDCOUNT[30:16]														
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 0	ERRFLG	0	R/W	Flag indicating that a transfer error occurred. This bit is cleared to 0 when written. If SCIFA0 to SCIFA5, SCIFB, TSIF0, or TSIF1 issues a DMA request, a transfer error occurs even if the value set in the total size register is exceeded. 0: No transfer error occurred. 1: A transfer error occurred.
14 to 0	TRANSDCOUNT30 to TRANSDCOUNT16	H'0000_0000	R	Indicate, in bytes, the amount of remaining DMA transfer data.

10.1.9 XXXX Pack Data Register 0(,1)

XXXX Pack Data Register 0(,1) is accessed by DMAC as the source or destination when the DREQPAK function is used. This register cannot be accessed from the CPU.

Bit:	15	14	13	12	11	11	9	8	7	6	5	4	3	2	1	0
	PACKDATA[15:0]															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 0	PACKDATA31 to PACKDATA0	Undefined	R/W	Packed data

10.1.10 YYYY Target Address Register 0(,1)

YYYY Target Address Register 0(,1) specifies the lower 16-bit address of the register to be packed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	TGTADR15 to TGTADR0	H'0000	R/W	Specify the lower 16-bit address of the YYYY register to be packed.

10.1.11 YYYY Pack Total Size Register 0(,1)

YYYY Pack Total Size Register 0(,1) specifies, in bytes, the total size of data to be transferred in a single DMAC start. For transmission, specify the total size in a multiple of 4.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TOTALSIZE[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOTALSIZE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	TOTALSIZE31 to TOTALSIZE0	H'0000_0000	R/W	Specify, in bytes, the total size of data to be transferred in a single DMAC start.

10.1.12 YYYY Pack Control Register 0(,1)

YYYY Pack Control Register 0(,1) specifies whether to use the DREQPAK function and settings when the function is used.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

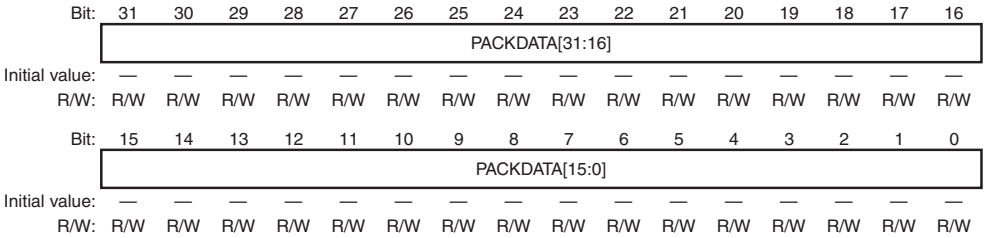
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	DREQMASK[2:0]			—	—	—	—	—	—	FREE RUN	RWSIZE[1:0]		RW SEL	RST	PKEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 12	DREQMASK	0	R/W	Module DREQ Control Function. This function is valid when the PKEN bit is 0. 0: Normal 1: The next DREQ is masked till DMAACK arrives once. 2: The next DREQ is masked till DMAACK arrives twice. 3: The next DREQ is masked till DMAACK arrives four times. 4: The next DREQ is masked till DMAACK arrives eight times. 7: Unconditional mask
11 to 6	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	FREERUN	0	R/W	Free Run Mode Setting 0: Normal mode 1: Free run mode
4, 3	RWSIZE1 and RWSIZE0	00	R/W	Register Access Size Set in Target Address Register 00: Longwords 01: Words 10: Bytes 11: Prohibited

Bit	Bit Name	Initial Value	R/W	Descriptions
2	RWSEL	0	R/W	DMA Transfer Direction Select. Set this bit tailored to the target DMA request. 0: YYYY is the DMA transfer source. 1: YYYY is the DMA transfer destination.
1	RST	0	R/W	Buffer Reset 0: The buffer is not cleared. 1: The buffer is cleared.
0	PKEN	0	R/W	DREQPAK Use/Nonuse Select. This bit is cleared to 0 after data transfer is completed. 0: DREQPAK is not used. DMA transfer is performed in a single byte or word. 1: DREQPAK is used.

10.1.13 YYYY Pack Status Register 0(,1)

YYYY Pack Status Register 0(,1) indicates the status when the pack function is used.



Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ERR FLG	TRANSDCOUNT[30:16]														
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TRANSDCOUNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	ERRFLG	0	R/W	Flag indicating that a transfer error occurred. This bit is cleared to 0 when write-accessed. If HSI, MSIOF0/1, or BBIF1/2 issues a DMA request, a transfer error occurs even if the value set in the total size register is exceeded. 0: No transfer error occurred. 1: A transfer error occurred.
30 to 0	TRANSDCOUNT30 to TRANSDCOUNT0	H'0000_0000	R	Indicate, in bytes, the amount of remaining DMA transfer data.

10.1.14 YYYY Pack Data Register 0(,1)

YYYY Pack Data Register 0(,1) is accessed by DMAC as the source or destination when the DREQPAK function is used. This register cannot be accessed from the CPU.

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	PACKDATA31 to PACKDATA0	Undefined	R/W	Packed data

10.1.15 Principles of Operation

To perform DMA transfer between a peripheral module and memory by using DREQPAK, use the following procedure:

1. Setting DMAC
2. Setting DREQPAK
3. Setting the peripheral module
4. <Starting DMA transfer>
5. <Ending DMA transfer>
6. Setting the peripheral module
7. Setting DREQPAK
8. Setting DMAC

The following describes the above procedure by transmission and reception.

(1) Transfer from the peripheral module to memory (reception)

1. Setting DMAC

Set necessary settings in DMAC. DMAC setting when DREQPAK is used differs from when DREQPAK is not used in the following points:

- Set the address of the DREQPAK pack data register in the source address register.
- Specify 32 bytes as the transfer size of the channel control register.
- If 32 bytes is specified as the transfer size, the total transfer data amount (a number represented by n times a multiple of 32) is set in the transfer count register. If the amount of data you want to transfer does not become a multiple of 32, set the transfer amount rounded up to a multiple of 32 as the value to be set in the transfer count register. For example, if you want to use 66-byte transfer, set 3 as the transfer count.

Set the DMA Enable (DE) bit of DMAC to 1 to start data transfer.

2. Setting DREQPAK

Make the following settings:

- Set the register to store the source data of the peripheral module as the target address register.
- Set, in bytes, the amount of data you want to transfer to the pack total size register. You need not round up the amount of data to a multiple of 32.
- Set reception in the pack control register. Set the access size of the register to store source data as the access size. Set the RWSEL bit to 0 and the RST and PKEN bits to 1.

3. Setting the peripheral module

Enable reception DMA transfer request output.

4. <Starting DMA transfer>
5. <Ending DMA transfer>
6. Setting the peripheral module

Disable reception DMA transfer request output.

7. Setting DREQPAK

Check error occurrence, etc., in the status register as required.

8. Setting DMAC

Clear the interrupt mask and status as required.

(2) Transfer from memory to peripheral module (transmission)

1. Setting DMAC

Set necessary settings in DMAC. DMAC setting when DREQPAK is used differs from when DREQPAK is not used in the following points:

- Set the address of the DREQPAK pack data register in the destination address register.
- Specify 32 bytes as the transfer size of the channel control register.
- If 32 bytes is specified as the transfer size, the total transfer data amount (a number represented by n times a multiple of 32) is set in the transfer count register. If the amount of data you want to transfer does not become a multiple of 32, set the transfer amount rounded up to a multiple of 32 as the value to be set in the transfer count register. For example, if you want to use 66-byte transfer, set 3 as the transfer count.

Set the DMA Enable (DE) bit of DMAC to 1 to start data transfer.

2. Setting DREQPAK

Make the following settings:

- Set the register to store peripheral module data as the target address register.
- Set, in bytes, the amount of data you want to transfer to the pack total size register. You need not round up the amount of data to a multiple of 32.
- Set transmission in the pack control register. Set the access size of the register to store source data as the access size. Set the RWSEL bit to 1 and the RST and PKEN bits to 1.

3. Setting the peripheral module

Enable transmission DMA transfer request output.

4. <Starting DMA transfer>
5. <Ending DMA transfer>
6. Setting the peripheral module

Disable transmission DMA transfer request output.

7. Setting DREQPAK

Check error occurrence, etc., in the status register as required.

8. Setting DMAC

Clear the interrupt mask and status as required.

10.1.16 About free run mode

Setting the free run bit (bit 5) of the pack control register to 1 continues operation without reference to the values set in the pack total size register and enables data transfer beyond the number of bytes set in the pack total size register. This mode assumes use with DMAC repeat mode.

In free run mode, the transfer size is a multiple of 32 bytes. Factions less than a multiple of 32 are not processed.

When using free run mode, set 32(H'20) in the pack total size register.

10.1.17 About the module DREQ control function

The module DREQ control function is a support function that provides direct multibyte access between DMAC modules without DREQPAK. Multibyte transfer that uses this function can be used by the following modules that output DMAREQ and can control the FIFO threshold:

MSIOF0, MSIOF1, MSIOF2, BBIF1, BBIF2, TSIF

Example of use:

To perform 32-byte transfer via BBIF1:

1. Set 32 bytes as the DMAC transfer size.
2. Set the DREQMASK bits of DREQPAK to 8 (= 32 ÷ 4 (FIFO register size of BBIF)).

3. Set the FIFO water mark of the BBIF1 FIFO control register to "empty" or "valid eight-stage data" (x4 = 32 bytes. For transmission, set TFWM to 101. For reception, set RFWM to 010).

Note: When the DREQMASK bits (bits 14 to 12) are set to 7 (unconditional mask)

When data transfer is completed, DREQPAK automatically returns to normal mode (the PKEN bit of the pack control register is 0). If DMAC operation is continued in repeat mode and a finite size is set in DREQPAK, the module side may issue a DMA request after the data transfer of the size set in DREQPAK is completed. In this case, the DMA transfer request will directly arrive at DMAC because DREQPAK setting returns to nonuse. Setting the unconditional mask here enables data transfer to be stopped because the DMA transfer request is blocked after data transfer by DREQPAK is completed. Unconditional mask setting can be used in the following modules:

MSIOF0, MSIOF1, MSIOF2, BBIF1, BBIF2, SIU, TSIF

10.1.18 Notes on specifications

In some modules (e.g., SCIF) that do not manage the DMA transfer count on the module side, DMA requests are always asserted without reference to operation on the DMAC side as long as DMA request output setting is enabled. In such modules, the error flag of the pack status register is set to 1 even if data transfer is successfully completed. For this reason, ignore the error.

10.2 DDM (Descriptor DMAC)

The DDM is a module that reconfigures the DMAC. The OS on the main CPU is highly sophisticated and the overhead from interrupt notification to reconfiguration increases. To solve this problem, the DDM reconfigures the DMAC in a fast response time on behalf of the CPU.

Figure 10.3 shows the relationship diagram of DDM DMAC connection.

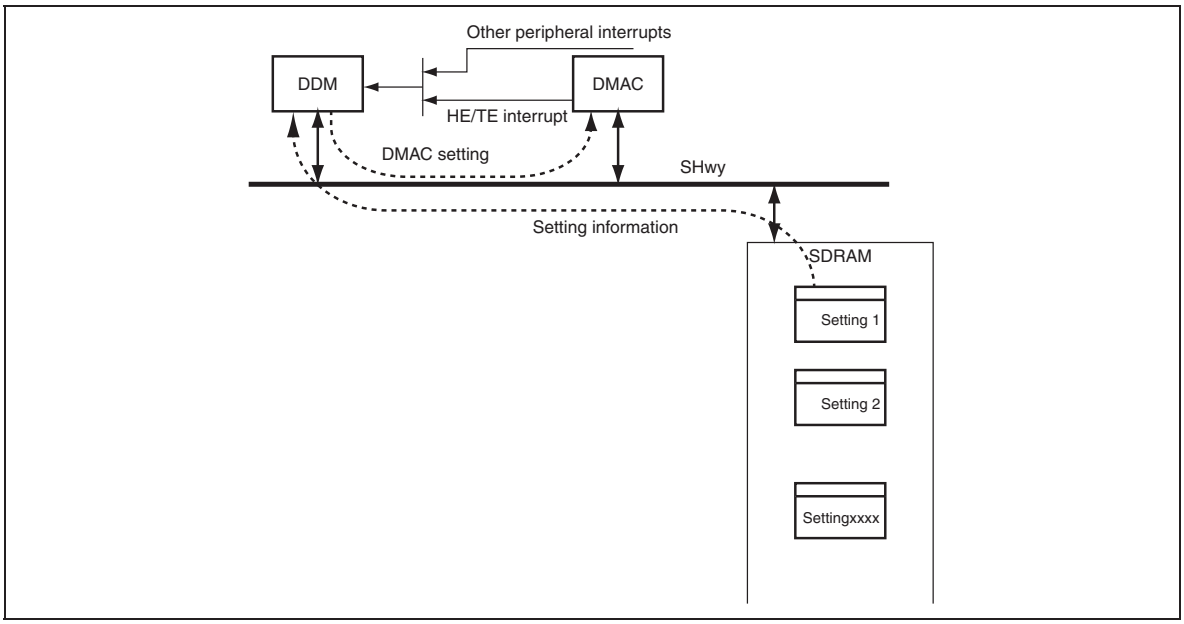


Figure 10.3 Relationship Diagram of DDM Connection

10.2.1 DDM Register Descriptions

Table 10.3 shows the DDM register configuration. Table 10.4 shows the register states in each operating mode.

Table 10.3 DDM Control Registers

Name	Register Abbreviation	R/W	Initial Value	Address	Access Size (Bits)
DDM interrupt source mask register	DDIREQMSK	R/W	H'00000000	H'FE080008	32
DDM interrupt source register	DDIREQSTA	R	H'00000000	H'FE08000C	32

10.2.2 DDM Interrupt Source Mask Register

The DDM Interrupt Source Mask Register enables and disables interrupt sources from the DDM.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERR8	END8	ERR7	END7	ERR6	END6	ERR5	END5	ERR4	END4	ERR3	END3	ERR2	END2	ERR1	END1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	ERR8	0	R/W	Interrupt Output by CH8 DDM_ERR 0: Disables interrupt output. 1: Enables interrupt output.
14	END8	0	R/W	Interrupt Output by CH8 DDM_END 0: Disables interrupt output. 1: Enables interrupt output.
13	ERR7	0	R/W	Interrupt Output by CH7 DDM_ERR 0: Disables interrupt output. 1: Enables interrupt output.
12	END7	0	R/W	Interrupt Output by CH7 DDM_END 0: Disables interrupt output. 1: Enables interrupt output.
11	ERR6	0	R/W	Interrupt Output by CH6 DDM_ERR 0: Disables interrupt output. 1: Enables interrupt output.
10	END6	0	R/W	Interrupt Output by CH6 DDM_END 0: Disables interrupt output. 1: Enables interrupt output.
9	ERR5	0	R/W	Interrupt Output by CH5 DDM_ERR 0: Disables interrupt output. 1: Enables interrupt output.
8	END5	0	R/W	Interrupt Output by CH5 DDM_END 0: Disables interrupt output. 1: Enables interrupt output.

Bit	Bit Name	Initial Value	R/W	Descriptions
7	ERR4	0	R/W	Interrupt Output by CH4 DDM_ERR 0: Disables interrupt output. 1: Enables interrupt output.
6	END4	0	R/W	Interrupt Output by CH4 DDM_END 0: Disables interrupt output. 1: Enables interrupt output.
5	ERR3	0	R/W	Interrupt Output by CH3 DDM_ERR 0: Disables interrupt output. 1: Enables interrupt output.
4	END3	0	R/W	Interrupt Output by CH3 DDM_END 0: Disables interrupt output. 1: Enables interrupt output.
3	ERR2	0	R/W	Interrupt Output by CH2 DDM_ERR 0: Disables interrupt output. 1: Enables interrupt output.
2	END2	0	R/W	Interrupt Output by CH2 DDM_END 0: Disables interrupt output. 1: Enables interrupt output.
1	ERR1	0	R/W	Interrupt Output by CH1 DDM_ERR 0: Disables interrupt output. 1: Enables interrupt output.
0	END1	0	R/W	Interrupt Output by CH1 DDM_END 0: Disables interrupt output. 1: Enables interrupt output.

10.2.3 DDM Interrupt Source Register

The DDM Interrupt Source Register indicates the currently output interrupt source. This register is read-only. You cannot clear the interrupt source in this register. Clear the interrupt source by using the control register of each channel.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERR8	END8	ERR7	END7	ERR6	END6	ERR5	END5	ERR4	END4	ERR3	END3	ERR2	END2	ERR1	END1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	ERR8	0	R	Interrupt output by CH8 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
14	END8	0	R	Interrupt output by CH8 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
13	ERR7	0	R	Interrupt output by CH7 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
12	END7	0	R	Interrupt output by CH7 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
11	ERR6	0	R	Interrupt output by CH6 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
10	END6	0	R	Interrupt output by CH6 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
9	ERR5	0	R	Interrupt output by CH5 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
8	END5	0	R	Interrupt output by CH5 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
7	ERR4	0	R	Interrupt output by CH4 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.

Bit	Bit Name	Initial Value	R/W	Descriptions
6	END4	0	R	Interrupt output by CH4 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
5	ERR3	0	R	Interrupt output by CH3 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
4	END3	0	R	Interrupt output by CH3 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
3	ERR2	0	R	Interrupt output by CH2 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
2	END2	0	R	Interrupt output by CH2 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
1	ERR1	0	R	Interrupt output by CH1 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
0	END1	0	R	Interrupt output by CH1 DDM_END 0: The interrupt is not output. 1: The interrupt is output.

10.2.4 DDM Start Source Polarity Reversal Registers 1 and 2

DDM Start Source Polarity Reversal Registers 1 and 2 reverse the start source input polarity to the DDM.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DDINTINV[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDINTINV[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	DDINTINV31 to DDINTINV0	H'0000_0000	R/W	Reverse the DDM start source polarity.

DDM CHn Start Source Mask Registers 1 and 2

DDM CHn Start Source Mask Registers 1 and 2 mask DDM start sources.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DDINTMSK[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDINTMSK[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	DDINTMSK31 to DDINTMSK0	H'0000_0000	R/W	Start Source Mask 0: Does not mask the start source. 1: Masks the start source.

The current source assignment is as follows:

Bit Name	Bit	Assigned Start Source
DDINTMSK5	31 to 4	Reserved
	3	RTDMAC2 CH5 CHCR HE bit
	2	RTDMAC2 CH4 CHCR HE bit
	1	RTDMAC2 CH3 CHCR HE bit
	0	RTDMAC2 CH2 CHCR HE bit
DDINTMSK4	31	RTDMAC2 CH1 CHCR HE bit
	30	RTDMAC2 CH0 CHCR HE bit
	29	RTDMAC2 CH5 CHCR TE bit
	28	RTDMAC2 CH4 CHCR TE bit
	27	RTDMAC2 CH3 CHCR TE bit
	26	RTDMAC2 CH2 CHCR TE bit
	25	RTDMAC2 CH1 CHCR TE bit
	24	RTDMAC2 CH0 CHCR TE bit
	23 to 0	Reserved
DDINTMSK3	31 to 0	Reserved
DDINTMSK2	31 to 16	Reserved
	15	RTDMAC CH5 CHCR HE bit
	14	RTDMAC CH4 CHCR HE bit
	13	RTDMAC CH3 CHCR HE bit
	12	RTDMAC CH2 CHCR HE bit
	11	RTDMAC CH1 CHCR HE bit
	10	RTDMAC CH0 CHCR HE bit
	9	DMAC1 CH5 CHCR HE bit
	8	DMAC1 CH4 CHCR HE bit
	7	DMAC1 CH3 CHCR HE bit
	6	DMAC1 CH2 CHCR HE bit
	5	DMAC1 CH1 CHCR HE bit
	4	DMAC1 CH0 CHCR HE bit
	3	DMAC2 CH5 CHCR HE bit

Bit Name	Bit	Assigned Start Source
	2	DMAC2 CH4 CHCR HE bit
	1	DMAC2 CH3 CHCR HE bit
	0	DMAC2 CH2 CHCR HE bit
DDINTMSK1	31	DMAC2 CH1 CHCR HE bit
	30	DMAC2 CH0 CHCR HE bit
	29	DMAC3 CH5 CHCR HE bit
	28	DMAC3 CH4 CHCR HE bit
	27	DMAC3 CH3 CHCR HE bit
	26	DMAC3 CH2 CHCR HE bit
	25	DMAC3 CH1 CHCR HE bit
	24	DMAC3 CH0 CHCR HE bit
	23	RTDMAC CH5 CHCR TE bit
	22	RTDMAC CH4 CHCR TE bit
	21	RTDMAC CH3 CHCR TE bit
	20	RTDMAC CH2 CHCR TE bit
	19	RTDMAC CH1 CHCR TE bit
	18	RTDMAC CH0 CHCR TE bit
	17	DMAC1 CH5 CHCR TE bit
	16	DMAC1 CH4 CHCR TE bit
	15	DMAC1 CH3 CHCR TE bit
	14	DMAC1 CH2 CHCR TE bit
	13	DMAC1 CH1 CHCR TE bit
	12	DMAC1 CH0 CHCR TE bit
	11	DMAC2 CH5 CHCR TE bit
	10	DMAC2 CH4 CHCR TE bit
	9	DMAC2 CH3 CHCR TE bit
	8	DMAC2 CH2 CHCR TE bit
	7	DMAC2 CH1 CHCR TE bit
	6	DMAC2 CH0 CHCR TE bit
	5	DMAC3 CH5 CHCR TE bit
	4	DMAC3 CH4 CHCR TE bit
	3	DMAC3 CH3 CHCR TE bit
	2	DMAC3 CH2 CHCR TE bit
	1	DMAC3 CH1 CHCR TE bit
	0	DMAC3 CH0 CHCR TE bit

10.2.5 DDM CHn Descriptor Pointer

The DDM CHn Descriptor Pointer indicates the start address of setting code allocated onto memory.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DDPTR[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DDPTR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	DDPTR31 to DDPTR0	H'0000_0000	R/W	Descriptor pointer.

10.2.6 DDM CHn Control Register

The DDM CHn Control Register controls start and stop of DDM.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PRI[3:0]				—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	STOP	KICK	DDM_ERR	DDM_END	DDE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 28	PRI3 to PRI0	H'0	R/W	PRI value on the SHwy bus.
27 to 5	—	H'000_000	R	Reserved
4	STOP	0	R/W	Forced Stop Function 0: Does not perform forced stop. 1: Performs forced stop.
3	KICK	0	R/W	Forced Start Function without Start Source 0: Does not perform forced start. 1: Performs forced start. This bit is automatically cleared to 0 after 1 is written.
2	DDM_ERR	0	R	Error Occurrence. The error is cleared by setting the DDE bit to 0. 0: No error occurred. 1: An error occurred.
1	DDM_END	0	R	DDM End. DDM end is cleared by setting the DDE bit to 0. 0: The DDM did not end. 1: The DDM ended.

Bit	Bit Name	Initial Value	R/W	Descriptions
0	DDE	0	R/W	Start Enable 0: Does not enable DDM start. 1: Enables DDM start according to the start source.

10.2.7 Principles of Operation

To reconfigure the DMAC by using the DDM, use the following procedure:

1. Describing setting codes
2. Starting and ending the DDM

(1) Describing setting codes

(a) Data structure

A setting code is fixed-length data consisting of four longwords.

Setting code data consists of the following fields, starting from the beginning:

Field	bit
Operation field	32bit
Address field	32bit
Data field	32bit
Bit mask field	32bit

Note: Arrange a setting code in 16 byte boundary.

The following describes the operation field.

(b) Operation field

The structure of the operation field is as follows:

Bit	Bit Name	Descriptions
31 to 16	HEADER	Indicates DDM setting data. H'DDDD: Normal DDM setting code Usually, set this value. H'EEEE: DDM end code Set this value when ending the channel without starting the DDM the next time. If the HEADER bits have other values, an error occurs. The channel of the DDM stops immediately.
15 to 8	—	Reserved
7 to 4	SIZE	Specify the data access size to be set. 0000: Bytes 0001: Words 0010: Longwords
3	ENDFLG	End Flag of Setting Processing Based on This Start Source 0: Continuation 1: Setting end. The DDM waits for the next start source.

Bit	Bit Name	Descriptions
2 to 0	OPC	Operation Code 000: read (cmp/eq) (read) 001: write (write) 010: rmodw (read modify write) 011: add (addition) 100: jmp/eq (branch)

The address field, data field, and bit mask field each consist of 32 bits. The data field and bit mask field use the LSB side for word- and byte-size access.

(c) read (cmp/eq)

The read (cmp/eq) code reads the target address and compares the address with the expected values written in the data field and bit mask field.

When the comparison result becomes true, the TFLG internal variable is set to 1. TFLG is cleared to 0 when jmp/eq is executed or operation with ENDFLG is performed.

Description example:

The read (cmp/eq) code in this example reads the H'FE00802C address in longwords and checks if bit 1 is set to 1.

H'DDDD0020
H'FE00802C
H'00000002
H'00000002

(d) write

The write code writes data to the target address.

Description example:

The write code in this example accesses the H'FE00802C address in longwords and writes H'00105400.

H'DDDD0021
H'FE00802C
H'00105400
H'FFFFFFFF (don't care)

(e) rmodw

The rmodw code reads the target address and performs modify-write according to the values of the bit mask field.

Description example:

The rmodw code in this example reads the H'FE00802C address in longwords and applies H'54 modify-write to bits 11 to 4.

H'DDDD0022
H'FE00802C
H'00000540
H'00000FF0

(f) add

The add code reads the target address and performs add-modify-write according to the values of the bit mask field.

Description example:

The add code in this example reads the H'FE00802C address in longwords and applies H'200 add-modify-write to bits 11 to 0.

H'DDDD0023
H'FE00802C
H'00000200
H'00000FFF

Use 0 as the addition data corresponding to the area where the bit mask is 0.

(g) jmp/eq

If TFLG is set to 1 by the cmp/eq code, jmp/eq changes the descriptor pointer to the values of the data field. Descriptor pointer change by jmp/eq is not reflected in execution based on the next start source. Changing the descriptor pointer for the next start requires that the CHn descriptor pointer be reconfigured.

Description example:

The jmp/eq code in this example changes the descriptor pointer when TFLG is 1 to H' E558000E.

H'DDDD0024
H'00000000 (don't care)
H'E558000E
H'00000000 (don't care)

(h) Settings description order

Describe settings in the following order:

(1) Clearing the start source (source output side, not the DDM start source mask register)
(2) Changing the DDM source mask setting as required
(3) Reconfiguring registers such as DMAC
(4) Reconfiguring the next descriptor pointer

If several start sources are set, the last write may be unable to catch up with the next start. In such a case, end next descriptor pointer setting in (4) in read after write (do not end it in write).

(i) Example of setting DMAC restart

Use DDM CH1. The following shows an example of describing setting codes for reconfiguration when the TE bit of the DMAC1 CH0 channel control register is HI.

//TE bit read
H'DDDD0020
H'FE00802C
H'00000002
H'00000002
//TE bit clear
H'DDDD0021

H'FE00802C
H'00105400
H'FFFFFFFF
//SAR setting
H'DDDD0021
H'FE008020
H'58000000
H'FFFFFFFF
//DAR setting
H'DDDD0021
H'FE008024
H'00000000
H'FFFFFFFF
//TCR setting
H'DDDD0021
H'FE008028
H'00000010
H'FFFFFFFF
//DE bit write. DMA start
H'DDDD0021
H'FE00802C
H'00105401
H'FFFFFFFF
//Next descriptor pointer write. Setting end by this start.
H'DDDD0029
H'FE080050
H'580002D0
H'FFFFFFFF

(2) Start and end

(a) Starting the DDM

Make necessary settings in the DDM.

- Enabling interrupt output as required
- Setting a DDM start source
- Setting a descriptor pointer

After setting the above, set the DDM Enable bit of the DDM control register to 1 to enable DDM start.

Setting example:
Enable the interrupt by DDM CH1 end.
Address: H'FE080008 Write data: H'00000001
Enable DDM CH1 start when the DMAC1 TE bit is changed.
Address: H'FE080030 Write data: H'00001000
Set the DDM CH1 descriptor pointer to H'58000210.
Address: H'FE080050 Write data: H'58000210

Enable DDM CH1 start.

Address: H'FE080054 Write data: H'00000001

Set the KICK bit to forced start after setting the DDM Enable bit to 1. Do not set these bits at the same time.

(b) Ending the DDM

When the DDM ends, the DDM_END bit is set to 1. DDM end is cleared by setting the DDE bit to 0. To restart the DDM, you must clear the DDM_END bit by setting the DDE bit to 0.

Procedure for stopping the DDM by the STOP bit

Set the STOP bit to 1. Keep the DDE bit at 1.

Check that the DDM_END bit is 1.

Set the DDE bit to 0.

Section 11 Clock Pulse Generator (CPGA)

This LSI has a clock pulse generator (CPGA).

The CPGA generates the system domain clocks in the AP block: the system CPU clock (Zϕ and ZXϕ), system CPU debug trace clock (ZTϕ), SGX clock (ZGϕ), and high-speed peripheral clock (HPϕ).

The CPGA also generates the realtime domain clocks in the AP block: the realtime CPU clock (Iϕ), media clock (Bϕ), VPU clock (M1ϕ), CSI2 RX clock (CSIRϕ), ISP byte clock (ISPBϕ), and high-speed peripheral clock (HPϕ).

In addition, the CPGA generates the common domain clocks: the SHwy clock (Sϕ, ZSϕ), common peripheral clock (CPϕ), SDRAM clock for SBSC1 (ZB3ϕ), DDRP clock (DDRPϕ), and bus clock (ZBϕ).

The CPGA consists of an oscillator, PLL circuits C0, C1 and C2, and dividers.

11.1 Features

- Various clocks generated for LSI internal operation

  In the realtime domain of the AP block, the realtime CPU clock (Iϕ) used by the realtime CPU (CPU, DSP, cache, and TLB), media clock (Bϕ) used by the RTDMAC and media-related modules, VPU clock (M1ϕ) used by VPU, CSI2 RX clock (CSIRϕ) used by CSIR2 RX, ISP byte clock (ISPBϕ) used by ISP, and high-speed peripheral clock (HPϕ) used by the high-speed peripheral modules can be generated independently.

  The following clocks can be generated independently: (1) those in the system domain of the AP block: the system CPU clock (Zϕ and ZXϕ) used by the system CPU (CPU, cache, and TLB), the system CPU debug trace clock (ZTRϕ) and system CPU debug trace bus clock (ZTϕ), used by the system CPU for debugging, SGX clock (ZGϕ) used by the SGX540, and the high-speed peripheral clock (HPϕ) used by the high-speed peripheral modules; and (2) those in the common block: the common peripheral clock (CPϕ) used by the common peripheral modules, the SHwy clock (ZSϕ) used by the SHwy, the SDRAM clock for SBSC1 (ZB3ϕ) used by the SBSC1, the DLL clock (DDRPϕ) for SDRAM interface PHI and the bus clock (ZBϕ) used by the external bus interface.

  As other generated clocks : Video clock 1 (VCK1ϕ), Video clock 2 (VCK2ϕ), Video clock 3 (VCK3ϕ), FMSI input port clock (FMSIϕ), FMSO output port clock (FMSOϕ), FSIA clock (FSIAϕ), FSIB clock (FSIBϕ), SUB clock (SUBϕ), SUP clock (SUPϕ), VOU clock (VOUϕ), HDMI clock (HSMIϕ), DSI TX Link clock (DSITϕ), DSI0 TX PHY clock (DSIPϕ), DSI1 TX PHY clock (DSI1Pϕ)

- Frequency change function

  The frequencies of the system CPU clock can be changed independently using PLL circuit C0 or dividers in the CPG. Other frequencies of the realtime CPU clock, RT-SHway clock, media clock, VPU clock, ISP clock, CSI2 RX clock, CPU debug trace bus clock, CPU debug trace clock, SGX clock, SHwy clock, bus clock, SDRAM clock for SBSC1, DLL clock for SDRAM interface PHI , high-speed peripheral clock, and common peripheral clock can be changed independently using PLL circuit C1 or dividers in the CPG. Frequencies are changed by software using the frequency control register A (FRQCRA), frequency control register B (FRQCRB), frequency control register (FRQCRC) or frequency control register D (FRQCRD) settings.
- Power-down mode control

  The clock can be stopped for sleep mode, and specific modules can be stopped using the power cutoff mode, core standby mode, and module standby function.
- Music player mode

  Power supply on/off of the A4S4 area, PLLC0, PLLC1, and source oscillation on/off are controlled automatically for the power consumption reduction in music player mode.
- Clock source

  The AP / common domain block operates with the external clock input through the EXTAL1 pin.

A block diagram of the CPGA is shown in figure 11.1.

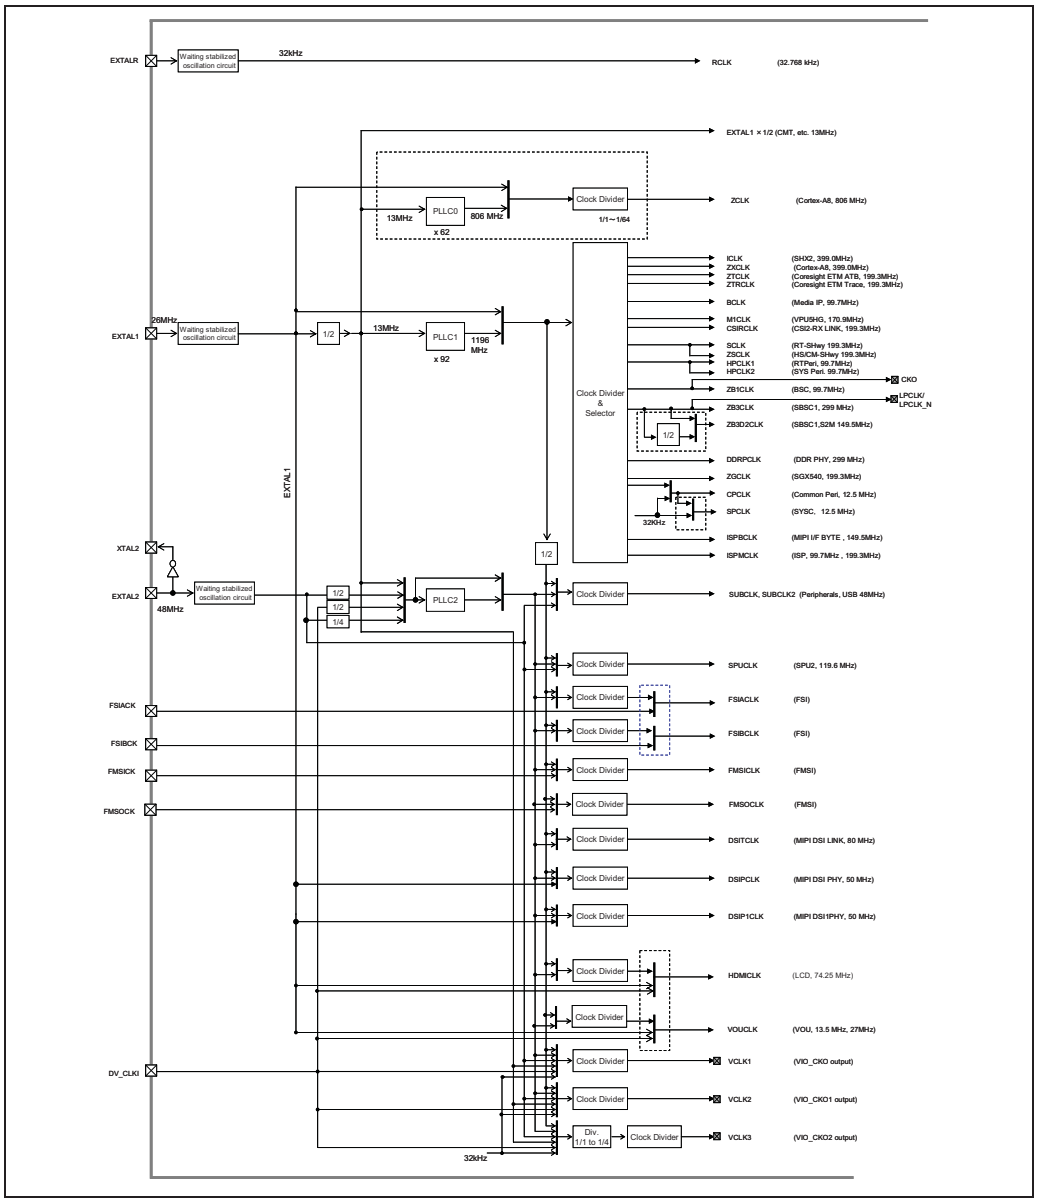

Figure 11.1 Block Diagram of CPGA

Each block of the CPGA in the AP block functions as follows:

(1) PLL Circuit C0

PLL circuit C0 multiplies the clock frequency input from the AP / Common domain main clock by the ratio of ×40 to ×92. The multiplication ratio is set by the frequency control register B (FRQCRB). Turning on and off PLL circuit C0 is set by the PLLC0 control register (PLLC01CR).

(2) Divider C0

The dividers (C0) generate the system CPU clock. The division ratio is set by each frequency control register.

(3) PLL Circuit C1

PLL circuit C1 multiplies the clock frequency input from the AP / Common domain main clock by the ratio of ×40 to ×92. The multiplication ratio is set by the frequency control register C (FRQCRC). Turning on and off PLL circuit C1 is set by the PLLC1 control register (PLLC01CR).

(4) PLL Circuit C2

PLL circuit C2 multiplies the frequency of the clock input from the AP / Common domain main clock, the clock input from the EXTAL2 pin being divided by 2, the clock input from the EXTAL2 pin being divided by 4, or the clock input from the DV_CKI pin being divided by 2 by the ratio of ×40 to ×92 as an input clock. Turning on and off PLL circuit C2 is set by the PLLC2 control register (PLLC2CR).

(5) Divider C1

The dividers (C1) generate the realtime CPU clock, media clock, VPU clock , ISP clock, CSI2 RX clock, ZG clock, high-speed peripheral clock, , system CPU debug trace clock, system CPU debug trace bus clock, SHwy clock, bus clock, SDRAM clock for SBSC1, DLL clock for SDRM interface PHY , and common peripheral clock. The division ratio is set by each frequency control register.

(6) Clock Frequency Control Circuit

The clock frequency control circuit controls the clock frequency according to the settings of the frequency control register A (FRQCRA), frequency control register B (FRQCRB), frequency control register C (FRQCRC), and frequency control register D (FRQCRD).

(7) Standby Control Circuit

The standby control circuit controls the state of the on-chip oscillation circuit and other modules during clock switching and in sleep mode or core standby mode.

(8) Frequency Control Register A (FRQCRA)

The frequency control register has bits for setting the multiplication ratio of PLL circuit C1, and the frequency division ratios of the realtime CPU clock, ZG clock , and media clock.

(9) Frequency Control Register B (FRQCRB)

The frequency control register has bits for setting the frequency division ratios of the system CPU clock for debugging and trace, system CPU clock debug trace clock, system CPU clock, and high-speed peripheral clock.

(10) Frequency Control Register C (FRQCRC)

The frequency control register has bits for setting the frequency division ratios of the SHwy clock, bus clock, SDRAM clock for SBSC1, and common peripheral clock.

(11) Frequency Control Register D (FRQCRD)

The frequency control register has bits for setting the frequency division ratios of the DLL clock for SDRAM interface PHI .

(12) Realtime Standby Control Register (RTSTBCR)

The realtime standby control register has bits for controlling the power-down modes.

(13) System Standby Control Register (SYSTBCR)

The system standby control register has bits for controlling the power-down modes.

(14) PLLC0,1 Control Register (PLLC01CR)

The PLLC0,1 control register has control bits assigned for turning on or off PLL circuit C0, C1.

(15) PLLC2 Control Register (PLLC2CR)

The PLLC2 control register has control bits assigned for turning on or off PLL circuit C2, and setting the multiplication ratio.

11.2 Input/Output Pins

Table 11.1 lists the CPGA pin configuration in the AP block.

Table 11.1 Pin Configuration and Functions of CPGA

Pin Name	Function	I/O	Description
XTAL2	Clock input pins	Output	Outputs amplified negative feedback of EXTAL2.
EXTAL2		Input	Used as an external clock input pin (e.g. 48 MHz).
EXTALR		Input	Connects the RTC clock.*
EXTAL1		Input	Used as an external clock input pin (26 MHz).*
CKO	Clock output pin	Output	Used as an external clock output pin.
LPCLK / LPCLK_N	Main pin of the SDRAM clock for SBSC1	Output	Used as the clock output pin for SBSC1.
VIO_CKO	Video clock output pin	Output	Used as a pin for video clock output 1.
VIO_CKO1	Video clock output pin	Output	Used as a pin for video clock output 2.
VIO_CKO2	Video clock output pin	Output	Used as a pin for video clock output 3.
DV_CLKI	Video clock input	Input	Used as the external clock input pin. This input signal can be used as a clock source of VCK1ϕ, VCK2ϕ, VCK3ϕ, HDMIϕ, and VOUϕ, and can be used as a reference of PLLC2.
FSIACK	Clock input for FSI port A	Input	Used as an external input clock for FSI clock A.
FSIBCK	Clock input for FSI port B	Input	Used as an external input clock for FSI clock B.
FMSICK	Clock input for FMSI input port	Input	Used as an external input clock of FMSI input clock.
FMSOCK	Clock input for FSMI output port	Input	Used as an external input clock of FSMI output clock.

Note: * Always input the RTC clock and EXTAL1 clock in this LSI.

11.3 Clock Operating Modes

Table 11.2 shows the initial clock settings.

PLL circuit C0, PLL circuit C1 and PLL circuit C2 are started in the PLL-OFF state during booting. After booting, set the PLLC01CR and PLLC2C to oscillate PLL circuit C0, oscillate PLL circuit C1 and PLL circuit C2.

Table 11.2 Clock Operating Modes

PLL Circuit C0	PLL Circuit C1	PLL Circuit C2	PLL Circuit C0 Multiplication Rate Setting	PLL Circuit C1 Multiplication Rate Setting
OFF	OFF	OFF	x40	x40

I	ZG	B	M1	CSIR	M1	ZTR	ZT	Z	HP	ZS	ZB3	ZB	CP	HP	CP
1/2	1/2	1/2	1/2	1/2	1/2	1/2	1/2	1	1/2	1/2	1/4	1/2	1/2	1/2	1/2

11.4 Clock Assignment to Modules

Table 11.3 shows the clocks assigned to each module.

11.5.1 Frequency Control Register A (FRQCRA)

FRQCRA is a 32-bit readable/writable register that specifies the frequency multiplication ratio of PLL circuit C1, and the frequency division ratios of the CPU clock (Iϕ), SGX clock (ZGϕ), CSI2 RX clock (CSIRϕ), and media clock (Bϕ). FRQCRA can be accessed only in longwords. The FRQCRA setting involves restrictions on the clock ratio as shown in table 11.6 of section 11.6 (6).

11.5.2 Frequency Control Register B (FRQCRB)

FRQCRB is a 32-bit readable/writable register that specifies the frequency division ratios of the system CPU clock (Zϕ and ZXϕ), system CPU clock for debugging and trace (ZTRϕ), system CPU debug and trace bus clock (ZTϕ), and high-speed peripheral clock (HPϕ). FRQCRB can be accessed only in longwords. The FRQCRB setting involves restrictions on the clock ratio as shown in table 11.6 of section 11.6 (6).

11.5.3 Frequency Control Register C (FRQCRC)

FRQCRC is a 32-bit readable/writable register that specifies the frequency division ratios of the SHwy clock (Sϕ, ZSϕ), bus clock (ZBϕ), SDRAM clock for SBSC1 (ZB3ϕ), and common peripheral clock (CPϕ). FRQCRC can be accessed only in longwords. The FRQCRC setting involves restrictions on the clock ratio as shown in table 11.6 of section 11.6 (6).

11 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

11.5.5 PLLC01 Control Register (PLLC01CR)

PLLC01CR is a 32-bit readable/writable register that turns on or off PLL circuits C0 and C1. PLLC01CR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	PLL01E	-	-	-	-	-	-	-	-	-	-	-	CKO DIVSTP	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14	PLL1E	0	R/W	PLL Circuit C0 and C1 Enable Turns PLL circuit C0 and C1 on or off. 0: PLL circuit C0 and C1 is turned off. The input to PLL circuit C0 and C1 is supplied as a clock. 1: PLL circuit C0 and C1 is turned on. The output from PLL circuit C0 and C1 is supplied as a clock
13 to 3	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	CKODIVSTP	0	R	Stop Bit of Divider for CKO* This bit sets whether the divider for CKO is to be turned on or off. 0: The divider for CKO is turned on. 1: The divider for CKO is turned off.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: * When BROMMD0 in CMNCR of BSC is set to 1, the clock to be output to the CKO pin becomes an inverted ZB clock, making it unnecessary to output the divider for CKO. Therefore, this bit can be set to 1 to stop any unnecessary circuit in the CPG macro.

11.5.6 PLLC0 and PLLC1 Stop Condition Register (PLLC01STPCR)

PLLC01STPCR is a 32-bit readable/writable register that specifies the stop condition of PLLC0 and PLLC1 when PLLC01CR.PLLE is set to 1. PLLC01STPCR can be accessed only in longwords.

If the power supply status meets the stop condition of PLLC0 and PLLC1 specified in this register, the CPGA cancels the oscillation stop request to PLLC0 and PLLC1. PLLC0 and PLLC1 oscillate when this register is set to the initial value, meaning that the oscillation request from the application part always is enabled.

PLLC0 and PLLC1 are controlled by the same stop conditions. However as for control by the A3SM area, PLLC0 is controlled by the PLLC0STP bit when the A3SMSTP bit is cleared to 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	PLLC0STP	0	R/W	PLLC0 Stop Condition by A3SM Power Status This bit is enabled only when A3SMSTP bit is cleared to 0. 0: PLLC0 does not stop when the power supply of the A3SM area is turned off. 1: PLLC0 stops when the power supply of the A3SM area is turned off.
27 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	A3SGSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A3SG Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A3SG area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A3SG area is turned off.
12	A3SMSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A3SM Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A3SM area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A3SM area is turned off.
11	A3SPSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A3SP Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A3SP area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A3SP area is turned off.
10	A4SSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A4S Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A4S area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A4S area is turned off.

Bit	Bit Name	Initial Value	R/W	Description
9	A3RLSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A3RL Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A3RL area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A3RL area is turned off.
8	A3RISTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A3RI Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A3RI area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A3RI area is turned off.
7	A2SLSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A2SL Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A2SL area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A2SL area is turned off.
6	A3RVSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A3RV Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A3RV area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A3RV area is turned off.
5	A4RSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A4R Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A4R area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A4R area is turned off.
4	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	D4STP	0	R/W	PLLC0 and PLLC1 Stop Condition by D4 Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the D4 area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the D4 area is turned off.

Bit	Bit Name	Initial Value	R/W	Description
2	A4MPSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A4MP Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A4MP area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A4MP area is turned off.
1	A4LCSTP	0	R/W	PLLC0 and PLLC1 Stop Condition by A3LC Power Status 0: PLLC0 and PLLC1 do not stop when the power supply of the A3LC area is turned off. 1: PLLC0 and PLLC1 stop when the power supply of the A3LC area is turned off.
0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

11.5.7 PLLC2 Control Register (PLLC2CR)

PLLC2CR is a 32-bit readable/writable register that controls PLLC2. PLLC2CR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PLLE	-	STC[5:0]						-	-	-	-	-	-	-	-
Initial value:	0	0	0	1	0	0	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	CKSEL[1:0]		-	-	-	-	-	OE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	PLLE*[1]	0	R/W	PLLC2 Enable Turns PLL circuit C2 on or off. This bit is read as 1 after the oscillation settling time has passed. 0: PLL circuit C2 is oscillated. The output from PLL circuit C2 is supplied as a clock. 1: PLL circuit C2 is oscillated. The output from PLL circuit C2 is supplied as a clock.
30	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 24	STC[5:0]	010011	R/W	PLL Circuit C2 Multiplication Ratio PLL circuit C2 performs multiplication with a ratio of (setting + 1) × 2. 010011: × 40 : 101101: × 92
23 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 6	CKSEL [1:0]	00	R/W	PLL Circuit C2 Clock Source Select 00: EXTAL1 output ×1/2 01: EXTAL2/XTAL2 (crystal resonator) output 10: DV_CLKI output ×1/2 11: EXTAL2/XTAL2 (crystal resonator) output ×1/4 Other than above: Setting prohibited
5 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	XOE	1	R/W	XTAL2 (Crystal Resonator) Oscillation Enable 0: Enables XTAL2 oscillation 1: Stops XTAL2 oscillation

11.5.8 Video Clock Frequency Control Register 1 (VCLKCR1)

VCLKCR1 is a 32-bit readable/writable register that controls video clock frequency 1. VCLKCR1 can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	EXSRC[2:0]			-	-	-	CKSTP	-	-	VDIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R/W	R/W	R/W	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 12	EXSRC [2:0]	000	R/W	Clock Source Select 000: PLL circuit C1 output × 1/2 001: PLL circuit C2 output 010: DV_CLKI input 011: EXTAL2 input 100: AP / common domain clock × 1/2 101: EXTALR Other than above: Setting prohibited
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	CKSTP	0	R/W	Clock Stop 0: Supplies video clock 1 1: Stops video clock 1
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	VDIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of video clock 1. The frequency is set to the clock source specified by EXSRC[2:0] × 1 / (setting + 1).

11.5.9 Video Clock Frequency Control Register 2 (VCLKCR2)

VCLKCR2 is a 32-bit readable/writable register that controls video clock frequency 2. VCLKCR2 can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	EXSRC[2:0]			-	-	-	CKSTP	-	-	VDIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R/W	R/W	R/W	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
14 to 12	EXSRC[2:0]	000	R/W	Clock Source Select 000: PLL circuit C1 outpu t × 1/2 001: PLL circuit C2 output 010: DV_CLK input 011: EXTAL2 input 100: AP / common domain clock × 1/2 101: EXTALR Other than above: Setting prohibited
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies video clock 2 1: Stops video clock 2
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	VDIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of video clock 2. The frequency is set to the clock source specified by EXSRC[2:0] × 1 / (setting + 1) .

11.5.10 Video Clock Frequency Control Register 3 (VCLKCR3)

VCLKCR2 is a 32-bit readable/writable register that controls video clock frequency 3. VCLKCR3 can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	EXSRC[2:0]			-	-	-	CKSTP	-	-	VDIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R/W	R/W	R/W	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 12	EXSRC[2:0]	000	R/W	Clock Source Select 000: PLL circuit C1 outpu t × 1/2 001: PLL circuit C2 output 010: DV_CLKI input 011: EXTAL2 input 100: AP / common domain clock × 1/2 101: EXTALR Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies video clock 3 1: Stops video clock 3
7, 6	—	All 0	R	Division Ratio 00: × 1/1 01: × 1/2 10: Setting prohibited 11: × 1/4
5 to 0	VDIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of video clock 2. The clock source specified by the EXSRC2 to EXSRC0 bits is set to the division ratio of PDIV1 or PDIV0 × 1 / (setting + 1).

11.5.11 FMSI Clock A Frequency Control Register (FMSICKCR)

FMSICKCR is a 32-bit readable/writable register that controls the FMS input port clock frequency. FMSICKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	EXSRC[1:0]		DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies FMSI input port clock 1: Stops FMSI input port clock
7, 6	EXSRC[1:0]	00	R/W	Clock Source Select Selects the SIU clock A source. 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: External input clock (pin name: FMSICK) 11: Setting prohibited
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of SIU clock A. The clock source specified by EXSRC is set to the division ratio of 1 / (setting + 1).

11.5.12 MFSO Clock Frequency Control Register (FMSOCKCR)

FMSOCKCR is a 32-bit readable/writable register that controls the FMSI output port clock frequency. FMSOCKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	EXSRC[1:0]		DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies FMSI output port clock B 1: Stops FMSI output port clock B
7, 6	EXSRC[1:0]	00	R/W	Clock Source Select Selects the FMSI output port source. 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: External input clock (pin name: FMSOCK) 11: Setting prohibited
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of SIU clock B. The clock source specified by EXSRC is set to the division ratio of 1 / (setting + 1).

11.5.13 FSIA Clock Frequency Control Register (FSIACKCR)

FSIACKCR is a 32-bit readable/writable register that controls the FSIA clock frequency. FSIACKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	EXSRC[1:0]		DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies FSIA clock 1: Stops FSIA clock
7, 6	EXSRC[1:0]	00	R/W	Clock Source Select Selects the FSIA source. 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: External input clock (pin name: FSIACK) 11: Setting prohibited
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of SIU clock B. The clock source specified by EXSRC is set to the division ratio of 1 / (setting + 1).

11.5.14 FSIB Clock Frequency Control Register (FSIBCKCR)

FSIBCKCR is a 32-bit readable/writable register that controls the FSIB clock frequency. FSIBCKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	EXSRC[1:0]		DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies FSIB clock 1: Stops FSIB clock
7, 6	EXSRC[1:0]	00	R/W	Clock Source Select Selects the FMSI output port source. 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: External input clock (pin name: FSIBCK) 11: Setting prohibited
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of SIU clock B. The clock source specified by EXSRC is set to the division ratio of 1 / (setting + 1).

11.5.15 SUB Clock Frequency Control Register (SUBCKCR)

SUBCKCR is a 32-bit readable/writable register that controls the SUB clock. SUBCKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	E2MON	E2DET	-	-	-	SUBCK2 STP	SUBCK STP	-	CKSEL[1:0]		DIV[5:0]					
Initial value:	*[1]	1*[1]	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	E2MON	*[1]	R	EXTAL2-Connected Clock Frequency Monitor 1: 36 MHz ≤ EXTAL2 0: Clock not connected or EXTAL2 < 36 MHz
14	E2DET	1*[1]	R	EXTAL2-Connected Clock Detection Period Monitor 1: Clock input to EXTAL2 is being detected. 0: Detection of clock input to EXTAL2 has ended.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	SUBCK2STP	0	R/W	Clock Stop 0: Supplies SUBCK2 1: Stops SUBCK2
9	SUBCKSTP	0	R/W	Clock Stop 0: Supplies SUBCK 1: Stops SUBCK
8	—	1	R/W	Reserved These bits are always read as 1. The write value should always be 1.
7, 6	CKSEL [1:0]	*	R/W	Clock Select 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: EXTAL2 11: Setting prohibited
5 to 0	DIV[5:0]	000000	R/W	Division Ratio These bits set the frequency division ratio of SUB clock. The clock source specified by the CKSEL1 and CKSEL0 bits is set to the division ratio of 1 / (setting + 1).

Notes: * After this LSI is booted, the E2DET bit is set to 1 (clock being detected) and the E2MON bit is cleared to 0 when one EXTALR cycle has passed. Use the E2MON value after the E2DET bit is cleared to 0.

11.5.16 SUP Clock Frequency Control Register (SUPCKCR)

SPUCKCR is a 32-bit readable/writable register that controls the SPU clock. SPUCKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	EXSRC[1:0]		DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies SPU clock 1: Stops SPU clock
7	EXSRC	0	R/W	Clock Source Select 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: EXTAL2 11: Setting prohibited
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of SPU clock. The clock source specified by EXSRC is set to the division ratio of 1 / (setting + 1).

11.5.17 VOU Clock Frequency Control Register (VOUCKCR)

VOUCKCR is a 32-bit readable/writable register that controls the MSU clock. VOUCKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	EXSRC[1:0]		DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies VOU clock 1: Stops VOU clock
7,6	EXSRC	0	R/W	Clock Source Select 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: DV_CLKI 11:EXTAL1
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of VOU clock. The clock source specified by EXSRC is set to the division ratio of 1 / (setting + 1).

11.5.18 HDMI Clock Frequency Control Register (HDMICKCR)

HDMICKCR is a 32-bit readable/writable register that controls the HDMI clock frequency. HDMICKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	EXSRC[1:0]		DIV[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies HDMI clock 1: Stops HDMI clock
7, 6	EXSRC[1:0]	00	R/W	Clock Source Select 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: DV_CLKI 11: Setting prohibited
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of HDMI clock. The clock source specified by EXSRC is set to the division ratio of 1 / (setting + 1).

11.5.19 DSI TX Link Clock Frequency Control Register (DSITCKCR)

DSITCKCR is a 32-bit readable/writable register that controls the MIPI DSI TX Link clock frequency. DSITCKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W:	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies DSI TX Link clock 1: Stops DSI TX Link clock
7	EXSRC	00	R/W	Clock Source Select 0: PLL circuit C1 output × 1/2 1: PLL circuit C2 output
6	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of DSI TX Link clock. The clock source specified by EXSRC is set to the division ratio of 1 / (setting + 1).

11.5.20 DSI PHY0 Frequency Control Register (DSIPCKCR)

DSIPCKCR is a 32-bit readable/writable register that controls the frequency of MIPI VOU DSI PHY 0. DSIPCKCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies DSI PHY0 clock 1: Stops DSI PHY0 clock
7,6	EXSRC	0	R/W	Clock Source Select 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: EXTAL1 11: Setting prohibited
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of multi-function clock 1. The clock source specified by the EXSRC1 and EXSRC0 bits is set to the division ratio of 1 / (setting + 1).

11.5.21 DSI PHY 1 Clock Frequency Control Register (DSI1PCR)

DSI1PCR is a 32-bit readable/writable register that controls the frequency of MIPI VOU DSI PHY 1. DSI1CRCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CKSTP	EXSRC[1:0]		DIV[5:0]

R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CKSTP	0	R/W	Clock Stop 0: Supplies DSI PHY1 clock 1: Stops DSI PHY1 clock
7,6	EXSRC	0	R/W	Clock Source Select 00: PLL circuit C1 output × 1/2 01: PLL circuit C2 output 10: EXTAL1 11: Setting prohibited
5 to 0	DIV[5:0]	111111	R/W	Division Ratio These bits set the frequency division ratio of DSI PHY1 clock. The clock source specified by EXSRC1 and EXSRC0 is set to the division ratio of 1 / (setting + 1).

11.5.22 Music Play Mode Control Register (MPMODE)

MPMODE is a 32-bit readable/writable register that specifies the power management in music player mode. The power supply of the A4S area, PLLC0, PLLC1, and the clock signal input on the EXTAL1 pin are automatically controlled by the request from the SPU in music player mode. The range of automatic control of hardware is specified by setting this register.

The MPMODE register can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-					MPCKCFG	MPPLL	MPXTAL	MPPDWU
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	MPCKCFG	0	R/W	MPMODE Clock Configuration Set MPCKCFG bit according to the SPU clock configuration. 0: SPU clock is EXTAL2 1: SPU clock is PLLC2 output, and PLLC2 clock source is EXTAL1 x 1/2

Bit	Bit Name	Initial Value	R/W	Description
2	MPPLL	0	R/W	MPMODE PLLC1 control 0 : Controls PLLC1 oscillation automatically when SPU request power & clock. 1 : Always request oscillation of PLLC1
1	MPXTAL	0	R/W	MPMODE XTAL1 control 0 : Controls EXTAL1 oscillation automatically when SPU request power & clock. 1 : Always request oscillation of EXTAL1
0	MPPDWU	0	R/W	MPMODE Power down/Wake Up control 0 : Controls A4S area power automatically when SPU request power & clock. 1 : Always request power on of A4S area

11.5.23 Realtime Standby Control Register (RTSTBCR)

RTSTBCR is a 32-bit readable/writable register that selects the state available when the realtime CPU core has executed the SLEEP instruction. RTSTBCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	CSYBY	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CSTBY	0	R/W	Realtime CPU Core Standby Executing the SLEEP instruction from the SH after setting this bit makes a transition to CPU core standby mode. 0: Realtime CPU sleep 1: Realtime CPU core standby
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

11.5.24 System Standby Control Register (SYSTBCR)

SYSTBCR is a 32-bit readable/writable register that selects the state available when the system CPU has executed the "wait for interrupt" instruction and controls the software NMI. SYSTBCR can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	CSYBY	-	-	-	SFTNMI
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CSTBY	0	R/W	System CPU Core Standby Executing the Wait for Interrupt instruction from the system CPU after setting this bit makes a transition to system CPU core standby mode. 0: System CPU sleep 1: System CPU core standby
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SFTNMI	1	R/W	Software NMI 0: Drives the NMI signal to the INTCS at a low level 1: Drives the NMI signal to the INTCS at a high level

11.5.25 Module Stop Starts Register 0 (MSTPSR0)

MSTPCR0 is a 32-bit readable register that state of the module assigned to each bit.

MSTPCR0 can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MSTP ST031	MSTP ST030	MSTP ST029	-	-	MSTP ST026	-	-	MSTP ST023	MSTP ST022	MSTP ST022	-	MSTP ST019	MSTP ST018	MSTP ST017	MSTP ST016

Bit	Bit Name	Initial Value	R/W	Description
31	MSTPST 031	0	R	Module Stop Status 031 Displays clock supply status of RT-CPU TLB 0: TLB operates 1: Clock supply to TLB halted
30	MSTPST 030	0	R	Module Stop Status 030 Displays clock supply status of RT-CPU Instruction Cache (IC) 0: IC operates 1: Clock supply to IC halted
29	MSTPST 029	0	R	Module Stop Status 029 Displays clock supply status of RT-CPU Operand Cache (OC) 0: OC operates 1: Clock supply to OC halted

Bit	Bit Name	Initial Value	R/W	Description
28, 27	—	All 0	R	Reserved These bits are always read as 0
26	MSTPST026	0	R	Module Stop Status 026 Displays clock supply status of RT-CPU X/Y memory 0: X/Y memory operates 1: Clock supply to X/Y memory halted
25, 24	—	All 0	R	Reserved These bits are always read as 0
23	MSTPST023	0	R	Module Stop Status 023 Displays clock supply status of RT-DMAC2 0: RT-DMAC2 operates 1: Clock supply to RT-DMAC2 halted
22	MSTPST022	0	R	Module Stop Status 022 Displays clock supply status of INTCS 0: INTCS operates 1: Clock supply to INTCS halted
21	MSTPST021	0	R	Module Stop Status 021 Displays clock supply status of RT-DMAC1 0: RT-DMAC1 operates 1: Clock supply to RT-DMAC1 halted
20	—	0	R	Reserved These bits are always read as 0
19	MSTPST019	0	R	Module Stop Status 019 Displays clock supply status of H-UDI 0: H-UDI operates 1: Clock supply to H-UDI halted
18	MSTPST018	0	R	Module Stop Status 018 Displays clock supply status of debug module 0: debug module operates 1: Clock supply to debug module halted

Bit	Bit Name	Initial Value	R/W	Description
17	MSTPST017	0	R	Module Stop Status 017 Displays clock supply status of UBC 0: UBC operates 1: Clock supply to UBC halted
16	MSTPST016	0	R	Module Stop Status 016 Displays clock supply status of debug module 0: debug module operates 1: Clock supply to debug module halted
15	MSTPST015	0	R	Module Stop Status 015 Displays clock supply status of ILRAM 0: ILRAM operates 1: Clock supply to ILRAM halted
14 to 8	—	All 0	R	Reserved These bits are always read as 0
7	MSTPST007	0	R	Module Stop Status 007 Displays clock supply status of ICB 0: ICB operates 1: Clock supply to ICB halted
6 to 3	—	All 0	R	Reserved These bits are always read as 0
2	—	1	R	Reserved These bits are always read as 1
1	MSTPST001	0	R	Module Stop Status 001 Displays clock supply status of IIC2 0: IIC2 operates 1: Clock supply to IIC2 halted
0	MSTPST000	0	R	Module Stop Status 000 Displays clock supply status of MSIOF0 0: MSIOF0 operates 1: Clock supply to MSIOF0 halted

11.5.26 Module Stop Starts Register 1 (MSTPSR1)

MSTPCR1 is a 32-bit readable register that state of the module assigned to each bit.

MSTPCR1 can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MSTP ST131	MSTP ST130	MSTP ST129	MSTP ST128	MSTP ST127	MSTP ST126	MSTP ST125	MSTP ST124	-	-	-	-	-	MSTP ST118	MSTP ST117	MSTP ST116

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	MSTPST 131	1	R	Module Stop Status 131 Displays clock supply status of VEU3 0: VEU3 operates 1: Clock supply to VEU3 halted
30	MSTPST 130	1	R	Module Stop Status 130 Displays clock supply status of VEU2 0: VEU2 operates 1: Clock supply to VEU2 halted
29	MSTPST 129	1	R	Module Stop Status 129 Displays clock supply status of VEU1 0: VEU1 operates 1: Clock supply to VEU1 halted

Bit	Bit Name	Initial Value	R/W	Description
28	MSTPST128	1	R	Module Stop Status 128 Displays clock supply status of VEU0 0: VEU0 operates 1: Clock supply to VEU0 halted
27	MSTPST127	1	R	Module Stop Status 127 Displays clock supply status of CEU 0: CEU operates 1: Clock supply to CEU halted
26	MSTPST126	1	R	Module Stop Status 126 Displays clock supply status of CSI2 RX 0: CSI2 RX operates 1: Clock supply to CSI2 RX halted
25	MSTPST125	1	R	Module Stop Status 125 Displays clock supply status of TMU0 0: TMU0 operates 1: Clock supply to TMU0 halted
24	MSTPST124	1	R	Module Stop Status 124 Displays clock supply status of CMT0 0: CMT0 operates 1: Clock supply to CMT0 halted
23 to 19	—	All 1	R	Reserved These bits are always read as 0
18	MSTPST118	0	R	Module Stop Status 118 Displays clock supply status of DSI TX Link 0: DSI TX Link operates 1: Clock supply to DSI TX Link halted
17	MSTPST117	0	R	Module Stop Status 117 Displays clock supply status of LCDC1 0: LCDC1 operates 1: Clock supply to LCDC1 halted

Bit	Bit Name	Initial Value	R/W	Description
16	MSTPST116	1	R	Module Stop Status 116 Displays clock supply status of IIC0 0: IIC0 operates 1: Clock supply to IIC0 halted 1: Clock supply to RT-DMAC1 halted
15	MSTPST115	1	R	Module Stop Status 115 Displays clock supply status of 2D-DMAC 0: 2D-DMAC operates 1: Clock supply to 2D-DMAC halted
14	—	1	R	Reserved These bits are always read as 1
13	MSTPST113	0	R	Module Stop Status 113 Displays clock supply status of MERAM 0: MERAM operates 1: Clock supply to MERAM halted
12	MSTPST112	1	R	Module Stop Status 112 Displays clock supply status of SGX540 0: SGX540 operates 1: Clock supply to SGX540 halted
11	MSTPST111	1	R	Module Stop Status 111 Displays clock supply status of TMU1 0: TMU1 operates 1: Clock supply to TMU1 halted
10	—	1	R	Reserved These bits are always read as 1
9	MSTPST109	1	R	Module Stop Status 109 Displays clock supply status of TSIF1 0: TSIF1 operates 1: Clock supply to TSIF1 halted

Bit	Bit Name	Initial Value	R/W	Description
8	MSTPST108	1	R	Module Stop Status 108 Displays clock supply status of TSIF0 0: TSIF0 operates 1: Clock supply to TSIF0 halted
7	—	1	R	Reserved These bits are always read as 1
6	MSTPST106	1	R	Module Stop Status 106 Displays clock supply status of JPU 0: JPU operates 1: Clock supply to JPU halted
5	MSTPST105	1	R	Module Stop Status 105 Displays clock supply status of JPU6E 0: JPU6E operates 1: Clock supply to JPU6E halted
4	MSTPST104	1	R	Module Stop Status 104 Displays clock supply status of BEU2 0: BEU2 operates 1: Clock supply to BEU2 halted
3	MSTPST103	1	R	Module Stop Status 103 Displays clock supply status of BEU1 0: BEU1 operates 1: Clock supply to BEU1 halted
2	MSTPST102	1	R	Module Stop Status 103 Displays clock supply status of BEU0 0: BEU0 operates 1: Clock supply to BEU0 halted
1	MSTPST101	1	R	Module Stop Status 102 Displays clock supply status of VPU 0: VPU operates 1: Clock supply to VPU halted

Bit	Bit Name	Initial Value	R/W	Description
0	MSTPST000	0	R	Module Stop Status 000 Displays clock supply status of MSIOF0 0: MSIOF0 operates 1: Clock supply to MSIOF0 halted

11.5.27 Module Stop Starts Register 2 (MSTPSR2)

MSTPCR2 is a 32-bit readable register that state of the module assigned to each bit.

MSTPCR2 can be accessed only in longwords.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

20 to 16	—	All 0	R	Reserved These bits are always read as 0

Bit	Bit Name	Initial Value	R/W	Description
15	MSTPST415	0	R	Module Stop Status 415 Displays clock supply status of SDHI2 0: SDHI2 operates 1: Clock supply to SDHI2 halted
14	MSTPST314	0	R	Module Stop Status 414 Displays clock supply status of MIPI-HSI 0: MIPI-HSI operates 1: Clock supply to MIPI-HSI halted
13	MSTPST413	0	R	Module Stop Status 413 Displays clock supply status of HDMI 0: HDMI operates 1: Clock supply to HDMI halted
12	MSTPST412	0	R	Module Stop Status 412 Displays clock supply status of CEC 0: CEC operates 1: Clock supply to CEC halted
11	MSTPST411	0	R	Module Stop Status 411 Displays clock supply status of IIC3 0: IIC3 operates 1: Clock supply to IIC3 halted
10	MSTPST410	0	R	Module Stop Status 410 Displays clock supply status of IIC4 0: IIC4 operates 1: Clock supply to IIC4 halted
9	MSTPST409	0	R	Module Stop Status 409 Displays clock supply status of ACMFI1/ACMFI2 RAM 0: ACMFI1/ACMFI2 RAM operates 1: Clock supply to ACMFI1/ACMFI2 RAM halted
8	MSTPST408	0	R	Module Stop Status 408 Displays clock supply status of SIB(ACMFI1/ACMFI2) 0: SIB(ACMFI1/ACMFI2) operates 1: Clock supply to SIB(ACMFI1/ACMFI2) halted

Bit	Bit Name	Initial Value	R/W	Description
7	MSTPST407	0	R	Module Stop Status 407 Displays clock supply status of USB DMAC1 0: USB DMAC1 operates 1: Clock supply to USB DMAC1 halted
6	MSTPST406	0	R	Module Stop Status 406 Displays clock supply status of USB1 0: USB1 operates 1: Clock supply to USB1 halted
5	MSTPST405	0	R	Module Stop Status 405 Displays clock supply status of CMT4 0: CMT4 operates 1: Clock supply to CMT4 halted
4	MSTPST404	0	R	Module Stop Status 404 Displays clock supply status of CMT3 0: CMT3 operates 1: Clock supply to CMT3 halted
3	MSTPST403	0	R	Module Stop Status 403 Displays clock supply status of KEYSC 0: KEYSC operates 1: Clock supply to KEYSC halted
2	MSTPST402	0	R	Module Stop Status 402 Displays clock supply status of RWDT0 0: RWDT0 operates 1: Clock supply to RWDT0 halted
1	—	0	R	Reserved These bits are always read as 0
0	MSTPST400	0	R	Module Stop Status 400 Displays clock supply status of CMT2 0: CMT2 operates 1: Clock supply to CMT2 halted

11.5.30 Module stop control register 0 (RMSTPCR0/ SMSTPCR0)

RMSTPCR0, SMSTPCR0 is a 32-bit readable/ writable register that individually starts or stops the module assigned to each bit. RMSTPCR0 and SMSTPCR0 assume the control from corresponding RT-CPU and SYS-CPU. It enters the state of the module stop when both of RMSTPCR0 and SMSTPCR0 settings are stops. The module stop is displayed in MSTPSR0. MSTPCR0 can be accessed only in longwords.

11.5.33 Module stop control register 3 (RMSTPCR3/ SMSTPCR3)

RMSTPCR3, SMSTPCR3 is a 32-bit readable/ writable register that individually starts or stops the module assigned to each bit. RMSTPCR3 and SMSTPCR3 assume the control from corresponding RT-CPU and SYS-CPU. It enters the state of the module stop when both of RMSTPCR3 and SMSTPCR3 settings are stops. The module stop is displayed in MSTPSR2. MSTPCR3 can be accessed only in longwords.

11.5.35 Software Reset Register 0 (SRCR0)

SRCR0 is a 32-bit readable/writable register. Each bit is assigned to a module in the system domain. Writing 1 to a bit resets the corresponding module and writing 0 cancels the reset. After writing 1 to a software reset bit in this register, wait for at least one EXTALR cycle before writing 0 to cancel the reset. Before applying a software reset to a module connected to the SHwy, be sure to stop data transfer to the module.

11.5.38 Software Reset Register 3 (SRCR3)

SRCR3 is a 32-bit readable/writable register. Each bit is assigned to a module in the system domain. Writing 1 to a bit resets the corresponding module and writing 0 cancels the reset. After writing 1 to a software reset bit in this register, wait for at least one EXTALR cycle before writing 0 to cancel the reset. Before applying a software reset to a module connected to the SHwy, be sure to stop data transfer to the module.

3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

11.5.39 Software Reset Register 4 (SRCR4)

SRCR4 is a 32-bit readable/writable register. Individual bits correspond to those modules in the common domain. When 1 is written, a module reset is issued. When 0 is written, the reset is canceled. When 1 has been written to the software reset bit in this register, a time equivalent to at least one cycle of EXTALR must be allowed before 0 is written to cancel the reset. If a software reset is applied to a module connected to SHwy, data transfer to the module must be stopped before the software reset.

15,14	VREF1CR [3:0]	0	R/W	VREF1 pin control register 00 : Automatic control (High: A4S power on, Low: A4S power off) 10 : Low level 11 : High level other value: setting prohibited
13 to 0	—	00001010001010	R	Reserved Please set read value of these bits at the time of write acccess to VREFCR.

11.6 Changing Frequency

The clock frequencies controlled by the frequency control registers can be changed either by changing the multiplication ratio of PLL circuits C0 and C1 or by changing the division ratio of the dividers. They are controlled by software through the frequency control registers. The methods are described below.

11.6.1 Changing Multiplication Ratio of PLL Circuit C0

Changing the multiplication ratio of PLL circuit 0 can be done by modifying the STC[5:0] bits in FRQCRC and writing 1 to the KICK bit in FRQCRB. The RWDT setting is not required because the PLL oscillation settling time is internally detected automatically.

11.6.2 Changing Multiplication Ratio of PLL Circuit C1

Changing the multiplication ratio of PLL circuit 1 can be done by modifying the STC[5:0] bits in FRQCRA and writing 1 to the KICK bit in FRQCR**B**. The RWDT setting is not required because the PLL oscillation settling time is internally detected automatically.

11.6.3 Changing Division Ratio

Changing the division ratio can be done by modifying each set of bits for setting the division ratio in FRQCRA, FRQCRB or FRQCRC and writing 1 to the KICK bit in FRQCRB. Before changing the division ratio, the KICK bit must be checked for 0. After 1 is written to the KICK bit in FRQCRB, 0 can be read if the setting change is completed. While the setting is being changed with the KICK bit being 1, no writing into FRQCRA, FRQCRB, or FRQCRC must be performed. When the KICK bit is 1, 0 must not be written into the KICK bit.

11.6.4 Turning On/Off of PLL Circuit C1

PLL circuits C0 and C1 can be turned on or off by modifying the PLL01E bit in PLLC01CR.

In the same way as multiplication ratio change for PLL circuits C0 andC1 or division ratio change the oscillation settling time of PLL circuits C0 and C1 is internally detected automatically.

11.6.5 Changing Multiplication Ratio of PLL Circuit C2

Change the multiplication ratio of PLL circuit C2 with the following procedure.

1. Check that the module that uses the clock is not operating.
2. Set the PLLE bit in PLLC2CR to 0 to reset PLL circuit C2.
3. Set the multiplication ratio in STC4 to STC0 in PLLC2CR.
4. Set 1 to the PLLE bit in PLLC2CR to oscillate PLL circuit C2.
5. If the oscillation of PLL circuit C2 is settled, 1 can be read into the PLLE bit in PLLC2CR. In this case, do not access the module using the clock of PLL circuit C2 until it becomes possible to read 1 into the PLLE bit in PLLC2CR.

11.6.6 Example of Activating PLL and Specifying Frequency Division and Multiplication Ratios

(1) Wait until FRQCRB bit31 (KICK bit) is cleared to 0.
(2) Set H'2D13 05C8 in FRQCRA.
(3) Set H'9E40 352E in FRQCRC.
(4) Set H'8033 1050 in FRQCRB.
(5) Wait until FRQCRB bit31 (KICK bit) is cleared to 0 (the division setting is completed).
(6) Set H'0000 2000 in FRQCRD.
(7) Wait until FRQCRD bit31 (DDRPCHG bit) is cleared to 0 (the division setting is completed).
(8) Set H'00004000 in PLLC01CR.
(9) Wait until PLLC01CR (PLLC01E bit) is set to 1 (the oscillation of PLL circuit C1 is settled).

Through these steps (1) to (14), the frequency of each system clock available when the clock input frequency of EXTAL1 is 26 MHz is determined as follows.

RT domain: Iϕ = 398.7 MHz, Bϕ = 99.7 MHz, M1ϕ = 170.9MHz, CSIRϕ = 49.8 MHz, ISPBϕ = 149.5MHz

SY domain: ZGϕ = 199.3HMz, ZTϕ = 199.3MHz, ZTRϕ = 199.3HMz, Zϕ = 806MHz, ZXϕ = 398.7 MHz, HPϕ = 99.7 MHz

Common domain: ZSϕ = 199.3 MHz, ZBϕ = 99.7 MHz, ZB3ϕ = 299.00 MHz, CPϕ = 12.5 MHz

11.6.7 Restrictions on Clock Ratio

The clock ratio specified by each frequency control register involves the restrictions shown in table 11.6.

Table 11.6 Restrictions on Clock Ratio

Domain	Clock	Clock Limitation	Clock Ratio	Setting Example
Realtime	Iϕ:ZSϕ	Integer clock ratio	Iϕ:ZSϕ = N:1 *	398.7MHz: 199.3MHz
		Inverted clock ratio	Iϕ:Sϕ = 1:N *	
	ZSϕ:Bϕ	Integer clock ratio	Sϕ:Bϕ = N:1 *	When CSI2 is used, the setting of ZSϕ:Bϕ=1:1 is prohibited.
	Iϕ:HPϕ	Integer clock ratio	Iϕ:HPϕ = N:1 *	
System	ZXϕ:ZSϕ	Integer clock ratio	ZXϕ:ZSϕ = N:1 *	398.7MHz : 199.3Hz
Realtime/ System	ZSϕ:HPϕ	Integer clock ratio	ZSϕ:HPϕ = N:1 *	
Common	ZSϕ:ZBϕ	Integer clock ratio	ZSϕ:ZBϕ = N:1 *	
Others	HPϕ:TCKϕ	Magnitude relation	HPϕ > TCK	

Note: * N = 16,12,8,4,3,2,1

11.7 Sleep Mode

11.7.1 Transition to SH-CPU Core Sleep Mode

Executing the SLEEP instruction in the SH-CPU core causes a transition from the program execution state to sleep mode. Although the SH-CPU core halts immediately after executing the SLEEP instruction, the contents of the SH-CPU core registers remain unchanged. The on-chip peripheral modules in the Realtime block continue to operate in sleep mode.

11.7.2 Canceling SH-CPU Core Sleep Mode

Sleep mode is canceled by an interrupt (software NMI, IRQ, or on-chip peripheral module in the Realtime block) or a reset.

Interrupts are accepted in sleep mode even when the BL bit in SR is 1. If necessary, save SPC and SSR in the stack before executing the SLEEP instruction.

11.7.3 Transition to System CPU Sleep Mode

Executing the WFI instruction in the system CPU causes a transition from the program execution state to system CPU sleep mode. Although the system CPU halts immediately after executing the WFI instruction, the contents of the system CPU registers remain unchanged. The on-chip peripheral modules in the System block continue to operate in sleep mode.

11.7.4 Canceling System CPU Sleep Mode

System CPU sleep mode is canceled by an interrupt (NMI, IRQ, or on-chip peripheral module in the System block) to the system CPU or a reset.

11.8 Core Standby Mode

11.8.1 Transition to SH-CPU Core Standby Mode

Executing the SLEEP instruction in the SH-CPU core when the CSTBY bit in RTSTBCR is 1 causes a transition from the program execution state to SH-CPU core standby mode. The SH-CPU core halts immediately after executing the SLEEP instruction. In core standby mode, the cache in the SH-CPU core enters RAM standby state and the power supply to the SH-CPU core logic is turned off. The on-chip peripheral modules in the Realtime block continue to operate in core standby mode.

11.8.2 Canceling SH-CPU Core Standby Mode

SH-CPU core standby mode is canceled by an interrupt (software NMI, IRQ, or on-chip peripheral module in the Realtime block) or a reset.

Interrupts are accepted in SH-CPU core standby mode even when the BL bit in SR is 1.

11.8.3 Transition to System CPU Core Standby Mode

Executing the WFI instruction in the system CPU when the CSTBY bit in SYSTBCR is 1 causes a transition from the program execution state to system CPU core standby mode. The system CPU halts immediately after executing the WFI instruction. In system CPU core standby mode, the cache in the system CPU enters RAM standby state and the power supply to the system CPU logic is turned off. The on-chip peripheral modules in the System block continue to operate in sleep mode.

11.8.4 Canceling System CPU Core Standby Mode

System CPU core standby mode is canceled by an interrupt (NMI, IRQ, or on-chip peripheral module in the System block) to the system CPU or a reset.

11.9 Module Standby Function

11.9.1 Transition to Module Standby State

Setting the MSTP bits in the module stop control registers to 1 stops the clock supply to the corresponding on-chip peripheral modules. This function can be used to reduce power consumption in normal mode.

Modules in module standby state keep the state immediately before the transition to the module standby state. The registers keep the contents before the clock supply is stopped, and the external pins keep the state before the clock supply is stopped. When the module standby state is canceled, operation is restarted from the condition immediately before the clock supply is stopped.

Note: Make sure to set the MSTP bit to 1 while the corresponding module has completed the operation and is in an idle state and no other module or external pin may activate the module.

11.9.2 Canceling Module Standby State

The module standby state can be canceled by clearing the respective MSTP bit to 0.

After clearing the respective MSTP bit, be sure to read the MSTP bit and check that the bit value has changed.

11.10 Music Player Mode

The power supply of the A4S area, PLLC0, PLLC1, and the clock signal input on the EXTAL1 pin are automatically controlled by the request from the SPU, which indicates the music player mode.

Set the MPMODE register to the following value according to the clocks used by the SPUϕ and SUBϕ.

— When SPUϕ and SUBϕ are generated from EXTAL2

The power supply of the A4S area, PLLC0, PLLC1, and the clock signal input on the EXTAL1 pin are automatically controlled by the request from the SPU.

CPGA.MPMODE = H'0000 0000

— When SPUϕ and SUBϕ are generated from the signal generated by dividing PLLC2 output and the PLLC2 input is generated by dividing EXTAL1 by two

The power supply of the A4S area, PLLC0, and PLLC1 are automatically controlled by the request from the SPU. The clock signal input on the EXTAL1 pin is not automatically controlled by the request from the SPU.

CPGA.MPMODE = H'0000 000A

Set the SYSC register to the following value to enable the control of the power supply of the A4S area and the clock signal input on the EXTAL1 pin by the SPU request.

SYSC.A4SPOWCR = H'0000 000C
SYSC.SYSCKENMSK = H'0000 0020

Clear the A4SSTP bit in the SYSC.APSCSTP register to 0 so that the clock signal input on the EXTAL1 pin is not disabled by power supply condition of the A4S area.

Example: SYSC.APSCSTP = H'0000 3822 (A3SG, A3SM, A3SP, A4R, A4LC)

The SPU request controls only PLLC1 by setting the PLLC0STP bit (bit 28) in the CPGA.PLLC01STPCR register to 1. PLLC0 is controlled by the power supply status of the A3SM area with the PLLC0STP bit set to 1.

Example: CPGA.PLLC01STPCR = H'1000 0400
(PLLC0 A3SM synchronization , PLLC1 A4S synchronization)

11.11 Clock Control

An outline of the control registers in CPGA and each AP clock control is explained.

11.11.1 Control of PLL Circuit C0 , PLL Circuit C1 and PLL Circuit C2

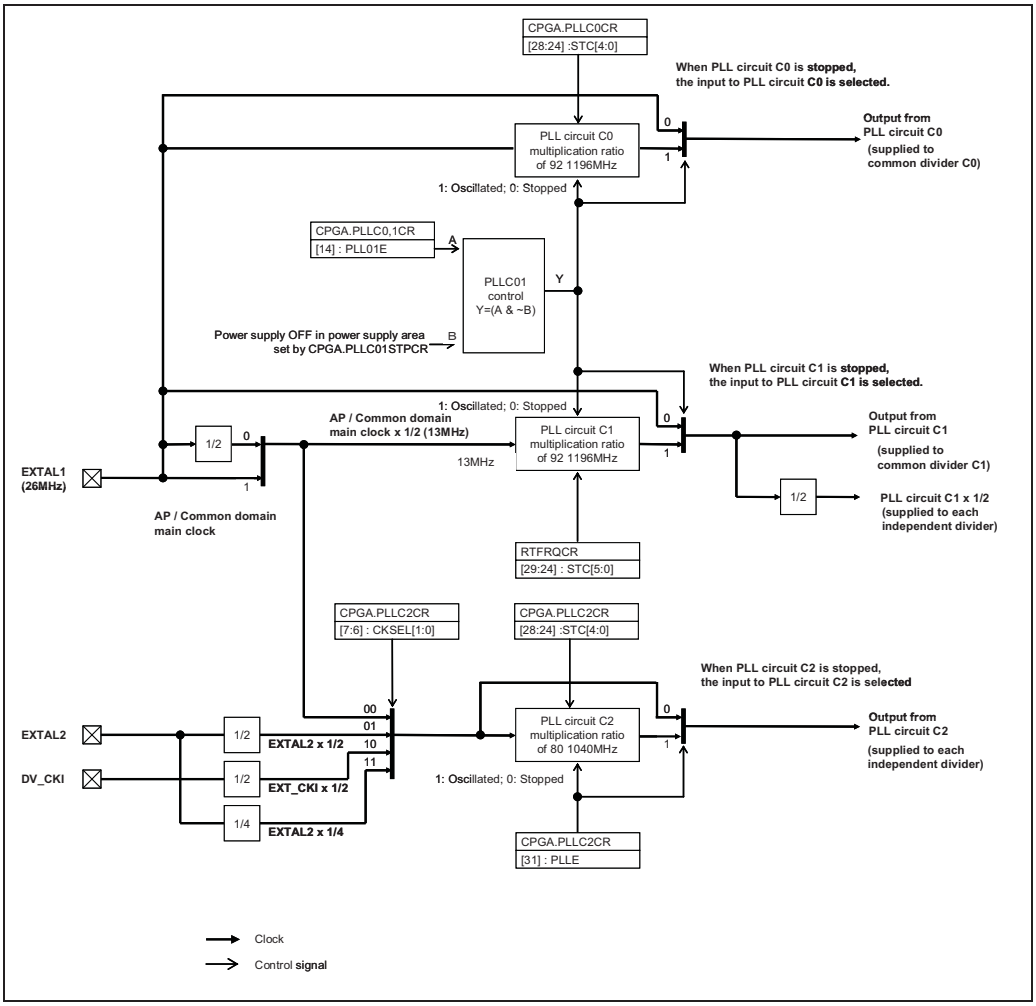

Figure 11.2 Control of PLL Circuit C0 , PLL Circuit C1 and PLL Circuit C2

11.11.2 Clock Control Related to Divider C0 and Divider C1

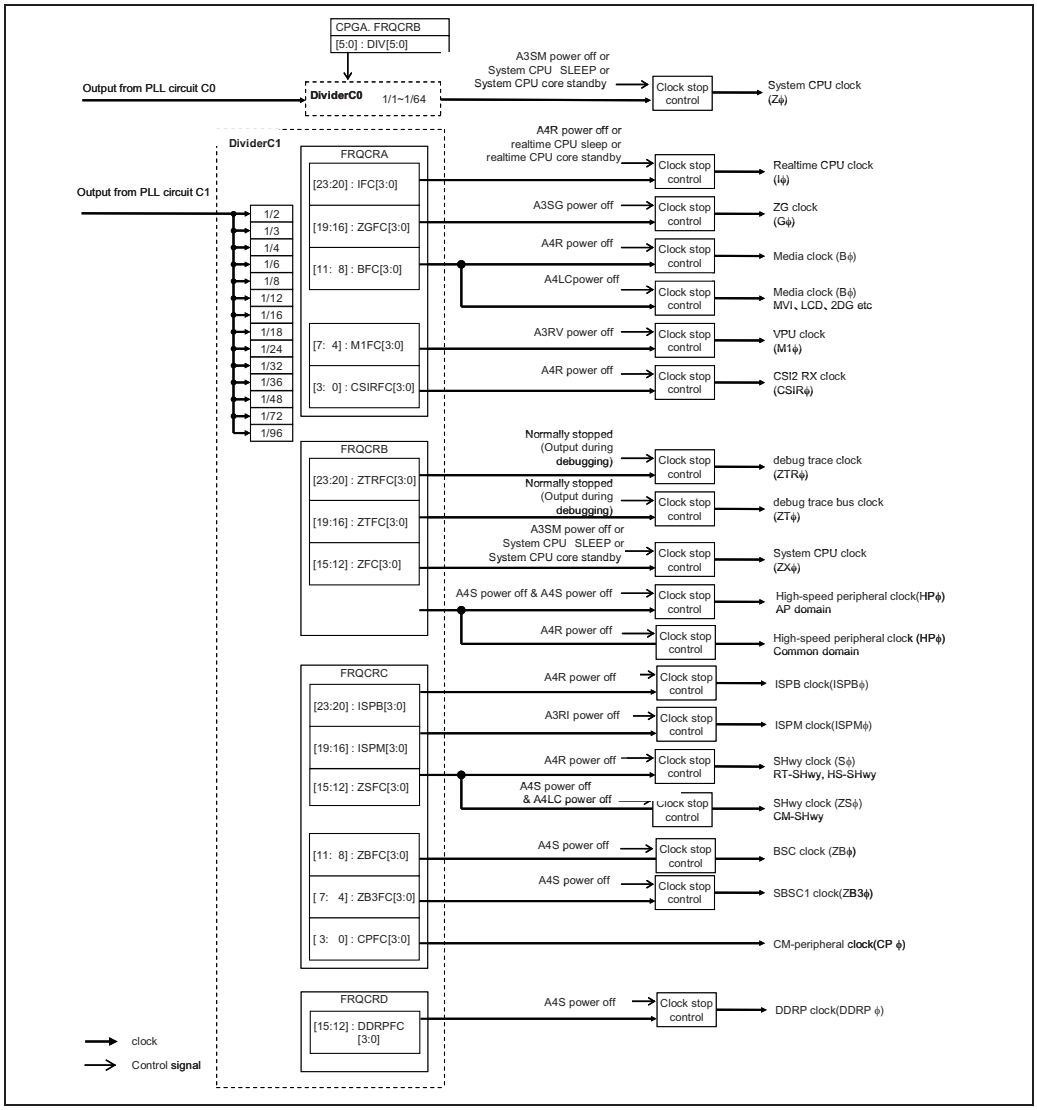

Figure 11.3 Clock Control Related to Divider C0 and Divider C1

11.11.3 Clock Control Related to Independent Divider

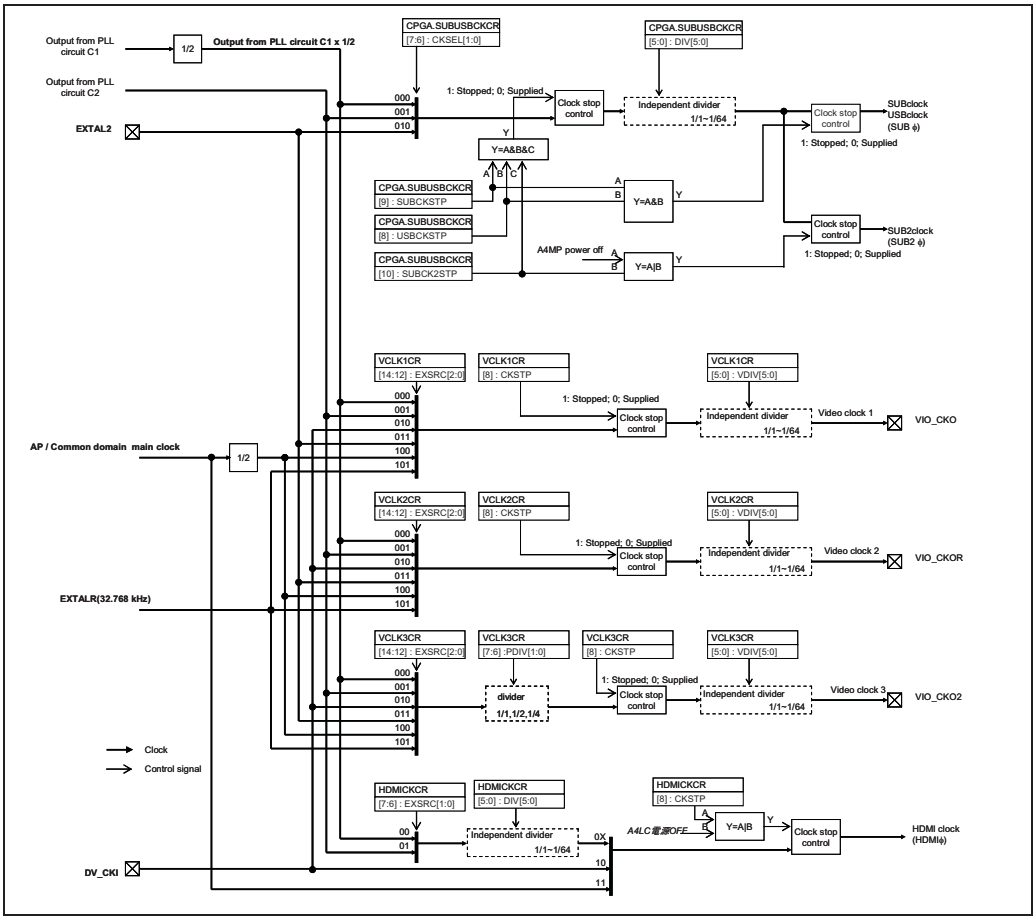

Figure 11.4 Clock Control Related to Independent Divider (1)

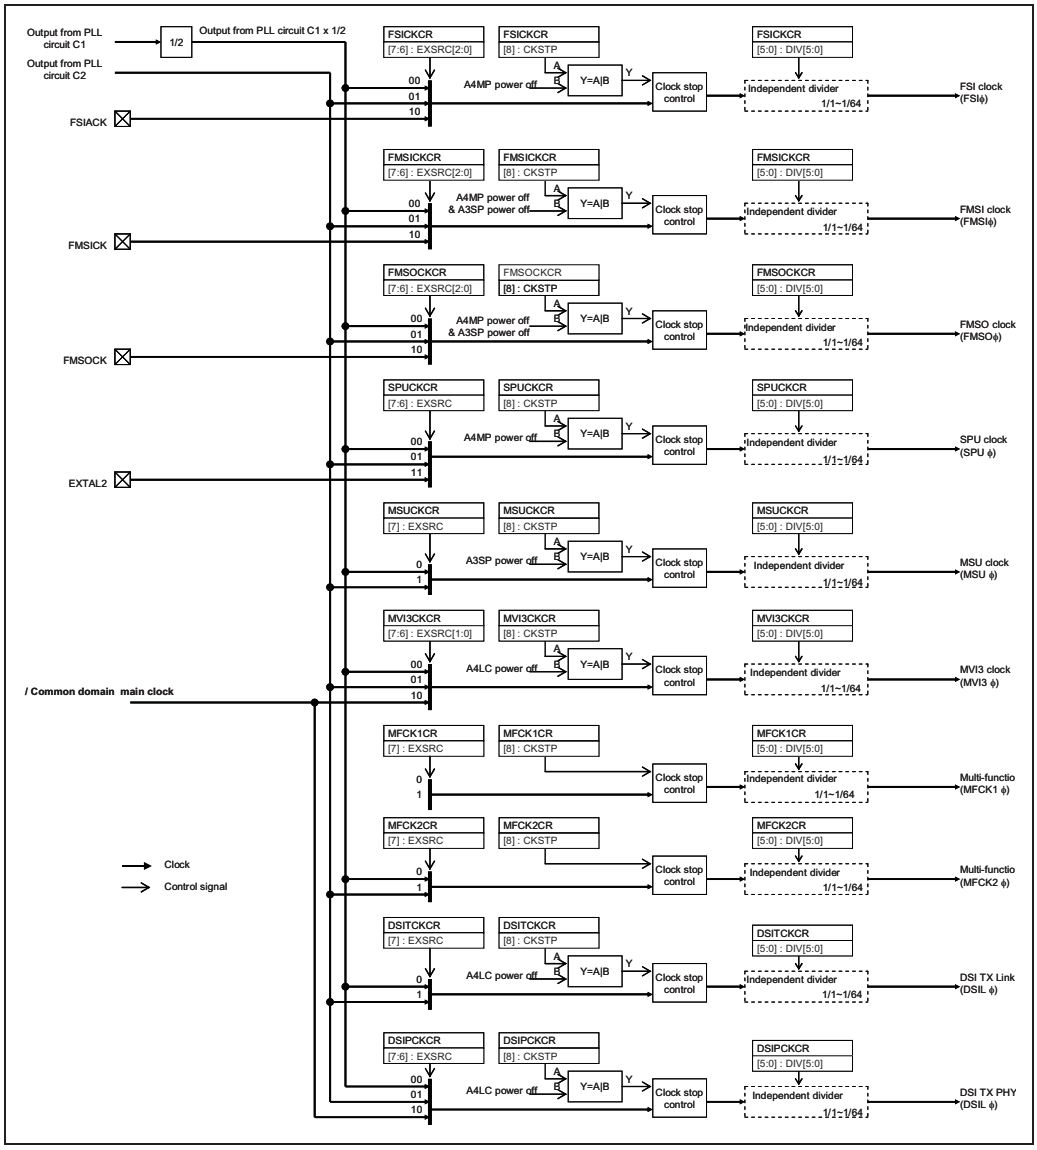

Figure 11.5 Clock Control Related to Independent Divider (2)

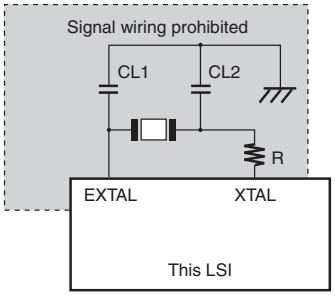
11.12 Notes on Board Designing

11.12.1 Bypass Capacitor

Insert laminated ceramic capacitors as bypass capacitors for each V_{SS}/V_{CC} pair. Mount the bypass capacitor near the power supply pins of the LSI. Use components with a frequency characteristic suitable for the operating frequency of the LSI, as well as a suitable capacitance value.



11.12.2 When Using a PLL Oscillation Circuit

Keep the wiring from the PLL V_{DD} and V_{SS} connection pattern to the power supply pins short, and make the pattern width large, to minimize the inductance component.

The analog power supply system of the PLL circuits is sensitive to noise. Therefore system malfunction may occur by the intervention with another power supply. Do not supply the analog power supply with the same resource as the digital power supply of V_{DD} and $V_{CC}Q$.

11.12.3 When Using an External Crystal Resonator

Place the crystal resonator, capacitors CL1 and CL2, and damping resistor R as close to the XTAL2, and EXTAL2 pins as possible. To minimize induction and thus obtain oscillation at the correct frequency, the capacitors to be attached to the resonator must be grounded to the same ground. Do not bring wiring patterns close to these components.

Note: The values for CL1, CL2, and damping resistance should be determined after consultation with the crystal resonator manufacturer.

Figure 11.6 Note on Using a Crystal Resonator

Section 12 RCLK Watchdog Timer (RWDT)

This LSI includes the RCLK watchdog timer (RWDT).

This LSI can be reset by the overflow of the counter when the value of the counter has not been updated because of a system runaway.

The RWDT is a single-channel timer that uses a RTC clock as an input and can be used as a watchdog timer.

12.1 Features

- One channel are provided in the common domain.
- Can be used as a watchdog timer. A system reset is generated when the counter overflows.
- A counter input clock can be chosen from:
  Clocks (RCLK/1 to RCLK/(128×60×30)) that are obtained by dividing the RCLK.

Figure 12.1 shows block diagrams of the RWDT.

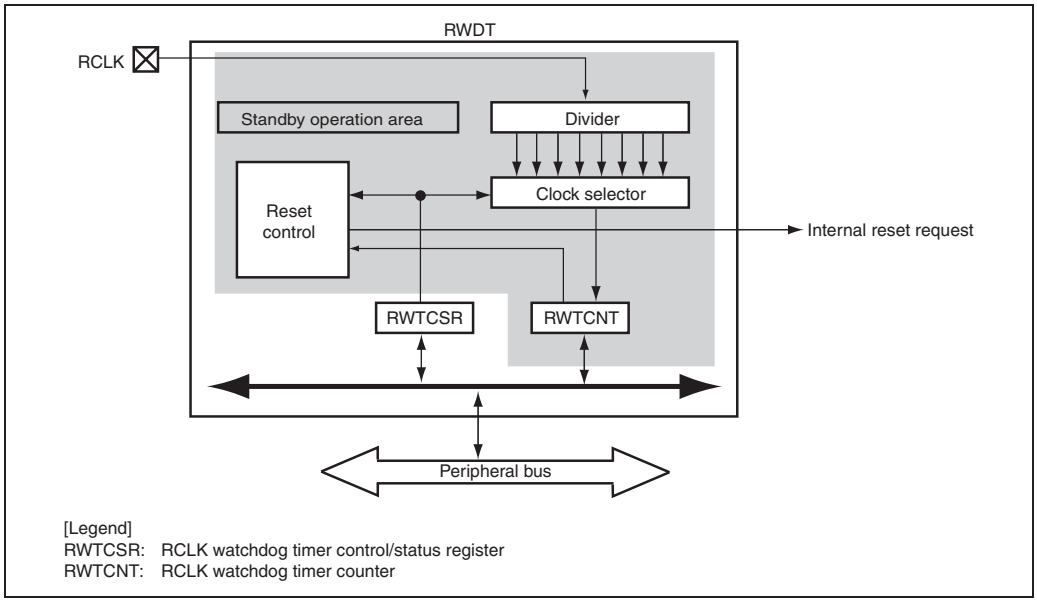


Figure 12.1 Block Diagram of RWDT

12.2 Input/Output Pins for RWDT

Table 12.1 shows the pin configuration and functions of the RWDT.

Table 12.1 RWDT Pin Configuration

Pin Name	Function	I/O	Description
EXTALR (RCLK)	RTC clock	Input	Clock input from an external RTC

12.3 Register Descriptions for RWDT

Table 12.2 shows the RWDT register configuration. Table 12.3 shows the register state in each processing mode.

Table 12.2 Register Configuration of RWDT

Name	Abbreviation	R/W	Address*[3]	Access Size
RCLK watchdog timer counter 0	RWTCNT0	R/W	H'E602 0000 H'E702 0000	8/16*[1]
RCLK watchdog timer control/status register A0	RWTCSRA0	R/W	H'E602 0004 H'E702 0004	8/16*[2]
RCLK watchdog timer control/status register B0	RWTCSRB0	R/W	H'E602 0008 H'E702 0008	8/16*[2]
RCLK watchdog timer counter 1	RWTCNT1	R/W	H'E603 0000 H'E703 0000	8/16*[1]
RCLK watchdog timer control/status register A1	RWTCSRA1	R/W	H'E603 0004 H'E703 0004	8/16*[2]
RCLK watchdog timer control/status register B1	RWTCSRB1	R/W	H'E603 0008 H'E703 0008	8/16*[2]

Notes: 1. Write is performed in 16 bits and read in 8 bits.
2. This register is accessible both from HPBC (E6 space) and HPBD (E7 space).

Table 12.3 Register State of RWDT in Each Processing Mode

Register Abbreviation				
Register	**Bit**	**Power-On Reset**	**System Reset (Including RWDT Overflow Reset)**	**RWDT Software Reset**
RWTCNT0	All	Initialized	Initialized	Initialized
RWTCSRA0	WOVF	Initialized*	Retained	Initialized
	Other than WOVF	Initialized	Initialized	Initialized
RWTCSRB0	All	Initialized*	Initialized	Initialized
RWTCNT1	All	Initialized	Initialized	Initialized
RWTCSRA1	WOVF	Initialized*	Retained	Initialized
	Other than WOVF	Initialized	Initialized	Initialized
RWTCSRB1	All	Initialized*	Initialized	Initialized

Note: * The WOVF bit is initialized only by a power-on reset (RESETP/software), and not by an RWDT overflow reset.

12.3.1 RCLK Watchdog Timer Counter (RWTCNT)

RWTCNT is an 8-bit readable/writable register that increments on the selected clock. When an overflow occurs, it generates a system reset or a power-on reset. The RWTCNT counter is initialized to H'00 by a power-on reset, system reset, and RWDT software reset.

Use a word access to write to the RWTCNT counter, with H'5A in the upper byte. Use a byte access to read RWTCNT.

Bit:	7	6	5	4	3	2	1	0
	RWTCNT							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

12.3.2 RCLK Watchdog Timer Control/Status Register A (RWTCSRA)

RWTCSRA is an 8-bit readable/writable register composed of bits to select the clock used for the count, overflow flags, and enable bit.

RWTCSRA is initialized to H'87 by a power-on reset and RWDT software reset. Except for the WOVF bit, the system reset is initialized.

Use a word access to write to RWTCSRA, with H'A5 in the upper byte. Use a byte access to read RWTCSRA.

Bit:	7	6	5	4	3	2	1	0
	TME	—	WR FLG	WOVF	WOVFE	CKS[2:0]		
Initial value:	1	0	0	0	1	1	1	1
R/W:	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	TME	1	R/W	Starts and stops timer operation. 0: Timer disabled: Count-up stops and RWTCNT value is retained 1: Timer enabled
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5	WRFLG	0	R	Write Status Flag The writing to the RWTCNT is disabled during this bit is 1.The writing to the RWTCNT is masked for the prescribed period to synchronize after the writing to the RWTCNT. Confirm that this bit is 0 to write to continuously the RWTCNT.
4	WOVF	0	R/W	Indicates that the RWTCNT has overflowed. This bit is not initialized by a reset generated upon an RWDT overflow. Write 0 to this bit before using the RWDT. 0: No overflow 1: RWTCNT has overflowed
3	WOVFE	1	R/W	Overflow Interrupt Disable/Enable 0: Disables interrupts due to overflow 1: Enables interrupts due to overflow
2 to 0	CKS0[2:0]	111	R/W	RTC Clock Select These bits select the clock to be used for the RWTCNT count from the eight types obtainable by dividing the RTC clock. The overflow period that is shown inside the parenthesis in the table is the value when the RTC clock is 32.768 kHz. 000: Rϕ (7.8 ms) 001: Rϕ/4 (31.3 ms) 010: Rϕ/16 (125.0 ms) 011: Rϕ/32 (250.0 ms) 100: Rϕ/64 (500.0 ms) 101: Rϕ/128 (1.0 s) 110: Rϕ/1024 (8.0 s) 111: RTC clock select expanded mode The clock cycle varies depending on the CKS1 bit in RWTCSRB. Its initial value is Rϕ/4096 (32.0 s).

Note: * If bits CKS[2:0] are modified when the RWDT is operating, the up-count may not be performed correctly. Ensure that the bits CKS[2:0] are modified only when the RWDT is not operating.

12.3.3 RCLK Watchdog Timer Control/Status Register B (RWTCSRB)

RWTCSRB is an 8-bit readable/writable register composed of bits to select the clock used for the count.

RWTCSRB is initialized to H'00 by a power-on reset. Use a word access to write to RWTCSRB, with H'A5 in the upper byte. Use a byte access to read RWTCSRB.

Bit:	7	6	5	4	3	2	1	0
	—	—	CKS1[5:0]					
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5 to 0	CKS1[5:0]	All 0	R/W	RTC Clock Select for RTC Clock Select Expanded Mode Selects the clock used for the RWTCNT count when the CKS0 bit in RWTCSRA is B'111. The following table shows the time values used to cause an overflow from the counter H'00. Assuming that Rϕ/128 = 1 s, the overflow cycle in the table is calculated for the case when the RTC clock is 32.768 kHz.

CKS[5:4] / CKS[3:0]	2'b00	2'b01	2'b10	2'b11
H'0	32s			
H'1	1 s	5 s	1 min	5 min
H'2	2 s	10 s	2 min	10 min
H'3	3 s	15 s	3 min	15 min
H'4	4 s	20 s	4 min	20 min
H'5	5 s	25 s	5 min	25 min
H'6	6 s	30 s	6 min	30 min
H'7	7 s	35 s	7 min	—
H'8	8 s	40 s	8 min	—
H'9	9 s	45 s	9 min	—
H'A	10 s	50 s	10 min	—
H'B	—	55 s	—	—
H'C	—	60 s	—	—
from H'D	—	—	—	—

Note: * If the CKS15 to CKS10 bits are modified when the RWDT is running, the up-count may not be performed correctly. Ensure that these bits are modified only when the RWDT is not running.

12.3.4 Notes on Register Access

The writing procedure to RWTCNT, RWTCSRA, and RWTCSRB differs from that of other registers with the purpose of preventing an unintended write. The procedure for writing to these registers is given below.

Writing to RWTCNT, RWTCSRA, and RWTCSRB:

- These registers must be written by a word transfer instruction. They cannot be written by a byte or longword transfer instruction.
- When writing to RWTCNT, set the upper byte to H'5A and transfer the lower byte as the write data. When writing to RWTCSRA and RWTCSRB, set the upper byte to H'A5 and transfer the lower byte as the write data.

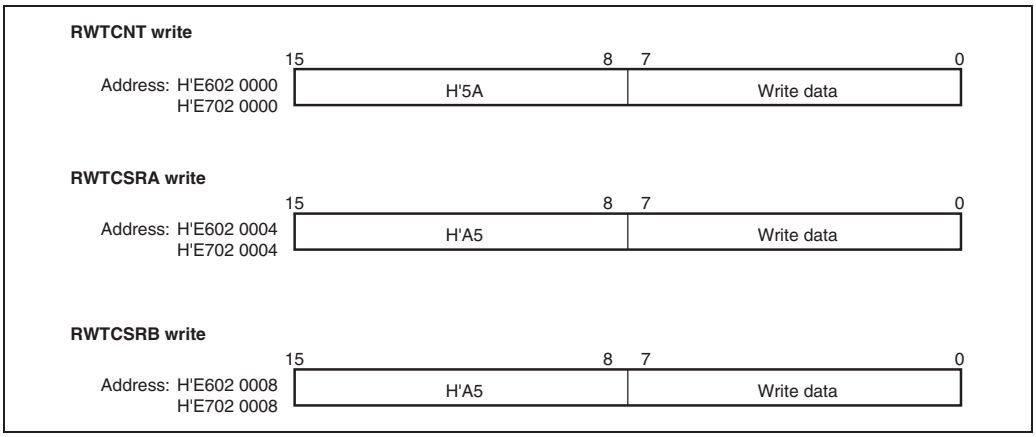

Figure 12.2 Writing to RWTCNT, RWTCSRA, and RWTCSRB

12.4 RWDT Usage

12.4.1 Control of System Runaway

After a power-on reset, RWDT is in the operating state and the counter operates with the Rϕ/4096 clock (initial setting). When the counter overflow occurs, an internal reset is again generated. By this function, a reset can be automatically generated even when this LSI has caused a system runaway. While this LSI is operating correctly, write H'00 to RWTCNT periodically so that RWTCNT does not overflow.

Take the following steps to use the RWDT.

1. Clear the TME bit in RWTCSRA to 0 to temporarily stop counting.
2. Clear the WOVF bit in RWTCSRA to 0.
3. Set the kind of count clock to the CKS2 to CKS0 bits in RWTCSRA.
4. Start the counting by setting the TME bit in RWTCSRA to 1.
5. While this LSI is operating correctly, write H'00 to RWTCNT periodically so that RWTCNT does not overflow.
6. When RWTCNT overflows, a system reset is generated because the RWDT sets the WOVF flag in RWTCSRA to 1. At this time, RWTCNT, RWTCSRA (excluding the WOVF bit), and RWTCSRB are initialized.

   For each reset type and setting, see section 13, System Controller (SYSC).

12.4.2 Debugging Operation

When debugging the CPU core consisting of application processor AP-System/AP-Realtime unit stop counting up RWTCNT and retain the value of RWTCNT.

Section 13 System Controller（SYSC）

The system controller (SYSC) consists of the following two blocks.

1. SYSCIF, the bus interface block, which is resided on common peripheral bus (HPB-C) and operated on CP Clock.
2. SYSC, the main control block which is operated on SP clock. The frequency of SP clock is same as that of CP clock when the External oscillator is enabled and equals to RCK when the oscillator is disabled.

13.1 Features

The following functions are implemented by SYSC

- Boot mode management
- Reset Generation
- Power management (power domain management, Voltage switch control, etc.,)

13.2 Prolonged music play back mode (PMPB)

SYSC implements this mode of operation in conjunction with CPGA and SPU modules. Refer to CPGA module specifications for more details on PMPB. SYSC/CPGA performs optimal power management during this mode by receiving control signals from SPU. During this mode, power of A4S, PLL and EXTAL1 are hardware controlled.

13.3 Debug mode

When the LSI is operated in emulator debug mode, the power supply for all areas is set to be ON by default. That means when a power down request for an area/areas is occurred, the power down sequence is executed but the power supply of that aera/areas in not turned off. The power supply can be made to turn off in debug mode by setting configuration registers. Refer to DBGPOWCR, RESCNT registers.

13.3.1 Operating mode

The LSI can be made to operate in one of the following modes by setting the mode pins TST_N, MD7, MD6, MD4, and MD3 and MD2.

Table 13.1 Operating modes for LSI development phase

TST_N	MD4	MD3	MD2	MD6	MD7	Boot Area	Master processor	Remarks
1	1	0	0	0	0	External memory	System CPU	External ROM
1	0	0	0	0	0	External memory	System CPU	ROM Debug mode*3
1	0/1	0	0	0	1	External memory	System CPU	ROM Debug mode*3
1	0/1	1	0/1	0/1	0/1	built-in memory	System CPU	MaskROM*1
1	0/1	0/1	1	0/1	0/1	built-in memory	System CPU	MaskROM*1
1	0/1	0/1	0/1	1	0/1	built-in memory	System CPU	MaskROM*1
0	1	0	1	0/1	0/1	External memory	System CPU	Standalone mode*2
0	1	1	0	0/1	0/1	External memory	Realtime CPU	Standalone mode*2

Table 13.2 Operating modes for mass production

TST_N	MD4	MD3	MD2	MD6	MD7	Boot Area	Maste Processor	Remarks
0	1	0	1	0/1	0/1	External memory	System CPU	Standalone mode*2
0	1	1	0	0/1	0/1	External memory	Realtime CPU	Standalone mode*2
1	0/1	0/1	0/1	0/1	0/1	Built-in memory	System CPU	MaskROM*1

Note:

**1 Refer to Appendix B for MMFROM programming specifications*

**2 Pin multiplexing for this mode is different from Normal mode. Set TSTMD pin to high when using this mode.*

**3 This mode is used for debugging MaskRom. The boot area is mapped to CS4 area.*

13.4 LSI Pins connected to SYSC

LSI external pins connected to SYSC are shown in the following table.

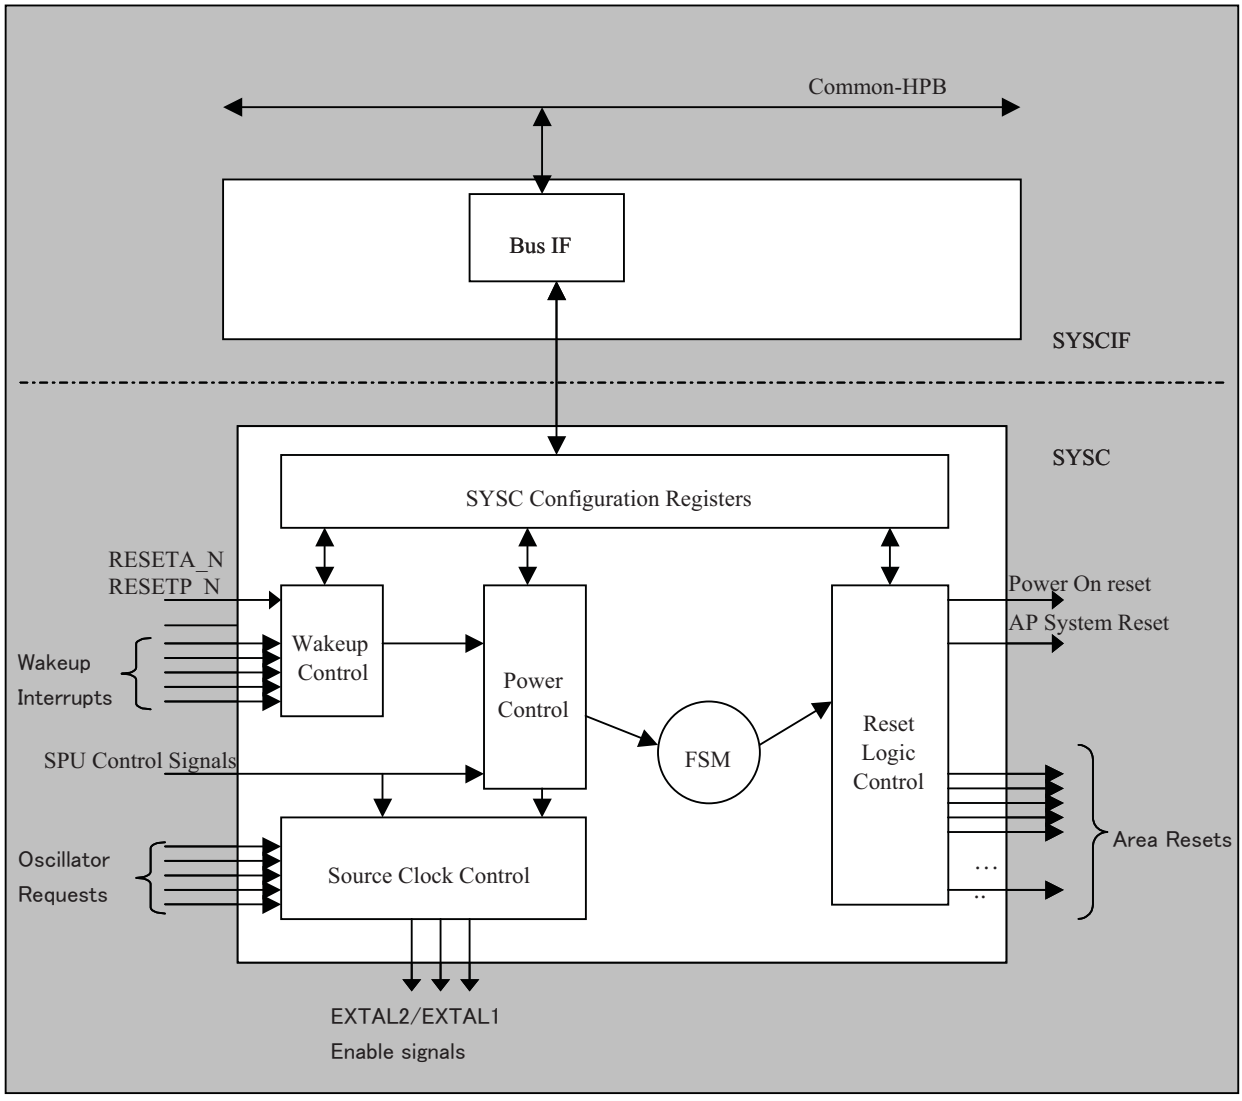

Table 13.3 External pins for SYSC

Pin Name	Function	Direction	Remarks
RESETP_N	Power On Reset	IN	Power On Reset
RESETA_N	AP block system reset	IN	Ap block's system reset
RESETOUTS_N	Indicates internal Reset (System reset /CPU reset)	OUT	System reset /CPU reset can be selected by RESCNT.ROBMD[1:0] bits

13.5 Block diagram

SYSC block diagram is shown in the following figure.

Figure 13.1 Block Diagram

Note:

1 Registers with address H'E618 8* should be updated through HPB semaphore. Please release the semaphore bit once the write accesses to these registers is completed. (Refer Appendix A for semaphore register details)*

**2 The CPU number which can access these registers is registered in one of the semaphore registers.Please don't access these registers from CPU's other than this CPU.*

**3 To clear the flag write `0`. Please write 1 to other flag to avoid unintentional clears.*

13.6.1 Standby Flag Register（STBCHRn）

STBCHRn are 8-bit Read/Write registers. These registers are accessed byte wise. Moreover STBCHR0 to 3 are combined to form a single 32-bit register, in that case this register is accessed in long words.

This register is defined purely for software purpose. Setting this register doesn't influence the LSI operation. As this bit is initialized only during Power On Reset caused by RESETP, the programmer can use this register at their convenience.

Bit	7	6	5	4	3	2	1	0

Bit	Name	Initial Value	R/W	Details
7 to 0	STBn[7:0]	B'00000000	R/W	defined purely for software purpose

13.6.2 RT Power Down Control Register（RPDCR）

RPDCR is a 32 bit Read/Write register, which can be accessed only in long words. Writing 1 to these bits generates a power down request for the corresponding areas. When the power down sequence of the requested area/areas is completed, the corresponding bits are cleared automatically. When power supply of an area is turned off by setting this register, the areas, which are under lower hierarchy of that area, are also turned off at the same time. For example, if A4S area is set to turn off, A3SP/ A3SM areas are also turned off automatically.

This register should be accessed only from RT-CPU

This register is only initialized on Power On Reset.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications.

0	—	0	R	Reserved When read, returns 0. The write value should always be 0

*Note: *1 The bits of this register cannot be written when the corresponding bits of RT write Block control register are set. Do not attempt a Write access to this register when any of these bits are set to 1.*

13.6.3 SYS Power Down Control Register（SPDCR）

SPDCR is a 32 bit Read/Write register, which can be accessed only in long words. Writing 1 to these bits generates a power down request for the corresponding areas. When the power down sequence of the requested area/areas is completed, the corresponding bits are cleared automatically. When power supply of an area is turned off by setting this register, the areas, which are under lower hierarchy of that area, are also turned off at the same time. For example, if A4S area is set to turn off, A3SP/ A3SM areas are also turned off automatically.

This register should be accessed only from SYS-CPU

This register is only initialized on Power On Reset.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications.

0	—	0	R	Reserved When read, returns 0. The write value should always be 0

*Note: *1 The bits of this register cannot be written when the corresponding bits of RT write Block control register are set.*

Do not attempt a Write access to this register when any of these bits are set to 1.

13.6.4 RT Wakeup Control Register（RWUCR）

RWUCR is a Read/Write 32 bit register, which can be accessed only in long words. Writing 1 to these bits generates a Wake up request to the corresponding areas. When the Wake up sequence of the requested area/areas is completed, the corresponding bits are cleared automatically.

When power supply of an area is turned on by setting this register, the areas, which are under higher hierarchy of that area, are also turned on at the same time. For example, if A3SP area is set to turn on, A4S area is also turned on automatically.

This register should be accessed only from RT-CPU

This register is only initialized on Power On Reset.

For power domain hierarchy, refer to section 12.5, Power Domain Specifications.

*Note: *1 The bits of this register cannot be written when the corresponding bits of RT write Block control register are set.*

Do not attempt a Write access to this register when any of these bits are set to 1.

13.6.5 SYS Wakeup Control Register（SWUCR）

SWUCR is a Read/Write 32 bit register, which can be accessed only in long words. Writing 1 to these bits generates a Wake up request to the corresponding areas. When the Wake up sequence of the requested area/areas is completed, the corresponding bits are cleared automatically.

When power supply of an area is turned on by setting this register, the areas, which are under higher hierarchy of that area, are also turned on at the same time. For example, if A3SP area is set to turn on, A4S area is also turned on automatically.

This register should be accessed only from SYS-CPU

This register is only initialized on Power On Reset.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications.

R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	SBAR[31:12]	H'00000	R/W	SYS-CPU Boot Address When SYS-CPU accesses a physical address within the first 4- to 512-Kbyte area (H'0000 0000 to H'0000 0FFF/H'0007 FFFF)*1, bits 31 to 12 in the address are replaced with the value specified in the SBAR [31:12] bits. As this conversion is performed always, set the SBAR [31:12] bits to H'00000 to disable this conversion.
11 to 2	—	All 0	R	Reserved When read, returns 0. The write value should always be 0.
1, 0	BTMD[1:0]	00 *2	R/W	Specifies the Boot area of SYS CPU During Hardware Power On Reset the initial value of these bits depends upon /TST, MD7, MD6, MD4, MD3, MD2 pin setting . Refer to Table 13.1 for boot mode specifications. 00：SBAR[31:12] is assigned to Boot address, set SBAR[11:0] to 0. 01：Boots From SMFRAM. 10：Boots from Built-in memory. 11：Prohibited.

Note *1 *The address range can be specified in APARMBAREA. For details, refer to section 2, AP-System Core in the AP Block manual*

*2 *Initial value depends upon TST_N, MD7, MD6, MD4, MD3, MD2 pin setting.*

13.6.8 WakeuR Factor Mask Register (WUPRMSK)

WUPRMSK is a 32-bit read/write register, which can be accessed only in long words. RT-CPU Wakeup factor can be masked by setting this register. This register is initialized on Power On Reset. The wakeup factor, which can be masked by this register, wakes up all the power off areas that are required to operate RT-CPU (A4R).This register doesn't specify the areas that can be waken up by WakeUpR.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications

13.6.9 WakeupS Factor Mask Register (WUPSMSK)

WUPSMSK is a 32-bit read/write register, which can be accessed only in long words. SYS-CPU Wakeup factor can be masked by setting this register.

The wakeup factor, which can be masked by this register, wakes up all the power off areas that are required to operate SYS CPU (A4S/A3SM). This register doesn't specify the areas that can be waken up by WakeUpS. This register is initialized on Power On Reset.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications

13.6.10 WakeupR Factor Mask Register2 (WUPRMSK2)

WUPRMSK is a 32-bit read/write register, which can be accessed only in long words. RT-CPU Wakeup factor can be masked by setting this register.

The wakeup factor, which can be masked by this register, wakes up all the power off areas that are required to operate RT CPU (A4R).This register doesn't specify the areas that can be waken up by WakeUpR. This register is initialized on Power On Reset.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications

13.6.11 WakeupS Factor Mask Register2 (WUPSMSK2)

WUPSMSK is a 32-bit read/write register, which can be accessed only in long words. SYS-CPU Wakeup factor can be masked by setting this register.

The wakeup factor, which can be masked by this register, wakes up all the power off areas that are required to operate SYS CPU (A4S/A3SM). This register doesn't specify the areas that can be waken up by WakeUpS. This register is initialized on Power On Reset.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications

13.6.12 Standby Flag Register B (STBCHRn)

STBCHRn are 8-bit Read/Write registers. These registers are accessed byte wise. More over STBCHR0 to 3 are combined to form a single 32-bit register, in that case this register is accessed in long words. This register is defined purely for software purpose. Setting this register doesn't influence the LSI operation. As this bit is initialized only during Power On Reset caused by RESETP, the programmer can use this register at their convenience.

MMFROM uses STBCHRB2, STBCHRB3 registers. Refer to Appendix B, MMFROM programming specifications.

Bit	7	6	5	4	3	2	1	0
	STBBn[7:0]							
Initial Value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Name	Initial Value	R/W	Description
7 to 0	STBBn[7:0]	B'00000000	R/W	defined purely for software purpose

13.6.13 Power Status Register (PSTR)

PSTR is a Read-Only 32 bit register. It can be accessed only in long words.

This Register indicates Power status of each area. When Power is supplied to an area the corresponding bit is read as 1 and reads as 0 when the power is not supplied.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications

0	C5ST	1	R	C5 Area Power Status Bit 0： Power is not supplied to C5area 1： Power is supplied to C5 area

13.6.14 EXTAL2 State Monitor Register (EXSTMON2)

EXSTMON2 is a Read-Only 32 bit register. It can be accessed only in long words.
The Status of the EXTAL2 clock is known from this register. The remaining time that the EXTAL2 clock could be in unstable state is also known from this register.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	EX2MSK
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCNT[15:0]															
Initial Value	0	0	0	0	0	0	0	0	1	0	1	0	0	1	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Name	Initial Value	R/W	Description
31 to 17	—	ALL 0	R	Reserved When read, returns 0. The write access is prohibited.
16	EX2MSK	0	R	EXTAL2 input clock mask status bit 0：EXTAL2 clock is supplied to internal parts of LSI. 1：EXTAL2 clock is masked(clock is not stable)
15 to 0	RCNT[15:0]	H'00A4	R	Remaining Count These bits indicate the remaining count value (RCLKs) that is required by EXTAL2 to supply a stable clock. Refer to EXMSKCNT2.CNT [15:0] to setup the unstable clock time... When this value matches with EXMSKCNT2.CNT [15:0] EXTAL2 clock is said to be stabilized and supplied to internal parts of the LSI.

13.6.15 EXTAL1 State Monitor Register（EXSTMON1）

EXSTMON1 is a Read-Only 32 bit register. It can be accessed only in long words.
The Status of the EXTAL1 clock is known from this register. The remaining time that the EXTAL1 clock could be in unstable state is also known from this register.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Name	Initial Value	R/W	Description
31 to 17	—	ALL 0	R	Reserved When read, returns 0. The write access is prohibited.
16	EX1MSK	0	R	EXTAL1 input clock mask status bit 0：EXTAL1 clock is supplied to internal parts of LSI. 1：EXTAL1 clock is masked(clock is not stable)
15 to 0	RCNT[15:0]	H'00A4	R	Remaining Count These bits indicate the remaining count value (RCLKs) that is required by EXTAL1 to supply a stable clock. Refer to EXMSKCNT1.CNT [15:0] to setup the unstable clock time... When this value matches with EXMSKCNT1.CNT [15:0] EXTAL1 clock is said to be stabilized and supplied to internal parts of the LSI.

13.6.16 WakeupR Interrupt Factor Register

WUPRFAC is a Read-Only 32 bit register. It can be accessed only in long words. The interrupt factor is cleared by reading this register. This register stores WakeUpR interrupt factor. Please read this register and clear the factor when wakeup process is completed. Moreover, please make sure that all factors are cleared before executing power down Sequence.

This register is cleared automatically when RT-CPU area's power supply is off.

For power domain hierarchy, refer to section 13.7, Power Domain's Specifications

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

13.6.18 RT Reset Flag Register (RRSTFR)

RRSTFR is a Read/Write 32 bit register. It can be accessed only in long words. However, the write access is performed only to clear the flag bits. Please access this register from RT-CPU. This register sets the reset flags when soft Power On Reset (Power On Reset other than RESETP_N) or system reset is detected. By reading this register at the time of reboot etc., it is known that what kind of reset was detected. These flags cannot be cleared during reset process (i.e. when Reset pin is still not released or reset bit is still not cleared).

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4	RCWD1	0	R/(W)*1	Power On Reset Factor Bit 0：RWDT0 is not soft Power On Reset factor. 1：RWDT0 is soft Power On Reset factor.
3	－	UnKnown	R	Reserved When read, returns 0. The write value should always be 0.
2	RAF	0	R/(W)*1	AP Block system reset detection bit 0：Indicates AP Block System Reset is not detected 1：Indicates AP Block System Reset is detected.
1	－	UnKnown	R	Reserved When read, returns 0. The write value should always be 0.
0	RPF	0	R/(W)*1	Power On Reset detection bit (soft Power On Reset) 0：Power On Reset other than RESETP_N is not detected 1：Power On Reset other than RESETP_N is detected.

Note *1 *Write 0 to clear the flags. Write 1 to the other bits to avoid unintentional clears*
Regarding the systems which assert RESETA_N instead of RESETP_N during Cold Reset, initialization values for system reset detection bits may be '1'.

13.6.20 Debug Mode Power Control Register（DGBPOWCR）

DGBPOWCR is a Read/Write 32 bit register. It can be accessed only in long words. This register is intended for debug purpose. This register controls the power supply of each power area during power down sequence. This register operation is enabled only when RESCNT.DBGNOPDNEN bit is set to 1.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

9 to 0	—	ALL 0	R	Reserved When read, returns 0. The write value should always be 0.

*Note : *1 Initialized only on RESETP_N Power On Reset.*

13.6.21 RT Write Block Control Register（RWBCR）

RWBCR is a 32-bit read/write register, which can be accessed only in long words.
Setting bits of this register, prohibits write operations to the corresponding bits in RPDCR/RWUC. To prevent the unintentional power down wakeup operations of area whose power is not controlled from RT-CPU, write access to corresponding bits in RPDCR/RWUCR can be prohibited by setting this register. This register is initialized on Power On Reset.
For power domain hierarchy, refer to section 13.7, Power Domain Specifications.

Bit	Name	Initial Value	R/W	Description
31 to 14	—	ALL 0	R	Reserved When read, returns 0. The write value should always be 0.
13	A3SGBL	0	R/W	A3SG Power area mask bit 0：A3SG area's power is allowed to be controlled by RPDCR/RWUCR 1：A3SG area's power is not allowed to be controlled by RPDCR/RWUCR
12	A3SMBL	0	R/W	A3SM Power area mask bit 0：A3SM area's power is allowed to be controlled by RPDCR/RWUCR 1：A3SM area's power is not allowed to be controlled by RPDCR/RWUCR
11	A3SPBL	0	R/W	A3SP Power area mask bit 0：A3SP area's power is allowed to be controlled by RPDCR/RWUCR 1：A3SP area's power is not allowed to be controlled by RPDCR/RWUCR
10	A4SBL	0	R/W	A4S Power area mask bit 0：A4S area's power is allowed to be controlled by RPDCR/RWUCR 1：A4S area's power is not allowed to be controlled by RPDCR/RWUCR

Bit	Name	Initial Value	R/W	Description
9	—	0	R	Reserved When read, returns 0. The write value should always be 0
8	A3RIBL	0	R/W	A3RV Power area mask bit 0：A3RI area's power is allowed to be controlled by RPDCR/RWUCR 1：A3RI area's power is not allowed to be controlled by RPDCR/RWUCR
7	—	0	R	Reserved When read, returns 0. The write value should always be 0.
6	A3RVBL	0	R/W	A3RV Power area mask bit 0：A3RV area's power is allowed to be controlled by RPDCR/RWUCR 1：A3RV area's power is not allowed to be controlled by RPDCR/RWUCR
5	A4RBL	0	R/W	A4R Power area mask bit 0：A4R area's power is allowed to be controlled by RPDCR/RWUCR 1：A4R area's power is not allowed to be controlled by RPDCR/RWUCR
4	—	0	R	Reserved When read, returns 0. The write value should always be 0.
3	D4BL	0	R/W	D4 Power area mask bit 0：D4 area's power is allowed to be controlled by RPDCR/RWUCR 1：D4 area's power is not allowed to be controlled by RPDCR/RWUCR
2	A4MPBL	0	R/W	A4MP Power area mask bit 0：A4MP area's power is allowed to be controlled by RPDCR/RWUCR 1：A4MP area's power is not allowed to be controlled by RPDCR/RWUCR
1	A4LCBL	0	R/W	A4LC Power area mask bit 0：A4LC area's power is allowed to be controlled by RPDCR/RWUCR 1：A4LC area's power is not allowed to be controlled by RPDCR/RWUCR
4	—	0	R	Reserved When read, returns 0. The write value should always be 0.

13.6.22 SYS Write Block Control Register (SWBCR)

SWBCR is a 32-bit read/write register, which can be accessed only in long words.
Setting bits of this register, prohibits write operations to the corresponding bits in SPDCR/SWUC. To prevent the unintentional power down wakeup operations of area whose power is not controlled from SYS-CPU, write access to corresponding bits in SPDCR/SWUCR can be prohibited by setting this register. This register is initialized on Power On Reset.
For power domain hierarchy, refer to section 13.7, Power Domain Specifications.

1	A4LCBL	0	R/W	A4LC Power area mask bit 0：A4LC area's power is allowed to be controlled by SPDCR/SWUCR 1：A4LC area's power is not allowed to be controlled by SPDCR/SWUCR
4	—	0	R	Reserved When read, returns 0. The write value should always be 0.

13.6.23 EXTAL2 Mask Count Register (EXMSKCNT2)

EXMSKCNT2 is a 32-bit read/write register, which can be accessed only in long words. EXTAL2 Clock supply to the internal parts of the LSI is masked when the clock is not stable using this register. Time required for EXTAL2 to supply a stable clock is set by this register in terms of RCLK. The initial value is H'A4 (164RCLK cycles = 5 ms). When setting this register, perform a 32 bit write operation by placing H'A55 to the upper 12bits in the data field.
This register is initialized by a Power On Reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	X2ON

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Name	Initial Value	R/W	Description
31 to 17	—	ALL 0	R	Reserved When read, returns 0. The write value should be H'A550.
16	X2ON	0	R/W	Crystal Oscillator Control bit. 0：CPG holds the XTAL2 Crystal Oscillator control. 1：XTAL2 Crystal Oscillator is forcibly ON.
15 to 0	CNT[15:0]	H'00A4	R/W	UnStable clock time Time required for EXTAL2 to supply a stable clock is set by this register in terms of RCLK. When EXTAL2 is enabled, an internal counter starts counting up and continues to count up until the count value reaches CNT[15:0]. To know the remaining count value refer to EXSTMON2

13.6.24 EXTAL1 Mask Count Register (EXMSKCNT1)

EXMSKCNT1 is a 32-bit read/write register, which can be accessed only in long words. EXTAL1 Clock supply to the internal parts of the LSI is masked when the clock is not stable using this register. Time required for EXTAL1 to supply a stable clock is set by this register in terms of RCLK. The initial value is H'A4 (164RCLK cycles = 5 ms). When setting this register, perform a 32 bit write operation by placing H'A55 to the upper 12bits in the data field.
This register is initialized by a Power On Reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	X1ON

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Name	Initial Value	R/W	Description
31 to 17	—	ALL 0	R	Reserved When read, returns 0. The write value should be H'A550.
16	X1ON	0	R/W	Crystal Oscillator Control bit. 0：CPG holds the XTAL1 Crystal Oscillator control. 1：XTAL1 Crystal Oscillator is forcibly ON.
15 to 0	CNT[15:0]	H'00A4	R/W	UnStable clock time Time required for EXTAL1 to supply a stable clock is set by this register in terms of RCLK. When EXTAL1 is enabled, an internal counter starts counting up and continues to count up until the count value reaches CNT[15:0]. To know the remaining count value refer to EXSTMON1.

13.6.25 Reset Control Register（RESCNT）

RESCNT is a 32-bit read/write register, which can be accessed only in long words. The initialization condition differs by bit. For details, refer to the description of each bit. This register is protected by HPB semaphore.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R/W	R	R/W	R	R	R/W	R/W	R	R	R	R	R	R	R	R	R

Bit	Name	Initial Value	R/W	Description
31	/TST*[1]	/TST	R	TST_N Pin Monitor TST_N Pin level is monitored. 0：TST_N Pin level is 0 at Power On 1：TST_N Pin level is 1 at Power On This bit captures the TST_ Nin value at Power On Reset.
30	MD4*[1]	MD4	R	MD4 Pin Monitor MD4 Pin level is monitored. 0：MD4 Pin level is 0 at Power On 1：MD4 Pin level is 1 at Power On This bit captures the MD4in value at Power On Reset.
29	MD3*[1]	MD3	R	MD3 Pin Monitor MD3 Pin level is monitored. 0：MD3 Pin level is 0 at Power On 1：MD3 Pin level is 1 at Power On This bit captures the MD3in value at Power On Reset.
28	MD2*[1]	MD2	R	MD2 Pin Monitor MD2 Pin level is monitored. 0：MD2 Pin level is 0 at Power On 1：MD2 Pin level is 1 at Power On This bit captures the TST_ Pin value at Power On Reset.

Bit	Name	Initial Value	R/W	Description
27	MD6*[1]	MD6	R	MD6 Pin Monitor MD6 Pin level is monitored. 0：MD6 Pin level is 0 at Power On 1：MD6 Pin level is 1 at Power On This bit captures the TST_ Pin value at Power On Reset.
26	MD7*[1]	MD7	R	MD7 Pin Monitor MD7 Pin level is monitored. 0：MD7 Pin level is 0 at Power On 1：MD7 Pin level is 1 at Power On This bit captures the TST_ Pin value at Power On Reset.
25 to 24	—	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write.
23	RSTOUTSEL	1	R/W	RESETOUTS_N pin's assert condition selection bit This bit in conjunction with ROBMD[1:0] controls the assert condition for RESETOUTS output pins. Refer to ROBMD[1:0] bits for different conditions. This bit is initialized only when hard Power On Reset. 0：RESETOUTS_N pin is asserted when processor reset is asserted 1：RESETOUTS_N pin is asserted when system reset is asserted *Note : RESETOUTS_N pin active period depends upon various factors like areas whose power is turned down, extal2/1 status, type of reset it is connected to, etc., The minimum and maximum periods are 40uS/5.5mS respectively*
22	DBGNOPDNEN	0	R/W	DBGPOWCR Enable bit 0： Disable DBGPOWCR Register functionality 1： Enable DBGPOWCR Register functionality This bit is initialized only when hard Power On Reset
21 to 20	—	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write.
19	SRESLNK	1	R/W	System reset domain selection bit This bit selects the power areas which are initialized on system reset. This bit is initialized on Power On Reset. 0: All power areas excluding C5, and D4 are initialized 1: All power areas including C5, and D4 are initialized
18	—	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write.
17	RESV	1	R/W	RESETA_N Pin enable bit This bit indicates whether RESETA_N is enabled or disabled. This bit is initialized on Power On Reset. 0：RESETA_N Pin is disabled 1：RESETA_N Pin is enabled

Bit	Name	Initial Value	R/W	Description
16	－	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write.
15, 14	－	00	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write.
13, 12	ROBMD[1:0]	00	R/W	RESETOUTS_N Pin assert condition Indicates RESETOUTS_N assert condition. This bit is initialized on Power On Reset. When RSTOUTSEL＝0 00：Reserved 01：Reserved 10：RESETOUTS_N is asserted along with processor reset 11：Reserved When RSTOUTSEL＝0 00：Reserved 01：Reserved 10：RESETOUTS_N is asserted along with System reset 11：Reserved
11	－	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write.
10	MSTPAS	*2	R/W	SYS-CPU Module stop This bit is used to stop System CPU's clock and hold the boot start process after a system reset is released. This bit should only be used when the master processor controls the boot sequence of the slave CPU. In RT master mode, activate System CPUs by clearing MSTPS bit to 0. When System CPU is the master processor, this bit is set to 1 as the initial value. This bit is initialized on Power On Reset. 0：clock is supplied 1：clock is stopped
9	MSTPAR	*2	R/W	RT-CPU Module stop This bit is used to stop Real-time CPU's clock and hold the boot start process after a system reset is released. This bit should only be used when the master processor controls the boot sequence of the slave CPU. In SYS master mode, activate RT CPUs by clearing MSTPR bit to 0. When RT CPU is the master processor, this bit is set to 1 as the initial value. This bit is initialized on Power On Reset. 0：clock is supplied 1：clock is stopped
8 to 0	－	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write

*Note: *1. The boot mode depends on the TST_N, MD4, MD3, MD2, MD6 and MD7 pin settings. For details*

on the boot mode, refer to section 13.3, Operating Modes.

**2. Depends on the setting of the TST_N, MD4, MD3, MD2, MD6 and MD7 Mode pins*

13.6.26 Reset Control Register2（RESCNT2）

RESCNT2 is a 32-bit read/write register, which can be accessed only in long words. The initialization condition differs by bit. For details, refer to the description of each bit. This register is protected by HPB semaphore.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Name	Initial Value	R/W	Description
31	PRES	0	R/W	Soft Power On Reset Soft Power On Reset is asserted. This bit is initialized on Power On Reset. 0：Ignored 1：Power On Reset is asserted. *Note: Soft Power On Reset is asserted when 1 is written to this bit. When Power On Reset process is completed, this bit gets cleared. (All power areas including C5, and D4 are initialized)*
30	—	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write
29	MRES	0	R/W	System reset. System reset is asserted. This bit is initialized on Power On Reset. 0：Ignored. 1：system reset is asserted. *Note: This bit is cleared by hardware automatically. SRESLNK bit selects the system reset domain.*
28 to 16	—	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write
15 to 14	—	UnKnown	R	Reserved When read, returns 0. The writing performa Read-Modify-Write

Bit	Name	Initial Value	R/W	Description
13 to 12	RWD0A	1	R/W	RWDT0-system reset selection bit These bits select whether to generate a system reset or soft Power On Reset on RWDT0 expiration. This bit is initialized on Power On Reset. 00：Reserved 01：Reserved 10：System Reset is asserted 11：Soft Power On Reset is asserted
11 to 8	－	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write
7	CKEMD10	0	R/W	LPACKEA/B out put control bit This bit control LPACKEA/B out put during SBSC1 reset period（during Power On Reset, System reset, A4S power is turned off ） 0： LPACKEA/B of SBSC1 is set to low 1： LPACKEA/B of SBSC1 is set to High This bit is initialized only on RESETP_N Power On Reset
6	－	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write
5	－	0	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write
4 to 3	－	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write
2	RAFLG*[1]	0	R	System Reset Flag bit This bit is set when System Reset is asserted. This bit is initialized on Power On Reset. 0：System reset is not asserted 1：System reset is asserted
1 to 0	－	UnKnown	R	Reserved When read, returns 0. The writing perform a Read-Modify-Write

*Note : *1 Reset flag bit is cleared automatically when RESCNT2 register is read.*

13.6.27 Wakeup Area Selection Register (WUPSEL)

WUPSEL is a 32-bit read/write register, which can be accessed only in long words. By setting this register areas other than CPU can be waken up by Wakeup* interrupts.

This register is initialized on Power On Reset.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications

13.6.29 EXTAL1 Clock Stop Control Register (APSCSTP)

APSCSTP is a 32-bit read/write register, which can be accessed only in long words. This register can be used to generate EXTAL1 oscillator stop request when the desired power areas are shut down. Setting a particular bit also sets other bits, which are having hierarchal relation with that bit. For example, if A4S is set, A3SM, A3SP are also set automatically.

This register is initialized on Power On Reset.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications.

0	EXA4SMSK	1*[2]	R/W	EXTALB1's A4S On/OFF request mask bit 0：A4S areas Power cannot be turned down when EXTAL1 is on 1：A4S areas power can be turned down even when EXTAL1 is on

*Note: *1 {SPA4SMSK, SYCKENMSK. EXTAL1MSK[0]} = 01,10 setting is prohibited*

**2 {EXA4SMSK, SYCKENMSK. EXTAL1MSK[2]} = 01,10 setting is prohibited*

13.6.35 WakeUp Area Selection Register2 (WUPSEL2)

WUPSEL is a 32-bit read/write register, which can be accessed only in long words. By setting this register areas other than CPU can be waken up by Wakeup* interrupts.

This register is initialized on Power On Reset.

For power domain hierarchy, refer to section 13.7, Power Domain Specifications

13.6.36 A4S Area Power Control Register2 (PDNSEL)

PDNSEL is a 32-bit read/write register, which can be accessed only in long words. By setting this register, A4S areas power can be turned down automatically. When the power of the areas set in this register is turned off, Power of A4S area also turns down automatically. When multiple bits in this register are set, A4S power is turned off when all the areas set in this register are turned off. This register is initialized on Power On Reset

3 to 0	A4SPD[3:0]	1111	R/W	A4S Power down selection bits 0：A4S power down request is not generated 1：A4S power down request is generated. A4SPD[3]：A3SM power down request generates A4S power down request A4SPD[2]：A3SP power down request generates A4S power down request A4SPD[1]：A3SG power down request generates A4S power down request A4SPD[0]：A4R power down request generates A4S power down request

13.7 Power Domain Specifications

13.7.1 Power Area hierarchy

This LSI consists of 12 power areas. The hierarchal relationship between the power areas is shown in the following figure.

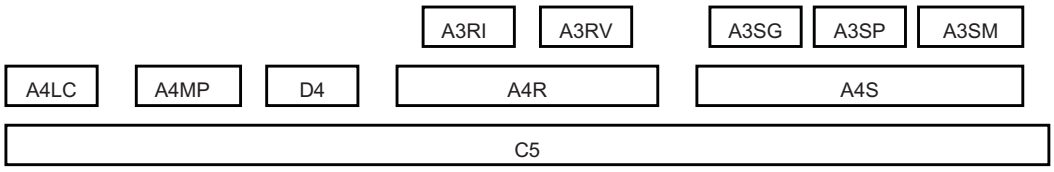

Fig 13.2 Power area hierarchy

13.7.2 Area wise module list

Modules that are placed in each power area are listed in the following table.

13.6 Module list separated by power area

	Area	Module
Common	C5	SYSC, WUC, PowerControlParts, GPIO, PAD (IO macro), HDMI-Phy, DBG Backup registers, CPG, CMT1/2/3/4, RWDT, KEYSC, SMFRAM
Debug	D4	Coresight-ETM
System	A4S	Common-SHwy, Common-HPB, BSC, MFIS,MFIM, MMFROM ACMFI1,ACMFI2, HS-SHwy, SYS-HPB, INTCA modules, SBSC
	A3SM	System CPU (Cortex-A8)
	A3SP	DMAC1/2/3, IPMMUD, DDM, FLCTL, SYS-HPB, BBIF1, MSIOF1/2, SCIFA,SCIFB, IIC1/3/4, IrDA, HDMI-Link, USBHS0/1, USBDMAC, SDHI0/1/2, CMT1, TPU, Crypt, DREQPAK (Sys), MIPI-HSI, MMCIF
	A3SG	SGX540
Realtime	A4R	Realtime CPU(SH-X2), Realtime CPU debug modules, H-UDI, RT-SHwy, INTCS modules, RT-HPB, TSIF, VPU, CEU, VEU, BEU, VOU, JPU, RTDMAC1/2,TSIF TMU, IIC0/2, MSIOF0, CMT0, ICB, DREQPAK (RT), 2DDMAC, IPMMUI,IPMMUR, IPMMUR2, CSI2
	A3RV	VPU
	A3RI	ISP
	A4LC	MERAM, LCDC, DSI
	A4MP	SPU2, FSI, FMSI, BBIF2

13.7.3 Power Control Flow

The power control flow of this LSI is shown in the following flow chart.

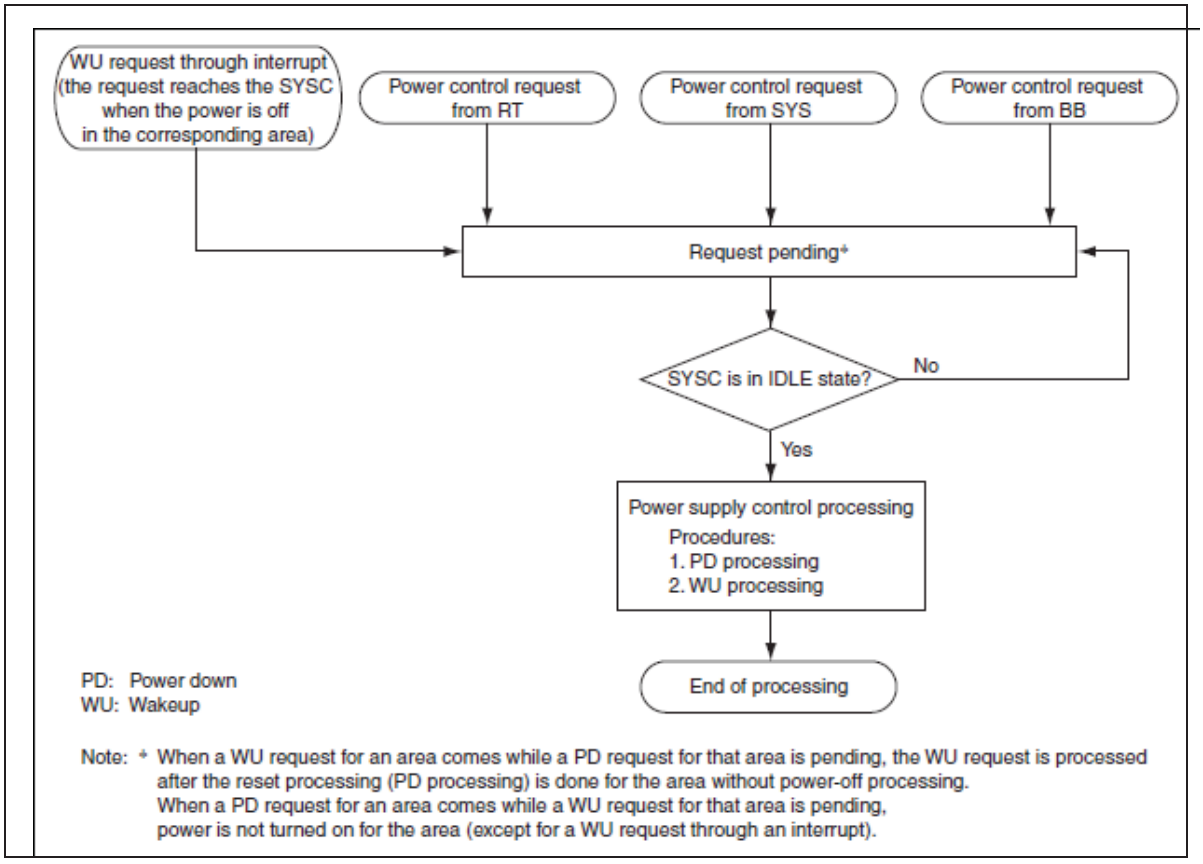

Fig 13.3 Power Control Flow chart

13.8 Reset Specifications

13.8.1 Reset Layer Structure

SYSC controls the following three types of resets.

(1) Power On Reset

Power On Reset initializes all modules of LSI. The following are the sources of this reset.

1. RESETP_N = 0 (Hard Power On Reset)
2. RESCNT2. PRES = 1
3. RESCNT2.MRES= 1 & RESCNT.SRESLNK=1
4. RESETA_N = 0 & RESCNT.SRESLNK=1
5. RWDT0 over flow & RESCNT2. RWD0A=11

All resources of the LSI including Test, Debug are initialized with this reset. Since TAP controller of the JTAG is only initialized by TRST, TRST is also asserted during Power On Reset.

When a Power On Reset is asserted the SYSC wakeup areas whose power was turned off, keeps asserting the internal Power On Reset signal for certain period necessary to initialize the internal resources and then releases it when the process is completed.

(2) System Reset

System Rest initializes all modules other than C5, and D4. Few modules residing in C5, D4 also gets initialized.

The following are the sources for this reset.

1. RESETA_N = 0 & RESCNT.SRESLNK=0
2. RESCNT2.MRES= 1 & RESCNT.SRESLNK=0
3. RWDT0 over flow & RESCNT2. RWD0A=10

When a Power On Reset is asserted the SYSC wakeup areas whose power was turned off, keeps asserting the internal Power On Reset signal for certain period necessary to initialize the internal resources and then releases it when the process is completed.

(3) Power Area Reset

Each of 11 power areas consists of area reset.

This reset is asserted during Power down/wakeup process. Modules other than backup modules are initialized by this reset before the power is turned OFF. Also during wakeup process the modules other than backup modules turned ON in initialization state. There exist some cases where area reset is asserted even though power down process is cancelled.

Area reset is asserted → Power down → Wakeup → Area reset release

Refer to CPGA module specification of more details on reset specifications..

(4) Reset Boundaries

The following figures shows reset boundaries.

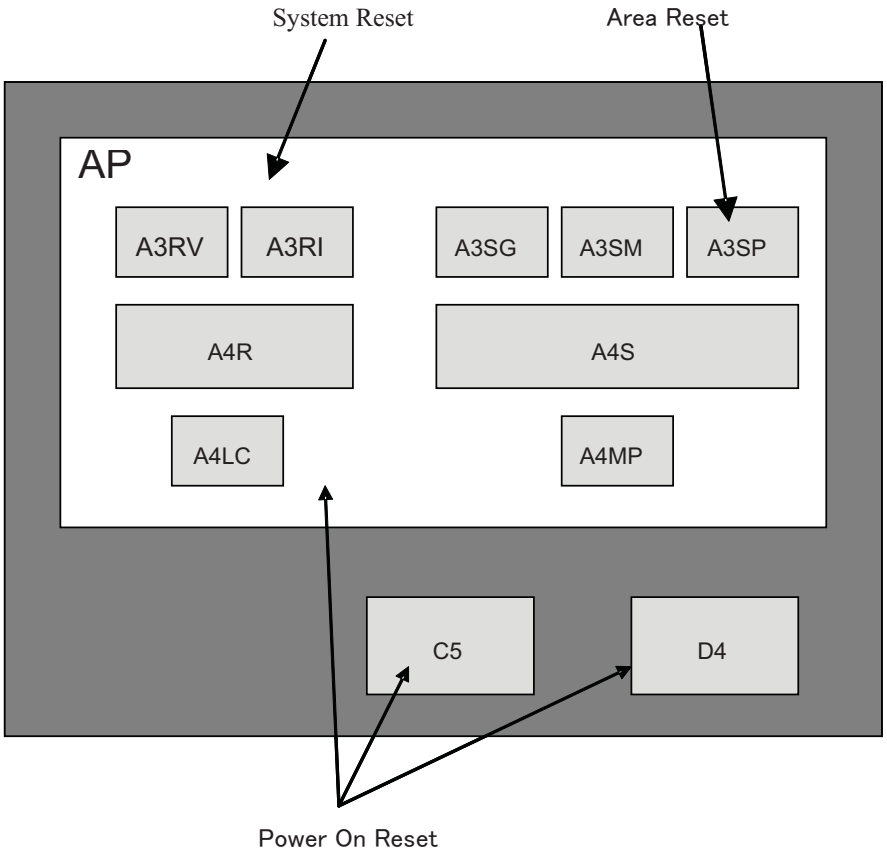

Fig13. 4 Reset Boundaries

Section 14 Timer Unit (TMU)

This LSI includes three-channel 32-bit timer unit (TMU) of two sets.

14.1 Features

- Three channels are provided in the real-time domain
- Each channel is provided with an auto-reload 32-bit down counter
- All channels are provided with 32-bit constant registers and 32-bit down counters that can be read or written to at any time
- All channels generate interrupt requests when the 32-bit down counter underflows (H'00000000 → H'FFFFFFFF)
- Allows selection among five counter input clocks: SUBϕ/4, SUBϕ/16, SUBϕ/64, SUBϕ/256, and SUBϕ/1024

Figure 14.1 shows a block diagram of the TMU.

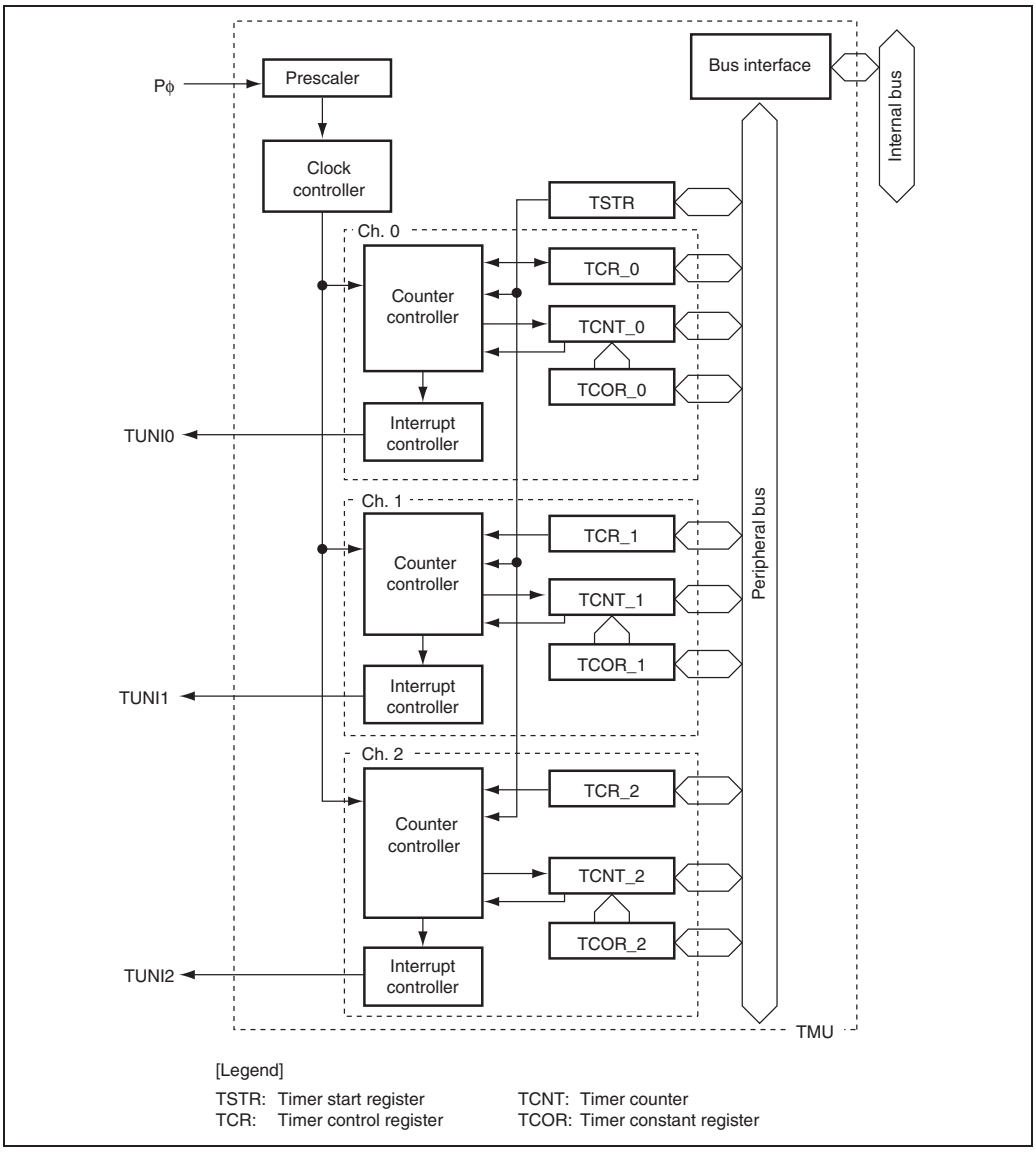

Figure 14.1 Block Diagram of TMU

14.2 Register Descriptions

Table 14.1 shows the TMU register configuration. Table 14.2 shows the register states in each operating mode. In the following descriptions, TCOR for channel 0 is noted as TCOR_0.

Table 14.1 Register Configuration

Register	Abbreviation	R/W	Address	Access Size
Timer start register 0	TSTR 0	R/W	H'FFF6 0004	8
Timer constant register0_0	TCOR0_0	R/W	H'FFF6 0008	32
Timer counter0_0	TCNT0_0	R/W	H'FFF6 000C	32

14.2.1 Timer Start Register (TSTR)

TSTR is an 8-bit readable/writable register that selects whether to operate or halt the timer counters (TCNT).

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	STR2	STR1	STR0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	STR2	0	R/W	Counter Start 2 Selects whether to operate or halt timer counter 2 (TCNT_2). 0: TCNT_2 count halted 1: TCNT_2 counts
1	STR1	0	R/W	Counter Start 1 Selects whether to operate or halt timer counter 1 (TCNT_1). 0: TCNT_1 count halted 1: TCNT_1 counts
0	STR0	0	R/W	Counter Start 0 Selects whether to operate or halt timer counter 0 (TCNT_0). 0: TCNT_0 count halted 1: TCNT_0 counts

14.2.2 Timer Control Registers (TCR)

TCR is a 16-bit readable/writable register that controls the timer counters (TCNT) and interrupts.

TCR controls the issuance of interrupts when the flag indicating timer counter (TCNT) underflow has been set to 1, and also carries out counter clock selection.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	UNF	—	—	UNIE	—	—	TPSC[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/(W)*	R	R	R/W	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	UNF	0	R/(W)*	Underflow Flag Status flag that indicates occurrence of a TCNT underflow. 0: TCNT has not underflowed [Clearing condition] 0 is written to UNF 1: TCNT has underflowed [Setting condition] TCNT underflows
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	UNIE	0	R/W	Underflow Interrupt Control Controls enabling of interrupt generation when the status flag (UNF) indicating TCNT underflow has been set to 1. 0: Interrupt due to UNF (TUNI) is disabled 1: Interrupt due to UNF (TUNI) is enabled
4, 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	TPSC[2:0]	000	R/W	Timer Prescaler 2, 1, and 0 Select the TCNT count clock. 000: Count on SUBϕ/4 001: Count on SUBϕ/16 010: Count on SUBϕ/64 011: Count on SUBϕ/256 100: Count on SUBϕ/1024 Others: Setting prohibited

Note: * Only 0 can be written to clear the flag.

14.2.3 Timer Constant Registers (TCOR)

TCOR is a 32-bit readable/writable register that specifies the value to be set in TCNT when TCNT underflows.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCOR															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCOR															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

14.2.4 Timer Counters (TCNT)

TCNT counts down upon input of a clock. The clock input is selected using bits TPSC[1:0] in TCR.

When a TCNT countdown results in an underflow (H'00000000 → H'FFFFFFFF), the underflow flag (UNF) in TCR that is corresponding to the channel is set. The TCOR value is simultaneously set in TCNT itself and the countdown continues from that value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCNT															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCNT															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

14.3 Operation

Each channel has a 32-bit TCNT and a 32-bit TCOR. TCNT counts down. The auto-reload function enables cyclic counting.

14.3.1 Counter Operation

When bits STR2 to STR0 in TSTR are set to 1, the corresponding TCNT starts counting. When TCNT underflows, the UNF flag in the corresponding TCR is set. At this moment, if the UNIE bit in TCR is 1, an interrupt request is sent to the CPU. Also, the value in TCOR is copied to TCNT and the count down operation continues.

(1) Count Operation Setting Procedure

An example procedure for setting the count operation is shown in figure 14.2.

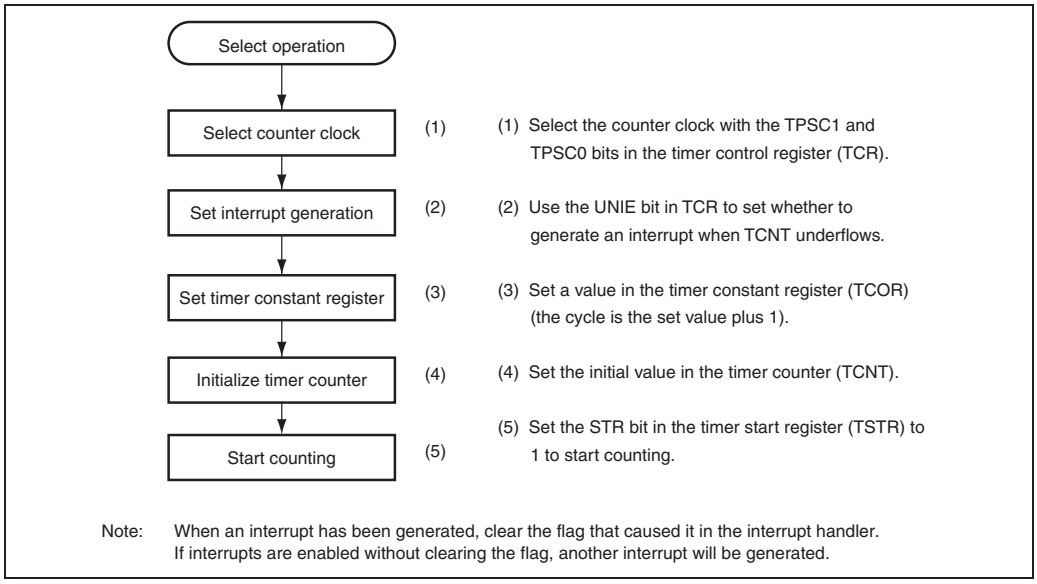

Figure 14.2 Setting Count Operation

(2) Auto-Reload Count Operation

Figure 14.3 shows the TCNT auto-reload operation.

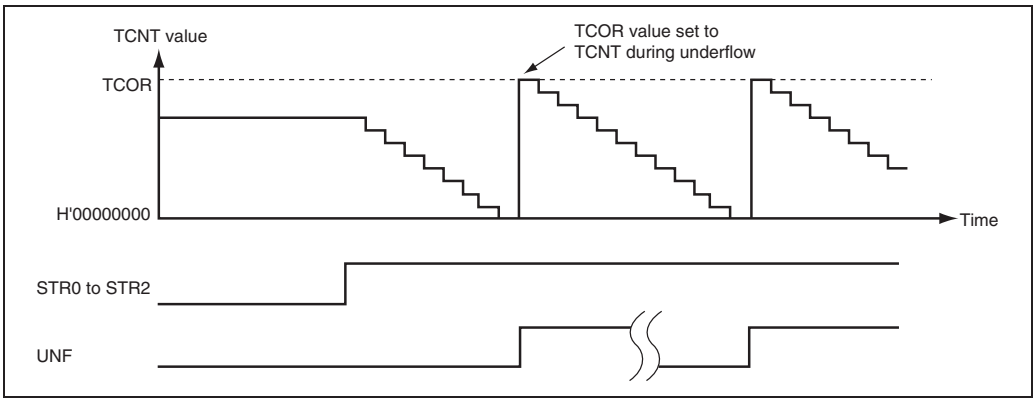

Figure 14.3 Auto-Reload Count Operation

(3) TCNT Count Timing

Setting bits TPSC1 and TPSC0 in TCR allows to select one of the five internal clocks (SUBϕ/4, SUBϕ/16, SUBϕ/64, SUBϕ/256, and SUBϕ/1024) that are generated by dividing the peripheral module clock. Figure 14.4 shows the timing.

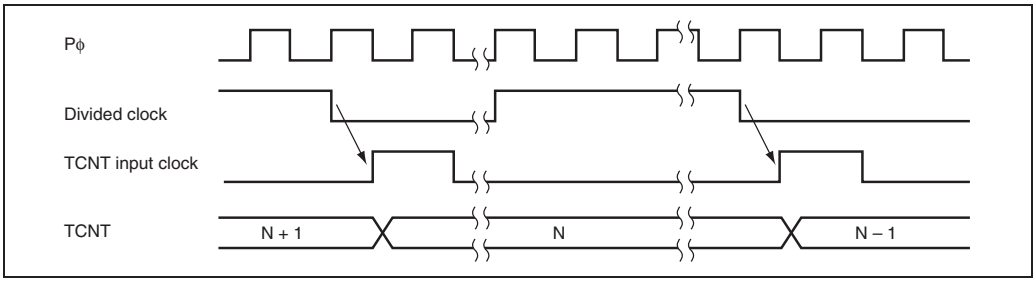

Figure 14.4 Count Timing when Internal Clock is Operating

14.4 Interrupts

There is one source of TMU interrupts: underflow interrupts (TUNI).

14.4.1 Status Flag Set Timing

The UNF bit is set to 1 when TCNT underflows. Figure 14.5 shows the timing.

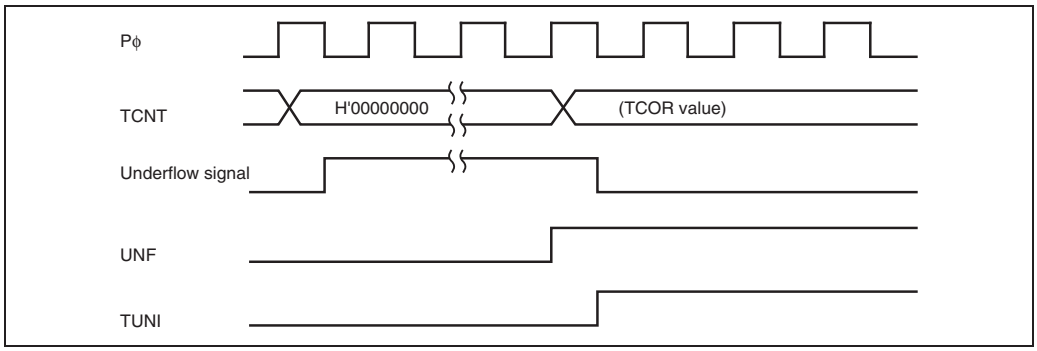

Figure 14.5 UNF Set Timing

14.4.2 Status Flag Clear Timing

The status flag can be cleared by writing 0 from the CPU. Figure 14.6 shows the timing.

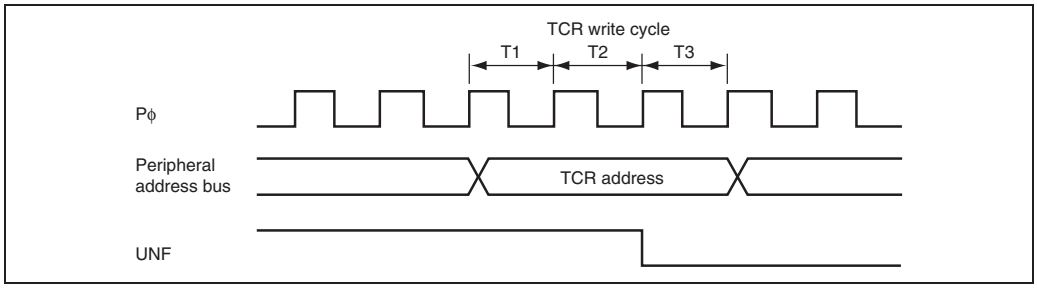

Figure 14.6 Status Flag Clear Timing

14.4.3 Interrupt Sources and Priorities

The TMU generates underflow interrupts for each channel. When the interrupt request flag and interrupt enable bit are both set to 1, the interrupt is requested. A specific code is set in the interrupt event register (INTEVT) for this interrupt and interrupt processing must be executed according to the code.

The priorities between channels are changeable by the interrupt controller. Table 14.3 lists TMU interrupt sources.

Table 14.3 TMU Interrupt Sources

Channel	Interrupt Source	Description	Priority
0	TUNI0	Underflow interrupt 0	High
1	TUNI1	Underflow interrupt 1	↕
2	TUNI2	Underflow interrupt 2	Low

14.5 Usage Notes

14.5.1 Writing to Registers

Synchronization processing is not performed for timer counting during register writes. When writing to registers, be sure to clear the start bits (STR2 to STR0) of the channel in TSTR and halt the timer counting.

14.5.2 Reading Registers

Synchronization processing is performed for timer counting during register reads. When the timer counting and register read are performed simultaneously, the register value stored before the TCNT countdown is read through the synchronization processing.

Section 15 16-Bit Timer Pulse Unit (TPU)

This LSI has a five on-chip 16-bit timer pulse units (TPU), which consists of four 16-bit timer channels.

15.1 Features

TPU 0 have the following features.

- 4-channel timers are mounted in the system domain.
- Up to four pulses output is possible.
  TPU 0 has a total of 16 timer general registers provided with four registers (TPU0_TGRA, TPU0_TGRB, TPU0_TGRC, TPU0_TGRD) for each channel. TPU0_TGRA enables an output compare setting. TPU0_TGRB, TPU0_TGRC, and TPU0_TGRD in each channel can be used as the timer counter clear registers. TPU0_TGRC and TPU0_TGRD can be used as the buffer registers.
- The following operation can be set for each channel:
  Waveform output by compare match: 0 output, 1 output, toggle output selection is possible.
  Counter clear operation: counter clearing possible by compare match
  PMW mode: PMW output of any duty cycle is possible.
  Up to four phases of PMW output is possible.
- Setting stepping motor control mode using channel 0 is possible.
- Buffer operation settable for each channel
  Automatic rewriting of output compare register possible
- One interrupt request from TPU 0
  Enabling or disabling the compare match/overflow interrupt request can be set independently for each interrupt source.
  In stepping motor control mode, setting of transition, data request, permission, and prohibition of data overflow interruption is possible by channel 0.

Table 15.1 describes the TPU functions.

Table 15.1 TPU Functions

Item		TPU0: Channel 0	TPU0: Channel 1	TPU0: Channel 2	TPU0: Channel 3
Count clock		CPϕ/1 CPϕ/4 CPϕ/16 CPϕ/64	CPϕ/1 CPϕ/4 CPϕ/16 CPϕ/64	CPϕ/1 CPϕ/4 CPϕ/16 CPϕ/64	CPϕ/1 CPϕ/4 CPϕ/16 CPϕ/64

15.4.1 Timer Control Register (TPU0_TCR)

TPU0_TCR controls the TPU0_TCNT for each channel. The TPU has one TPU0_TCR register for each channel. TPU0_TCR is initialized to H'0000 at a reset.

TPU0_TCR register settings should be made only while TPU0_TCNT operation is stopped.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0	O	O	O	O
1	O	O	O	O
2	O	O	O	O
3	O	O	O	O

[Legend]
O: Setting

Table 15.6 Count Clock Selection by the TPSC[2:0] Bits

Channel	TPSC[2]	TPSC[1]	TPSC[0]	Description
0 to 3	0	0	0	Internal clock: counts on CPϕ/1(initial value)
			1	Internal clock: counts on CPϕ/4
		1	0	Internal clock: counts on CPϕ/16
			1	Internal clock: counts on CPϕ/64
	1	*	*	Setting prohibited

[Legend]
*: Don't care.

15.4.2 Timer Mode Register (TPU0_TMDR)

TPU0_TMDR specifies the operation mode for each channel. The TPU has one TPU0_TMDR register for each channel. TPU0_TMDR is initialized to H'0000 at a reset.

TPU0_TMDR register settings should be made only while TPU0_TCNT operation is stopped.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	BFWT	BFB	BFA	—	MD[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
6	BFWT	0	R/W	Buffer Write Timing Specifies TPU0_TGRA and TPU0_TGRB update timing when TPU0_TGRC and TPU0_TGRD are used as a compare match buffer. When TPU0_TGRC and TPU0_TGRD are not used as a compare match buffer register, this bit does not function. 0: TPU0_TGRA and TPU0_TGRB are rewritten at compare match of each register. 1: TPU0_TGRA and TPU0_TGRB are rewritten at counter clearing.
5	BFB	0	R/W	Buffer Operation B Specifies whether TPU0_TGRB is used in normal operation, or TPU0_TGRB and TPU0_TGRD are used in combination for buffer operation. 0: TPU0_TGRB normal operation 1: TPU0_TGRB and TPU0_TGRD used for buffer operation
4	BFA	0	R/W	Buffer Operation A Specifies whether TPU0_TGRA is used in normal operation, or TPU0_TGRA and TPU0_TGRC are used in combination for buffer operation. 0: TPU0_TGRA normal operation 1: TPU0_TGRA and TPU0_TGRC used for buffer operation

Bit	Bit Name	Initial Value	R/W	Description
3	—	0	R	Reserved This bit is always read as 0 and cannot be modified.
2 to 0	MD[2:0]	000	R/W	Timer Operating Mode Set the timer-operating mode. 000: Normal operating 001: Setting prohibited 010: PWM mode 011: Setting prohibited 100: Setting prohibited 101: Setting prohibited 110: Setting prohibited 111: Setting prohibited

15.4.3 Timer I/O Control Register (TPU0_TIOR)

TPU0_TIOR controls the TPU0TO0 to 3 pin, and this LSI provides channel 0 only. TPU0_TIOR is initialized to H'0000 at a reset.

TPU0_TIOR register setting should be made only while TPU0_TCNT operation is stopped. Note that the setting of TPU0_TMDR may affect TPU0_TIOR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	IOA[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
2 to 0	IOA[2:0]	000	R/W	I/O Control Bits IOA2 to IOA0 specify the functions of TPU0_TGRA and the TPU0TO0 to 3 pin. For details, see table 15.7.

Table 15.7 Settings for Bits IOA[2:0], Initial States of Pin TPUTO0 to 3, and Results of Matching with TPU0_TGRA

Channel	IOA[2]	IOA[1]	IOA[0]	Description	
0 to 3	0	0	0	Always output 0 (initial value)	
			1	Initial output of the TPU0TO0 to 3 pin is 0	Output 0 on compare match with TPU0_TGRA*
		1	0		Output 1 on compare match with TPU0_TGRA
			1		Toggle output on compare match with TPU0_TGRA*
	1	0	0	Always output 1	
			1	Initial output of the TPU0TO0 to 3 pin is 1	Output 0 on compare match with TPU0_TGRA*
		1	0		Output 1 on compare match with TPU0_TGRA
			1		Toggle output on compare match with TPU0_TGRA*

Note: * Do not use this setting in PWM mode.

15.4.4 Timer Interrupt Enable Register (TPU0_TIER)

TPU0_TIER is used to enable and disable interrupt requests for each channel. The TPU has one TPU0_TIER register for each channel. TPU0_TIER is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TMDOFE	TMDRFE	TMS1ER	TMS1ET	TMS1EA	TMS1ES	—	—	—	TC1EV	TG1ED	TG1EC	TG1EB	TG1EA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
13	TMDOFE	0	R/W	Motor Control Data Transfer Data Overflow Detection Enable When the TMDOS flag in TPU0_TSR is set to 1 (data transfer overflow) in stepping motor control mode of channel 0, this bit enables or disables interrupt requests corresponding to the state of the TMDOFS flag. This bit is reserve bit in channel 1 to 3. This bit is always read as 0 and cannot be modified. 0: Interrupt requests by TMDOFS flag disabled 1: Interrupt requests by TMDOFS flag enabled
12	TMDRFE	0	R/W	Motor Control Data Transfer Request Detection Enable When the TMDRFS flag in TPU0_TSR is set to 1 (data transfer request) in stepping motor control mode of channel 0, this bit enables or disables interrupt requests corresponding to the state of the TMDRFS flag. This bit is reserve bit in channel 1 to 3. This bit is always read as 0 and cannot be modified. 0: Interrupt requests by TMDRFS flag disabled 1: Interrupt requests by TMDRFS flag enabled
11	TMS1ER	0	R/W	Motor Control Deceleration Transition Detection Enable When the TMCFR flag in TPU0_TSR is set to 1 (deceleration transition detection) in stepping motor control mode of channel 0, this bit enables or disables interrupt requests corresponding to the state of the TMCFR flag. This bit is reserve bit in channel 1 to 3. This bit is always read as 0 and cannot be modified. 0: Interrupt requests by TMCFR flag disabled 1: Interrupt requests by TMCFR flag enabled

Bit	Bit Name	Initial Value	R/W	Description
10	TMS1ET	0	R/W	Motor Control Normal Transition Detection Enable When the TMCFT flag in TPU0_TSR is set to 1 (acceleration normal transition detect) in stepping motor control mode of channel 0, this bit enables or disables interrupt requests corresponding to the state of the TMCFT flag. This bit is reserve bit in channel 1 to 3. This bit is always read as 0 and cannot be modified. 0: Interrupt requests by TMCFT flag disabled 1: Interrupt requests by TMCFT flag enabled
9	TMS1EA	0	R/W	Motor Control Acceleration Transition Detection Enable When the TMCFA flag in TPU0_TSR is set to 1 (acceleration normal transition detection) in stepping motor control mode of channel 0, this bit enables or disables interrupt requests corresponding to the state of the TMCFA flag. This bit is reserve bit in channel 1 to 3. This bit is always read as 0 and cannot be modified. 0: Interrupt requests by TMCFA flag disabled 1: Interrupt requests by TMCFA flag enabled
8	TMS1ES	0	R/W	Motor Control Stop Transition Detection Enable When the TMCFS flag in TPU0_TSR is set to 1 (stop transition detection) in stepping motor control mode of channel 0, this bit enables or disables interrupt requests corresponding to the state of the TMCFS flag. This bit is reserve bit in channel 1 to 3. This bit is always read as 0 and cannot be modified. 0: Interrupt requests by TMCFS flag disabled 1: Interrupt requests by TMCFS flag enabled
7 to 5	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
4	TC1EV	0	R/W	Overflow Interrupt Enable When the TCFV flag in TPU0_TSR is set to 1 (TCNT overflow occur), this bit enables or disables interrupt requests corresponding to the state of the TCFV flag. 0: Interrupt requests by TCFV flag disabled 1: Interrupt requests by TCFV flag enabled
3	TG1ED	0	R/W	TPU0_TGR Interrupt Enable D. When the TGFD bit in TPU0_TSR is set to 1 (compare match occurs between TPU0_TCNT and TPU0_TGRD), this bit enables or disables interrupt requests corresponding to the state of the TGFD bit. 0: Interrupt requests by TGFD bit disabled 1: Interrupt requests by TGFD bit enabled
2	TG1EC	0	R/W	TPU0_TGR Interrupt Enable C When the TGFC bit in TPU0_TSR is set to 1 (compare match occurs between TPU0_TCNT and TPU0_TGRC), this bit enables or disables interrupt requests corresponding to the state of the TGFC bit. 0: Interrupt requests by TGFC bit disabled 1: Interrupt requests by TGFC bit enabled
1	TG1EB	0	R/W	TPU0_TGR Interrupt Enable B When the TGFB bit in TPU0_TSR is set to 1 (compare match occurs between TPU0_TCNT and TPU0_TGRB), this bit enables or disables interrupt requests corresponding to the state of the TGFB bit. 0: Interrupt requests by TGFB bit disabled 1: Interrupt requests by TGFB bit enabled
0	TG1EA	0	R/W	TPU0_TGR Interrupt Enable A When the TGFA bit in TPU0_TSR is set to 1 (compare match occurs between TPU0_TCNT and TPU0_TGRA), this bit enables or disables interrupt requests corresponding to the state of the TGFA bit. 0: Interrupt requests by TGFA bit disabled 1: Interrupt requests by TGFA bit enabled

15.4.5 Timer Status Registers (TPU0_TSR)

TPU0_TSR displays information on the state of each channel. The TPU has one TPU0_TSR register for each channel. TPU0_TSR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TMDOFS	TMDRFS	TMCFR	TMCFT	TMCFA	TMCFS	—	—	TCFU	TCFV	TGFD	TGFC	TGFB	TGFA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
13	TMDOFS	0	R/(W)*	Motor Control Data Transfer Overflow Detection Enable Detection flag of data transfer overflow in channel 0 stepping motor control mode. This bit is reserve bit in channels 1 to 3. This bit is always read as 0 and cannot be modified. [Clearing condition] Writing 0 to the TMDOFS bit after reading TMDOFS bit when TMDOFS = 1 [Setting condition] When DMA transfer overflow occurs.
12	TMDRFS	0	R/(W)*	Motor Control Data Transfer Request Detection Enable Detection flag of data transfer request in channel 0 stepping motor control mode. Writing data in TGR0D using this interrupt when DMA transfer is not used. This bit is reserve bit in channels 1 to 3. This bit is always read as 0 and cannot be modified. [Clearing condition] Writing 0 to the TMDRFS bit after reading TMDRFS bit when TMDRFS = 1 [Setting condition] When data transfer request occurs.

Bit	Bit Name	Initial Value	R/W	Description
11	TMCFR	0	R/(W)*	Motor Control Deceleration Transfer Detection Enable Detection flag when sequence state transfers deceleration state in channel 0 stepping motor control mode. This bit is reserve bit in channels 1 to 3. This bit is always read as 0 and cannot be modified. [Clearing condition] Writing 0 to the TMCFR bit after reading TMCFR bit = 1 [Setting condition] When sequence state transfers deceleration state.
10	TMCFT	0	R/(W)*	Motor Control Normal Transfer Detection Enable. Detection flag when sequence state transfers normal state in channel 0 stepping motor control mode. This bit is reserve bit in channels 1s to 3. This bit is always read as 0 and cannot be modified. [Clearing condition] Writing 0 to the TMCFT bit after reading TMCFT bit = 1 [Setting condition] When sequence state transfers normal state.
9	TMCFA	0	R/(W)*	Motor Control Acceleration Transition Detection Enable Detection flag when sequence state transfers acceleration state in channel 0 stepping motor control mode. This bit is reserve bit in channels 1 to 3. This bit is always read as 0 and cannot be modified. [Clearing condition] Writing 0 to the TMCFA bit after reading TMCFA bit = 1 [Setting condition] When sequence state transfers acceleration state.

Bit	Bit Name	Initial Value	R/W	Description
8	TMCFS	0	R/(W)*	Motor Control Stop Transition Detection Enable Detection flag when sequence state transfers stop state in channel 0 stepping motor control mode. This bit is reserve bit in channels 1 to 3. This bit is always read as 0 and cannot be modified. [Clearing condition] Writing 0 to the TMCFS bit after reading TMCFS bit = 1 [Setting condition] When sequence state transfers stop state.
7, 6	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
5	TCFU	0	R/(W)*	Underflow Flag Status flag indicates TPU0_TCNT underflow in channel 2 and 3 phase figure mode. This bit is reserve bit in channels 0, 1. This bit is always read as 0 and cannot be modified. [Clearing condition] Writing 0 to the TCFU bit after reading TCFU bit = 1 [Setting condition] When the value of TPU0_TCNT underflow (H'0000→ H'FFFF)
4	TCFV	0	R/(W)*	Overflow Flag Status flag indicates TPU0_TCNT overflow occurs. [Clearing condition] Writing 0 to the TCFV bit after reading TCFV bit = 1 [Setting condition] When the value of TPU0_TCNT overflow (H'FFFF→ H'0000)

Bit	Bit Name	Initial Value	R/W	Description
3	TGFD	0	R/(W)*	Compare Flag D Status flag indicates TPU0_TCRD compare match occurs. [Clearing condition] Writing 0 to the TGFD bit after reading TGFD bit = 1 [Setting condition] When TPU0_TCNT = TPU0_TGRD
2	TGFC	0	R/(W)*	Compare Flag C Status flag indicates TPU0_TGRC compare match occurs. [Clearing condition] Writing 0 to the TGFC bit after reading TGFC bit = 1 [Setting condition] When TPU0_TCNT = TPU0_TGRC
1	TGFB	0	R/(W)*	Compare Flag B Status flag indicates TPU0_TGRB compare match occurs. [Clearing condition] Writing 0 to the TGFB bit after reading TGFB bit = 1 [Setting condition] When TPU0_TCNT = TPU0_TGRB
0	TGFA	0	R/(W)*	Output Compare Flag A Status flag indicates TPU0_TGRA compare match occurs. [Clearing condition] Writing 0 to the TGFA bit after reading TGFA bit = 1 [Setting condition] When TPU0_TCNT = TPU0_TGRA

Note: * Writing a 0 is the only way to clear this flag.

15.4.6 Timer Counter (TPU0_TCNT)

TPU0_TCNT indicates a 16-bit counter. The TPU has one TPU0_TCNT per channel.

TPU0_TCNT is initialized to H'0000 by a reset.

15.4.7 Timer General Register (TPU0_TGR)

TPU0_TGR indicates a 16-bit general register. Four general registers (TPU0_TGRA, TPU0_TGRB, TPU0_TGRC, and TPU0_TGRD) are provided for each channel. TPU0_TGRC and TPU0_TGRD can be designated for operation as buffer registers*. TPU0_TGR is initialized to H'FFFF by a reset.

Note: * The combination of TPU0_TGR and buffer register are TPU0_TGRA to TPU0_TGRC and TPU0_TGRB to TPU0_TGRD.

15.4.8 Timer Start Register (TPU0_TSTR)

TPU0_TSTR starts and stops TCNT operation for channels 0 to 3.

TPU0_TSTR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TMST	CST3	CST2	CST1	CST0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
4	TMST	0	R/W	Motor Control Sequence Start This bit selects either start or stop of motor control sequence. This bit is set to 0 in stop state after motor control operation. 0: Stops motor control sequence 1: Starts motor control sequence
3	CST3	0	R/W	Counter Start
2	CST2	0	R/W	These bits select either start or stop of TPU0_TCNT
1	CST1	0	R/W	0: Stops TPU0_TCNTm count operation
0	CST0	0	R/W	1: TPU0_TCNTm count operation [Legend] m = 3 to 0

15.4.9 Motor Control Setting Register (TPU0_TMIR)

TPU0_TMIR selects setting in motor control mode.

TPU0_TMIR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TDMAE	MTRPATDOWN	MTRPATKIND[1:0]		MTRON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
4	TDMAE	0	R/W	DMA used/unused Bit Select bit to determine to use DMA for step interval input (TPU0_TGR0D writing) in motor control mode. 0: DMA unused 1: DMA used
3	MTRPAT DOWN	0	R/W	Start and Stop Pattern Transition Ascending/Descending Select Bit Select bit to determine to select the direction of transition from ascending /descending of start and stop pattern in motor control mode. 0: Ascending 1: Descending
2, 1	MTRPAT KIND[1:0|	00	R/W	Start and Stop Pattern Type Select Bit Select bit to determine to select stop and start in motor control mode. 00: Four types 01: Eight types 10: Setting prohibited 11: Setting prohibited
0	MTRON	0	R/W	TPU mode/Stepping Motor Control Mode Select Bit 0: TPU mode 1: Stepping motor control mode Note: This bit is also a selecting signal to switch TPU0TO0 to 3 output. Set to 1 after initial pattern setting. Do not modify this bit during counter operation.

15.4.10 Motor Deceleration (Stop) Transition Register (TPU0_TMRR)

Setting TPU0_TMRR to transit from normal to deceleration in motor control mode

TPU0_TMRR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	REDUON0	REDUON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 2	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
1	REDUON0	0	R/W	This bit changes compulsorily from normal to deceleration (stop) in motor control mode. However, transition occurs when pattern is 0. If the state is other than normal, nothing is performed this bit automatically becomes 0, when transits to the stop state. 0: Nothing is performed. 1: Changes compulsorily from normal to deceleration (stop)
0	REDUON	0	R/W	This bit changes compulsorily from normal to deceleration (stop). If the state is other than normal, nothing is performed. This bit automatically becomes 0, when transits to the stop state. 0: Nothing is performed. 1: Changes compulsorily from normal to deceleration (stop)

15.4.11 Motor Control Status Register (TPU0_TMSR)

TPU0_TMSR is read only register and indicates the sequence transit state in motor control mode.

TPU0_TMSR is initialized to H'0001 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	SITR	SITT	SITA	SITS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
3	SITR	0	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is decelerating. 0: The sequence state is other than deceleration.
2	SITT	0	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is normal. 0: The sequence state is other than normal.
1	SITA	0	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is accelerating. 0: The sequence state is other than accelerating.
0	SITS	1	R	This bit indicates the sequence state in motor control mode. 1: The sequence state is stopped. 0: The sequence state is other than stopped.

15.4.12 Motor Operation Pattern Storing Register 0 (TPU0_TMMPR0)

TPU0_TMMPR0 is a register to set motor operation pattern [3 to 0] in motor control mode.

TPU0_TMMPR0 is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MP33	MP32	MP31	MP30	MP23	MP22	MP21	MP20	MP13	MP12	MP11	MP10	MP03	MP02	MP01	MP00

15.4.15 Motor Stop Pattern Storing Register 1 (TPU0_TMSPR1)

TPU0_TMSPR1 is a register to set motor operation pattern [7 to 4] in motor control mode.

TPU0_TMSPR1 is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

				SP40: TPU0TO0 output value in motor stop pattern [4]

15.4.16 Motor Output Pattern Storing Register (TPU0_TMOPR)

TPU0_TMOPR is a register to set motor output pattern in motor control mode. It indicates types of pattern currently outputted. When this register is written when stopped, a corresponding pattern is outputted. TPU0_TMOPR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	NOWPAT[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0 and cannot be modified.
2 to 0	NOWPAT [2:0]	000	R/W	In Motor Control Mode, Reading: A current output pattern number is read. Writing: Outputs pattern number when stopped.

15.4.17 Motor Acceleration the Number of Steps Register (TPU0_TMASR)

TPU0_TMASR is a register to set the number of steps in the acceleration state of motor control mode. TPU0_TMASR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AS[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	AS[15:0]	H'0000	R/W	The number of steps in the acceleration state of motor control mode. When H'0000 is set, skips the acceleration state.

15.4.18 Motor Normal the Number of Steps Register (TPU0_TMTSR)

TPU0_TMTSR is a register to set the number of steps in normal state of motor control mode. TPU0_TMTSR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TS[15:0]	H'0000	R/W	The number of steps in normal state of motor control mode. When H'0000 is set, the normal state is maintained until 1 is written to the REDUON0 bit or REDUON bit in TPU0_TMRR.

15.4.19 Motor Deceleration the Number of Steps Register (TPU0_TMRSR)

TPU0_TMRSR is a register to set the number of steps in deceleration state of motor control mode. TPU0_TMRSR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RS[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	RS[15:0]	H'0000	R/W	The number of steps in deceleration state of motor control mode. When H'0000 is set, skips deceleration state.

15.4.20 Motor Control Sequence Counter Register (TPU0_TMSCR)

TPU0_TMSCR is a register to read the sequence counter in motor control mode. It is possible to write only when motor control mode is in a normal state.

TPU0_TMSCR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	SC[15:0]	H'0000	R/W	The sequence counter number in motor control mode. Reading: A sequence counter value is read. Writing: Writing is possible only in the normal state. A written value is directly stored in the sequence counter.

15.4.21 Motor Control Normal Counter Register (TPU0_TMTCR)

TPU0_TMTCR is a read only register and indicates the number of steps in the normal state of motor control mode. TPU0_TMTCR is initialized to H'0000 by a reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TCR[15:0]	H'0000	R	The number of steps in the normal state of motor control mode

15.5 Operation

15.5.1 Overview

Operation overview for each mode is as follows.

(1) Ordinary Operation

Each channel is provided with TPU0_TCNT and TPU0_TGR registers. TPU0_TCNT performs up counting, and is also capable of free-running operation, periodic counting, and external event counting.

(a) Buffer Operation

When a compare match occurs, the buffer register value in the corresponding channel is transferred to TPU0_TGR. Updating timing to rewrite from buffer registers can be selected either when a compare match occurs or when the counter is cleared.

(b) PWM Mode

In PWM mode, PWM waveform is output. The output level can be set by TPU0_TGR. PWM waveform, whose duty cycle is in the range of 0 to 100%, can be output by the settings of TPU0_TGRA and TPU0_TGRB.

(c) Stepping Motor Control Mode

A defined pattern can be outputted from TPU0TO3 to TPU0TO0 by setting channel 0 to stepping motor control mode. It changes a pattern of one step period.

15.5.2 Basic Functions

(1) Counter Operation

When the bits CST3 to CST0 in TPU0_TSTR are set to 1, the TPU0_TCNT for the corresponding channel starts counting. TPU0_TCNT can operate as a free-running counter, periodic counter, and so on.

(a) Example of Count Operation Setting Procedure

Figure 15.2 shows an example of the count operation setting procedure.

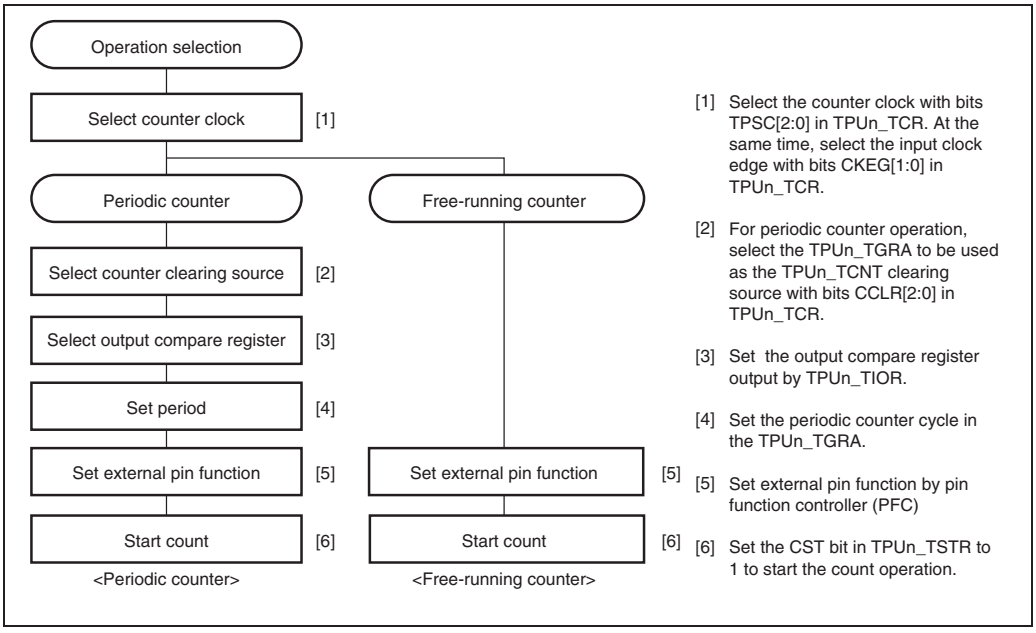

Figure 15.2 Example of Counter Operation Setting Procedure

(b) Free-Running Count Operation and Periodic Count Operation

Immediately after a reset, the TPU0_TCNT counters are all designated as free-running counters. When the relevant bit in TPU0_TSTR is set to 1, the corresponding TPU0_TCNT counter starts up-count operation as a free-running counter. When TPU0_TCNT has overflowed (changes from H'FFFF to H'0000), the TCFV bit in TPU0_TSR is set to 1. TPU0_TCNT starts counting up again from H'0000 after an overflow.

Figure 15.3 illustrates free-running counter operation.

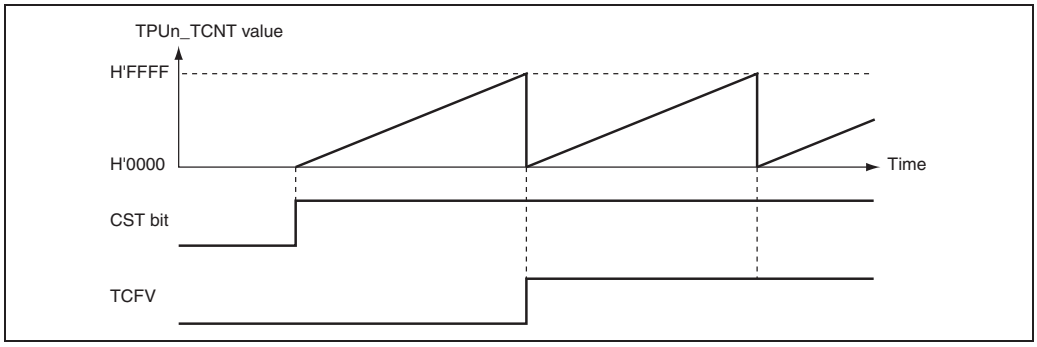

Figure 15.3 Free-Running Counter Operation

When a compare match is selected as the TPU0_TCNT clearing source, the TPU0_TCNT counter for the relevant channel performs periodic count operation. The TPU0_TGR register for setting the period is designated as an output compare register, and counter clearing by compare match is selected by means of bits CCLR[2:0] in TPU0_TCR. After the settings have been made, TPU0_TCNT starts count-up operation as a periodic counter when the corresponding bit in TPU0_TSTR is set to 1. When the count value matches the value in TPU0_TGR, the TGF bit in TPU0_TSR is set to 1 and TPU0_TCNT is cleared to H'0000.

After a compare match, TPU0_TCNT starts counting up again from H'0000.

Figure 15.4 illustrates periodic counter operation.

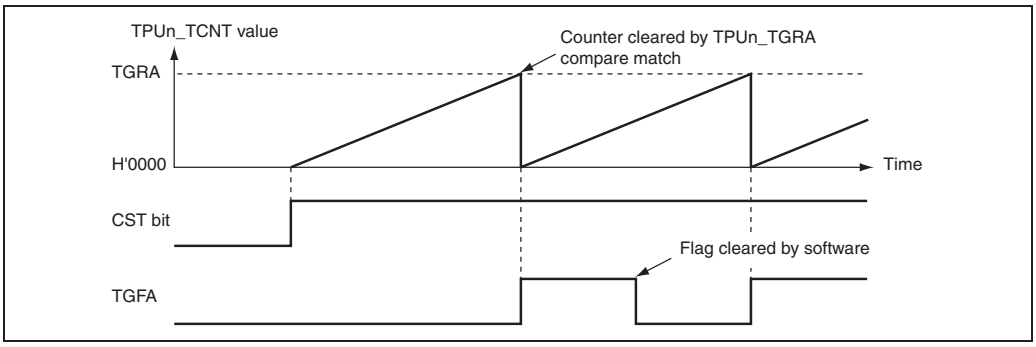

Figure 15.4 Periodic Counter Operation

(2) Waveform Output by Compare Match

The TPU can perform 0-, 1-, or toggle-output from the output pin (TPU0TO0 to 3 pins) using a TPU0_TGRA compare match.

(a) Example of Setting Procedure for Waveform Output by Compare Match

Figure 15.5 shows an example of the setting procedure for waveform output by a compare match.

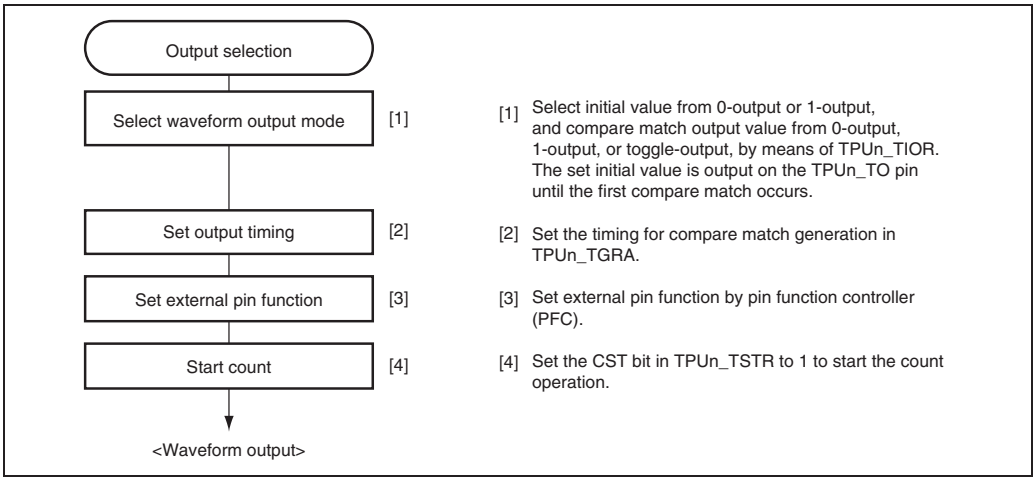

Figure 15.5 Example of Setting Procedure for Waveform Output by Compare Match

(b) Examples of Waveform Output Operation

Figure 15.6 shows an example of 0-output and 1-output.

In this example, TPU0_TCNT has been designated as a free-running counter, and settings have been made so that 1 or 0 is output by compare match A. When the set level and the pin level match, the pin level does not change.

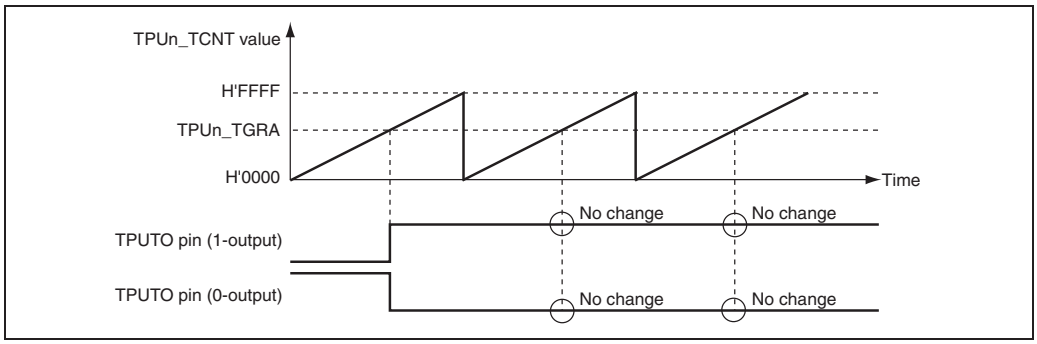

Figure 15.6 Example of 0-Output/1-Output Operation

Figure 15.7 shows an example of toggle output.

In this example, TPU0_TCNT has been designated as a periodic counter (with counter clearing performed by compare match B), and settings have been made so that output is toggled by compare match A.

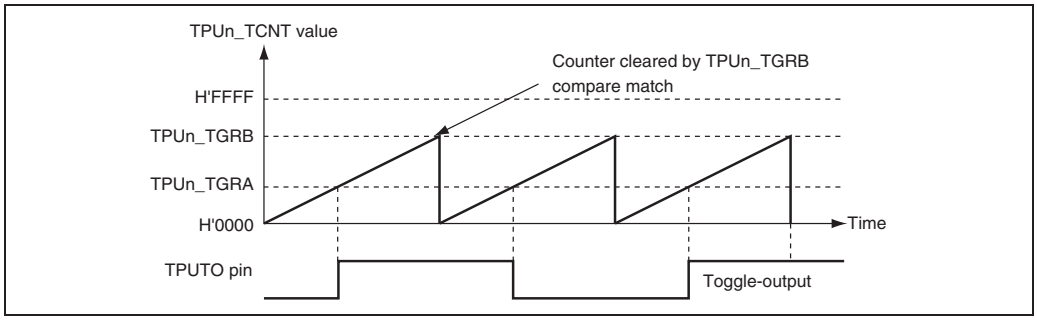

Figure 15.7 Example of Toggle Output Operation

15.5.3 Buffer Operation

TPU0_TGRC and TPU0_TGRD can be used as buffer registers.

Table 15.8 shows the register combinations used in buffer operation.

Table 15.8 Register Combinations in Buffer Operation

Timer General Register	Buffer Register
TPU0_TGRA	TPU0_TGRC
TPU0_TGRB	TPU0_TGRD

When a compare match occurs, the value in the buffer register for the corresponding channel is transferred to the timer general register. Updating timing to rewrite from buffer registers can be selected either when compare match occurs or when the counter is cleared.

This operation is illustrated in figure 15.8.

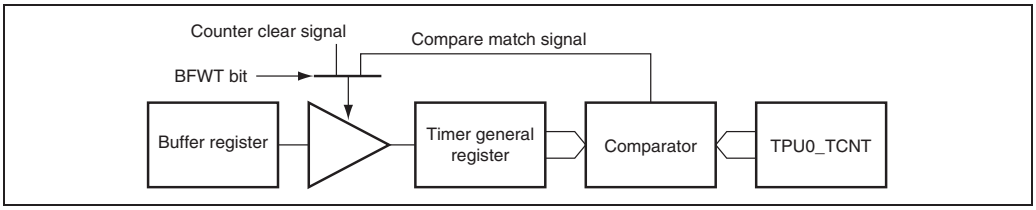

Figure 15.8 Compare Match Buffer Operation

(1) Example of Buffer Operation Setting Procedure

Figure 15.9 shows an example of the buffer operation setting procedure.

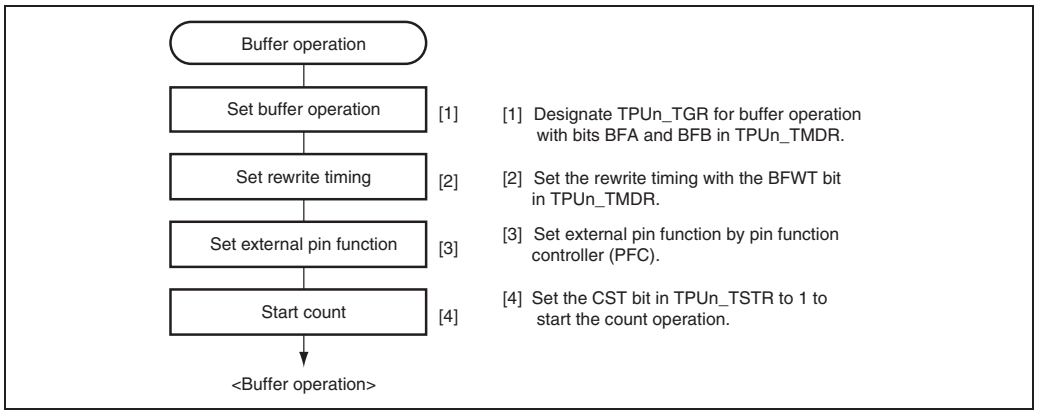

Figure 15.9 Example of Buffer Operation Setting Procedure

(2) Examples of Buffer Operation

Figure 15.10 shows an operation example in which PWM mode has been designated for channel 0, and buffer operation has been designated for TPU0_TGRA and TPU0_TGRC. The settings used in this example are TPU0_TCNT clearing by compare match B, 1-output (TPU0TO0 to 3 pin) at compare match A, initial value 0 output by counter clearing, and the rewrite timing from buffer register at counter clearing.

When compare match A occurs, the output changes. When a counter clear is generated by TPU0_TGRB, the output changes and the value in buffer register TPU0_TGRC is simultaneously transferred to the timer general register TPU0_TGRA. This operation is repeated every time compare match A occurs.

For details on PWM modes, see section 15.5.4, PWM Modes.

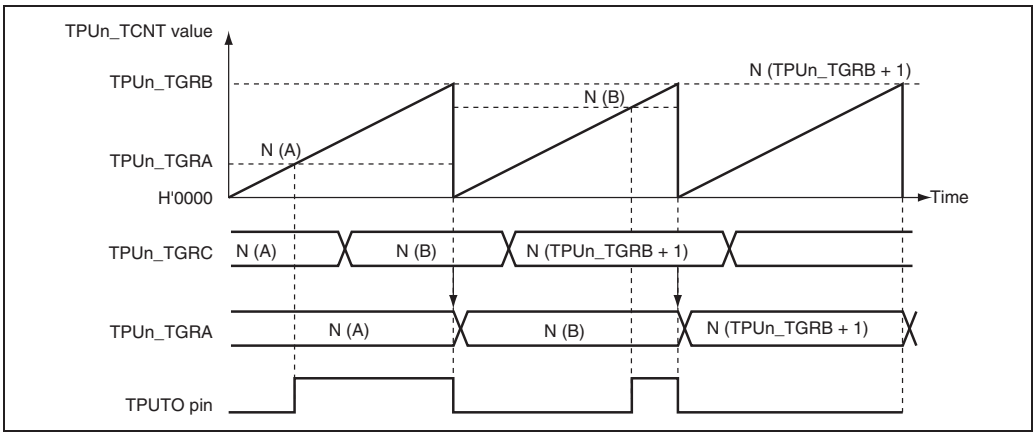

Figure 15.10 Example of Buffer Operation

15.5.4 PWM Modes

In PWM mode, PWM waveforms are output from the output pins. 0-, or 1-output can be selected as the output level in response to compare match of each TPU0_TGRA.

Designating TPU0_TGRB compare match as the counter clearing source enables the cycle to be set in that register. All channels can be designated for PWM mode independently.

PWM output is generated from the TPU0TO0 to 3 pins by using TPU0_TGRA and TPU0_TGRB as duty-cycle register and periodic register respectively. The initial output specified by TPU0_TIOR is output to TPU0TO0 to 3 pins by counter clearing due to periodic register compare match. Be sure to set TPU0_TIOR so that the initial output level is different from the compare match output. Selecting the same level or toggle output activates no operation.

Conditions on 0% and 100% duties are shown below.

- 0% duty cycle: When periodic register (TPU0_TGRB) is set to the value equal to duty-cycle register TGRA + 1
- 100% duty cycle: When duty-cycle register (TPU0_TGRA) is set to 0

In PWM mode, up to four types of PMW outputs are available.

(1) Example of PWM Mode Setting Procedure

Figure 15.11 shows an example of the PWM mode setting procedure.

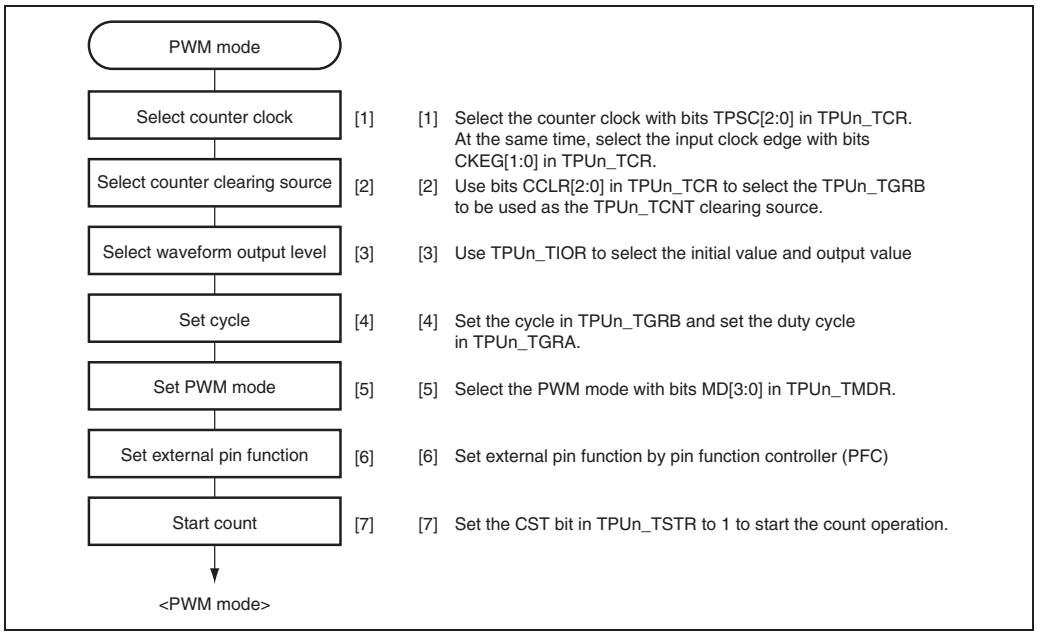

Figure 15.11 Example of PWM Mode Setting Procedure

(2) Examples of PWM Mode Operation

Figure 15.12 shows an example of PWM mode operation.

In this example, TPU0_TGRB compare match is set as the TPU0_TCNT clearing source, 0 is set for the TPU0_TGRA initial output value, and 1 is set as the output value.

In this case, the value set in TPU0_TGRB is used as the cycle, and the value set in TPU0_TGRA as the duty cycle.

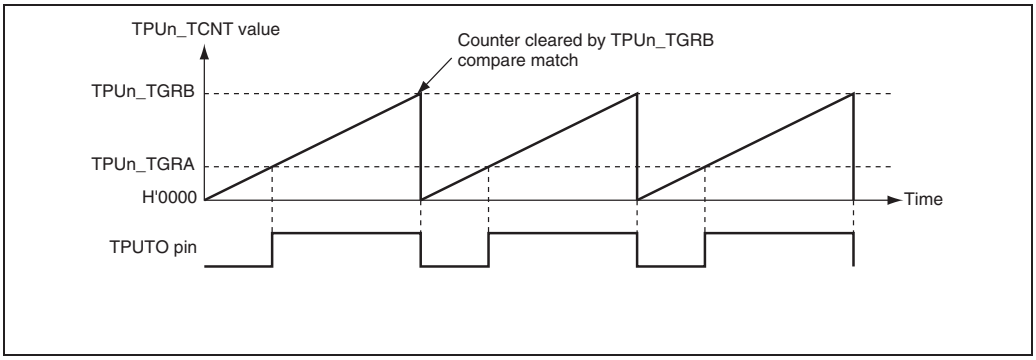

Figure 15.12 Example of PWM Mode Operation (1)

Figure 15.13 shows an example of PWM waveform output with 0% and 100% duty cycles in PWM mode.

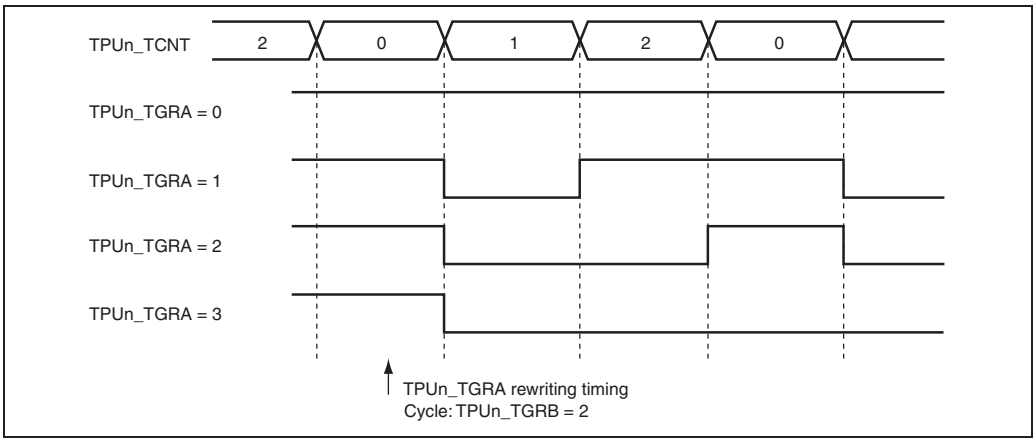

Figure 15.13 Example of PWM Mode Operation (2)

15.5.5 Stepping-Motor Control Mode

(1) Features of Stepping-Motor Control Mode

- In this mode, signals for stepping-motor control are output on four pins using only channel 0 is possible. This mode is only available on channel 0.
- States of the output pins change by counter compare matches on channel 0.

  By using the DMAC or an interrupt to rewrite the values of the compare-match registers, the intervals between transitions of the states of the output pins can be specified as desired.
- Specified patterns are output to the output pins.
- The pattern cycle consist of a four-pattern cycle and an eight-pattern cycle.
- The pattern-number counter increments or decrements by 1 by every counter compare match on channel 0.

  When the pattern-number counter overflows, its value returns to 0. When the pattern-number counter underflows, its value becomes 3 (for a four-pattern cycle) and 7 (for an eight-pattern cycle).
- Patterns consist of the stop pattern and operating patterns. Operating patterns are output while the counter is running, and a stop pattern is output while the counter is stopped.
- While the counter is running, the three states are present (the acceleration, deceleration, or normal state). Only for acceleration and deceleration, the interval of pattern change can be controlled by the DMAC or an interrupt.
- The acceleration or deceleration state can be skipped by writing H'0000 to TPU0_TMASR and TPU0_TMRSR.
- TPU0_TMRR can be used to force the transition from the normal to the deceleration state.

(2) Glossary

Sequence State:	The four states in the sequence, i.e. the acceleration, normal, deceleration, and stop states
Sequence Counter:	Counter to transit to the next sequence state. The counter is decremented with every counter compare match on channel 0 and, when the value reaches 1, the control state will make the transition to the next state in the sequence on a further counter compare match on channel 0.
Auto Mode:	Mode of operation when a value other than H'0000 has been written to TPU0_TMTSR In the normal state, pattern transitions are made by the number of times corresponding to TPU0_TMTSR, after which the transitions to the deceleration state is automatically made (when TPU0_TMRSR = H'0000, transits to the stop state).
Manual Mode:	Mode of operation when H'0000 has been written to TPU0_TMTSR. In this case, the transition from the normal to the deceleration state (stopped when TPU0_TMRSR = H'0000),) is not made unless B'1 is written to the REDUON0 and REDUON bits in TPU0_TMRR.
Pulse Mode:	Mode of operation when H'0000 has been written to TPU0_TMASR and TPU0_TMRSR. Operation is only in the normal state, so patterns with constant intervals are output.
Step:	The pattern is changed with every counter compare match on channel 0. Step refers to the interval of time between the change to one pattern and the change to the next.
Operation Pattern:	The four-bit patterns for output in the acceleration, normal, and deceleration states.
Stop Pattern:	The four-bit patterns for output in stop state.

(3) Setting up Basic Motor Control Operation

An example of operation in stepping motor control is shown in figure 15.14.

Stepping-motor control mode allows the output of patterns with a variable step interval.

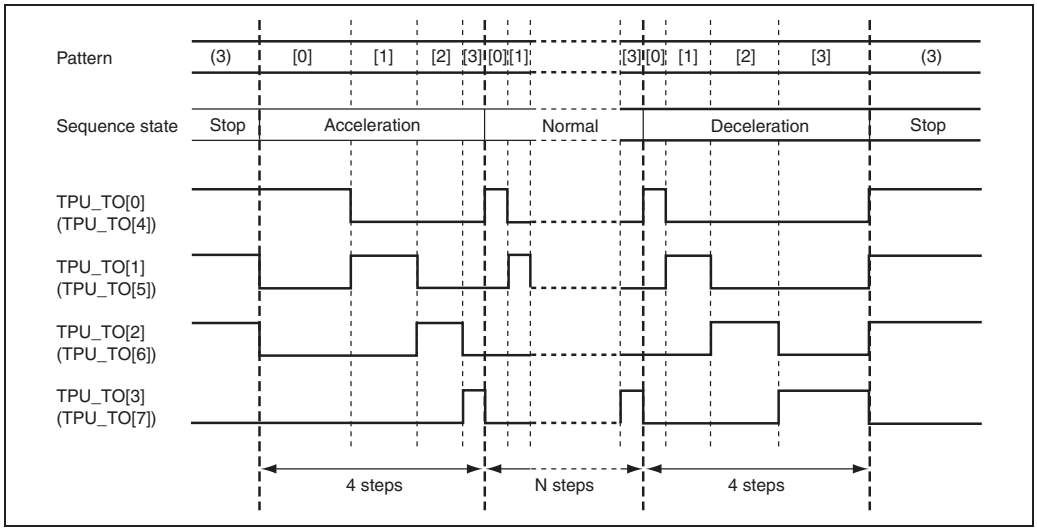

Figure 15.14 Example of Stepping-Motor Control

(a) Compare Match Settings on Channel 0

For stepping motor control, set TPU0_TCR0 and TPU0_TMDR0 as follows:

Table 15.9 Compare Match Settings on Channel 0

Register	Setting	Description
TPU0_TCR0	B'0000 0000 0100 0xxx	CCLR[2:0] bits = B'010 CKEG[1:0] bits = B'00 TPSC[2:0] bits = B'xxx (optional)
TPU0_TMDR0	B'0000 0000 0110 0000	BFWT bit = B'1 BFB bit = B'1 BFA bit = B'0 MD[2:0] bits = B'000

[Legend]
x: Don't care.

With the above settings, TPU0_TGR0B and TPU0_TGR0D can be used as buffer registers, and the contents of the buffer are rewritten when the counter is cleared. The step interval can be changed by using DMA transfer or an interrupt by writing a desired value in TPU0_TGR0D.

The TPSC[2:0] bits in TPU0_TCR0 are for a timer prescaler setting. The step interval is calculated from the following formula.

Let CPϕ be 33 MHz, TPSC[2:0] in TPU0_TCR0 contain =B'011, and TPU0_TGR0D contain H'1425.

$$\text{Step interval} = P\phi \text{ cycle} \times \left\{ \begin{array}{l} 1\ (\text{TPU0_TCR0.TPSC[2:0]} = \text{B'000}) \\ 4\ (\text{TPU0_TCR0.TPSC[2:0]} = \text{B'001}) \\ 16\ (\text{TPU0_TCR0_TPSC[2:0]} = \text{B'010}) \\ 64\ (\text{TPU0_TCR0.TPSC[2:0]} = \text{B'011}) \end{array} \right\} \times \text{TPU0_TGR0D}$$

The result for the above settings is 30.3 ns × 64 × 5157 (H'1425) = 10,000,454.4 ns ≅ 10 ms. The pattern will change after approximately 10 ms.

(b) Sequence State and the Number of Steps

In stepping-motor control mode, the three states (acceleration, normal, and deceleration) are present during counter operation. In acceleration and deceleration states, the step interval can be changed. In this case, the number of times patterns are changed is set to TPU0_TGR0D.

In the normal state, the step interval cannot be changed. So, TPU0_TGR0D is only set once for a given period.

The numbers of steps in the acceleration, normal, and deceleration states are set in TPU0_TMASR, TPU0_TMTSR, and TPU0_TMRSR, respectively. If H'0000 is written to TPU0_TMASR or TPU0_TMRSR, the corresponding state is skipped. Furthermore, the manual mode can be selected by writing H'0000 to TPU0_TMTSR. In this mode, the transition from normal mode can only be initiated by changing the value in TPU0_TMRR.

Table 15.10 gives descriptions of the sequence states and figure 15.15 shows the transitions between sequence states.

Table 15.10 Description of Sequence States

		Description	
Start/Stop	**State**	**Step Interval**	**Definition in TPU0_TGR0D**
Start	Acceleration	Variable	The number of steps specified for this state
	Normal	Not variable	Only once
	Deceleration	Variable	The number of steps specified for this state
Stop	Stop	—	—

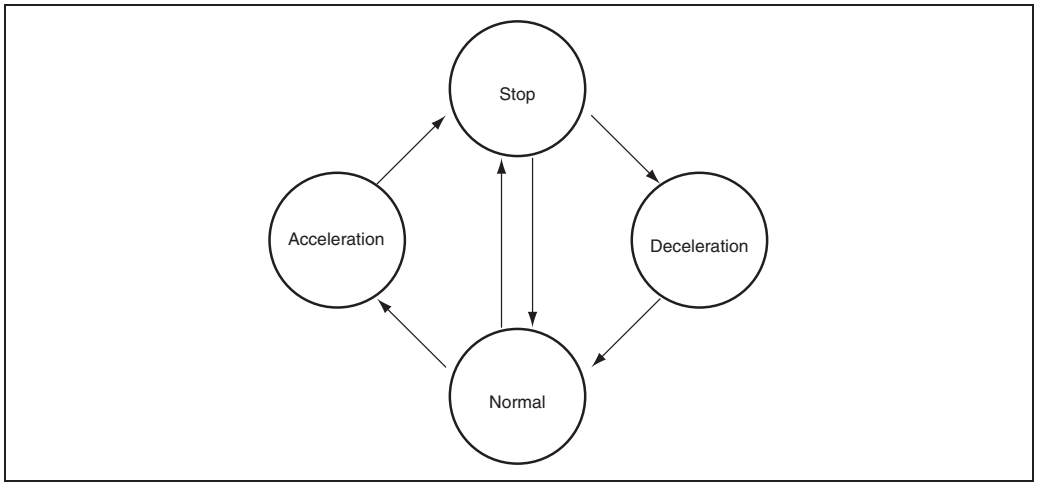

Figure 15.15 Sequence State Transition

(c) Setting of Step Interval

Direct memory access or interrupt-driven transfer can be used to set the step interval

- DMA transfer

Setting the TDMAE bit in TPU0_TMIR to B'1 allows the use of DMA transfer to modify the step interval.

The number of requests for DMA is given by TPU0_TMASR + 1 (the step interval in the normal state) + TPU0_TMRSR. The step intervals must be defined in sequence on the basis of the address indicated by the DMA source address register. Figure 15.16 shows an example of timing in operation with DMA transfer requests used to set up the step intervals. Figure 15.17 shows the definitions of step interval in the address map for this example.

Table 15.11 lists an example of DMA configurations.

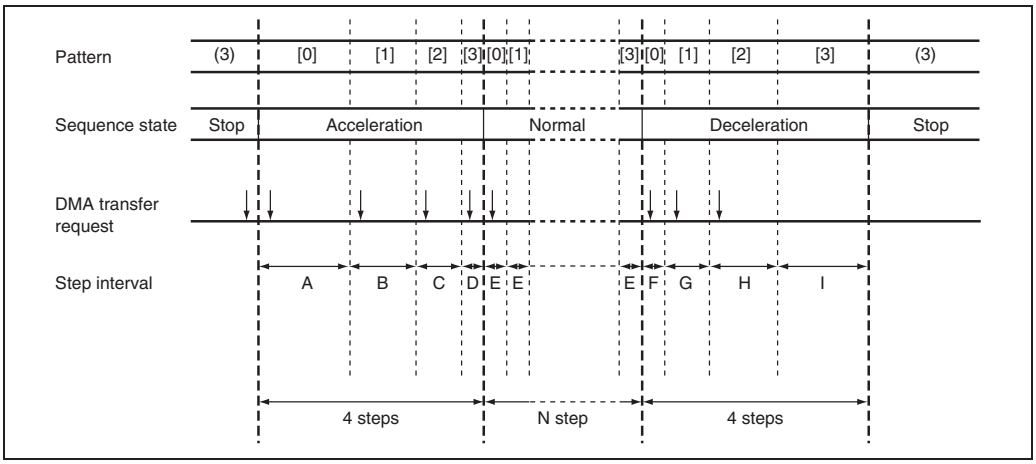

Figure 15.16 Operation with DMA Transfer Requests Used to Adjust the Step Interval

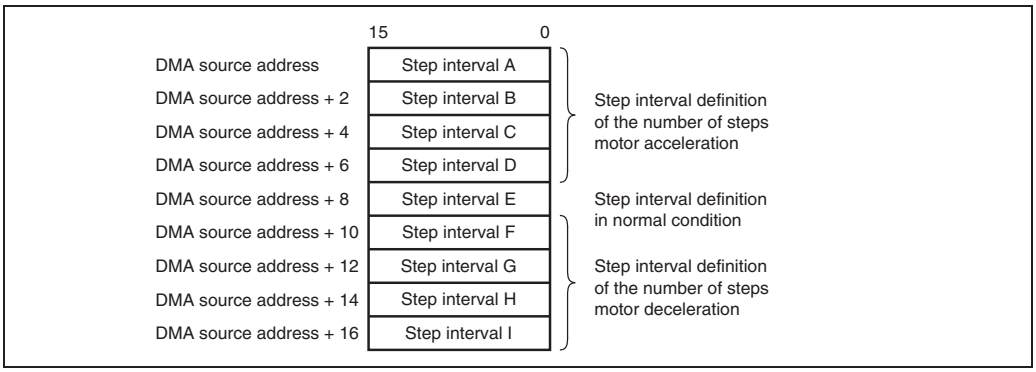

Figure 15.17 Address Map of Step Interval Definitions for the Example of Operation

Table 15.11 DMA Configurations

DMA Register	Setting	Description
DMA source address register	H'XXXX XXXX	Address where the table of step intervals starts
DMA destination address register	H'E660 0034, H'E661 0034, H'E662 0034 H'E663 0034, or H'E664 0034	Address of TPU0_TGR0D
DMA transfer count register	H'0000 0000	(The maximum number of transfer operations.) *
DMA transfer count register B	H'XXXX XXXX	The number of DMA transfer requests are set in the higher- and lower-order 16 bits. (for figure 15.16, H'0009 0009)
DMA channel control register	H'0E00 1809	Reload mode: Use source address registers (SARs) as the source for reloading. Fixed destination address. Incrementation of source address. Make selections with the DMA extension resource selector. DMA word (two-byte) unit transfer. The other bits are in the default settings
DMA extended resource register	H'F1 in the bit field for the selected DMA channel	TPU0
DMA operation register	H'0001	Permits DMA transfer on all channels. The other bits are in the default settings

Note: * Transfer is stopped when the DMA transfer counter is reaches 0. Rewrite the value of the DMA transfer counter to 1 after TPU-related operation is finished.

- Interrupt-driven transfer

Setting the TMDRFE bit in TPU0_TIER0 to B'1 allows the use of interrupt-driven transfer to change the step interval.

TPU0_TMASR−1 + 1 (the step interval in the normal state) + TPU0_TMRSR gives the number of times TPU0_TGR0D must be written to by interrupt-driven transfer.

This method is unlike DMA transfer in that an interrupt is not generated when the initial transfer is required. The Initial value should be written to TPU0_TGR0D before counter operation starts.

Once an interrupt is generated, write the step interval to TPU0_TGR0D on the interrupt subroutine and write B'0 after read B'1 from the TMDRFS bit.

Figure 15.18 shows an example of timing in operation with interrupt-driven transfer used to set up the step intervals.

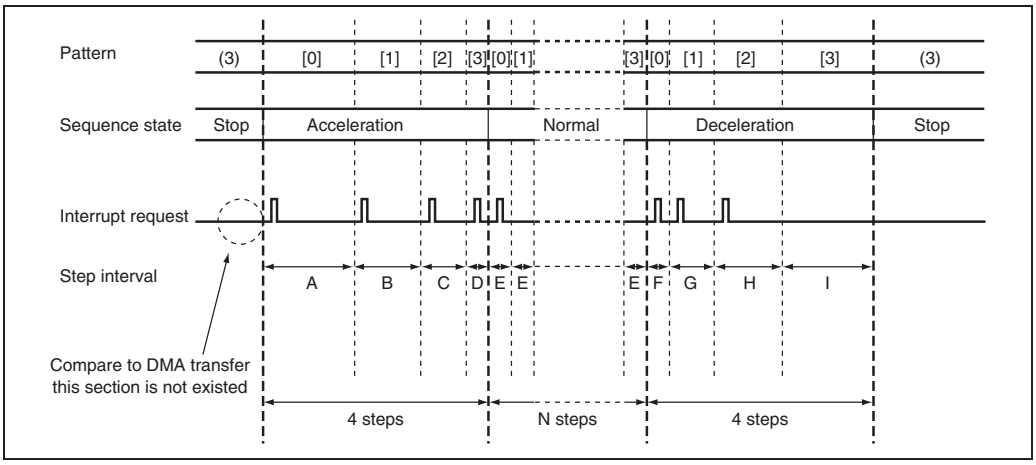

Figure 15.18 Interrupt Request and Step Interval

The step-interval definition in the example of operation shown in figure 15.18 is as follows.

Write step interval A in TPU0_TGR0D before counter starts.
Write step interval B in TPU0_TGR0D at first interrupt. } Step interval definition of the number
Write step interval C in TPU0_TGR0D at second interrupt. } of steps motor acceleration
Write step interval D in TPU0_TGR0D at third interrupt.
Write step interval E in TPU0_TGR0D at fourth interrupt. Step interval definition in normal condetion
Write step interval F in TPU0_TGR0D at fifth interrupt.
Write step interval G in TPU0_TGR0D at sixth interrupt. } Step interval definition of the number
Write step interval H in TPU0_TGR0D at seventh interrupt. } of steps motor deceleration
Write step interval I in TPU0_TGR0D at eighth interrupt.

(d) Pattern Setting

In stepping-motor control mode, each four-bit value for output on pins TPU0TO0 to TPU0TO3 is regarded as a single pattern. The patterns are in a sequence, and a counter compare match triggers the transition to the next pattern.

The following rules apply to pattern transfer.

- Either a four- or an eight-pattern cycle is available. This is determined by the MTRPATKIND bit in TPU0_TMIR0.
- Each pattern is indicated by a pattern number. The current pattern number is either incremented or decremented on each counter compare match. Incrementation or decrementation is determined by the MTRPATDOWN bit in TPU0_TMIR0.
- The pattern-number counter returns to 0 when it overflows. When it underflows, the pattern number is three (for a four-pattern cycle) or seven (for an eight-pattern cycle).
- Operating patterns are defined as the output patterns in the acceleration, normal, and deceleration states, and stop patterns are defined as the output patterns in the stop state. In transitions from an operating pattern to a stop pattern, the pattern number remains the same. In transitions from a stop pattern to an operating pattern, the current pattern number is changed to that of the next pattern.

Operating patterns are set in TPU0_TMMPR0 and TPU0_TMMPR1, and stop patterns are set in TPU0_TMSPR0 and TPU0_TMSPR1.

Table 15.12 lists the order of patterns for different settings of the MTRPATDOWN and MTRPATKIND bits in TPU0_TMIR.

Table 15.12 Settings of the MTRPATDOWN and MTRPATKIND Bits in TPU0_TMIR and Pattern Order

TPU0_TMIR		Example of Pattern Order
MTRPATDOWN Bit	MTRPATKIND Bits	(Operating Pattern [ ], Stop Pattern ( ))
B'0	B'00	[0]→[1]→[2]→[3]→[0]→[1]→[2]→[3]→(3)→[0]
B'1		[0]→[3]→[2]→[1]→[0]→[3]→[2]→[1]→(1)→[0]
B'0	B'01	[0]→[1]→[2]→[3]→[4]→[5]→[6]→[7]→(7)→[0]
B'1		[0]→[7]→[6]→[5]→[4]→[3]→[2]→[1]→(1)→[0]

(e) Specifying the Output Pattern in the Stop State

When a pattern number is specified in the NOWPAT[2:0] bits in TPU0_TMOPR in the stop state, the corresponding pattern is output on pins TPU0TO3 to TPU0TO0. The Initial value is 0.

(f) Selecting the Stepping-Motor control Mode

Stepping-motor control by the TPU circuit is selected by setting the MTRON bit in TPU0_TMIR to 1. The output on pins TPU0TO3 to TPU0TO0 is switched to the output corresponding to stepping-motor control.

Switching should be performed while the motor is stopped.

The stop pattern specified as pattern 0 in TPU0_TMOPR is output after switching. Therefore, verify the value in TPU0_TMOPR or write the desired pattern to TPU0_TMOPR.

(g) Start Stepping-Motor Control

Stepping-motor control is started by setting the TMST bit in TPU0_TSTR to 1. This bit is automatically cleared (to 0) in the stop state after motor-control operations are over.

(h) Example of the Procedure for Setting up Stepping-Motor Control

Figure 15.19 is a flowchart for stepping-motor control.

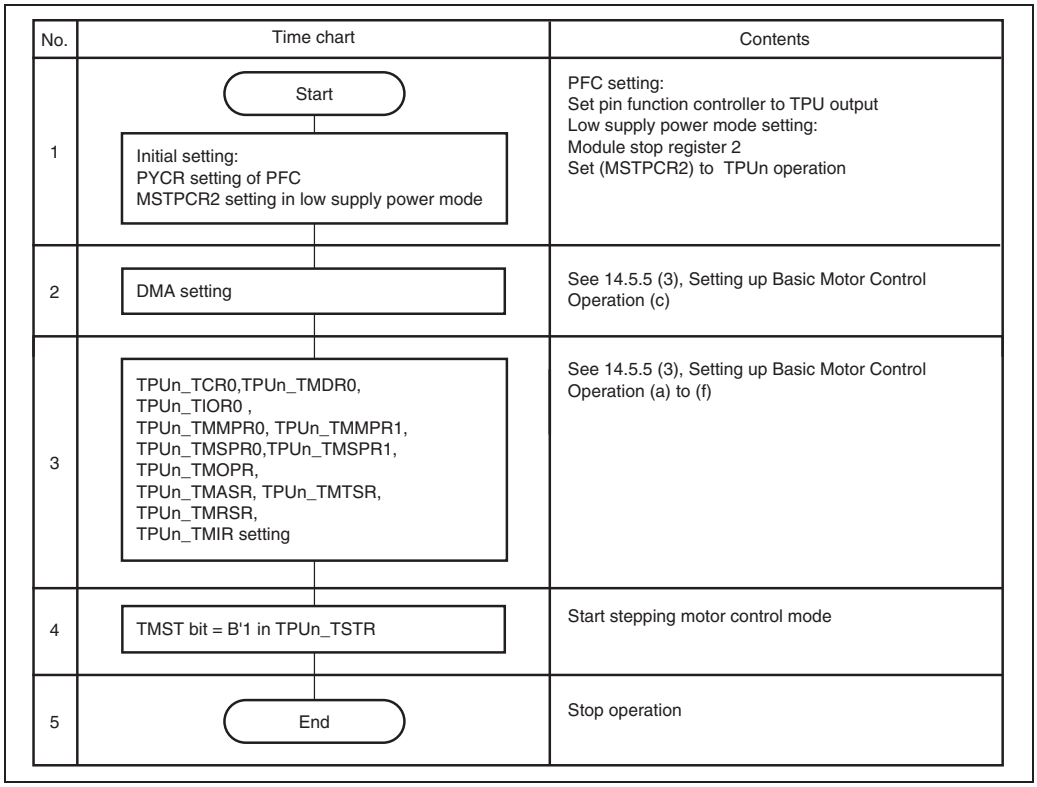

Figure 15.19 Flowchart

(4) Changing the Number of Steps in Normal State.

The number of steps in the normal state is set in TPU0_TMTSR. To change the number of steps, take the procedure given under (a) or (b) below.

In manual mode (TPU0_TMTSR = H'0000), it is impossible to switch from the normal state without performing (a).

(a) Changes by TPU0_TMRR

Writing 1 to the REDUON0 bit or the REDUON bit in TPU0_TMRR initiates the transition to the deceleration state (if TPU0_TMRSR = H'0000, the transition is to the stop state).

Table 15.13 describes how operation in response to the writing of 1 to the REDUON0 bit varies with the operating state. Table 15.14 describes how operation in response to the writing of 1 to the REDUON bit varies with the operating state.

Table 15.13 Timing of Writing 1 to the REDUON0 Bit and Operation

Timing of Writing 1 to the REDUON0 Bit	Operation
Acceleration	Operation continues normally until the end of acceleration. Control then enters the normal state and remains there until the pattern number becomes [0]. The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) is made at the end of the step in the normal state with pattern number [0].
Normal	Control remains in the normal state until the pattern number becomes [0]. The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) is made at the end of the step in the normal state with pattern number [0].
Deceleration	Writing 1 to the bit has no effect.
Stop	Writing to this bit after control has made the transition from the normal or deceleration state to the stop state clears TPU0_TMRR to H'0000. When 1 is written to the REDUON0 bit after the stop state, the normal state continues until the pattern number becomes [0] when it enters the normal state in the next round of the motor control. The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) is made at the end of the step in the normal state with pattern number [0].

Table 15.14 Timing of Writing 1 to the REDUON Bit and Operation

Timing to Write 1 in REDUON Bit	Operation
Acceleration	Operation continues normally until the end of acceleration. The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) is then made after a single step in the normal state.
Normal	The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) is made at the end of the current step interval
Deceleration	Writing 1 to the bit has no effect
Stop	Writing to this bit after control has made the transition from the normal or deceleration state to the stop state clears TPU0_TMRR to H'0000. In this case, the normal state in the next round of motor control will only continue through a single step. The transition to the deceleration state (or the stop state if TPU0_TMRSR is H'0000) is made at the end of that step.

(b) Changing the Number of Steps by Changing the Value in TPU0_TMSCR

In auto mode (TPU0_TMTSR ≠ H'0000), TMSCR indicates the remaining number of steps in the current state.

In the normal state, the number of steps can be changed by writing the desired number of steps. Writing is invalid in states other than the normal state.

Do not write to this register in manual mode (TPU0_TMTSR = H'0000).

(5) Acquiring the Number of Steps in the Normal State

In the stop state, TPU0_TMTCR can be read to acquire the number of steps in the immediately preceding normal state.

(6) Pulse Mode

Writing H'0000 to TPU0_TMASR and TPU0_TMSSR selects operation in the normal state alone, when the step interval is constant. Operation starts with the step interval defined for the normal mode and the interval does not subsequently change. Operation of this kind is referred to as pulse mode.

Examples of pulse-mode operation are described below.

(a) Single Pulse Shift in Pulse Mode and Auto Mode

Table 15.15 gives an example of register settings for a given number of pulse steps in auto mode.

Figure 15.20 is a timing chart for single pulse shift in auto mode

Table 15.15 Register Settings to Select the Number of Steps for One Pulse in Auto Mode

Register Setting Value	Contents
TPU0_TMASR: H'0000	No acceleration state
TPU0_TMTSR: H'0001	Only one step in the normal state
TPU0_TMRSR: H'0000	No deceleration state

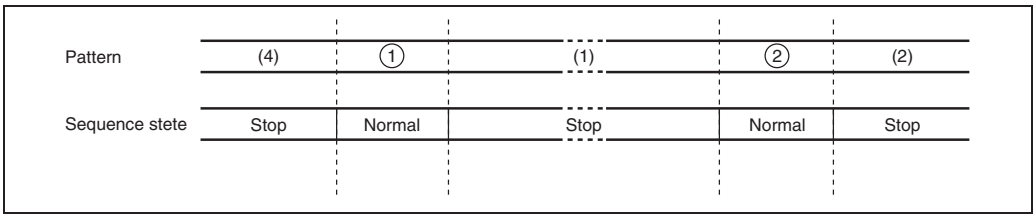

Figure 15.20 Timing of Single Pulse Shift in Auto Mode

(b) Single Pulse Shift in Pulse Mode and Manual Mode

Setting REDUON0 and REDUON bits in TPU0_TMRR to 1 in the normal state enables a single pulse shift in manual mode.

Table 15.16 gives an example of register settings for a given number of pulse steps in manual mode.

Figure 15.21 is a timing chart for single pulse shift in manual mode

Table 15.16 Register Settings to Select the Number of Steps for One Pulse in Manual Mode

Register Setting Value	Contents
TPU0_TMASR: H'0000	No acceleration state
TPU0_TMTSR: H'0000	Looping in the normal state
TPU0_TMRSR: H'0000	No deceleration state

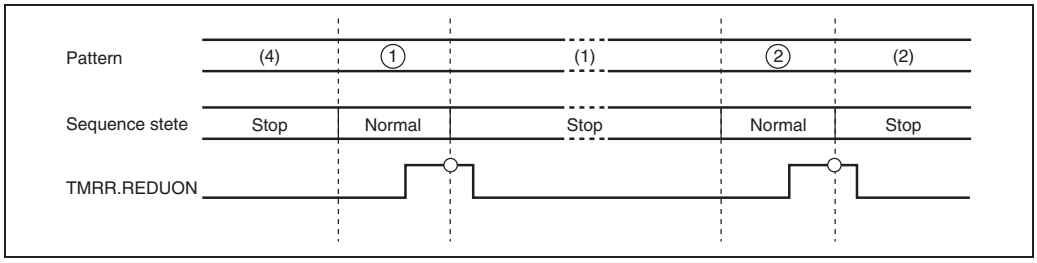

Figure 15.21 Timing of Single Pulse Shift in Manual Mode

(7) Interrupts

For stepping-motor control mode, six interrupt conditions have been added to channel 0.

The interrupt conditions are described below.

(a) Detection of Overflows of Data Transferred for Motor Control

Setting the TMDOFE bit in TPU0_TIER0 to 1 selects the detection of overflow of data transferred for motor control (motor control data transfer overflow). This condition arises when buffer operation, i.e. the transfer of the data from TPU0_TGR0D, is delayed; that is, when the operation TPU0_TGR0D→ TPU0_TGR0B is delayed. To cancel this interrupt, write 0 to the TMDOFS bit of TPU0_TSR0 after having read it as 1.

Figure 15.22 shows an example of DMA transfer where an overflow of data transferred for motor control occurs and detection of this overflow has been enabled.

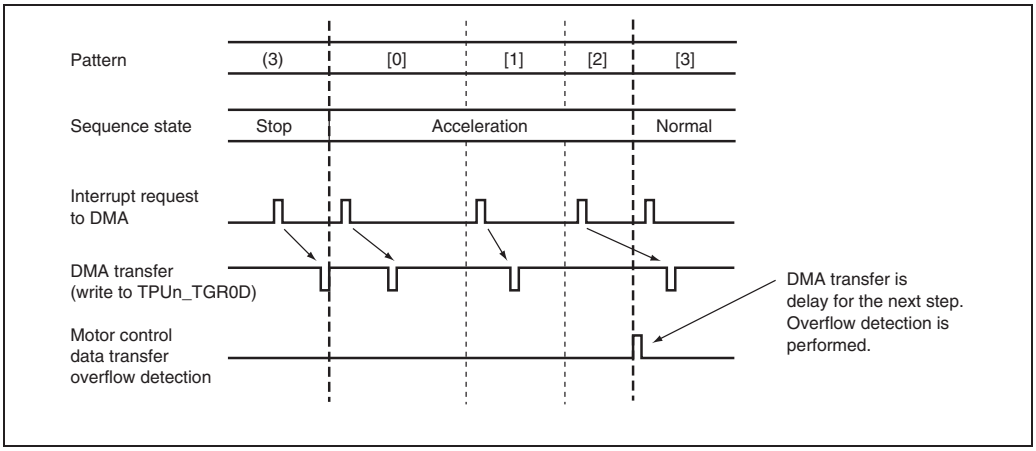

Figure 15.22 DMA Transfer with Detection of Motor Control Data Transfer Overflow Enabled

Since this interrupt is for use in the debugging of defective operation, normal operation will not be restored even if it is detected.

(b) Detection of Requirement for Transfer of Motor control Data

Detection of requirement for transfer of the motor control data (detect motor control data transfer request) is enabled by setting the TMDRFE bit of TPU0_TIER0. This interrupt occurs when the next pattern interval can change from the current interval. On detection of this interrupt, the setting for the next interval should be written to TPU0_TGR0D. After writing the new interval data, write 0 to the TMDRFS bit of TPU0_TGR0 after having read it as 1.

Do not use this interrupt if DMA transfer has been selected (the TDMAE bit in TPU0_TMIR = 1).

See figure 15.18 for an example of usage of this interrupt.

(c) Detecting the Transition to Deceleration.

Setting the TMS1ER bit in TPU0_TIER0 to B'1 enables detection of the transition to deceleration (detect motor control deceleration transition) After writing, write 0 to the TMCFR bit of TPU0_TSR0 after having read it as 1.

(d) Detecting the Transition to the Normal State

Setting the TMS1ET bit in TPU0_TIER0 to B'1 enables detection of the transition to the normal state (detect motor control normal transition). After writing, write 0 to the TMCFT bit of TPU0_TSR0 after having read it as 1.

(e) Detecting the Transition to Acceleration

Setting the TMS1EA bit in TPU0_TIER0 to B'1 enables detection of the transition to acceleration (detect motor control acceleration transition). After writing, write 0 to the TMCFA bit of TPU0_TSR0 after having read it as 1.

(f) Detecting the Transition to the Stop State

Setting the TMS1ES bit in TPU0_TIER0 to B'1 enables detection of the transition to the stop state (detect motor control stop transition) After writing, write 0 to the TMCFS bit of TPU0_TSR0 after having read it as 1.

(8) Checking the State of Operation

Read TPU0_TMSR and TPU0_TMSCR to check the current state of operations. TPU0_TMSCR indicates a value that is decremented (for every counter compare match) from the value in the number of steps register (TPU0_TMASR, TPU0_TMTSR, or TPU0_TMRSR) during sequence transition.

Figure 15.23 shows how the values in TPU0_TMSR and TPU0_TMSCR vary through the four states. As is shown in the figure, the current interval within the overall sequence of state transitions can be estimated by, for example reading TPU0_TMSR = H'0008 and TPU0_TMSCR = H'0003.

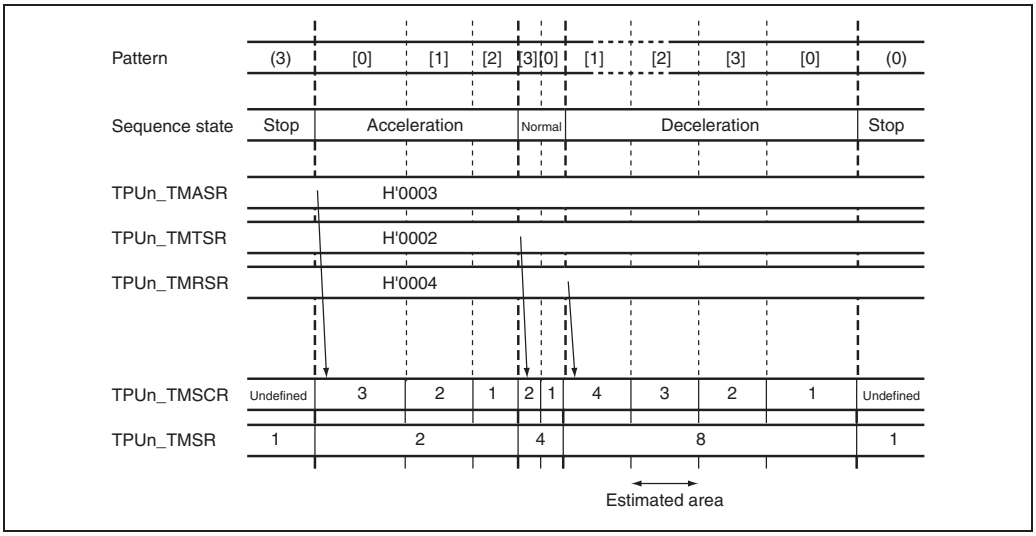

Figure 15.23 Values of TPU0_TMSR and TPU0_TMSCR

Section 16 Compare Match Timer 0 (CMT0)

This LSI includes a 32-bit compare match timer (CMT0) of one channel.

16.1 Features

- One channel installed in the real-time domain
- 16 bits/32 bits can be selected.
- Provided with an auto-reload up counter.
- Provided with 32-bit constant registers and 32-bit up counters that can be written or read at any time.
- The CMT0 can perform counting even if this LSI is in power control mode controlled by the SYSC.
- Allows selection among three counter input clocks:
  - External clock (RCLK) input: 1/8, 1/32, and 1/128
- One-shot operation and free-running operation are selectable.
- Allows selection of compare match or overflow for the interrupt source.
- Supports the cancel of the standby state in power control mode controlled by the SYSC.
- Module standby mode can be set.
- Allows selection of counter operation/stop during debugging with the debug mode operation selector.

Figure 16.1 shows a block diagram of the CMT0.

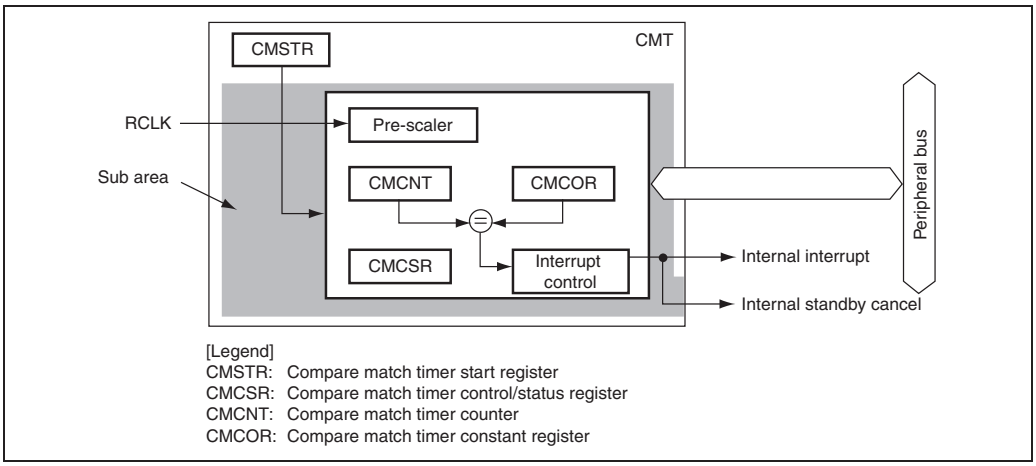

Figure 16.1 Block Diagram of CMT0

Table 16.1 shows the CMT functions list.

CMCNT	Initialized	Retained	Retained
CMCOR	Initialized	Retained	Retained

Note: * For details, refer to section 1-D Overview of reset.

16.2.1 Compare Match Timer Start Register (CMSTR)

CMSTR is a 16-bit register that selects whether the compare match timer counter (CMCNT) is operated or halted.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	STR5	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	STR5	0	R/W	Count Start Selects whether to operate or halt the compare match timer counter (CMCNT). 0: Halts CMCNT count 1: Starts CMCNT count
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

16.2.2 Compare Match Timer Control/Status Register (CMCSR)

CMCSR is a 16-bit register that indicates the occurrence of compare matches, enables interrupts, and sets the counter input clocks.

Do not change bits other than the CMF and OVF bits during the compare match timer counter (CMCNT) operation.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMF	OVF	WR FLG	—	—	—	CMS	CMM	CMTOUT_IE	—	CMR[1:0]		DBG IVD	CKS[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0
R/W:	R/(W)*	R/(W)*	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	CMF	0	R/(W)*	Compare Match Flag This flag indicates whether or not values of the compare match timer counter (CMCNT) and compare match timer constant register (CMCOR) have matched. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMCNT and CMCOR values have not matched [Clearing condition] • Write 0 to CMF 1: CMCNT and CMCOR values have matched
14	OVF	0	R/(W)*	Overflow Flag This flag indicates whether or not the compare match timer counter (CMCNT) has overflowed and been cleared to 0. Software cannot write 1 to this bit. 0: CMCNT has not overflowed [Clearing condition] • Write 0 to OVF 1: CMCNT has overflowed

Bit	Bit Name	Initial Value	R/W	Description
13	WRFLG	0	R	Write State Flag CMCNT cannot be written to when this bit is 1. This bit indicates the period that the writing to CMCNT is masked for synchronization after the writing to CMCNT. Confirm that this flag is 0 when CMCNT is written to continuously.
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	CMS	0	R/W	Compare Match Timer Counter Size Selects whether the compare match timer counter (CMCNT) is used as a 16-bit counter or a 32-bit counter. This setting becomes the valid size for the compare match timer constant register (CMCOR). 0: Operates as a 32-bit counter 1: Operates as a 16-bit counter
8	CMM	0	R/W	Compare Match Mode Selects one-shot operation or free-running operation of the counter. 0: One-shot operation 1: Free-running operation
7	CMTOUT_IE	0	R/W	Compare Match Standby Mode Cancel Enable Enables or disables the cancel of various standby modes. 0: The cancel of various standby modes by this CMT0 is disabled. 1: The cancel of various standby modes by this CMT0 is enabled. This bit is backed up.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	CMR[1:0]	00	R/W	Compare Match Request These bits enable or disable an internal interrupt request in a compare match. 00: Disables an internal interrupt request. 01: Setting prohibited 10: Enables an internal interrupt request. 11: Setting prohibited Note: When various standby modes are canceled by the CMT0, these bits should be set to B'10. These bits are backed up.
3	DBGIVD	1	R/W	Debug Mode Operation Select Sets the counter operation in debug mode. 0: Stops the counter operation in debug mode. 1: Enables the counter operation even in debug mode.
2 to 0	CKS[2:0]	100	R/W	Clock Select These bits select the clock input to CMCNT. When the count start bit (STR5) in CMSTR is set to 1, CMCNT begins incrementing with the clock selected by these bits. 000: Setting prohibited 001: Setting prohibited 010: Setting prohibited 011: Setting prohibited 100: RCLK/8 101: RCLK/32 110: RCLK/128 111: Setting prohibited

Note: * Only 0 can be written to clear the flag.

16.2.3 Compare Match Timer Counter (CMCNT)

CMCNT is a 32-bit register that is used as an up-counter.

A counter operation is set by the compare match timer control/status register (CMCSR). Therefore, set CMCSR first, before starting a channel operation corresponding to the compare match timer start register (CMSTR). When the 16-bit counter operation is selected by the CMS bit, bits 15 to 0 of this register become valid. When the register should be written to, write the data that is added H'0000 to the upper half in a 32-bit operation. The contents of this register are initialized to H'00000000.

Counter operation of CMT0 is enabled even when the peripheral clock is stopped. Counter operation is also enabled in a state where the core-area power supply is turned off during power control mode controlled by the SYSC.

When CMCNT is going to be read during the counter operation, the value that is read out may be wrong because of an asynchronous clock. Read several times with software and compare the read-out values.

16.2.4 Compare Match Timer Constant Register (CMCOR)

CMCOR is a 32-bit register that sets the compare match period with CMCNT.

When the 16-bit counter operation is selected by the CMS bit in CMCSR, bits 15 to 0 of this register become valid. When the register should be written to, write the data that is added H'0000 to the upper half in a 32-bit operation.

An overflow is detected when CMCNT is cleared to 0 and this register is H'FFFFFFFF. The contents of this register are initialized to H'FFFFFFFF.

16.3 Operation

16.3.1 Counter Operation

The CMT0 starts the operation of the counter by writing B'1 to the STR5 bit in CMSTR after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than by clearing flag bits during the compare match timer (CMCNT) operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CMCSR to B'0. When the value in CMCNT matches the value in CMCOR, the value in CMCNT is cleared to H'00000000 and the CMF bit in CMCSR is set to B'1. Counting by CMCNT stops after it has been cleared.

  To detect an overflow interrupt, set the value in CMCOR to H'FFFFFFFF. When the value in CMCNT matches the value in CMCOR, CMCNT is cleared to H'00000000 and the CMF and OVF bits in CMCSR are set to B'1.

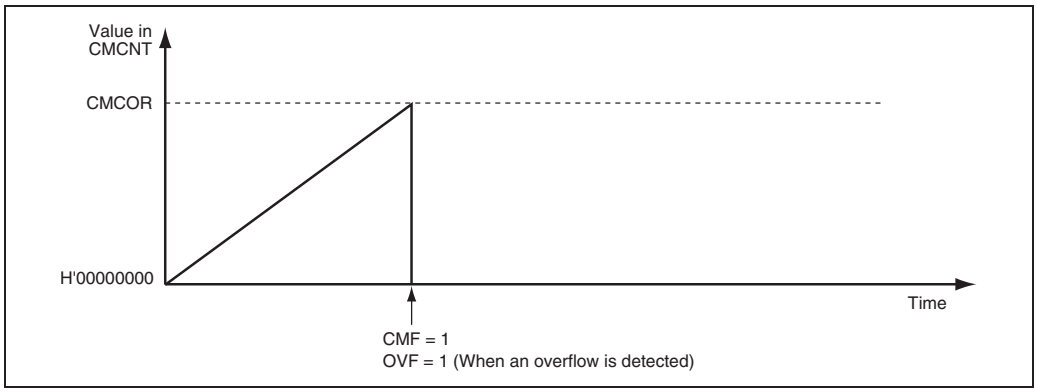

Figure 16.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CMCSR to B'1. When the value in CMCNT matches the value in CMCOR, CMCNT is cleared to H'00000000 and the CMF bit in CMCSR is set to B'1. CMCNT resumes counting-up after it has been cleared.

To detect an overflow interrupt, set CMCOR to H'FFFFFFFF. When the values in CMCNT and CMCOR match, CMCNT is cleared to H'00000000 and the CMF and OVF bits in CMCSR are set to B'1.

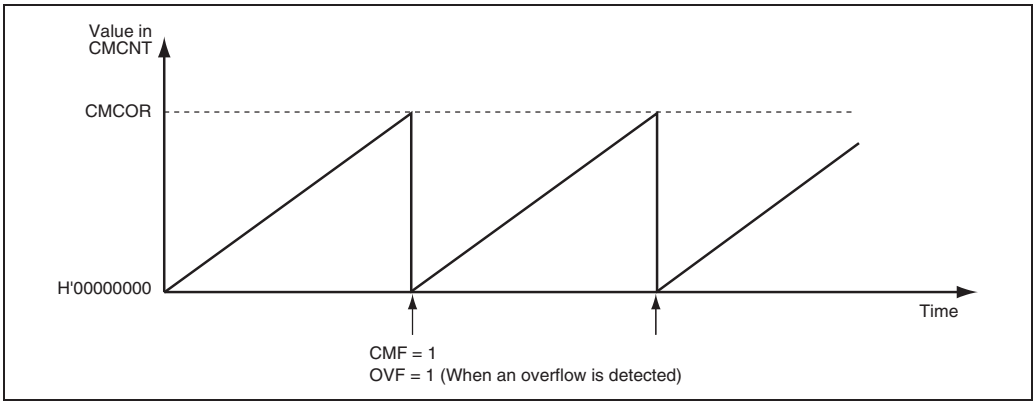

Figure 16.3 Counter Operation (Free-Running Operation)

16.3.2 Counter Size

In this module, the size of the counter is selectable as either 16 or 32 bits. This is selected by the CMS bit in CMCSR.

When the 16-bit size is selected, use a 32-bit value which has H'0000 as its upper half to set CMCOR. To detect an overflow interrupt, CMCOR must be set to H'0000FFFF.

16.3.3 Timing for Counting by CMCNT

In this module, the clock for the counter can be selected from among the following:

- External clock (RCLK): 1/8, 1/32, and 1/128

The clock for the counter is selected by the CKS bits in CMCSR. CMCNT is incremented at the rising edge of the selected clock.

16.3.4 Internal Interrupt Request to CPU

The setting of the CMR bits in CMCSR selects the sending of an internal interrupt request to the CPU at a compare match.

To clear the internal interrupt request to the CPU, the CMF bit should be set to B'0. Set the CMF bit to 0 in the handling routine for the CMT0 interrupt.

16.3.5 CMT0 Operation

As CMCNT can be operated only by the RCLK, it continues the counter operation even when this LSI makes the transition to power control mode controlled by the SYSC and the core-area power supply is turned off after the necessary register settings have been made and B'1 has been written to the STR5 bit in CMSTR.

- Register Access

  The counter for the CMT0 is located in the sub area because the counter has to be able to count-up even when this LSI is in power control mode controlled by the SYSC. The registers that are needed for the counter's operation are set from the core area. The following restrictions thus apply to the modification of the registers.

After the following registers have been modified, do not make the transition to power control mode controlled by the SYSC until you are sure that, according to the restrictions given below, the result of the modification has been reflected in the LSI's actual operation. Otherwise, the modification may not be reflected in an actual result.

- CMCSR: Bits CKS, CMM, CMS, and CMTOUT_IE
- CMCOR: Bits 31 to 0
- CMSTR: Bit STR5

Two RCLK cycles are necessary before this register is either read or any modification of the value it holds is reflected in the LSI's actual operation.

- CMCNT: Bits 31 to 0

Two RCLK cycles are necessary before this register is either read or any modification of the value it holds is reflected in the LSI's actual operation. Writing to this register, once started, is protected from further write operations until the writing operation has been completed.

- Cancel of Various Standby Modes
  When an interrupt occurs while the system is in standby mode or power control mode controlled by the SYSC, various standby modes can be canceled if the CMTOUT_IE bit in CMCSR is set to B'1 and the CMR bits to B'10.
  Set the CMF bit in CMCSR to B'0 after various standby modes are canceled.

16.3.6 Compare Match Flag Set Timing

The CMF bit in CMCSR is set to 1 by the compare match signal generated when CMCOR and CMCNT match. The compare match signal is generated upon the final state of the match (timing at which the CMCNT value is updated to H'0). Consequently, after CMCOR and CMCNT match, a compare match signal will not be generated until a CMCNT counter clock is input. Figure 16.4 shows the set timing of the CMF bit.

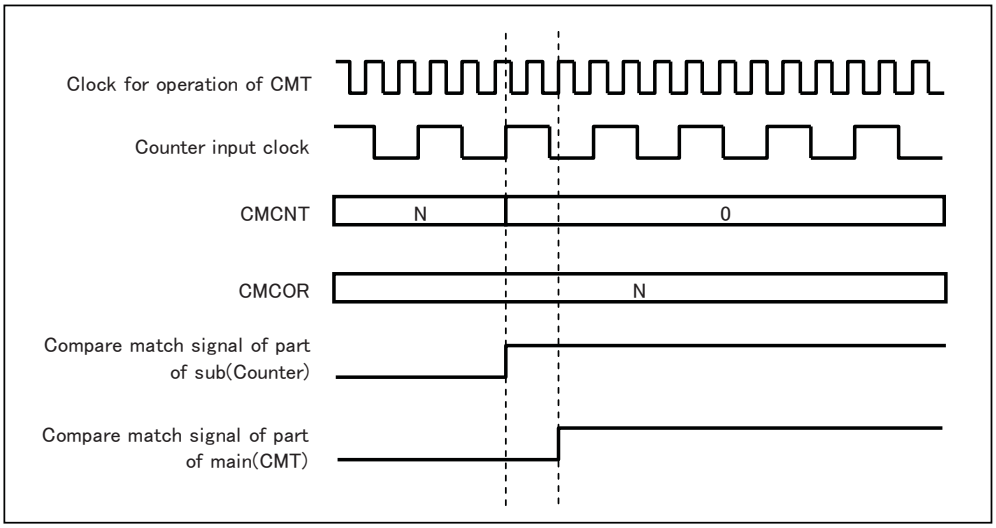

Figure 16.4 CMF Set Timing

Section 17 Compare Match Timer 1 (CMT1)

This LSI includes a 32-bit compare match timer (CMT1) of four channels (channel 0 to channel 3).

17.1 Features

- Six channels installed in the system domain
- 16 bits/32 bits/48 bits can be selected.
- Provided with an auto-reload up counter.
- Provided with 48-bit constant registers and 48-bit up counters that can be written or read at any time.
- Allows selection among eight counter input clocks for channel 0,4,5:
  - AP/COMMON MAIN CLOCK 1/2 (13 MHz) input: 1/8, 1/32, 1/128, and 1/1
  - External clock (RCLK) input: 1/8, 1/32, and 1/128
  - External clock (Pseudo32KHz) input: 1/1
- Allows selection among four counter input clocks for channels 1 and 2:
  - External clock (RCLK) input: 1/8, 1/32, and 1/128
  - External clock (Pseudo32KHz) input: 1/1
- Allows selection among five counter input clocks for channel 3:
  - External clock (RCLK) input: 1/1, 1/8, 1/32, and 1/128
  - External clock (Pseudo32KHz) input: 1/1
- One-shot operation and free-running operation are selectable.
- Allows selection of compare match for the interrupt source.
- Supports the cancellation of the standby state in power control mode controlled by the SYSC for channels 1 to 3.
- DMA transfer requests are enabled at a compare match for channel 0.
- Module standby mode can be set.
- RCLK-synchronous counter start/stop mode for channel 0 , enable interrupt request in RCLK-synchronous counter start/stop mode
- Counter operation can be enabled or disabled at the time of debugging using the debugging mode operation selector.

Figure 17.1 shows a block diagram of the CMT1.

17.2.1 Compare Match Timer Start Register (CMSTR)

CMSTR is a 16-bit register that selects whether the compare match timer counter (CMCNT) is operated or halted.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	STR0RS	–	–	STR5	STR4	STR3	STR2	STR1	STR0
Initial Value:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	STR0RS	0	R/W	RCLK-Synchronous Counter Start/Stop Mode Select (only in channel 0) 0: Normal operation Channel 0 starts or stops counting immediately after STR0 is written to. 1: RCLK-synchronous counter start/stop mode Channel 0 starts or stops counting on detecting an RCLK rising edge after STR0 is written to.
7 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	STR5	0	R/W	Count Start 5 to 0 These bits select whether to operate or halt the compare match timer counter (CMCNT5 to CMCNT0) of each channel. 0: Halts CMCNTn count 1: Starts CMCNTn count Note: n corresponds to the channel number from 5 to 0.
	STR4	0	R/W	
	STR3	1	R/W	
	STR2	0	R/W	
	STR1	0	R/W	
	STR0	0	R/W	

17.2.2 Compare Match Timer Control/Status Register 0 to 5 (CMCSR)

CMCSR is a 16-bit register that indicates the occurrence of compare matches, enables interrupts and DMA transfer requests, and sets the counter input clocks.

Do not change bits other than the CMF and OVF bits during the compare match timer counter (CMCNT) operation.

CMCSR0

Bit	Bit Name	Initial Value	R/W	Description

Bit	Bit Name	Initial Value	R/W	Description
15	CMF	0	R/(W)*	Compare Match Flag This flag indicates whether or not values of the compare match timer counter (CMCNT) and compare match timer constant register (CMCOR) have matched. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMCNT and CMCOR values have not matched [Clearing conditions] • Write 0 to CMF after reading CMF = 1 (channel 0) • Write 0 to CMF (channels 1 to 3) 1: CMCNT and CMCOR values have matched
14	OVF	0	R/(W)*	Overflow Flag This flag indicates whether or not the compare match timer counter (CMCNT) has overflowed and been cleared to 0. Software cannot write 1 to this bit. 0: CMCNT has not overflowed [Clearing conditions] • Write 0 to OVF after reading OVF = 1 (channel 0) • Write 0 to OVF (channels 1 to 3) 1: CMCNT has overflowed

Bit	Bit Name	Initial Value	R/W	Description
13	WRFLG	0	R	Write State Flag CMCNT cannot be written to when this bit is 1. This bit indicates the period that the writing to CMCNT is masked for synchronization after the writing to CMCNT. Confirm that this flag is 0 when CMCNT is written to continuously.
12	CH0STTF (valid only in channel 0)	0	R/(W)*	Channel 0 Start Flag When RCLK-synchronous channel 0 counter start/stop mode is selected, this flag indicates whether the counter in channel 0 started on detecting an RCLK rising edge after 1 was written to the STR0 bit in CMSR. 0: Channel 0 counter has not started. [Clearing condition] Write 0 to CH0STTF. 1: Channel 0 counter has started. This bit is valid only for channel 0 when RCLK-synchronous counter start/stop mode is selected.
11	CH0STPF (valid only in channel 0)	0	R/(W)*	Channel 0 Stop Flag When RCLK-synchronous channel 0 counter start/stop mode is selected, this flag indicates whether the counter in channel 0 stopped on detecting an RCLK rising edge after 1 was written to the STR0 bit in CMSR. 0: Channel 0 counter has not stopped. [Clearing condition] Write 0 to CH0STPF. 1: Channel 0 counter has stopped. This bit is valid only for channel 0 when RCLK-synchronous counter start/stop mode is selected.

Bit	Bit Name	Initial Value	R/W	Description
10	CH0SSIE (valid only in channel 0)	0	R/W	Channel 0 Start/Stop Interrupt Enable When RCLK-synchronous channel 0 counter start/stop mode is selected, this bit enables or disables an interrupt due to the start or stop of the counter in channel 0. 0: Disables an interrupt due to start or stop of channel 0 counter. 1: Enables an interrupt due to start or stop of channel 0 counter. This bit is valid only for channel 0 when RCLK-synchronous counter start/stop mode is selected.
9	CMS	0	R/W	Compare Match Timer Counter Size This bit and CMCSRH.CMSH select whether the compare match timer counter (CMCNTH[15:0]+CMCNT[31:0]) is used as a 16-bit counter or a 32-bit counter or a 48-bit counter. This setting becomes the valid size for the compare match timer constant register (CMCORH[15:0]+CMCOR[31:0]). CMCSRH.CMSH[9]+CMCSR.CMS[9] = 1x: Operates as a 48-bit counter 00: Operates as a 32-bit counter 01: Operates as a 16-bit counter
8	CMM	0 (1 for only channel 3)	R/W	Compare Match Mode Selects one-shot operation or free-running operation of the counter. 0: One-shot operation 1: Free-running operation
7	CMTOUT_IE	0	R/W	Compare Match Standby Mode Cancel Enable (channels 1 to 3) Enables or disables the cancellation of various standby modes. This bit is reserved in channel 0,4,5. This bit is always read as 0. The write value should always be 0. 0: The cancellation of various standby modes by this CMT1 is disabled. 1: The cancellation of various standby modes by this

0	CKSH	0	R/W	Clock Select This bit and CMCSR.CKS[2:0] select the clock input to CMCNT. When the count start bit (STRn (n = 5 to 0)) for the corresponding channel is set to 1, CMCNT begins incrementing with the clock selected by these bits. CMCSRH.CKSH[0]+CMCSR.CKS[2:0] = x000: (AP/COMMON MAIN CLOCK 1/2)/8 (This setting is valid in channel 0,4,5 and prohibited in channels 1 to 3.) x001: (AP/COMMON MAIN CLOCK 1/2)/32 (This setting is valid in channel 0,4,5 and prohibited in channels 1 to 3.) x010: (AP/COMMON MAIN CLOCK 1/2)/128 (This setting is valid in channel 0,4,5 and prohibited in channels 1 to 3.) x011: (AP/COMMON MAIN CLOCK 1/2)/1 (This setting is valid in channel 0,4,5 and prohibited in channels 1 to 3.) 0100: RCLK/8

Bit	Bit Name	Initial Value	R/W	Description
				0101: RCLK/32
				0110: RCLK/128
				0111: RCLK/1 (This setting is valid in channel 3 and prohibited in channels 0,1,2,4,5.)
				1111: Pseudo 32KHz/1

17.2.4 Compare Match Timer Counter 0 to 5 (CMCNT)

CMCNT is a 32-bit register that is used as an up-counter for each channel.

A counter operation is set by the compare match timer control/status register (CMCSR/CMCSRH). Therefore, set CMCSR/CMCSRH first, before starting operation of the channel corresponding to the compare match timer start register (CMSTR). When the 16-bit counter operation is selected by the CMCSRH.CMSH+CMCSR.CMS bits, bits 15 to 0 of this register become valid. When the register should be written to, write the data that is added H'0000 to the upper half in a 32-bit operation. The contents of this register are initialized to H'0000 0000.

Counter operation of channels 1 to 3 is enabled even when the peripheral clock is stopped. Counter operation is also enabled in a state where the core-area power supply is turned off during power control mode controlled by the SYSC. (* Counter operation of channels 0,4,5 also is enabled only when the counter is operated by RCLK(pseudo32KHz also includes).

17.2.5 Compare Match Timer Counter H0 to 5 (CMCNTH)

CMCNTH is a 16-bit register that is used as an up-counter for each channel.

A counter operation is set by the compare match timer control/status register (CMCSR/CMCSRH). Therefore, set CMCSR/CMCSRH first, before starting operation of the channel corresponding to the compare match timer start register (CMSTR). When the 48-bit counter operation is selected by the CMCSRH.CMSH+CMCSR.CMS bits, bits 15 to 0 of this register become valid as the upper 16-bit of 48-bit counter. The value written to this register is reflected at the same time the register CMCNT is written. Therefore, write to this register first, before writing to CMCNT. The value is not reflected even if it writes only to this register. The contents of this register are initialized to H'0000.

Counter operation of channels 1 to 3 is enabled even when the peripheral clock is stopped. Counter operation is also enabled in a state where the core-area power supply is turned off during power control mode controlled by the SYSC.(* Counter operation of channels 0,4,5 also is enabled only when the counter is operated by RCLK(pseudo32KHz also includes).

17.2.6 Compare Match Timer Constant Register 0 to 5 (CMCOR)

CMCOR is a 32-bit register that sets the compare match period with CMCNT for each channel.

When the 16-bit counter operation is selected by the CMCSRH.CMSH+CMCSR.CMS bits, bits 15 to 0 of this register become valid. When the register should be written to, write the data that is added H'0000 to the upper half in a 32-bit operation.

An overflow is detected when CMCNT is cleared to 0 and this register is H'FFFF FFFF(when the 16-bit counter operation it is H’0000 FFFF). The contents of this register are initialized to H'FFFF FFFF.

17.2.7 Compare Match Timer Constant Register H0 to 5 (CMCORH)

CMCORH is a 16-bit register that sets the compare match period with CMCNTH for each channel.

When the 48-bit counter operation is selected by the CMCSRH.CMSH+CMCSR.CMS bits, bits 15 to 0 of this register become valid as the upper 16-bit of 48-bit counter.

An overflow is detected when CMCNTH is cleared to 0 and this register is H'FFFF. The contents of this register are initialized to H'FFFF.

17.2.8 Compare Match Timer Counter 3 Backup 0 (CMCNT3BK0)

CMCNT3BK0 is a 32-bit register that stores a copy of the CMCNT3 value immediately after the counter in channel 0 stops in RCLK-synchronous channel 0 counter start/stop mode.

17.2.9 Compare Match Timer Counter 3 Backup 1 (CMCNT3BK1)

CMCNT3BK1 is a 32-bit register that stores a copy of the CMCNT3 value immediately after the counter in channel 0 starts in RCLK-synchronous channel 0 counter start/stop mode.

17.2.10 Compare Match Timer Match Control/Status Register (CMCSRM)

CMCSRM is a 16-bit register that resets to Compare match timer match counter, and sets the counter start/halt. This register is only for channel 0 and 3.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WRFLG	–	–	–	–	–	–	–	–	–	–	–	–	–	CMPCLR	CMP START
Initial Value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	WRFLG	0	R	Write state flag. When this Bit is 1, CMCNTM can not be cleared. After CMCNTM is cleared, this Bit become 1 for a while(*) as purpose of synchronization. Needs to confirm this flag is 0 or wait the period enough when continuously clearing. *In the maximum, "Counter input clock 5 cycle + CPCLK 3 cycle" ・Counter input clock CMCSR.CKS2=0: AP/common main clock 1/2 CMCSR.CKS2=1: RCLK
14 to 2	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
1	CMPCLR	0	R/W	Counter Clear [When writing] 0: No operation 1: CMCNTM becomes 0 (And CMCSRM.WRFLG will get high 1'b1.) When CMPCLR and CMPSTART are written 1 at the same time, the counter starts after clearing the counter. [When reading] This bit is always read as 0.
0	CMPSTART	0	R/W	Count Start This bit select whether to operate or halt the compare match timer match counter (CMCNTM) of each channel. 0: Halts CMCNTM count 1: Starts CMCNTM count

17.2.11 Compare Match Timer Match Counter (CMCNTM)

CMCNTM is a 32-bit register that is used as an up-counter. This register is only for channel 0 and 3.

A counter operation is set by the compare match timer match control/status register (CMCSRM). After the counter CMCNT starts, this counter increases whenever at a compare match.

17.3 Operation

17.3.1 Counter Operation

The CMT1 starts the operation of the counter by writing B'1 to the STRn (n = 5 to 0) bit in CMSTR after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than clearing flag bits during the compare match timer (CMCNT) operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CMCSR to B'0. When the value in CMCNT matches the value in CMCOR, the value in CMCNT is cleared to H'0000 0000 and the CMF bit in CMCSR is set to B'1. Counting by CMCNT stops after it has been cleared.

  To detect an overflow interrupt, set the value in CMCOR to H'FFFF FFFF. When the value in CMCNT matches the value in CMCOR, CMCNT is cleared to H'0000 0000 and the CMF and OVF bits in CMCSR are set to B'1.

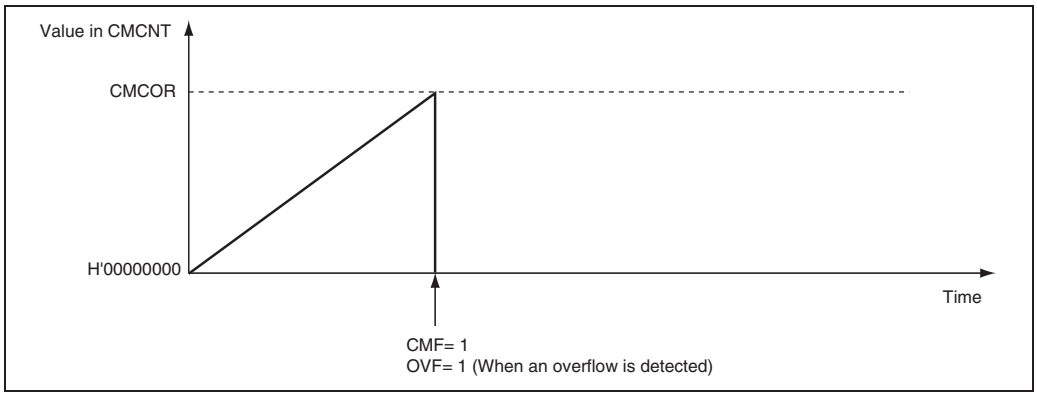

Figure 17.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CMCSR to B'1. When the value in CMCNT matches the value in CMCOR, CMCNT is cleared to H'0000 0000 and the CMF bit in CMCSR is set to B'1. CMCNT resumes counting-up after it has been cleared.

To detect an overflow interrupt, set CMCOR to H'FFFF FFFF. When the values in CMCNT and CMCOR match, CMCNT is cleared to H'0000 0000 and the CMF and OVF bits in CMCSR are set to B'1.

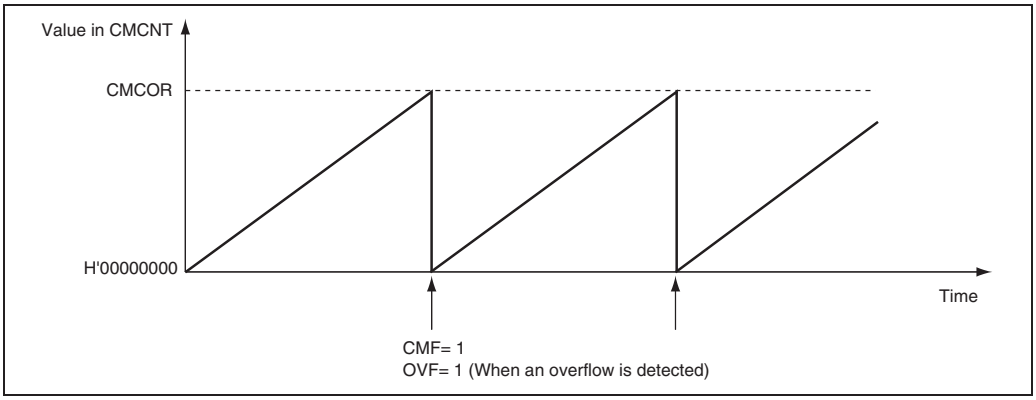

Figure 17.3 Counter Operation (Free-Running Operation)

17.3.2 Counter Size

In this module, the size of the counter is selectable as either 16 or 32 or 48 bits. This is selected by the CMS bit in CMCSR and CMSH bit in CMCSRH.

When the 16-bit/32-bit size is selected, it ignores the upper 32 bits/16 bits of CMCOR. To detect an overflow interrupt, the value 1 must be set to valid bits of CMCOR.
(ex. H’00000000FFFF, H’0000FFFFFFFF)

17.3.3 Timing for Counting by CMCNT

In this module, the clock for the counter can be selected from among the following:

Channels 0,4,5: (AP/COMMON MAIN CLOCK 1/2) clock: 1/8, 1/32, 1/128, and 1/1
External clock (RCLK): 1/8, 1/32, and 1/128
External clock (Pseudo32KHz): 1/1

Channels 1 to 2: External clock (RCLK): 1/8, 1/32, and 1/128
External clock (Pseudo32KHz): 1/1

Channel 3: External clock (RCLK): 1/1, 1/8, 1/32, and 1/128
External clock (Pseudo32KHz): 1/1

The clock for the counter is selected by the CKS bits in CMCSR and CKSH bit in CMCSRH. CMCNT is incremented at the rising edge of the selected clock.

17.3.4 DMA Transfer Request and Internal Interrupt Request to CPU

The setting of CMR bits in CMCSR for a DMA transfer request (this setting is only valid for channel 0) or the sending of an internal interrupt request (valid for all channels) to the CPU at a compare match.

When a DMA transfer request occurs, the request is continuously issued until the number of transfers set in the DMAC has been finished and output of the request is automatically halted on completion of the specified transfer count.

To clear the internal interrupt request to the CPU, the CMF bit should be set to B'0. Set the CMF bit to 0 in the handling routine for the CMT1 interrupt.

17.3.5 Operation of Channels 0 to 5 in power control mode

As CMCNT of channels 0 to 5 can be operated only by the RCLK(Pseudo32KHz), it continues the counter operation even when this LSI makes the transition to power control mode controlled by the SYSC and the core-area power supply is turned off after the necessary register settings have been made and B'1 has been written to the STRn (n = 5 to 0) bit in CMSTR.

- Register Access
  The counters for channels 0 to 5 are located in the sub-area because the counters have to be able to count-up even when this LSI is in power control mode controlled by the SYSC. The registers that are needed for the counter's operation are set from the core area. The following restrictions thus apply to the modification of the registers.

After the following registers have been modified, do not make the transition to power control mode controlled by the SYSC until you are sure that, according to the restrictions given below, the result of the modification has been reflected in the LSI's actual operation. Otherwise, the modification may not be reflected in an actual result.

- CMCSR: Bits CH0SSIE(ch0), CMS, CMM, CMTOUT_IE(ch1,2,3), CMR[1:0], DBGIVD, CKS[2:0]
- CMCOR: Bits 48 to 0
- CMSTR: Bit STR0RS, STRn (n = 5 to 0)
- CMCSRM: Bit CMPCLR, CMPSTART

Two RCLK cycles are necessary before this register is either read or any modification of the value it holds is reflected in the LSI's actual operation.

- CMCNT: Bits 48 to 0

Two RCLK cycles are necessary before this register is either read or any modification of the value it holds is reflected in the LSI's actual operation. Writing to this register, once started, is protected from further write operations until the writing operation has been completed.

- Cancellation of Various Standby Modes

  When an interrupt among channels 1 to 3 occurs while the system is in standby mode or power control mode controlled by the SYSC, various standby modes can be canceled if the CMTOUT_IE bit in CMCSR1 to CMCSR3 is set to B'1 and the CMR bits to B'10.

  Set the CMF bit in CMCSR1 to CMCSR3 to B'0 after various standby modes are canceled.

17.3.6 Compare Match Flag Set Timing

The CMF bit in CMCSR is set to 1 by the compare match signal generated when CMCOR and CMCNT match. The compare match signal is generated upon the final state of the match (timing at which the CMCNT value is updated to H'0). Consequently, after CMCOR and CMCNT match, a compare match signal will not be generated until a CMCNT counter clock is input. Figure 17.4 shows the set timing of the CMF bit.

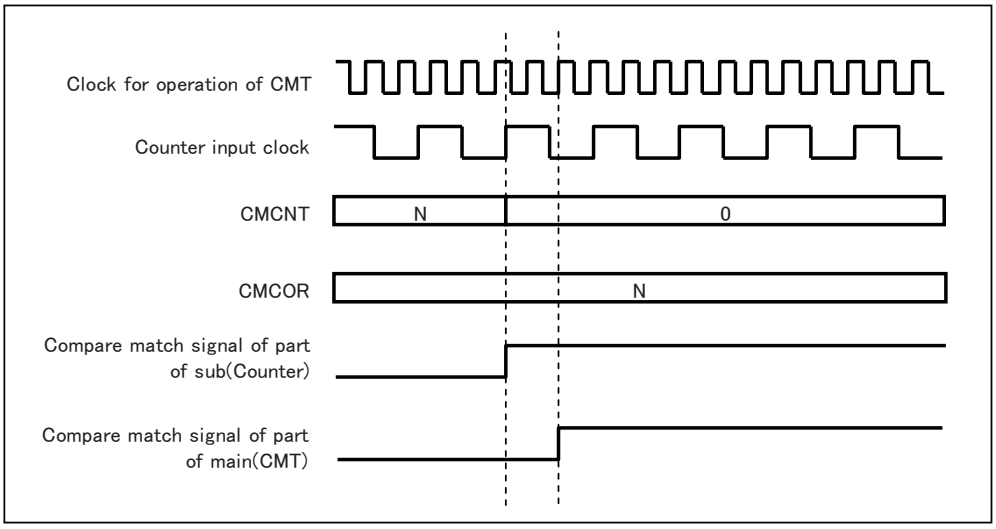

Figure 17.4 CMF Set Timing

17.3.7 RCLK-Synchronous Counter Start/Stop Mode in Channel 0

The CMT1 provides the RCLK-synchronous counter start/stop mode in channel 0, in which channels 0 and 3 can be used together for time measurement.

Figure 17.5 shows a flow chart for preparation.

Figure 17.6 shows a flow chart for starting measurement.

Figure 17.10 Calculation of Time Measured by Counters

Section 18 Compare Match Timer 2 (CMT2)

This LSI includes a 32-bit compare match timer (CMT2) of one channel.

18.1 Features

- One channel installed in the common domain
- 16 bits/32 bits can be selected.
- Provided with an auto-reload up counter.
- Provided with 32-bit constant registers and 32-bit up counters that can be written or read at any time.
- The CMT2 can perform counting even if this LSI is in power control mode controlled by the SYSC.
- Allows selection among four counter input clocks:
  - External clock (RCLK) input: 1/1, 1/8, 1/32, and 1/128
- One-shot operation and free-running operation are selectable.
- Allows selection of compare match or overflow for the interrupt source.
- Supports the cancel of the standby state in power control mode controlled by the SYSC.
- Module standby mode can be set.
- Allows selection of counter operation/stop during debugging with the debug mode operation selector.

Figure 18.1 shows a block diagram of the CMT2.

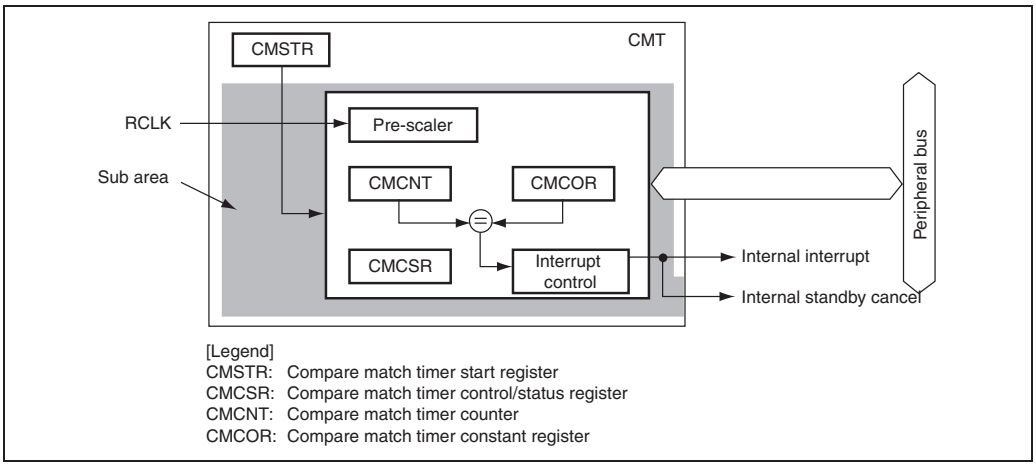

Figure 18.1 Block Diagram of CMT2

18.2 Register Descriptions

Table 18.1 shows the CMT2 register configuration. Table 18.2 shows the register states in each operating mode.

Table 18.1 Register Configuration

Register Name	Abbreviation	R/W	Address		Access Size
			Regular	Shadow	
Compare match timer start register	CM2STR	R/W	H'E613 0000	H'E713 0000	16

			H'E613 4048	H'E713 4048	

Note: * Accessing to H'E6130XXX, H'E7130XXX is off the subject of HPB semaphore.
Accessing to H'E6134XXX, H'E7134XXX is a subject of HPB semaphore.

Table 18.2 Register States in Each Operating Mode

Register Abbreviation	Reset *	Module Standby
CM2STR	Initialized	Retained
CM2CSR	Initialized	Retained
CM2CNT	Initialized	Retained
CM2COR	Initialized	Retained

Note: * For details, refer to section 1-D Overview of reset.

18.2.1 Compare Match Timer Start Register (CM2STR)

CM2STR is a 16-bit register that selects whether the compare match timer counter (CM2CNT) is operated or halted.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	STR5	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	STR5	1	R/W	Count Start Selects whether to operate or halt the compare match timer counter (CM2CNT). 0: Halts CM2CNT count. 1: Starts CM2CNT count.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

18.2.2 Compare Match Timer Control/Status Register (CM2CSR)

CM2CSR is a 16-bit register that indicates the occurrence of compare matches, enables interrupts, and sets the counter input clocks.

Do not change bits other than the CMF and OVF bits during the compare match timer counter (CM2CNT) operation.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMF	OVF	WR FLG	—	—	—	CMS	CMM	CMTOUT_IE	—	CMR[1:0]		DBG IVD	CKS[2:0]		
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	1	1	1	1
R/W:	R/(W)*	R/(W)*	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	CMF	0	R/(W)*	Compare Match Flag This flag indicates whether or not values of the compare match timer counter (CM2CNT) and compare match timer constant register (CM2COR) have matched. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CM2CNT and CM2COR values have not matched. [Clearing condition] • Write 0 to CMF 1: CM2CNT and CM2COR values have matched.
14	OVF	0	R/(W)*	Overflow Flag This flag indicates whether or not the compare match timer counter (CM2CNT) has overflowed and been cleared to 0. Software cannot write 1 to this bit. 0: CM2CNT has not overflowed. [Clearing condition] • Write 0 to OVF 1: CM2CNT has overflowed.

Bit	Bit Name	Initial Value	R/W	Description
13	WRFLG	0	R	Write State Flag CM2CNT cannot be written to when this bit is 1. This bit indicates the period that the writing to CM2CNT is masked for synchronization after the writing to CM2CNT. Confirm that this flag is 0 when CM2CNT is written to continuously.
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	CMS	0	R/W	Compare Match Timer Counter Size Selects whether the compare match timer counter (CM2CNT) is used as a 16-bit counter or a 32-bit counter. This setting becomes the valid size for the compare match timer constant register (CM2COR). 0: Operates as a 32-bit counter. 1: Operates as a 16-bit counter.
8	CMM	1	R/W	Compare Match Mode Selects one-shot operation or free-running operation of the counter. 0: One-shot operation 1: Free-running operation
7	CMTOUT_IE	0	R/W	Compare Match Standby Mode Cancel Enable Enables or disables the cancel of various standby modes. 0: The cancel of various standby modes by this CMT2 is disabled. 1: The cancel of various standby modes by this CMT2 is enabled.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	CMR[1:0]	00	R/W	Compare Match Request These bits enable or disable an internal interrupt request in a compare match. 00: Disables an internal interrupt request. 01: Setting prohibited 10: Enables an internal interrupt request. 11: Setting prohibited Note: When various standby modes are canceled by the CMT2, these bits should be set to B'10.
3	DBGIVD	1	R/W	Debug Mode Operation Select Sets the counter operation in debug mode. 0: Stops the counter operation in debug mode. 1: Enables the counter operation even in debug mode.
2 to 0	CKS[2:0]	111	R/W	Clock Select These bits select the clock input to CM2CNT. When the count start bit (STR5) in CM2STR is set to 1, CM2CNT begins incrementing with the clock selected by these bits. 000: Setting prohibited 001: Setting prohibited 010: Setting prohibited 011: Setting prohibited 100: RCLK/8 101: RCLK/32 110: RCLK/128 111: RCLK/1

Note: * Only 0 can be written to clear the flag.

18.2.3 Compare Match Timer Counter (CM2CNT)

CM2CNT is a 32-bit register that is used as an up-counter.

A counter operation is set by the compare match timer control/status register (CM2CSR). Therefore, set CM2CSR first, before starting a channel operation corresponding to the compare match timer start register (CM2STR). When the 16-bit counter operation is selected by the CMS bit, bits 15 to 0 of this register become valid. When the register should be written to, write the data that is added H'0000 to the upper half in a 32-bit operation. The contents of this register are initialized to H'00000000.

Counter operation of CMT2 is enabled even when the peripheral clock is stopped. Counter operation is also enabled in a state where the core-area power supply is turned off during power control mode controlled by the SYSC.

When CM2CNT is going to be read during the counter operation, the value that is read out may be wrong because of an asynchronous clock. Read several times with software and compare the read-out values.

18.2.4 Compare Match Timer Constant Register (CM2COR)

CM2COR is a 32-bit register that sets the compare match period with CM2CNT.

When the 16-bit counter operation is selected by the CMS bit in CM2CSR, bits 15 to 0 of this register become valid. When the register should be written to, write the data that is added H'0000 to the upper half in a 32-bit operation.

An overflow is detected when CM2CNT is cleared to 0 and this register is H'FFFFFFFF. The contents of this register are initialized to H'FFFFFFFF.

18.3 Operation

18.3.1 Counter Operation

The CMT2 starts the operation of the counter by writing B'1 to the STR5 bit in CM2STR after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than clearing flag bits during the compare match timer (CM2CNT) operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CM2CSR to B'0. When the value in CM2CNT matches the value in CM2COR, the value in CM2CNT is cleared to H'00000000 and the CMF bit in CM2CSR is set to B'1. Counting by CM2CNT stops after it has been cleared.

  To detect an overflow interrupt, set the value in CM2COR to H'FFFFFFFF. When the value in CM2CNT matches the value in CM2COR, CM2CNT is cleared to H'00000000 and the CMF and OVF bits in CM2CSR are set to B'1.

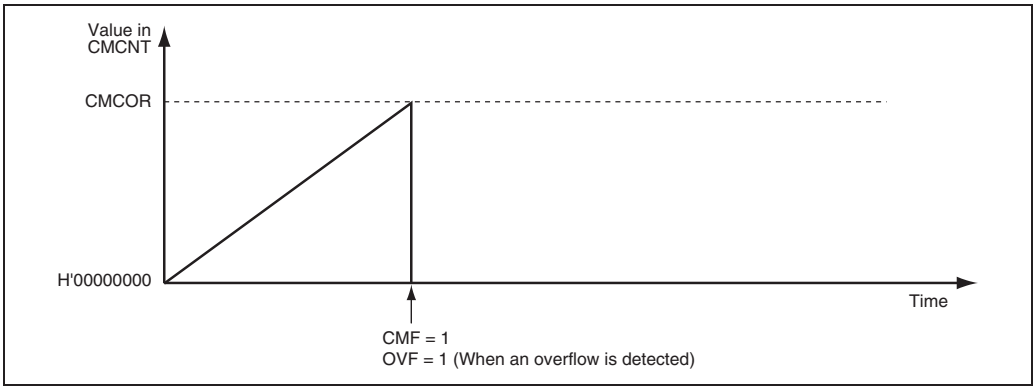

Figure 18.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CM2CSR to B'1. When the value in CM2CNT matches the value in CM2COR, CM2CNT is cleared to H'00000000 and the CMF bit in CM2CSR is set to B'1. CM2CNT resumes counting-up after it has been cleared.

To detect an overflow interrupt, set CM2COR to H'FFFFFFFF. When the values in CM2CNT and CM2COR match, CM2CNT is cleared to H'00000000 and the CMF and OVF bits in CM2CSR are set to B'1.

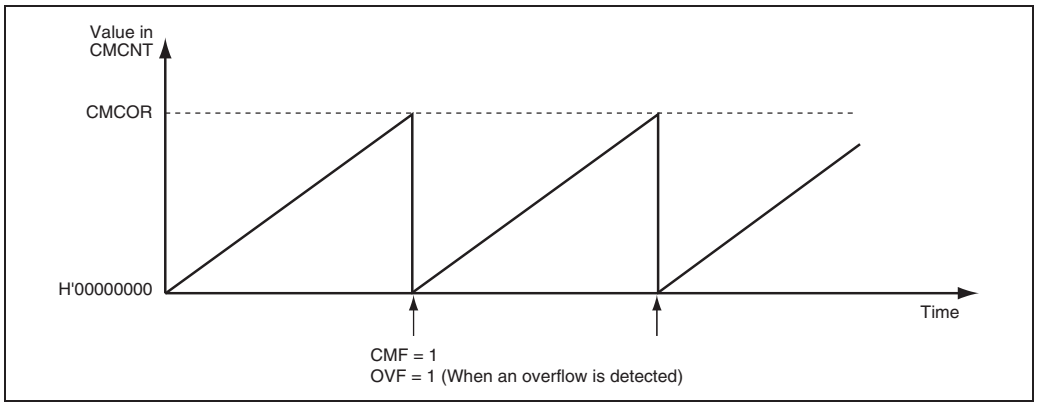

Figure 18.3 Counter Operation (Free-Running Operation)

18.3.2 Counter Size

In this module, the size of the counter is selectable as either 16 or 32 bits. This is selected by the CMS bit in CM2CSR.

When the 16-bit size is selected, use a 32-bit value which has H'0000 as its upper half to set CM2COR. To detect an overflow interrupt, CM2COR must be set to H'0000FFFF.

18.3.3 Timing for Counting by CM2CNT

In this module, the clock for the counter can be selected from among the following:

- External clock (RCLK): 1/1, 1/8, 1/32, and 1/128

The clock for the counter is selected by the CKS bits in CM2CSR. CM2CNT is incremented at the rising edge of the selected clock.

18.3.4 Internal Interrupt Request to CPU

The setting of the CMR bits in CM2CSR selects the sending of an internal interrupt request to the CPU at a compare match.

To clear the internal interrupt request to the CPU, the CMF bit should be set to B'0. Set the CMF bit to 0 in the handling routine for the CMT2 interrupt.

18.3.5 CMT2 Operation

As CM2CNT can be operated only by the RCLK, it continues the counter operation even when this LSI makes the transition to power control mode controlled by the SYSC and the core-area power supply is turned off after the necessary register settings have been made and B'1 has been written to the STR5 bit in CM2STR.

- Register Access

  The counter for the CMT2 is located in the sub area because the counter has to be able to count-up even when this LSI is in power control mode controlled by the SYSC. The registers that are needed for the counter's operation are set from the core area. The following restrictions thus apply to the modification of the registers.

After the following registers have been modified, do not make the transition to power control mode controlled by the SYSC until you are sure that, according to the restrictions given below, the result of the modification has been reflected in the LSI's actual operation. Otherwise, the modification may not be reflected in an actual result.

- CM2CSR: Bits CKS, CMM, CMS, and CMTOUT_IE
- CM2COR: Bits 31 to 0
- CM2STR: Bit STR5

Two RCLK cycles are necessary before this register is either read or any modification of the value it holds is reflected in the LSI's actual operation.

- CM2CNT: Bits 31 to 0

Two RCLK cycles are necessary before this register is either read or any modification of the value it holds is reflected in the LSI's actual operation. Writing to this register, once started, is protected from further write operations until the writing operation has been completed.

- Cancel of Various Standby Modes

  When an interrupt occurs while the system is in standby mode or power control mode controlled by the SYSC, various standby modes can be canceled if the CMTOUT_IE bit in CM2CSR is set to B'1 and the CMR bits to B'10.

  Set the CMF bit in CM2CSR to B'0 after various standby modes are canceled.

18.3.6 Compare Match Flag Set Timing

The CMF bit in CM2CSR is set to 1 by the compare match signal generated when CM2COR and CM2CNT match. The compare match signal is generated upon the final state of the match (timing at which the CM2CNT value is updated to H'0). Consequently, after CM2COR and CM2CNT match, a compare match signal will not be generated until a CM2CNT counter clock is input. Figure 18.4 shows the set timing of the CMF bit.

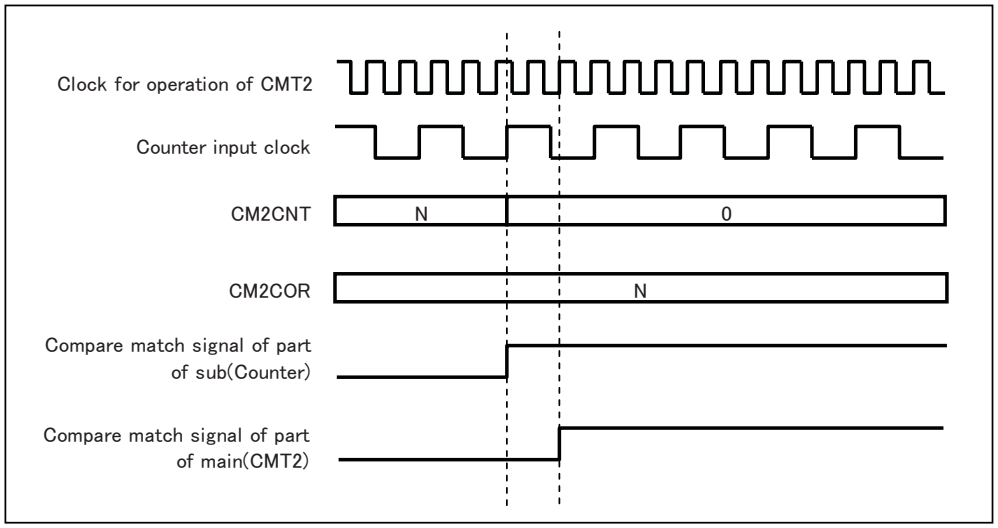

Figure 18.4 CMF Set Timing

Section 19 Compare Match Timer 3 (CMT3)

[Note: The CMT3 is reserved for use with TrustZone software. Do not use the CMT3 with other software.]

This LSI includes a 32-bit compare match timer (CMT3) of one channel.

19.1 Features

- One channel installed in the common domain
- 16 bits/32 bits can be selected.
- Provided with an auto-reload up-counter.
- Provided with 32-bit constant registers and 32-bit up-counters that can be written or read at any time.
- The CMT3 can perform counting even if this LSI is in power control mode controlled by the SYSC.
- Allows selection among four counter input clocks
  - External clock (RCLK) input: 1/1, 1/8, 1/32, and 1/128
- One-shot operation and free-running operation are selectable.
- Allows selection of compare match or overflow for the interrupt source.
- Module standby mode can be set.
- Counter operation ON/OFF function in debug mode.

Figure 19.1 shows a block diagram of the CMT3.

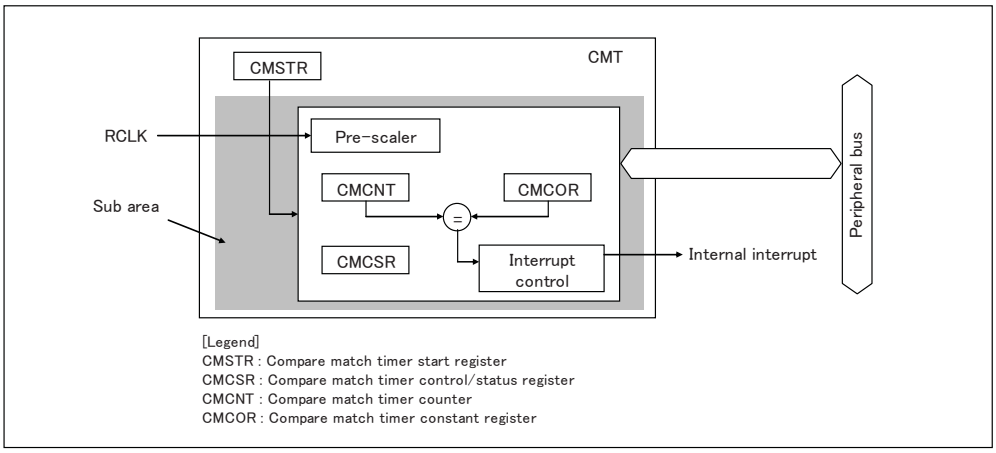

Figure 19.1 Block Diagram of CMT3

19.2 Register Descriptions

Table 19.1 shows the CMT3 register configuration. Table 19.2 shows the register states in each operating mode.

Table 19.1 Register Configuration

CM3CNT	Initialized	Retained
CM3COR	Initialized	Retained

Note: * For details, refer to section 1-D Overview of reset.

19.2.1 Compare Match Timer Start Register (CM3STR)

CM3STR is a 16-bit register that selects whether the compare match timer counter (CM3CNT) is operated or halted.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	STR5	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	STR5	1	R/W	Count Start Selects whether to operate or halt the compare match timer counter (CM3CNT). 0: Halts CM3CNT count. 1: Starts CM3CNT count.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

19.2.2 Compare Match Timer Control/Status Register (CM3CSR)

CM3CSR is a 16-bit register that indicates the occurrence of compare matches, enables interrupts, and sets the counter input clocks.

Do not change bits other than the CMF and OVF bits during the compare match timer counter (CM3CNT) operation.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMF	OVF	WRFLG	–	–	–	CMS	CMM	–	–	CMR[1:0]		DBG IVD	CKS[2:0]		
Initial Value:	0	0	0	0	0	0	0	1	0	0	0	0	1	1	1	1
R/W:	R/(W)*	R/(W)*	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	CMF	0	R/(W)*	Compare Match Flag This flag indicates whether or not the values of the compare match timer counter (CM3CNT) and the compare match timer constant register (CM3COR) have matched. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CM3CNT and CM3COR values have not matched. [Clearing condition] ● Write 0 to CMF 1: CM3CNT and CM3COR values have matched.
14	OVF	0	R/(W)*	Overflow Flag This flag indicates whether or not the compare match timer counter (CM3CNT) has overflowed and been cleared to 0. Software cannot write 1 to this bit. 0: CM3CNT has not overflowed. [Clearing condition] ● Write 0 to OVF 1: CM3CNT has overflowed.

Bit	Bit Name	Initial Value	R/W	Description
13	WRFLG	0	R	Write State Flag CM3CNT cannot be written to when this bit is 1. This bit indicates the period that the writing to CM3CNT is masked for synchornization after the writing to CM3CNT. Confirm that this flag is 0 when CM3CNT is written to continuously.
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	CMS	0	R/W	Compare Match Timer Counter Size This bit selects whether the compare match timer counter (CM3CNT) is used as a 16-bit counter or 32-bit counter. This register setting becomes the valid bit-size for the compare match timer constant register (CM3COR). 0: Operates as a 32-bit counter. 1: Operates as a 16-bit counter.
8	CMM	1	R/W	Compare Match Mode This bit selects one-shot operation or free-running operation of the counter. 0: One-shot operation 1: Free-running operation
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	CMR[1:0]	00	R/W	Compare Match Request These bits enable or disable an internal interrupt request at a compare match. 00: Disables an internal interrupt request. 01: Setting prohibited 10: Enables an internal interrupt request. 11: Setting prohibited These bits are backed up.
3	DBGIVD	1	R/W	Debug Mode Operation Select This bit sets counter operation when in debug mode. 0: Stops counter operation when in debug mode. 1: Enables counter operation even when in debug mode.
2 to 0	CKS[2:0]	111	R/W	Clock Select These bits select the clock input to CM3CNT. When the count start bit (STR5) in CM3STR is set to 1, CM3CNT begins incrementing with the clock selected by these bits. 000: Setting prohibited 001: Setting prohibited 010: Setting prohibited 011: Setting prohibited 100: RCLK/8 101: RCLK/32 110: RCLK/128 111: RCLK/1

Note: * Only 0 can be written, for flag clearing.

19.2.3 Compare Match Timer Counter (CM3CNT)

CM3CNT is a 32-bit register that is used as an up-counter.

A counter operation is set by the compare match timer control/status register (CM3CSR). Therefore, set CM3CSR first, before starting a channel operation corresponding to the compare match timer start register (CM3STR). When the 16-bit counter operation is selected by the CMS bit, bits 15 to 0 of this register become valid. When the register should be written to, write the data to which H'0000 has been added to the upper half in a 32-bit operation. The contents of this register are initialized to H'00000000.

Counter operation of the CMT3 is enabled even when the peripheral clock is stopped. Counter operation is also enabled in a state where the core-area power supply is turned off during power control mode controlled by the SYSC.

When CM3CNT is going to be read during the counter operation, the value that is read out may be wrong because of an asynchronous clock. Read several times with software and compare the readout values.

19.2.4 Compare Match Timer Constant Register (CM3COR)

CM3COR is a 32-bit register that sets the compare match period with the compare match timer counter (CM3CNT).

When the 16-bit counter operation is selected by the CMS bit in the compare match timer control/status register (CM3CSR), bits 15 to 0 of this register become valid. When the register should be written to, write the data to which H'0000 has been added to the upper half in a 32-bit operation.

An overflow is detected when CM3CNT is cleared to 0 and this register is set to H'FFFFFFFF. The contents of this register are initialized to H'FFFFFFFF.

19.3 Operation

19.3.1 Counter Operation

The CMT3 starts the operation of the counter by writing B'1 to the STR5 bit in CM3STR after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than by clearing flag bits during the compare match timer (CM3CNT) operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CM3CSR to B'0. When the value in CM3CNT matches the value in CM3COR, the value in CM3CNT is cleared to H'00000000, and the CMF bit in CM3CSR is set to B'1. Counting by CM3CNT stops after it has been cleared.

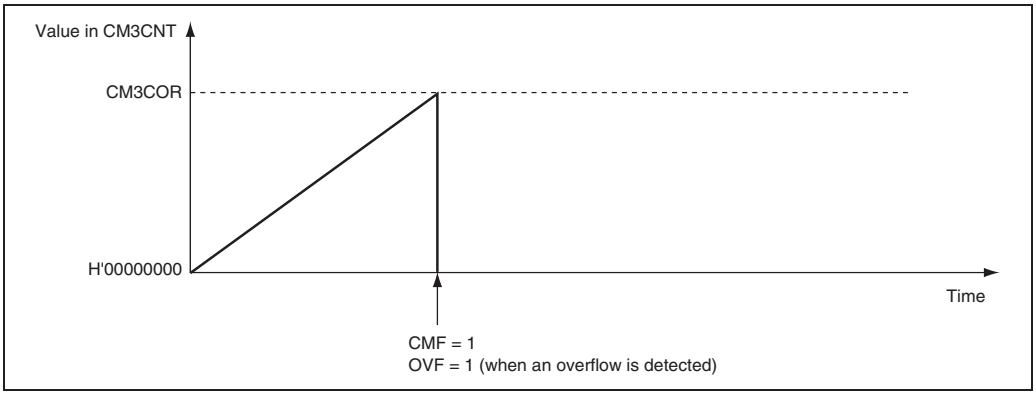

Figure 19.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CM3CSR to B'1. When the value in CM3CNT matches the value in CM3COR, CM3CNT is cleared to H'00000000 and the CMF bit in CM3CSR is set to B'1. CM3CNT resumes counting-up after it has been cleared.

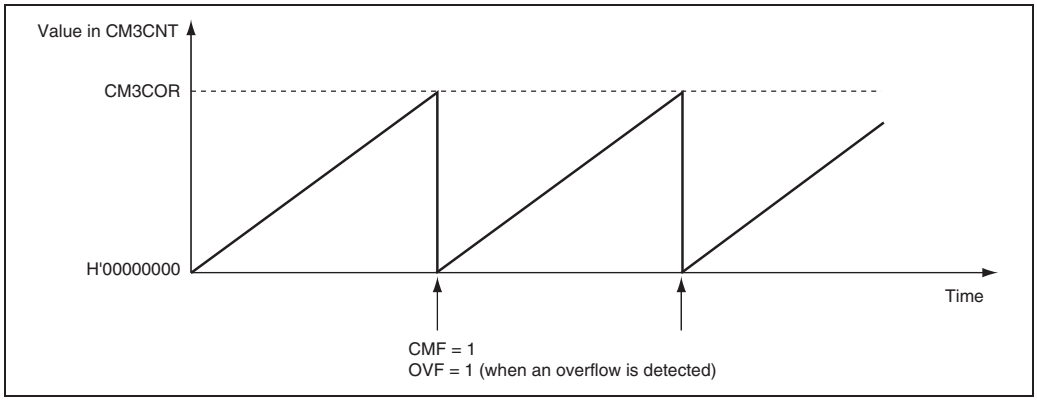

Figure 19.3 Counter Operation (Free-Running Operation)

19.3.2 Counter Size

In this module, the size of the counter is selectable as either 16 or 32 bits. This is selected by the CMS bit in CM3CSR.

When the 16-bit size is selected, use a 32-bit value which has H'0000 as its upper half to set CM3COR. To detect an overflow interrupt, CM3COR must be set to H'0000FFFF.

19.3.3 Timing for Counting by CM3CNT

In this module, the clock for the CM3CNT counter can be selected from among the following:

- External clock (RCLK): 1/1, 1/8, 1/32, and 1/128

The clock for the counter is selected by the CKS bits in CM3CSR. CM3CNT is incremented at the rising edge of the selected clock.

19.3.4 Internal Interrupt Request to CPU

The setting of the CMR bits in CM3CSR selects the sending of an internal interrupt request to the CPU at a compare match.

To clear an internal interrupt request to the CPU, the CMF bit should be set to B'0. Set the CMF bit to 0 in the handling routine for the CMT3 interrupt.

19.3.5 CMT3 Operation

As CM3CNT can be operated only by the RCLK, it continues the counter operation even when this LSI makes the transition to power control mode controlled by the SYSC and the core-area power supply is turned off after the necessary register settings have been made and B'1 has been written to the STR5 bit in CM3STR.

- Register Access

  The counter for the CMT3 is located in the sub-area because the counter has to be able to count-up even when this LSI is in power control mode controlled by the SYSC. The registers that are needed for the counter's operation are set from the core area. The following restrictions thus apply to the modification of registers.

After the following registers have been modified, do not make the transition to power control mode controlled by the SYSC until you are sure that, according to the restrictions given below, the result of the modification has been reflected in the LSI's actual operation. Otherwise, the modification may not be reflected in the register settings.

- CM3CSR: Bits CKS, CMM, and CMS
- CM3COR: Bits 31 to 0
- CM3STR: Bit STR5

These registers can be read immediately after being written to. However, two RCLK cycles are needed before the change is reflected.

- CM3CNT: Bits 31 to 0

After this register has been written to, two RCLK cycles are necessary before it can either be read or the value that it holds is reflected in the LSI's actual operation. Writing to this register, once started, is protected from further write operations until the writing operation has been completed.

19.3.6 Compare Match Flag Set Timing

The CMF bit in CM3CSR is set to 1 by the compare match signal generated when CM3COR and CM3CNT match. The compare match signal is generated upon the final state of the match (timing at which the CM3CNT value is updated to H'0). Consequently, after CM3COR and CM3CNT match, a compare match signal will not be generated until a CM3CNT counter clock is input. Figure 19.4 shows the set timing of the CMF bit.

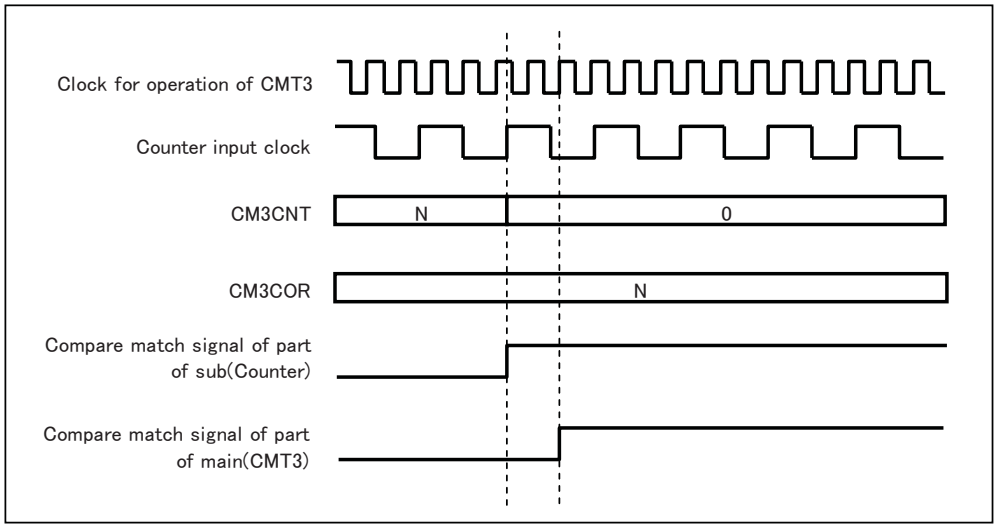

Figure 19.4 CMF Set Timing

Section 20 Compare Match Timer 4 (CMT4)

This LSI includes a 32-bit compare match timer (CMT4) of one channel.

20.1 Features

- One channel installed in the common domain
- 16 bits/32 bits can be selected.
- Provided with an auto-reload up counter.
- Provided with 32-bit constant registers and 32-bit up counters that can be written or read at any time.
- The CMT4 can perform counting even if this LSI is in power control mode controlled by the SYSC.
- Allows selection among four counter input clocks:
  — External clock (RCLK) input: 1/1, 1/8, 1/32, and 1/128
- One-shot operation and free-running operation are selectable.
- Allows selection of compare match or overflow for the interrupt source.
- Module standby mode can be set.
- Allows selection of counter operation/stop during debugging with the debug mode operation selector.

Figure 20.1 shows a block diagram of the CMT4.

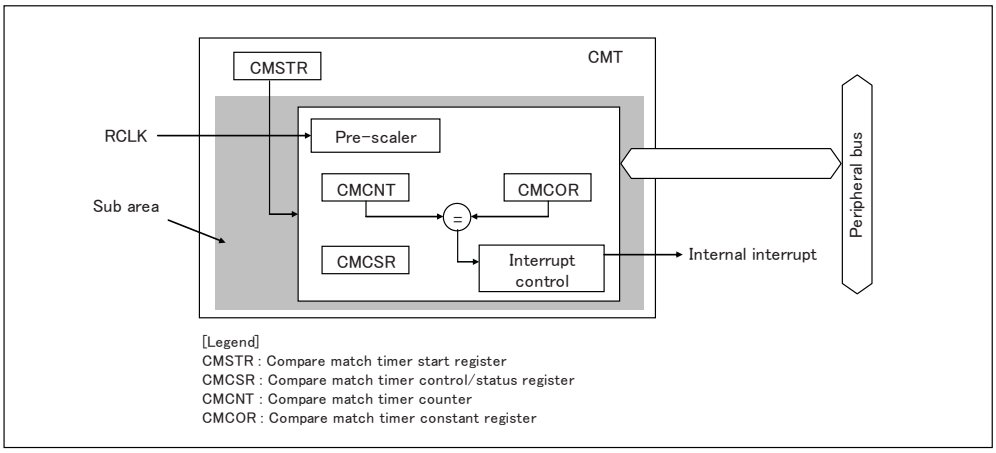

Figure 20.1 Block Diagram of CMT4

20.2 Register Descriptions

Table 20.1 shows the CMT4 register configuration. Table 20.2 shows the register states in each operating mode.

20.2.1 Compare Match Timer Start Register (CM4STR)

CM4STR is a 16-bit register that selects whether the compare match timer counter (CM4CNT) is operated or halted.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	STR5	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	STR5	1	R/W	Count Start Selects whether to operate or halt the compare match timer counter (CM4CNT). 0: Halts CM4CNT count. 1: Starts CM4CNT count.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

20.2.2 Compare Match Timer Control/Status Register (CM4CSR)

CM4CSR is a 16-bit register that indicates the occurrence of compare matches, enables interrupts, and sets the counter input clocks.

Do not change bits other than the CMF and OVF bits during the compare match timer counter (CM4CNT) operation.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMF	OVF	WRFLG	–	–	–	CMS	CMM	–	–	CMR[1:0]		DBG IVD	CKS[2:0]		
Initial Value:	0	0	0	0	0	0	0	1	0	0	0	0	1	1	1	1
R/W:	R/(W)*	R/(W)*	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	CMF	0	R/(W)*	Compare Match Flag This flag indicates whether or not values of the compare match timer counter (CM4CNT) and compare match timer constant register (CM4COR) have matched. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CM4CNT and CM4COR values have not matched. [Clearing condition] • Write 0 to CMF 1: CM4CNT and CM4COR values have matched.
14	OVF	0	R/(W)*	Overflow Flag This flag indicates whether or not the compare match timer counter (CM4CNT) has overflowed and been cleared to 0. Software cannot write 1 to this bit. 0: CM4CNT has not overflowed. [Clearing condition] • Write 0 to OVF 1: CM4CNT has overflowed.

Bit	Bit Name	Initial Value	R/W	Description
13	WRFLG	0	R	Write State Flag CM4CNT cannot be written to when this bit is 1. This bit indicates the period that the writing to CM4CNT is masked for synchronization after the writing to CM4CNT. Confirm that this flag is 0 when CM4CNT is written to continuously.
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	CMS	0	R/W	Compare Match Timer Counter Size Selects whether the compare match timer counter (CM4CNT) is used as a 16-bit counter or a 32-bit counter. This setting becomes the valid size for the compare match timer constant register (CM4COR). 0: Operates as a 32-bit counter. 1: Operates as a 16-bit counter.
8	CMM	1	R/W	Compare Match Mode Selects one-shot operation or free-running operation of the counter. 0: One-shot operation 1: Free-running operation
7, 6	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	CMR[1:0]	00	R/W	Compare Match Request These bits enable or disable an internal interrupt request in a compare match. 00: Disables an internal interrupt request. 01: Setting prohibited 10: Enables an internal interrupt request. 11: Setting prohibited
3	DBGIVD	1	R/W	Debug Mode Operation Select Sets the counter operation in debug mode. 0: Stops the counter operation in debug mode. 1: Enables the counter operation even in debug mode.
2 to 0	CKS[2:0]	111	R/W	Clock Select These bits select the clock input to CM4CNT. When the count start bit (STR5) in CM4STR is set to 1, CM4CNT begins incrementing with the clock selected by these bits. 000: Setting prohibited 001: Setting prohibited 010: Setting prohibited 011: Setting prohibited 100: RCLK/8 101: RCLK/32 110: RCLK/128 111: RCLK/1

Note: * Only 0 can be written to clear the flag.

20.2.3 Compare Match Timer Counter (CM4CNT)

CM4CNT is a 32-bit register that is used as an up-counter.

A counter operation is set by the compare match timer control/status register (CM4CSR). Therefore, set CM4CSR first, before starting a channel operation corresponding to the compare match timer start register (CM4STR). When the 16-bit counter operation is selected by the CMS bit, bits 15 to 0 of this register become valid. When the register should be written to, write the data that is added H'0000 to the upper half in a 32-bit operation. The contents of this register are initialized to H'00000000.

Counter operation of CMT4 is enabled even when the peripheral clock is stopped. Counter operation is also enabled in a state where the core-area power supply is turned off during power control mode controlled by the SYSC.

When CM4CNT is going to be read during the counter operation, the value that is read out may be wrong because of an asynchronous clock. Read several times with software and compare the read-out values.

20.2.4 Compare Match Timer Constant Register (CM4COR)

CM4COR is a 32-bit register that sets the compare match period with CM4CNT.

When the 16-bit counter operation is selected by the CMS bit in CM4CSR, bits 15 to 0 of this register become valid. When the register should be written to, write the data that is added H'0000 to the upper half in a 32-bit operation.

An overflow is detected when CM4CNT is cleared to 0 and this register is H'FFFFFFFF. The contents of this register are initialized to H'FFFFFFFF.

20.3 Operation

20.3.1 Counter Operation

The CMT4 starts the operation of the counter by writing B'1 to the STR5 bit in CM4STR after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than clearing flag bits during the compare match timer (CM4CNT) operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CM4CSR to B'0. When the value in CM4CNT matches the value in CM4COR, the value in CM4CNT is cleared to H'00000000 and the CMF bit in CM4CSR is set to B'1. Counting by CM4CNT stops after it has been cleared.

  To detect an overflow interrupt, set the value in CM4COR to H'FFFFFFFF. When the value in CM4CNT matches the value in CM4COR, CM4CNT is cleared to H'00000000 and the CMF and OVF bits in CM4CSR are set to B'1.

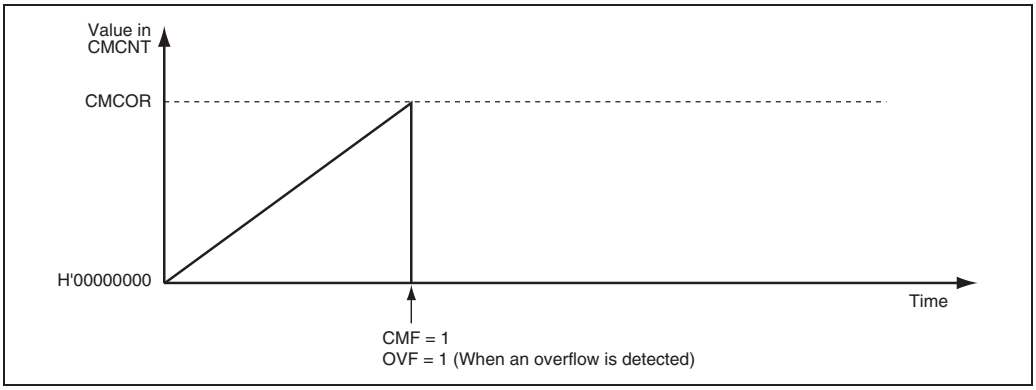

Figure 20.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CM4CSR to B'1. When the value in CM4CNT matches the value in CM4COR, CM4CNT is cleared to H'00000000 and the CMF bit in CM4CSR is set to B'1. CM4CNT resumes counting-up after it has been cleared.

To detect an overflow interrupt, set CM4COR to H'FFFFFFFF. When the values in CM4CNT and CM4COR match, CM4CNT is cleared to H'00000000 and the CMF and OVF bits in CM4CSR are set to B'1.

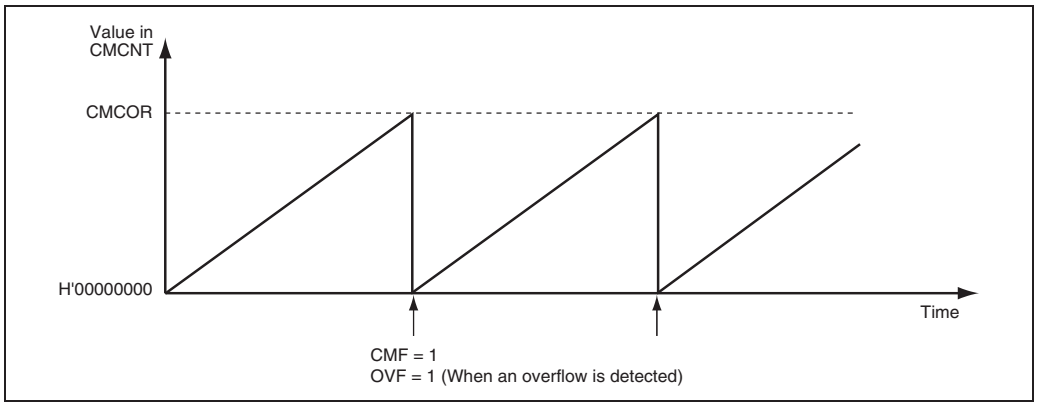

Figure 20.3 Counter Operation (Free-Running Operation)

20.3.2 Counter Size

In this module, the size of the counter is selectable as either 16 or 32 bits. This is selected by the CMS bit in CM4CSR.

When the 16-bit size is selected, use a 32-bit value which has H'0000 as its upper half to set CM4COR. To detect an overflow interrupt, CM4COR must be set to H'0000FFFF.

20.3.3 Timing for Counting by CM4CNT

In this module, the clock for the counter can be selected from among the following:

- External clock (RCLK): 1/1, 1/8, 1/32, and 1/128

The clock for the counter is selected by the CKS bits in CM4CSR. CM4CNT is incremented at the rising edge of the selected clock.

20.3.4 Internal Interrupt Request to CPU

The setting of the CMR bits in CM4CSR selects the sending of an internal interrupt request to the CPU at a compare match.

To clear the internal interrupt request to the CPU, the CMF bit should be set to B'0. Set the CMF bit to 0 in the handling routine for the CMT4 interrupt.

20.3.5 CMT4 Operation

As CM4CNT can be operated only by the RCLK, it continues the counter operation even when this LSI makes the transition to power control mode controlled by the SYSC and the core-area power supply is turned off after the necessary register settings have been made and B'1 has been written to the STR5 bit in CM4STR.

- Register Access

  The counter for the CMT4 is located in the sub area because the counter has to be able to count-up even when this LSI is in power control mode controlled by the SYSC. The registers that are needed for the counter's operation are set from the core area. The following restrictions thus apply to the modification of the registers.

After the following registers have been modified, do not make the transition to power control mode controlled by the SYSC until you are sure that, according to the restrictions given below, the result of the modification has been reflected in the LSI's actual operation. Otherwise, the modification may not be reflected in an actual result.

- CM4CSR: Bits CKS, CMM, and CMS
- CM4COR: Bits 31 to 0
- CM4STR: Bit STR5

Two RCLK cycles are necessary before this register is either read or any modification of the value it holds is reflected in the LSI's actual operation.

- CM4CNT: Bits 31 to 0

Two RCLK cycles are necessary before this register is either read or any modification of the value it holds is reflected in the LSI's actual operation. Writing to this register, once started, is protected from further write operations until the writing operation has been completed.

20.3.6 Compare Match Flag Set Timing

The CMF bit in CM4CSR is set to 1 by the compare match signal generated when CM4COR and CM4CNT match. The compare match signal is generated upon the final state of the match (timing at which the CM4CNT value is updated to H'0). Consequently, after CM4COR and CM4CNT match, a compare match signal will not be generated until a CM4CNT counter clock is input. Figure 20.4 shows the set timing of the CMF bit.

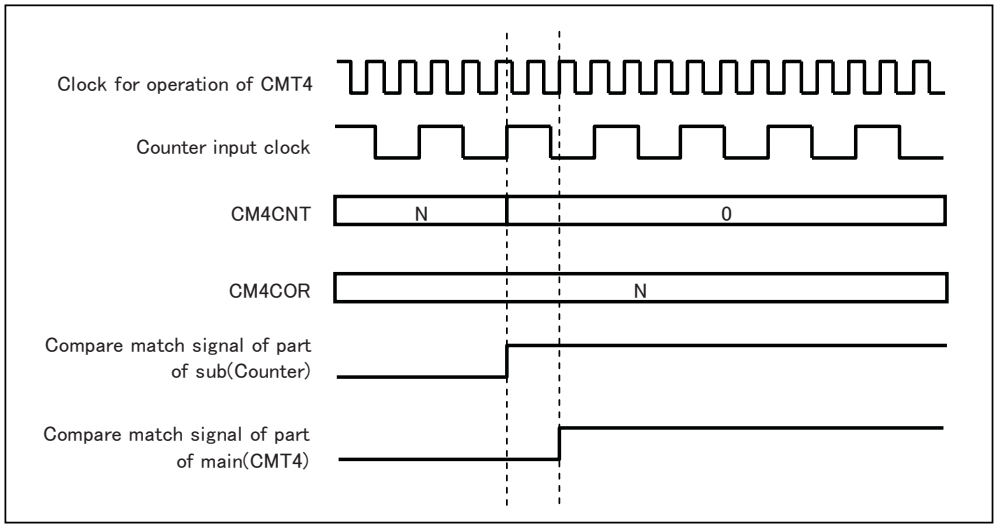

Figure 20.4 CMF Set Timing

Section 21 Serial Communications Interface with FIFO A (SCIFA)

This LSI has six serial communications interfaces incorporating FIFO buffers (Serial Communications Interface with FIFO A: SCIFA) that can perform both asynchronous and clocked synchronous serial communications.

Each interface includes two 64-stage buffers, one for the transmit FIFO register and one for the receive FIFO register, enabling fast, efficient, and continuous communications.

21.1 Features

- Six channels installed in the system domain
- Asynchronous mode

  Serial data communications is executed using an asynchronous system in which synchronization is achieved character by character. Serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA).

  There is a choice of 8 serial data communication formats.

  — Data length: 7 or 8 bits
  — Stop bit length: 1 or 2 bits
  — Parity: Even/odd/none
  — LSB-first transfer
  — Receive error detection: Parity, framing, and overrun errors
  — Break detection: If a framing error is following by at least one frame at the space "0" (low level), a break is detected.
- Clocked synchronous mode

  Serial data communications is synchronized with a clock. Serial data communications can be carried out with other LSIs that have a clocked synchronous communications function.

  — Data length: 8 bits
  — Receive error detection: Overrun errors
  — A rising or falling edge of a clock is selectable as the data transmit/receive timing.
- On-chip baud rate generator allows any bit rate to be selected.
- Serial clock source: Internal clock signal generated by the baud-rate generator.

- Seven interrupt sources

  There are seven interrupt sources—transmit-data-stop, transmit-FIFO-data-empty, receive-FIFO-data-full, receive-error (framing/parity error), break-receive, and receive-data-ready interrupts. The vectors of each interrupt source are the same.
- The DMA controller (DMAC) can be activated to execute a data transfer in the event of a transmit-FIFO-data-empty, transmit-data-stop, or receive-FIFO-data-full interrupt. The DMAC requests of transmit-FIFO-data-empty and transmit-data-stop interrupts are the same.
- DMA multi-byte data transfer supported
- On-chip modem control functions (CTS_N and RTS_N)
- On-chip transmit-data-stop functions
- When not in use, SCIFA can be stopped by halting its clock supply to reduce power consumption.
- The amount of data in the transmit/receive FIFO registers, and the number of receive errors in the receive data in the receive FIFO register, can be ascertained.

Figure 21.1 shows a block diagram of SCIFA.

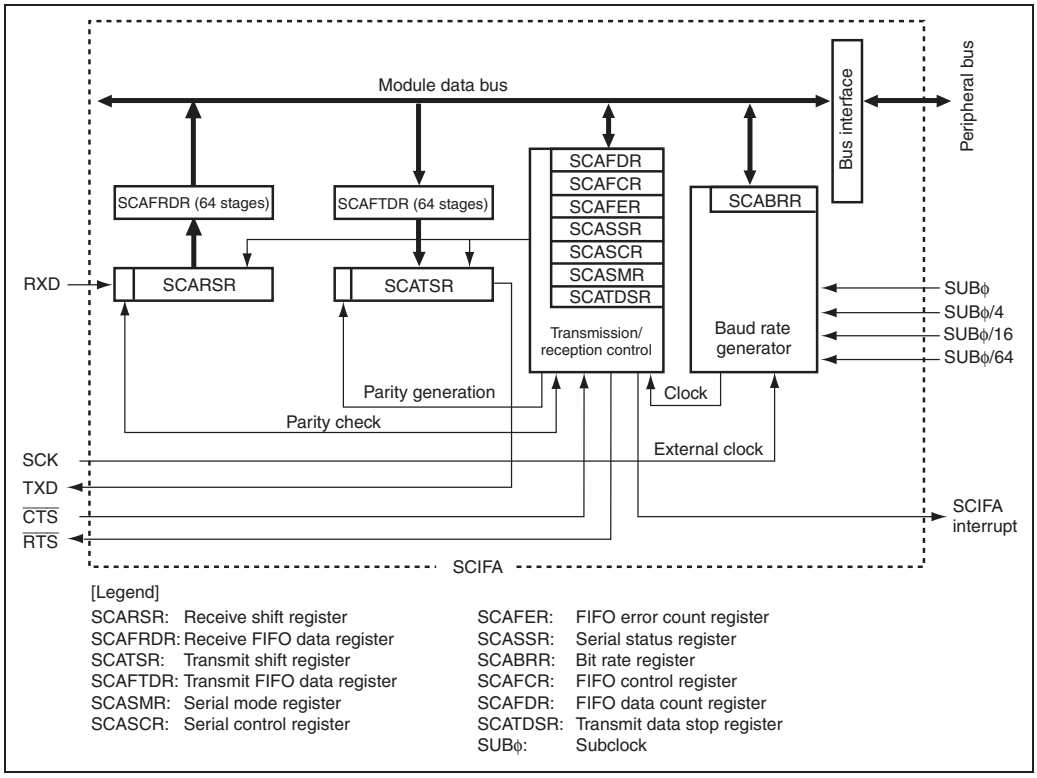

Figure 21.1 Block Diagram of SCIFA

21.2 Input/Output Pins

Table 21.1 shows the SCIFA pin configuration.

Table 21.1 Pin Configuration

Channel	Pin Name	I/O	Function
0	SCIFA0_SCK	Output	Clock output
	SCIFA0_RXD	Input	Receive data input
	SCIFA0_TXD	Output	Transmit data output
	SCIFA0_CTS_N	Input	Transmission enabled
	SCIFA0_RTS_N	Output	Transmit request
1	SCIFA1_SCK1	Output	Clock output
	SCIFA1_RXD1	Input	Receive data input
	SCIFA1_TXD1	Output	Transmit data output
	SCIFA1_CTS1_N	Input	Transmission enabled
	SCIFA1_RTS1_N	Output	Transmit request
2	SCIFA2_SCK1	Output	Clock output
	SCIFA2_RXD1	Input	Receive data input
	SCIFA2_TXD1	Output	Transmit data output
	SCIFA2_CTS1_N	Input	Transmission enabled
	SCIFA2_RTS1_N	Output	Transmit request

Channel	Pin Name	I/O	Function
3	SCIFA3_SCK	Output	Clock output
	SCIFA3_RXD	Input	Receive data input
	SCIFA3_TXD	Output	Transmit data output
	SCIFA3_CTS1_N	Input	Transmission enabled
	SCIFA3_CTS2_N		
	SCIFA3_RTS1_N	Output	Transmit request
	SCIFA3_RTS2_N		
4	SCIFA4_RXD	Input	Receive data input
	SCIFA4_TXD	Output	Transmit data output
5	SCIFA5_RXD	Input	Receive data input
	SCIFA5_TXD	Output	Transmit data output

Notes: The channel number is omitted, and SCK, RxD, TxD, CTS_N, and RTS_N are used as generic terms in the following descriptions.

21.3 Register Descriptions

Table 21.2 shows the SCIFA registers. Table 21.3 shows the register states in the respective processing modes.

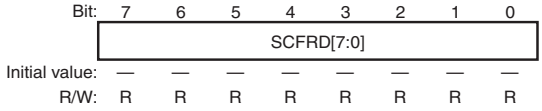
21.3.1 Receive Shift Register (SCARSR)

SCARSR is the register used to receive serial data.

SCIFA sets serial data input from the RxD pin in SCRASR in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is automatically transferred to SCAFRDR.

SCARSR cannot be directly read from or written to by the CPU.



21.3.2 Receive FIFO Data Register (SCAFRDR)

SCAFRDR is a 64-stage FIFO register that stores received serial data.

When SCIFA has received one byte of serial data, it transfers the received data from SCARSR to SCAFRDR where it is stored, and completes the receive operation. SCARSR is then enabled for reception, and consecutive receive operations can be performed until SCAFRDR is full (64-character data).

SCAFRDR is a read-only register, and cannot be written to by the CPU.

If a read is performed when there is no receive data in SCAFRDR, an undefined value will be returned. When SCAFRDR is full of receive data, subsequent serial data is lost.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFRD[7:0]	Undefined	R	Serial receive data FIFO

21.3.3 Transmit Shift Register (SCATSR)

SCATSR is the register used to transmit serial data.

To perform serial data transmission, SCIFA first transfers transmit data from SCAFTDR to SCATSR, then sends the data to the TxD pin starting with the LSB (bit 0).

When transmission of one byte is completed, the next transmit data is transferred from SCAFTDR to SCATSR, and transmission started automatically.

SCATSR cannot be directly read from or written to by the CPU.

21.3.4 Transmit FIFO Data Register (SCAFTDR)

SCAFTDR is an 8-bit 64-stage FIFO data register that stores data for serial transmission.

If SCATSR is empty when transmit data has been written to SCAFTDR, SCIFA transfers the transmit data written in SCAFTDR to SCATSR and starts serial transmission.

SCAFTDR is a write-only register, and cannot be read by the CPU.

The next data cannot be written when SCAFTDR is filled with 64 bytes of transmit data. Data written in this case is ignored.

Bit:	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFTD[7:0]	Undefined	W	Serial transmit data FIFO

21.3.5 Serial Mode Register (SCASMR)

SCASMR is a 16-bit readable/writable register used to set SCIFA's serial transfer format and select the baud rate generator clock source and the sampling rate.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
12	CKEDG	0	R/W	Transmit/Receive Clock Edge Select Selects the clock edge at which the serial data is output in clocked synchronous mode. 0: Serial data is transmitted at the falling edge of output clock. Serial data is received at the rising edge of output clock. 1: Serial data is transmitted at the rising edge of output clock. Serial data is received at the falling edge of output clock.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10 to 8	SRC[2:0]	000	R/W	Sampling Control These bits select the sampling rate. 000: Sampling rate 1/16 001: Sampling rate 1/5 010: Sampling rate 1/7 011: Sampling rate 1/11 100: Sampling rate 1/13 101: Sampling rate 1/17 110: Sampling rate 1/19 111: Sampling rate 1/27
7	C/$\overline{A}$	0	R/W	Communication Mode Selects asynchronous mode or clocked synchronous mode as the SCIFA operating mode. 0: Asynchronous mode 1: Clocked synchronous mode

Bit	Bit Name	Initial Value	R/W	Description
6	CHR	0	R/W	Character Length Selects 7 or 8 bits as the data length. 0: 8-bit data 1: 7-bit data* Note: * When the 7-bit character is selected, the MSB (bit 7) in SCAFTDR is not transmitted.
5	PE	0	R/W	Parity Enable Selects whether or not parity bit addition is performed in transmission, and parity bit checking in reception. 0: Parity bit addition and checking disabled 1: Parity bit addition and checking enabled* Note: * When the PE bit is set to 1, the parity (even or odd) specified by the O/E bit is added to transmit data before transmission. In reception, the parity bit is checked for the parity (even or odd) specified by the O/E bit.
4	O/E	0	R/W	Parity Mode Selects either even or odd parity for use in parity addition and checking. The O/E bit setting is only valid when the PE bit is set to 1, enabling parity bit addition and checking. The O/E bit setting is invalid when parity addition and checking is disabled. 0: Even parity*[1] 1: Odd parity*[2] Notes: 1. When even parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is even. 2. When odd parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is odd.

Bit	Bit Name	Initial Value	R/W	Description
3	STOP	0	R/W	Stop Bit Length Selects 1 or 2 bits as the stop bit length. In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit; if it is 0, it is treated as the start bit of the next transmit character. 0: 1 stop bit*[1] 1: 2 stop bits*[2] Notes: 1. In transmission, a single logic-1 bit (stop bit) is added to the end of a transmit character before it is sent. 2. In transmission, two logic-1 bits (stop bits) are added to the end of a transmit character before it is sent.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	CKS[1:0]	00	R/W	Clock Select These bits select the clock sources for the on-chip baud rate generator. 00: SUBϕ 01: SUBϕ/4 10: SUBϕ/16 11: SUBϕ/64 Note: SUBϕ: Subclock

21.3.6 Serial Control Register (SCASCR)

SCASCR is a 16-bit readable/writable register that performs enabling or disabling of SCIFA transfer operations and interrupt requests, and selection of the serial clock source.

ビット:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TDRQE	RDRQE	–	TENDE	TSIE	ERIE	BRIE	DRIE	TIE	RIE	TE	RE	–	–	–	CKE0
初期値:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	TDRQE	0	R/W	Transmit Data Transfer Request Enable Switches the transmit FIFO empty interrupt or DMA transfer request when TIE = 1 and the transmit FIFO empty occurs. 0: Interrupt request to CPU is issued 1: Transmit data transfer request to DMAC is issued
14	RDRQE	0	R/W	Receive Data Transfer Request Enable Switches the receive FIFO-data-full interrupt or DMA transfer request when RIE = 1 and the receive FIFO-data-full occurs. 0: Interrupt request to CPU is issued 1: Receive data transfer request to DMAC is issued
13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	TENDE	0	R/W	Transmit End interrupt enable Enables or disables generation of a transmit-end interrupt when the TEND flag in SCASSR is set to 1. 0: Transmit-end interrupt disabled* 1: Transmit-end interrupt enabled
11	TSIE	0	R/W	Transmit Data Stop Interrupt Enable Enables or disables generation of a transmit-data-stop interrupt when the TSE bit in SCAFCR is enabled and the TSF flag in SCASSR is set to 1. 0: Transmit-data-stop interrupt disabled* 1: Transmit-data-stop interrupt enabled

Note: * The TDI interrupt request is cleared by clearing the TSF flag to 0 after reading 1 from it or clearing the TSIE bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
10	ERIE	0	R/W	Receive Error Interrupt Enable Enables or disables generation of a receive-error (framing or parity error) interrupt when the ER flag in SCASSR is set to 1. 0: Receive-error interrupt disabled* 1: Receive-error interrupt enabled Note: * The ERI interrupt request is cleared by clearing the ER flag to 0 after reading 1 from it or clearing the ERIE bit to 0.
9	BRIE	0	R/W	Break Interrupt Enable Enables or disables generation of a break-receive interrupt when the BRK flag in SCASSR is set to 1. 0: Break-receive interrupt disabled* 1: Break-receive interrupt enabled Note: * The BRI interrupt request is cleared by clearing the BRK flag to 0 after reading 1 from it or clearing the BRIE bit to 0.
8	DRIE	0	R/W	Receive Data Ready Interrupt Enable Enables or disables generation of a receive-data-ready interrupt when the DR flag in SCASSR is set to 1. 0: Receive-data-ready interrupt disabled* 1: Receive-data-ready interrupt enabled Note: * The DRI interrupt request is cleared by clearing the DR flag to 0 after reading 1 from it or clearing the DRIE bit to 0.
7	TIE	0	R/W	Transmit Interrupt Enable Enables or disables generation of a transmit-FIFO-data-empty interrupt request when the TDFE flag in SCASSR is set to 1. 0: Transmit-FIFO-data-empty interrupt request disabled* 1: Transmit-FIFO-data-empty interrupt request enabled Note: * Interrupt requests can be cleared by writing transmit data exceeding the transmit trigger set number to SCAFTDR, reading 1 from the TDFE flag, then clearing it to 0, or by clearing the TIE bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
6	RIE	0	R/W	Receive Interrupt Enable Enables or disables generation of a receive-FIFO-data-full interrupt request when the RDF flag in SCASSR is set to 1. 0: Receive-FIFO-data-full interrupt request disabled* 1: Receive-FIFO-data-full interrupt request enabled Note: * Interrupt requests can be cleared by reading 1 from the RDF flag, then clearing the flag to 0, or by clearing the RIE bit to 0.
5	TE	0	R/W	Transmit Enable Enables or disables the start of serial transmission by SCIFA. 0: Transmission disabled 1: Transmission enabled* Note: * SCASMR and SCAFCR settings must be made, the transmit format decided, and the transmit FIFO reset, before the TE bit is set to 1.
4	RE	0	R/W	Receive Enable Enables or disables the start of serial reception by SCIFA. 0: Reception disabled*[1] 1: Reception enabled*[2] Notes: 1. Clearing the RE bit to 0 does not affect the DR, ER, BRK, RDF, FER, PER, and ORER flags, which retain their state. 2. Serial mode register (SCASMR) and FIFO control register (SCAFCR) settings must be made, the receive format decided, and the receive FIFO reset, before the RE bit is set to 1.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	CKE0	0	R/W	Clock Enable Enables or disables the clock output from the SCK pin. The CKE0 bit must be set before determining the SCIFA operating mode with SCASMR. 0: SCK pin disabled SCK pin state is Hi-Z. 1: Clock output from SCK* Note: * In clocked synchronous mode, outputs a clock with the same frequency as the bit rate.

21.3.7 FIFO Error Count Register (SCAFER)

SCAFER is a 16-bit read-only register that indicates the number of receive errors (framing errors and parity errors)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	PER[5:0]						—	—	FER[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 8	PER[5:0]	000000	R	Parity Error Count These bits indicate the number of data in which parity errors are generated, in receive data stored in SCAFRDR. After the ER bit in SCASSR is set, the value of bits PER5 to PER0 indicate the number of data in which parity errors are generated. When all 64 bytes of receive data in SCAFRDR have parity errors, these bits indicate 0.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	FER[5:0]	000000	R	Framing Error Count These bits indicate the number of data in which framing errors are generated, in receive data stored in SCAFRDR. After the ER bit in SCASSR is set, the value of bits FER5 to FER0 indicate the number of data in which framing errors are generated. When all 64 bytes of receive data in SCAFRDR have framing errors, these bits indicate 0.

21.3.8 Serial Status Register (SCASSR)

SCASSR is a 16-bit readable/writable register that indicates the SCIFA status.

However, 1 cannot be written to the ORER, TSF, ER, TDFE, BRK, RDF, and DR flags. Also note that in order to clear these flags to 0, they must be read as 1 beforehand. The TEND, FER, and PER flags are read-only flags and cannot be modified.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ORER	TSF	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/(W)*	R/(W)*	R/(W)*	R	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	ORER	0	R/(W)*	Overrun Error Indicates that an overrun error occurred during reception. This bit setting is valid only in asynchronous mode. 0: Reception in progress, or reception has ended normally*[1] [Clearing conditions] • Power-on reset or manual reset • When 0 is written to ORER after reading ORER = 1 1: An overrun error occurred during reception*[2] [Setting condition] • When serial reception is completed while receive FIFO is full Notes: 1. The ORER flag is not affected and retains its previous state when the RE bit in SCASCR is cleared to 0. 2. The receive data prior to the overrun error is retained in SCAFRDR, and the data received subsequently is lost. Serial reception cannot be continued while the ORER flag is set to 1.
8	TSF	0	R/(W)*	Transmit Data Stop Indicates that the number of transmit data matches the value of SCATDSR. This bit setting is valid only in asynchronous mode. 0: Number of transmit data does not match value of SCATDSR [Clearing conditions] • Power-on reset or manual reset • When 0 is written to TSF after reading TSF = 1 1: Number of transmit data matches value of SCATDSR

Bit	Bit Name	Initial Value	R/W	Description
7	ER	0	R/(W)*	Receive Error Indicates that a framing error or parity error occurred during reception.*[1] This bit setting is valid only in asynchronous mode. 0: No framing error or parity error occurred during reception [Clearing conditions] • Power-on reset or manual reset • When 0 is written to ER after reading ER = 1 1: A framing error or parity error occurred during reception [Setting conditions] • When SCIFA checks whether the stop bit at the end of the receive data is 1 when reception ends, and the stop bit is 0*[2] • When, in reception, the number of logic-1 bits in the receive data and in the parity bit does not match the parity setting (even or odd) specified by the O/E bit in SCASMR Notes: 1. The ER flag is not affected and retains its previous state when the RE bit in SCASCR is cleared to 0. When a receive error occurs, the receive data is still transferred to SCAFRDR, and reception continues. The FER and PER bits in SCASSR can be used to determine whether there is a receive error in the data read from SCAFRDR. 2. When the stop length is 2 bits, only the first stop bit is checked for a value of 1; the second stop bit is not checked.

Bit	Bit Name	Initial Value	R/W	Description
6	TEND	1	R	Transmit End Indicates that there is no valid data in SCAFTDR when the last bit of the transmit character is sent, and transmission has been ended. 0: Transmission is in progress [Clearing condition] • When data is written to SCAFTDR 1: Transmission has been ended [Setting condition] • When there is no transmit data in SCAFTDR on transmission of a 1-byte serial transmit character
5	TDFE	1	R/(W)*	Transmit FIFO Data Empty Indicates that data has been transferred from SCAFTDR to SCATSR, the number of data bytes in SCAFTDR has fallen to or below the transmit trigger data number set by bits TTRG1 and TTRG0 in SCAFCR, and new transmit data can be written to SCAFTDR. 0: A number of transmit data bytes exceeding the transmit trigger set number have been written to SCAFTDR [Clearing condition] • When transmit data exceeding the transmit trigger set number is written to SCAFTDR, and 0 is written to TDFE after reading TDFE = 1 1: The number of transmit data bytes in SCAFTDR does not exceed the transmit trigger set number [Setting conditions] • Power-on reset or manual reset • When the number of SCAFTDR transmit data bytes falls to or below the transmit trigger set number as the result of a transmit operation* Note: * As SCAFTDR is a 64-byte FIFO register, the maximum number of bytes that can be written when TDFE = 1 is 64 – (transmit trigger set number). Data written in excess of this will be ignored. The number of data bytes in SCAFTDR is indicated by SCAFDR.

Bit	Bit Name	Initial Value	R/W	Description
4	BRK	0	R/(W)*	Break Detect Indicates that a receive data break signal has been detected. This bit setting is valid only in asynchronous mode. 0: A break signal has not been received [Clearing conditions] • Power-on reset or manual reset • When 0 is written to BRK after reading BRK = 1 1: A break signal has been received* [Setting condition] • When data with a framing error is received, followed by the space 0 level (low level) for at least one frame length Note: * When a break is detected, the receive data (H'00) following detection is not transferred to SCAFRDR. When the break ends and the receive signal returns to mark 1, receive data transfer is resumed.
3	FER	0	R	Framing Error Indicates a framing error in the data read from SCAFRDR. This bit setting is valid only in asynchronous mode. 0: There is no framing error in the receive data read from SCAFRDR [Clearing conditions] • Power-on reset or manual reset • When there is no framing error in SCAFRDR read data 1: There is a framing error in the receive data read from SCAFRDR [Setting condition] • When there is a framing error in SCAFRDR read data

Bit	Bit Name	Initial Value	R/W	Description
2	PER	0	R	Parity Error Indicates a parity error in the data read from SCAFRDR. This bit setting is valid only in asynchronous mode. 0: There is no parity error in the receive data read from SCAFRDR [Clearing conditions] • Power-on reset or manual reset • When there is no parity error in SCAFRDR read data 1: There is a parity error in the receive data read from SCAFRDR [Setting condition] • When there is a parity error in SCAFRDR read data
1	RDF	0	R/(W)*	Receive FIFO Data Full Indicates that the received data has been transferred from SCARSR to SCAFRDR, and the number of receive data bytes in SCAFRDR is equal to or greater than the receive trigger number set by bits RTRG1 and RTRG0 in SCAFCR. 0: The number of receive data bytes in SCAFRDR is less than the receive trigger set number [Clearing conditions] • Power-on reset or manual reset • When SCAFRDR is read until the number of receive data bytes in SCAFRDR falls below the receive trigger set number, and 0 is written to RDF after reading RDF = 1 1: The number of receive data bytes in SCAFRDR is equal to or greater than the receive trigger set number [Setting condition] • When SCAFRDR contains at least the receive trigger set number of receive data bytes* Note: * SCAFRDR is a 64-byte FIFO register. When RDF = 1, at least the receive trigger set number of data bytes can be read. If data is read when SCAFRDR is empty, an undefined value will be returned. The number of receive data bytes in SCAFRDR is indicated by the lower bits of SCAFDR.

Bit	Bit Name	Initial Value	R/W	Description
0	DR	0	R/(W)*	Receive Data Ready Indicates that there are data bytes fewer than the receive trigger set number in SCAFRDR, and no further data will arrive at least 15 etu after the stop bit of the last data received. This bit setting is valid only in asynchronous mode. 0: Reception is in progress or has ended normally and there is no receive data left in SCAFRDR [Clearing conditions] (initial value) • Power-on reset or manual reset • When all the receive data in SCAFRDR has been read, and 0 is written to DR after reading DR = 1 1: No further receive data has arrived [Setting condition] • When SCAFRDR contains data bytes fewer than the receive trigger set number, and no further data will arrive at least 15 etu after the stop bit of the last data received* Note: * Corresponds to 1.5 frame time in 8-bit one-stop-bit format. etu: Elementary time unit (time for transfer of 1 bit)

Note: * Only 0 can be written for clearing the flags.

21.3.9 Bit Rate Register (SCABRR)

SCABRR is an 8-bit readable/writable register that sets the serial transfer bit rate in accordance with the baud rate generator operating clock selected by bits CKS1 and CKS0 in SCASMR.

Bit:	7	6	5	4	3	2	1	0
	SCBRD[7:0]							
Initial value:	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCBRD[7:0]	H'FF	R/W	Bit Rate

The SCABRR setting is found by using the following equations.

(1) Asynchronous Mode:

When the sampling rate is 1/16,

$$N = \frac{SUB\phi}{16 \times 2^{2n} \times B} \times 10^6 - 1$$

When the sampling rate is 1/5,

$$N = \frac{SUB\phi}{5 \times 2^{2n} \times B} \times 10^6 - 1$$

When the sampling rate is 1/11,

$$N = \frac{SUB\phi}{11 \times 2^{2n} \times B} \times 10^6 - 1$$

When the sampling rate is 1/13,

$$N = \frac{SUB\phi}{13 \times 2^{2n} \times B} \times 10^6 - 1$$

When the sampling rate is 1/27,

$$N = \frac{SUB\phi}{27 \times 2^{2n} \times B} \times 10^6 - 1$$

(2) Clocked Synchronous Mode:

$$N = \frac{SUB\phi}{2 \times 2^{2n-1} \times B} \times 10^6 - 1$$

Where B: Bit rate (bits/s)

N: SCABRR setting for baud rate generator

Asynchronous mode ($0 \leq N \leq 255$)

Clocked synchronous mode ($1 \leq N \leq 255$)

SUBϕ: Subclock frequency (MHz)

n: Baud rate generator input clock (n = 0 to 3)

(See the table below for the relation between n and the clock.)

Table 21.4 SCASMR Settings

		SCASMR Setting
n	**Clock**	**CKS[1:0]**
0	SUBϕ	00
1	SUBϕ/4	01
2	SUBϕ/16	10
3	SUBϕ/64	11

The bit rate error in asynchronous mode is found by using the following equations.

When the sampling rate is 1/16,

$$\text{Error (\%)} = \left(\frac{SUB\phi \times 10^6}{(N + 1) \times 16 \times 2^{2n} \times B} - 1 \right) \times 100$$

When the sampling rate is 1/5,

$$\text{Error (\%)} = \left(\frac{SUB\phi \times 10^6}{(N + 1) \times 5 \times 2^{2n} \times B} - 1 \right) \times 100$$

When the sampling rate is 1/11,

$$\text{Error (\%)} = \left(\frac{SUB\phi \times 10^6}{(N + 1) \times 11 \times 2^{2n} \times B} - 1 \right) \times 100$$

When the sampling rate is 1/13,

$$\text{Error (\%)} = \left(\frac{\text{SUB}\phi \times 10^6}{(\text{N} + 1) \times 13 \times 2^{2n} \times \text{B}} - 1 \right) \times 100$$

When the sampling rate is 1/27,

$$\text{Error (\%)} = \left(\frac{\text{SUB}\phi \times 10^6}{(\text{N} + 1) \times 27 \times 2^{2n} \times \text{B}} - 1 \right) \times 100$$

21.3.10 FIFO Control Register (SCAFCR)

SCAFCR is a 16-bit readable/writable register that clears all data and sets the trigger data number for the transmit and receive FIFO registers, and also contains a loopback test enable bit.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSE	TCRST	—	—	—	RSTRG[2:0]			RTRG[1:0]		TTRG[1:0]		MCE	TFRST	RFRST	LOOP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	TSE	0	R/W	Transmit Data Stop Enable Enables or disables the transmit data stop function. 0: Transmit data stop function disabled 1: Transmit data stop function enabled
14	TCRST	0	R/W	Transmit Count Reset Clears the transmit count to 0. This bit is valid only when the transmit data stop function is used. 0: Transmit count reset disabled* 1: Transmit count reset enabled (clearing to 0) Note: * Transmit count reset (clearing to 0) is performed at a power-on reset or module reset.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	RSTRG[2:0]	000	R/W	RTS_N Output Active Trigger The RTS_N signal becomes high when the number of receive data stored in SCAFRDR reaches the trigger number shown below. 000: 63 001: 1 010: 8 011: 16 100: 32 101: 48 110: 54 111: 60
7, 6	RTRG[1:0]	00	R/W	Receive FIFO Data Number Trigger Set the number of receive data bytes that sets the RDF flag in SCASSR. The RDF flag is set when the number of receive data bytes in SCAFRDR is equal to or greater than the trigger set number shown below. 00: 1 01: 16 10: 32 11: 48

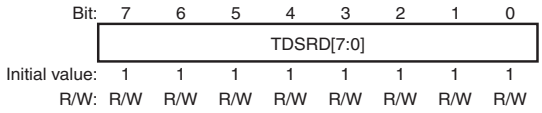
Bit	Bit Name	Initial Value	R/W	Description
5, 4	TTRG[1:0]	00	R/W	Transmit FIFO Data Number Trigger Set the number of remaining transmit data bytes that sets the TDFE flag in SCASSR. The TDFE flag is set when, as the result of a transmit operation, the number of transmit data bytes in SCAFTDR falls to or below the trigger set number shown below. 00: 32 (32) 01: 16 (49) 10: 2 (62) 11: 0 (64) Note: The values in parentheses are the number of empty bytes in SCAFTDR when the flag is set.
3	MCE	0	R/W	Modem Control Enable Enables the CTS_N and RTS_N modem control signals. 0: Modem signals disabled* 1: Modem signals enabled Note: * CTS_N is fixed at active-0 regardless of the input value, and RTS_N output is also fixed at 0. Note: The MCE bits of SCIFA4 and SCIFA5 are disabeled.
2	TFRST	0	R/W	Transmit FIFO Data Register Reset Invalidates the transmit data in SCAFTDR and resets it to the empty state. 0: Reset operation disabled* 1: Reset operation enabled Note: * A reset operation is performed at a power-on reset or manual reset.
1	RFRST	0	R/W	Receive FIFO Data Register Reset Invalidates the receive data in SCAFRDR and resets it to the empty state. 0: Reset operation disabled* 1: Reset operation enabled Note: * A reset operation is performed in the event of

a power-on reset or manual reset.

Bit	Bit Name	Initial Value	R/W	Description
0	LOOP	0	R/W	Loopback Test Internally connects the transmit output pin (TxD) to receive input pin (RxD) and RTS_N pin to CTS_N pin, enabling loopback testing. 0: Loopback test disabled 1: Loopback test enabled

21.3.11 FIFO Data Count Register (SCAFDR)

SCAFDR is a 16-bit read-only register that indicates the number of data bytes stored in SCAFTDR and SCAFRDR. The T6 to T0 bits show the number of transmit data bytes in SCAFTDR, and the R6 to R0 bits show the number of receive data bytes in SCAFRDR.



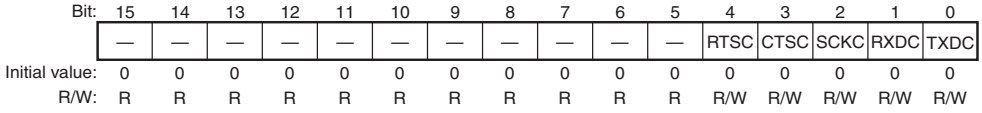
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	T[6:0]							—	R[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 8	T[6:0]	H'00	R	These bits show the number of untransmitted data bytes in SCAFTDR. A value of H'00 means that there is no transmit data, and a value of H'40 means that SCAFTDR is full of transmit data.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 0	R[6:0]	H'00	R	These bits show the number of receive data bytes in SCAFRDR. A value of H'00 means that there is no receive data, and a value of H'40 means that SCAFRDR is full of receive data.

21.3.12 Transmit Data Stop Register (SCATDSR)

SCATDSR is an 8-bit readable/writable register that sets the number of transmit data bytes. SCATDSR is valid only when the TSE bit in SCAFCR is enabled. Transmit operation is stopped when the number of data bytes set in SCATDSR is transmitted. The setting value should be H'00 (one byte) to H'FF (256 bytes).

SCATDSR is initialized to H'FF.



Bit	Bit Name	Initial Value	R/W	Description
7 to 0	TDSRD[7:0]	H'FF	R/W	Transmit Data Stop Setting

21.3.13 Serial Port Control Register (SCAPCR)

SCAPCR is a 16-bit readable/writable register. This register specifies whether the TXD, SCK and RTS_N pins function as output ports or the TXD, SCK and RTS_N pins, respectively. It also specifies whether the RXD and CTS_N pins function as input ports or the RXD and CTS_N pins, respectively.

SCAPCR is initialized to H'0000. This register function is valid only when the SCIFA pin function is selected through the pin function controller (PFC).

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	H'000	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	RTSC	0	R/W	Selects the RTS_N pin function. 0: The RTS_N pin functions as the RTS_N pin. 1: The RTS_N pin functions as an output port.
3	CTSC	0	R/W	Selects the CTS_N pin function. 0: The CTS_N pin functions as the CTS_N pin. 1: The CTS_N pin functions as an input port.
2	SCKC	0	R/W	Selects the SCK pin function. 0: The SCK pin functions as the SCK pin. 1: The SCK pin functions as an output port.
1	RXDC	0	R/W	Selects the RXD pin function. 0: The RXD pin functions as the RXD pin. 1: The RXD pin functions as an input port.
0	TXDC	0	R/W	Selects the TXD pin function. 0: The TXD pin functions as the TXD pin. 1: The TXD pin functions as an output port.

21.3.14 Serial Port Data Register (SCAPDR)

SCAPDR is a 16-bit readable/writable register. This register specifies data output to the TXD, SCK and RTS_N pins when the SCIFA pin function is selected by SCAPCR. It also specifies the pin level of the RXD and CTS_N pins.

SCAPCR is initialized to H'0000. This register function is valid only when the SCIFA pin function is selected through the pin function controller (PFC).

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	RTSD	CTSD	SCKD	RXDD	TXDD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	W	R	W	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	H'000	R	Reserved These bits are always read as 0. The write value should always be 0.
4	RTSD	0	W	Specifies data output to the RTS_N pin. 0: Outputs 0. 1: Outputs 1.
3	CTSD	Undefined	R	Specifies the CTS_N pin level. 0: CTS_N pin level is 0. 1: CTS_N pin level is 1.
2	SCKD	0	W	Specifies data output to the SCK pin. 0: Outputs 0. 1: Outputs 1.
1	RXDD	Undefined	R	Specifies the RXD pin level. 0: RXD pin level is 0. 1: RXD pin level is 1.
0	TXDD	0	R/W	Specifies data output to the TXD pin. 0: Outputs 0. 1: Outputs 1.

21.4 Operation

21.4.1 Overview

SCIFA supports serial communications in asynchronous mode, in which synchronization is achieved character by character, and in clocked synchronous mode, in which synchronization is achieved with clock pulses. 64-stage FIFO buffers are provided for both transmission and reception, reducing the CPU overhead and enabling continuous communications.

21.4.2 Asynchronous Mode

In the asynchronous mode, the transfer format is selected by the setting in SCASMR as shown in Table 21.5. Features in this mode are as follows.

- Data length: 7 or 8 bits
- The addition of parity (even, odd or none) and the choice of stop-bit length (1 or 2 bits), along with the data length, determine the transfer format and character length.
- Receive error detection: Framing, parity, and overrun errors, receive-FIFO-data-full, receive-data-ready, and breaks.
- Independent indications of the number of data stored in the registers of the transmit and receive FIFOs.
- Serial clock source: Internal clock signal generated by the baud-rate generator.

Table 21.5 SCASMR Settings for Serial Transfer Format Selection

SCASMR Settings					SCIFA Transfer Format		
Bit 7: C/$\overline{A}$	**Bit 6: CHR**	**Bit 5: PE**	**Bit 3: STOP**	**Mode**	**Data Length**	**Parity Bit**	**Stop Bit Length**
0	0	0	0	Asynchronous mode	8-bit data	No	1 bit
			1				2 bits
		1	0			Yes	1 bit
			1				2 bits
	1	0	0		7-bit data	No	1 bit
			1				2 bits
		1	0			Yes	1 bit
			1				2 bits
1	*	*	*	Clocked synchronous mode	8-bit data	No	No

Note: * Don't care.

21.4.3 Serial Operation in Asynchronous Mode

(1) Data Transfer Format

Table 21.6 shows the transfer formats that can be used in asynchronous mode. Any of eight transfer formats can be selected according to the SCASMR settings.

Table 21.6 Serial Transfer Formats

SCASMR Settings			Serial Transfer Format and Frame Length											
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	S	8-bit data								STOP		
		1	S	8-bit data								STOP	STOP	
	1	0	S	8-bit data								P	STOP	
		1	S	8-bit data								P	STOP	STOP
1	0	0	S	7-bit data							STOP			
		1	S	7-bit data							STOP	STOP		
	1	0	S	7-bit data							P	STOP		
		1	S	7-bit data							P	STOP	STOP	

[Legend]
S: Start bit
STOP: Stop bit
P: Parity bit

(2) Clock

An internal clock signal generated by the on-chip baud-rate generator provides the transfer clock for SCIFA.

(3) Data Transfer Operations:

1. SCIFA initialization

   Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCASCR to 0, then initialize SCIFA as described below.

   When the transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, SCATSR is initialized. Note that clearing the TE and RE bits to 0 does not change the contents of SCASSR, SCAFTDR, or SCAFRDR. The TE bit should be cleared to 0 after all transmit data has been sent and the TEND bit in SCASSR has been set to 1. Clearing to 0 can also be performed during transmission, but the data lines that transmit the data will go to the high-impedance state after the clearance. Before setting TE to 1 again to start transmission, the TFRST bit in SCAFCR should first be set to 1 to reset SCAFTDR.

Figure 21.2 shows a sample SCIFA initialization flowchart.

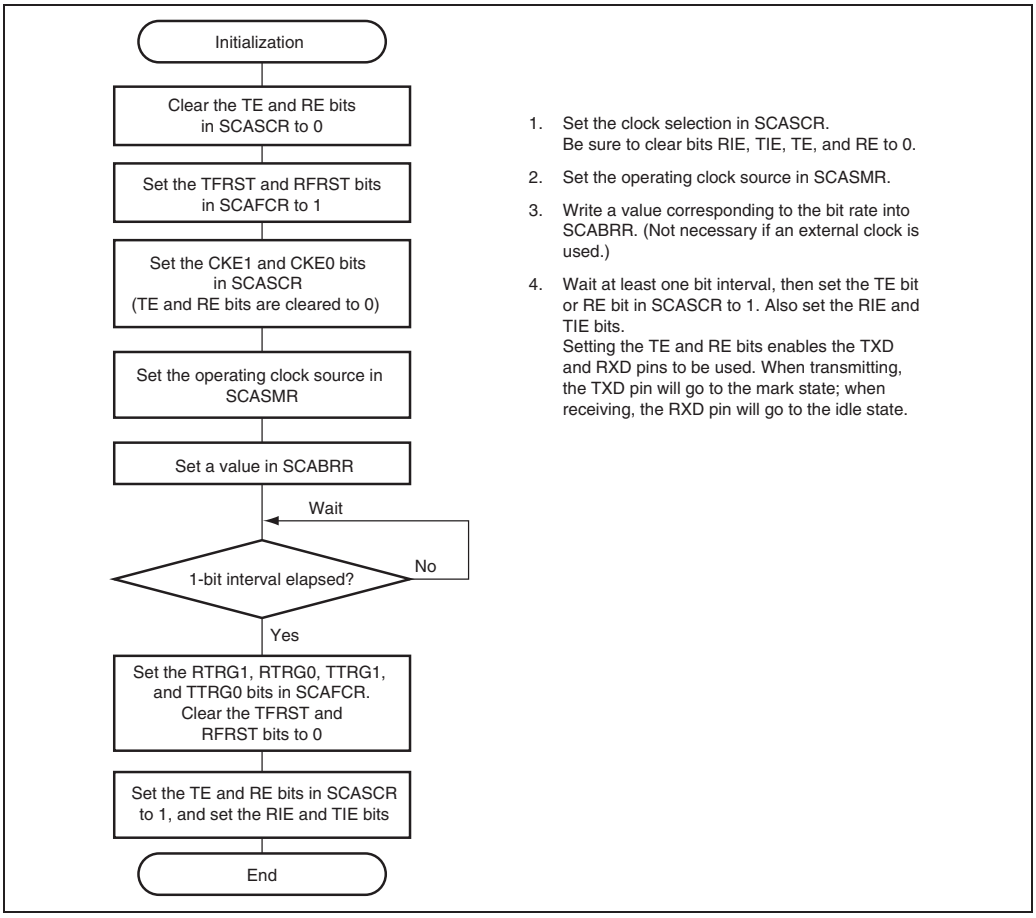


Figure 21.2 Sample SCIFA Initialization Flowchart

2. Serial data transmission

   Figure 21.3 shows a sample flowchart for serial transmission.

   Use the following procedure for serial data transmission after enabling SCIFA for transmission.

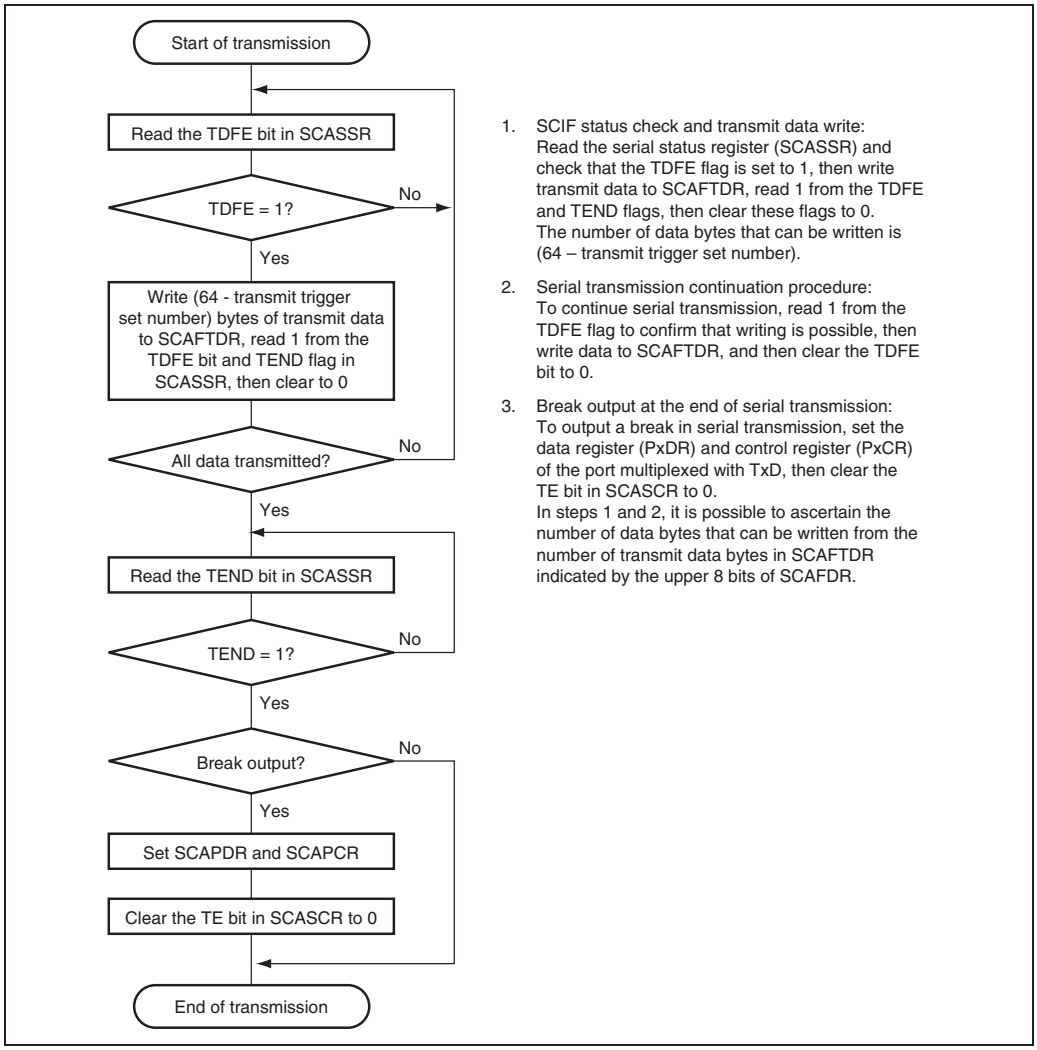

Figure 21.3 Sample Serial Transmission Flowchart

In serial transmission, SCIFA operates as described below.

A. When data is written into SCAFTDR, SCIFA transfers the data from SCAFTDR to SCATSR and starts transmitting. Confirm that the TDFE flag in SCASSR is set to 1 before writing transmit data to SCAFTDR. The number of data bytes that can be written is not less than (64 – transmit trigger set number).

B. When data is transferred from SCAFTDR to SCATSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCAFTDR. When the number of transmit data bytes in SCAFTDR falls to or below the transmit trigger number set in SCAFCR, the TDFE flag is set. If the TIE bit in SCASCR is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

   When the transmit data stop function is used and the number of data bytes set in SCATDSR is matched, transmit operation is stopped, and the TSF flag in SCASSR is set. If the TSIE bit in SCASCR is set to 1, a transmit-data-stop-interrupt (TDI) request is generated. The vectors of TXI and TDI are the same.

   The serial transmit data is sent from the TxD pin in the following order.

   a. Start bit: One logic-0 bit is output.
   b. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
   c. Parity bit: One parity bit (even or odd parity) is output.
   d. A format in which a parity bit is not output can also be selected.
   e. Stop bit(s): One or two logic-1 bits (stop bits) are output.
   f. Mark state: Output of 1 is continued until the start bit is sent to start the next transmission.

C. SCIFA checks the SCAFTDR transmit data at the timing for sending the stop bit. If data is present, the data is transferred from SCAFTDR to SCATSR, the stop bit is sent, and then serial transmission of the next frame is started.

   If there is no transmit data, the TEND flag in SCASSR is set to 1, the stop bit is sent, and then the line goes to the mark state in which 1 is output.

Figure 21.4 shows an example of the operation for transmission in asynchronous mode.

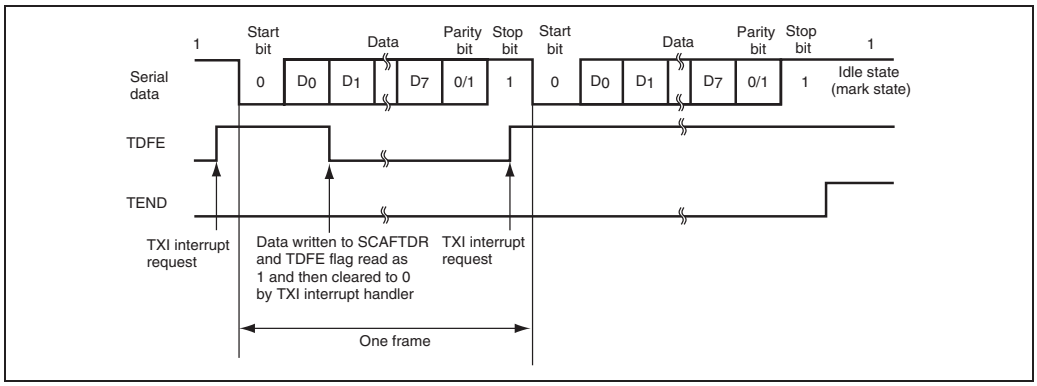

Figure 21.4 Example of Transmit Operation (Example with 8-Bit Data, Parity, One Stop Bit)

- Transmit data stop function
  When (value in SCATDSR + 1) is matched with the number of transmitted data bytes, this function stops the transmit operation. Interrupts can be generated and the DMAC can be activated by setting the TSIE bit (interrupt enable bit) to 1.

Figure 21.5 shows an example of operation for the transmit data stop function.

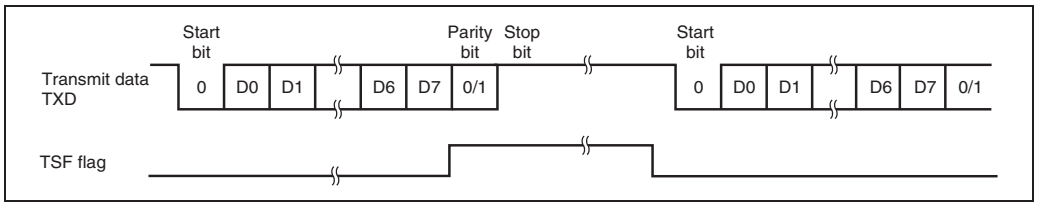

Figure 21.5 Example of Transmit Data Stop Function

Figure 21.6 shows a flowchart for the transmit data stop function.

Before using the transmit data stop function, set the TCRST bit in SCAFCR to 1 to clear the transmit counter. After modifying SCASSR, always confirm that data has been updated.

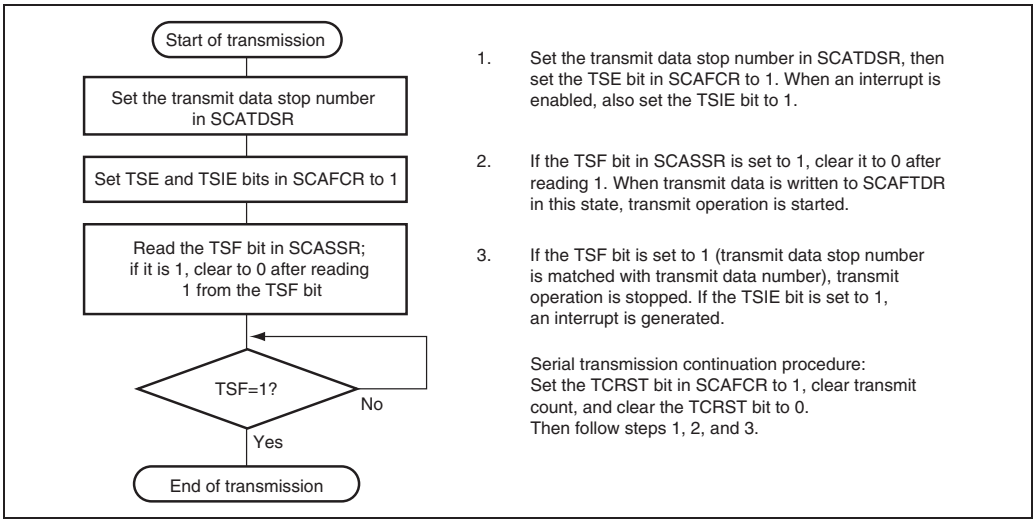

Figure 21.6 Transmit Data Stop Function Flowchart

3. Serial data reception

Figures 19.7 and 19.8 show sample flowcharts for serial reception.

Use the following procedure for serial data reception after enabling SCIFA for reception.

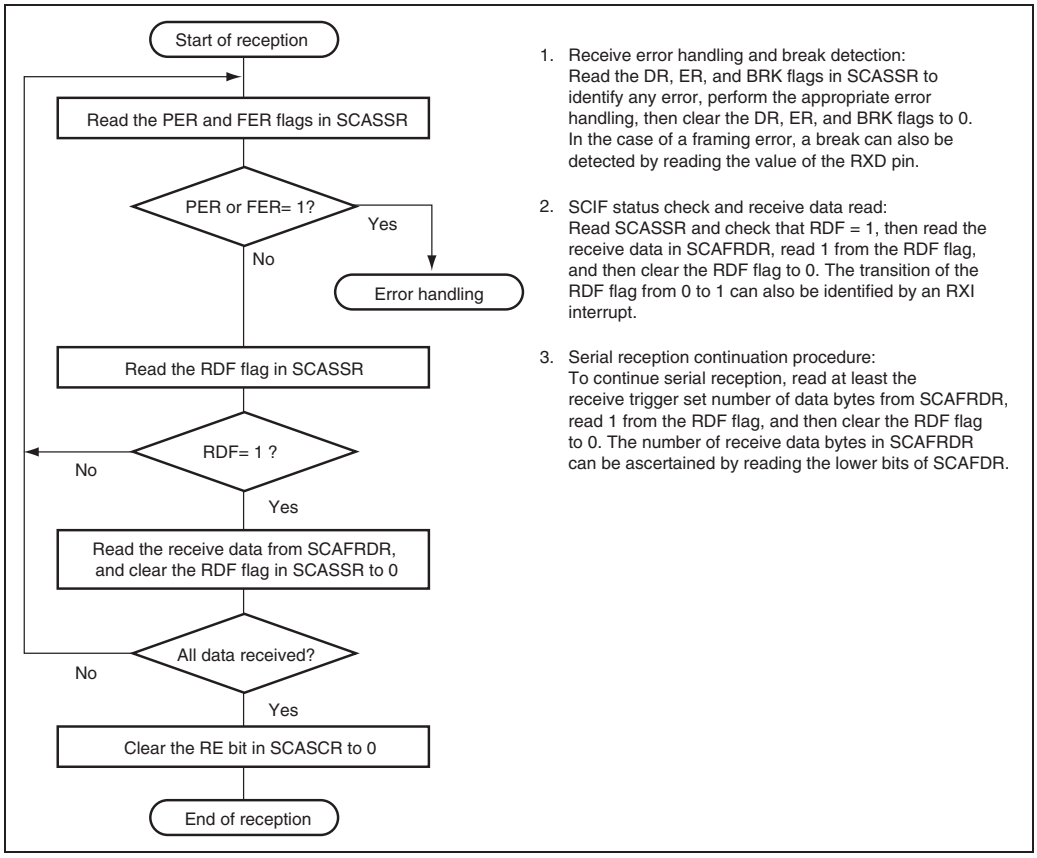

Figure 21.7 Sample Serial Reception Flowchart (1)

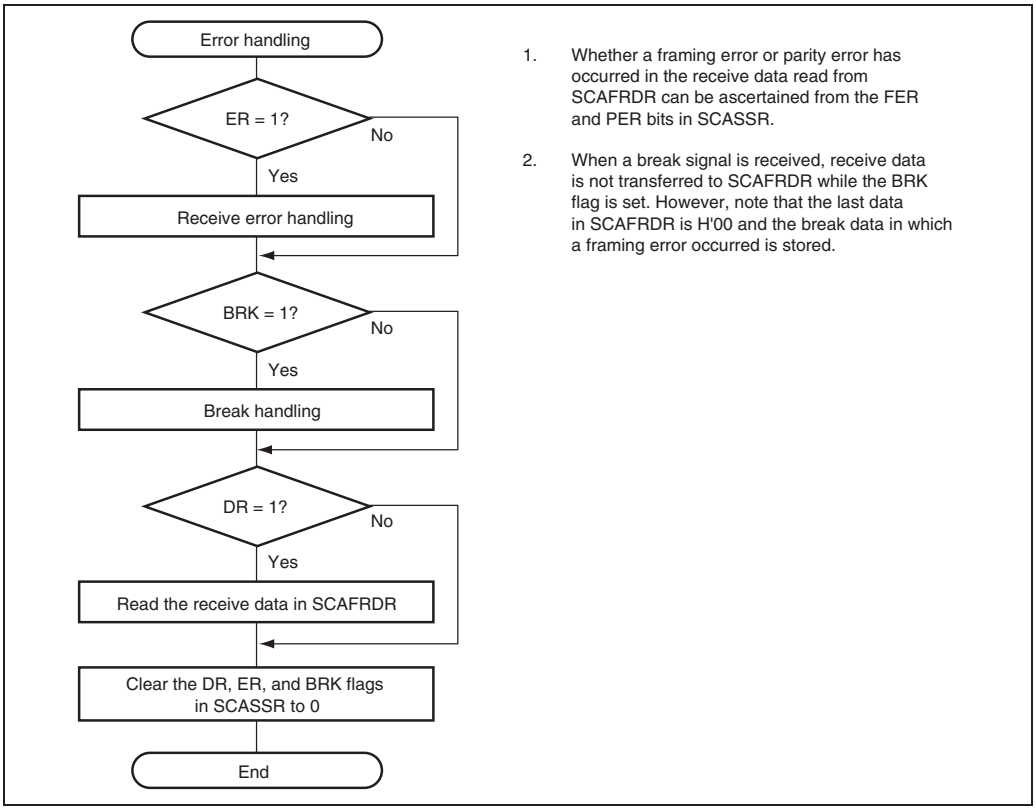

Figure 21.8 Sample Serial Reception Flowchart (2)

In serial reception, SCIFA operates as described below.

A. SCIFA monitors the communication line, and if a 0 start bit is detected, performs internal synchronization and starts reception.

B. The received data is stored in SCARSR in LSB-to-MSB order.

C. The parity bit and stop bit are received.

After receiving these bits, SCIFA carries out the following checks.

a. Stop bit check: SCIFA checks to see if the value in the stop bit position is 1. If the two-stop-bit setting has been made, only the value in the first stop-bit position is checked.

b. SCIFA checks whether received data can be transferred from SCARSR to SCAFRDR.

c. Break check: SCIFA checks to confirm that the BRK flag is 0, indicating that the break state has not been set.

If all the above checks are passed, the receive data is stored in SCAFRDR.

Note: Reception continues when a receive error (a framing error or parity error) occurs.

D. If the RIE bit in SCASCR is set to 1 when the RDF flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.

If the ERIE bit in SCASCR is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated.

If the BRIE bit in SCASCR is set to 1 when the BRK flag changes to 1, a break reception interrupt (BRI) request is generated.

If the DRIE bit in SCASCR is set to 1 when the DR flag changes to 1, a receive-data-ready interrupt (DRI) request is generated.

The vectors of each interrupt source are the same.

Figure 21.9 shows an example of the operation for reception in asynchronous mode.

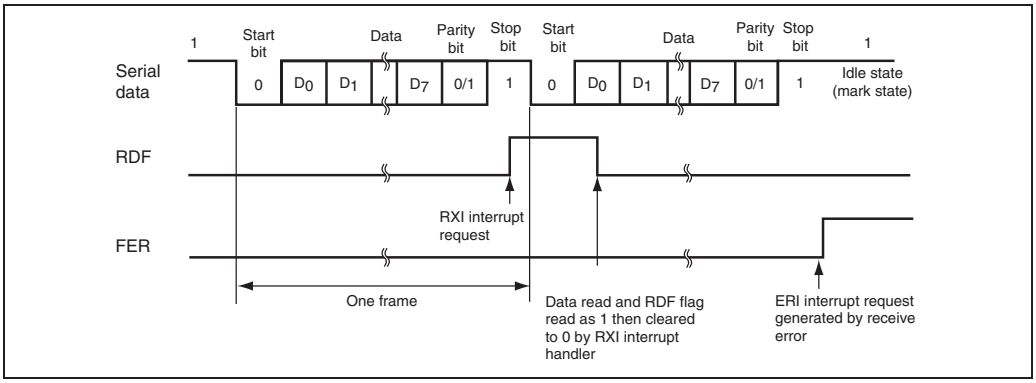

Figure 21.9 Example of SCIFA Receive Operation (Example with 8-Bit Data, Parity, One Stop Bit)

SCIFA has a modem function that allows the stoppage and resumption of transmission according to the input value of CTS_N. Setting CTS_N to 1places the transmission line in the mark state after transmission of the current frame. When CTS_N is set to 0, the next frame for transmission is output, with a start bit as its leader.

Figure 21.10 shows an example of the operation of CTS_N control.

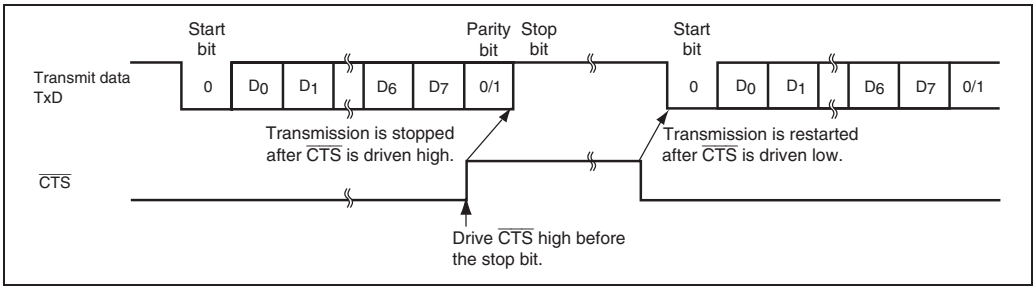

Figure 21.10 Example of CTS_N Control Operation

The RTS_N signal is driven high when the modem function is in use and the received data stored in the receive FIFO register (SCAFRDR) equals or exceeds the number of the RTS_N output triggers.

Figure 21.11 shows an example of the operation for RTS_N control.

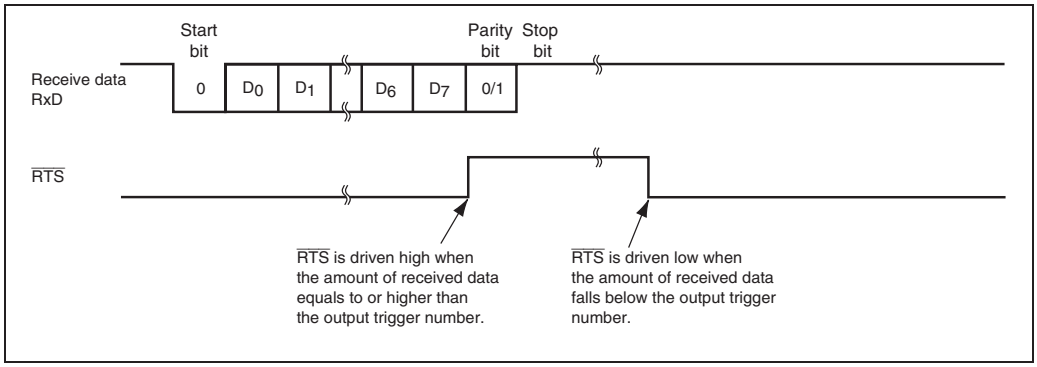

Figure 21.11 Example of RTS_N Control Operation

21.4.4 Operation in Clocked Synchronous Mode

Clocked synchronous mode, in which data is transmitted or received in synchronization with clock pulses, is suitable for fast serial communications.

Since the transmitter and receiver are independent units in SCIFA, full-duplex communications can be achieved by sharing the clock. Both the transmitter and receiver have a 64-stage FIFO buffer structure, so that data can be read or written during transmission or reception, enabling continuous data transfer and reception.

Through the setting of the CKEDG bit, the format for clocked synchronous communications can be selected.

Figures 19.12 and 19.13 show the format for clocked synchronous communications.

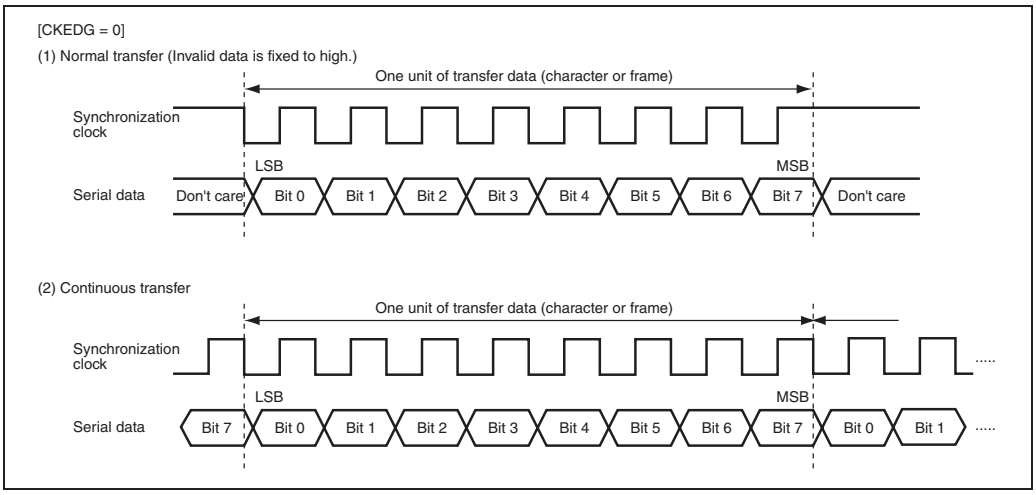

Figure 21.12 Data Format in Clocked Synchronous Communications (CKEDG = 0)

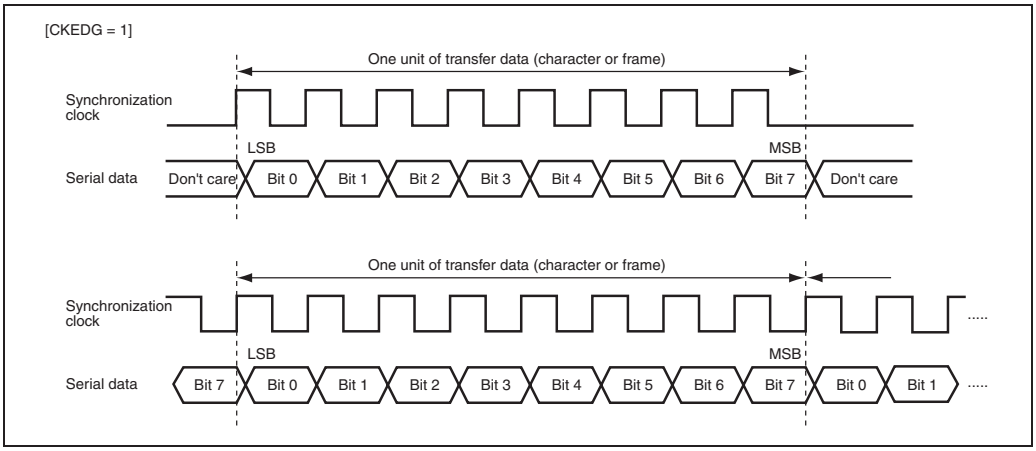

Figure 21.13 Data Format in Clocked Synchronous Communications (CKEDG = 1)

In clock synchronous serial communications, the data selected by the CKEDG bit on the communications line latched on one edge of the synchronization clock signal and output until the next edge. Accuracy of data is guaranteed on the next edge (i.e. that in the opposite direction to the latching edge).

In serial communications, each character is output starting with the LSB and ending with the MSB. After the MSB is output, the communications line remains in the state of the last bit.

Data is received on the opposite edge to that on which data is output.

(1) Data Transfer Format

A fixed 8-bit data format is used. No parity bit can be added.

(2) Clock

An internal clock signal generated by the on-chip baud-rate generator provides the transfer clock for SCIFA. For details on SCIFA clock source selection, see Table 21.5.

(3) SCIFA Initialization (Clocked Synchronous Mode)

Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCSCR to 0, then initialize SCIFA as described below.

When changing the operating mode or transfer format, etc., the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, SCTSR is initialized. Note that clearing the RE bit to 0 does not initialize the RDF, PER, FER, or ORER flag state or change the contents of SCFRDR.

Figure 21.14 shows a sample SCIFA initialization flowchart.

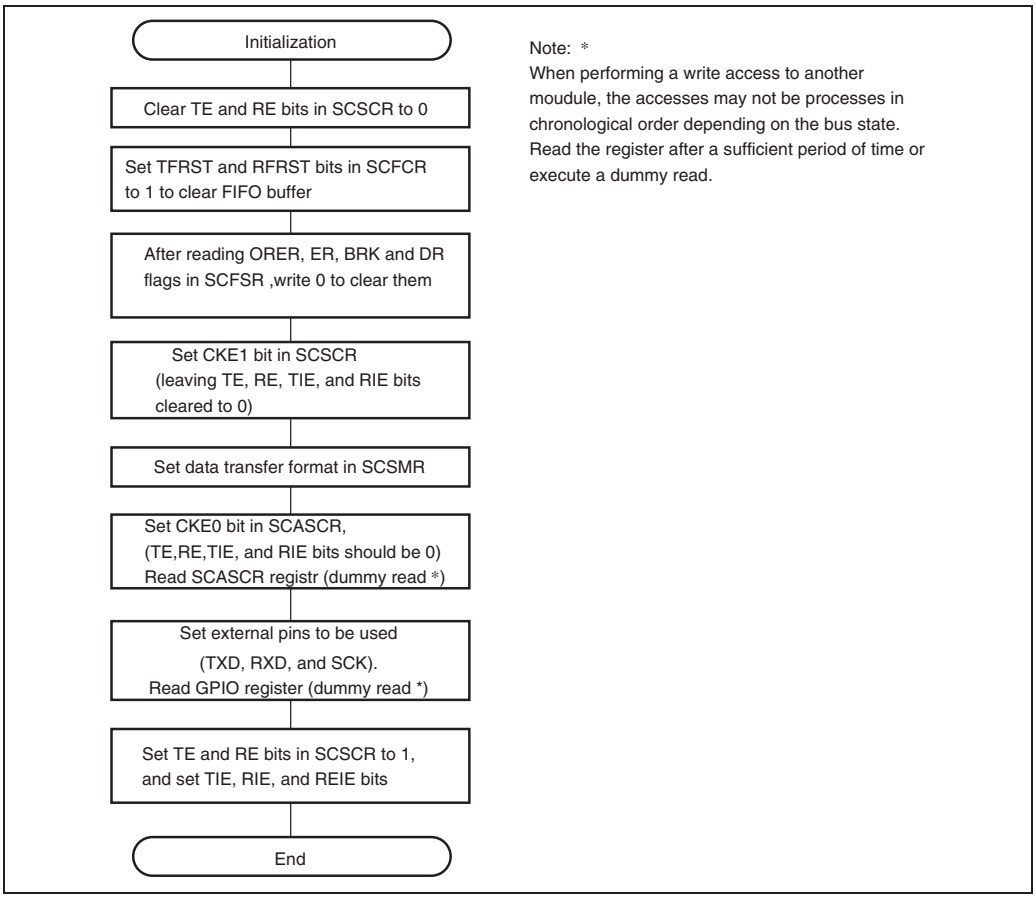

Figure 21.14 Sample Serial Transmission Flowchart

(4) Serial Data Transmission (Clocked Synchronous Mode)

Figure 21.15 shows a sample flowchart for serial transmission.

Use the following procedure for serial data transmission after enabling SCIFA for transmission.

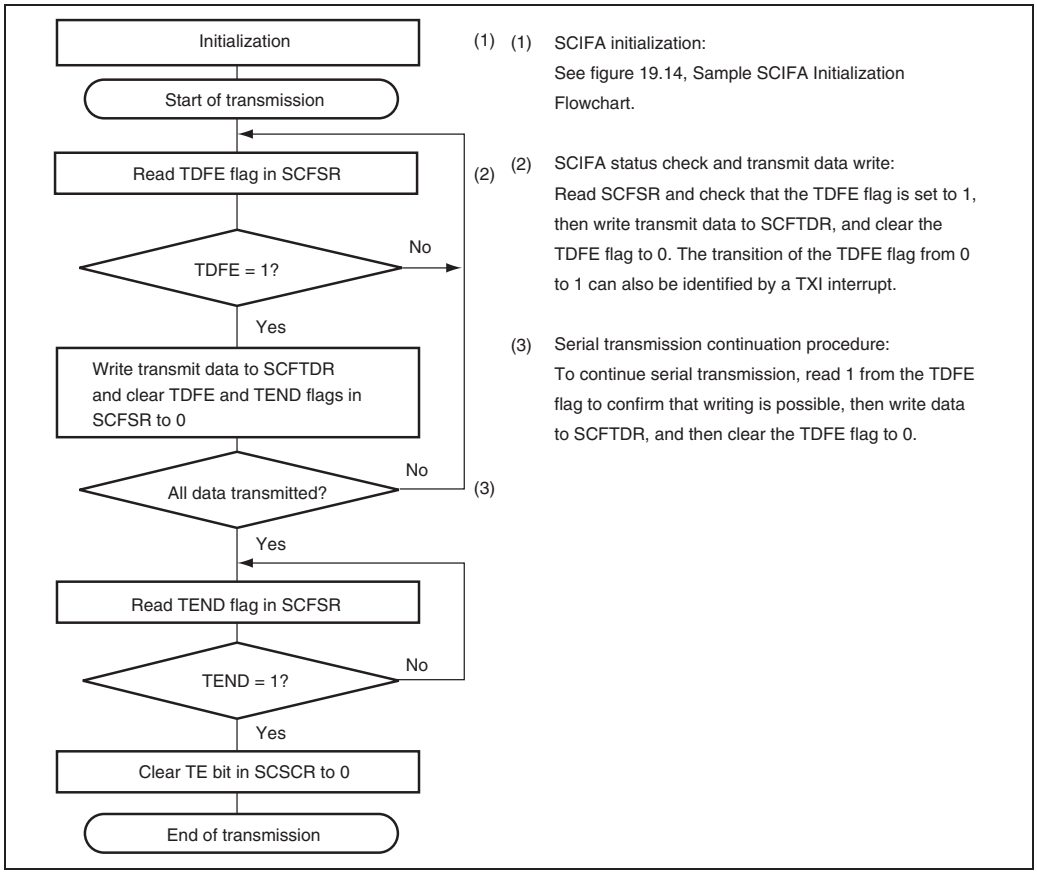

Figure 21.15 Sample Serial Transmission Flowchart

In serial transmission, SCIFA operates as described below.

1. When data is written into SCFTDR, SCIFA transfers data from SCFTDR to SCTSR and starts transmitting. Confirm that the TDFE flag in SCFSR is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least 16 – (transmit trigger set number).
2. When data is transferred from SCFTDR to SCTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR falls to or below the transmit trigger number set in SCFCR, the TDFE flag is set. If the TIE bit in SCSCR is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

   When the external clock is selected, data is output in synchronization with the input clock.

   The serial transmit data is sent from the TXD pin in the LSB-first order.
3. SCIFA checks the SCFTDR transmit data at the timing for sending the last bit. If data is present, the data is transferred from SCFTDR to SCTSR, and then serial transmission of the next frame is started. If there is no transmit data, the TEND flag in SCFSR is set to 1 after the last bit is sent, and the transmit data pin (TXD pin) retains the output state of the last bit.

Figure 21.16 shows an example of the operation for transmission in clocked synchronous mode.

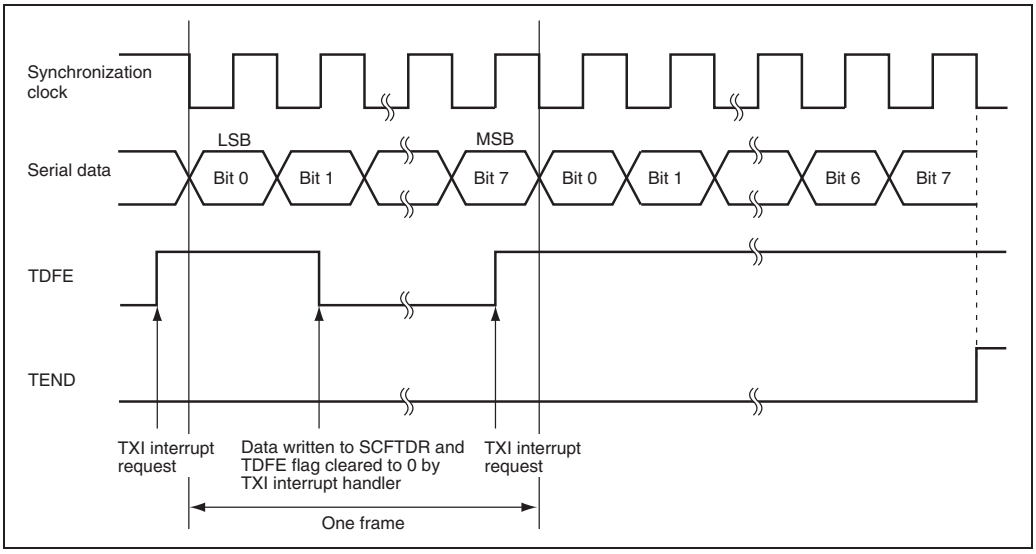

Figure 21.16 Sample SCIFA Transmission Operation in Clocked Synchronous Mode

(5) Serial Data Reception (Clocked Synchronous Mode)

Figures 19.17 and 19.18 show sample flowcharts for serial reception.

Use the following procedure for serial data reception after enabling SCIFA for reception.

When switching the operating mode from asynchronous mode to clocked synchronous mode without initializing SCIFA, make sure that the ORER flag in SCLSR, and PERC and FERC flags in SCLSR are cleared to 0.

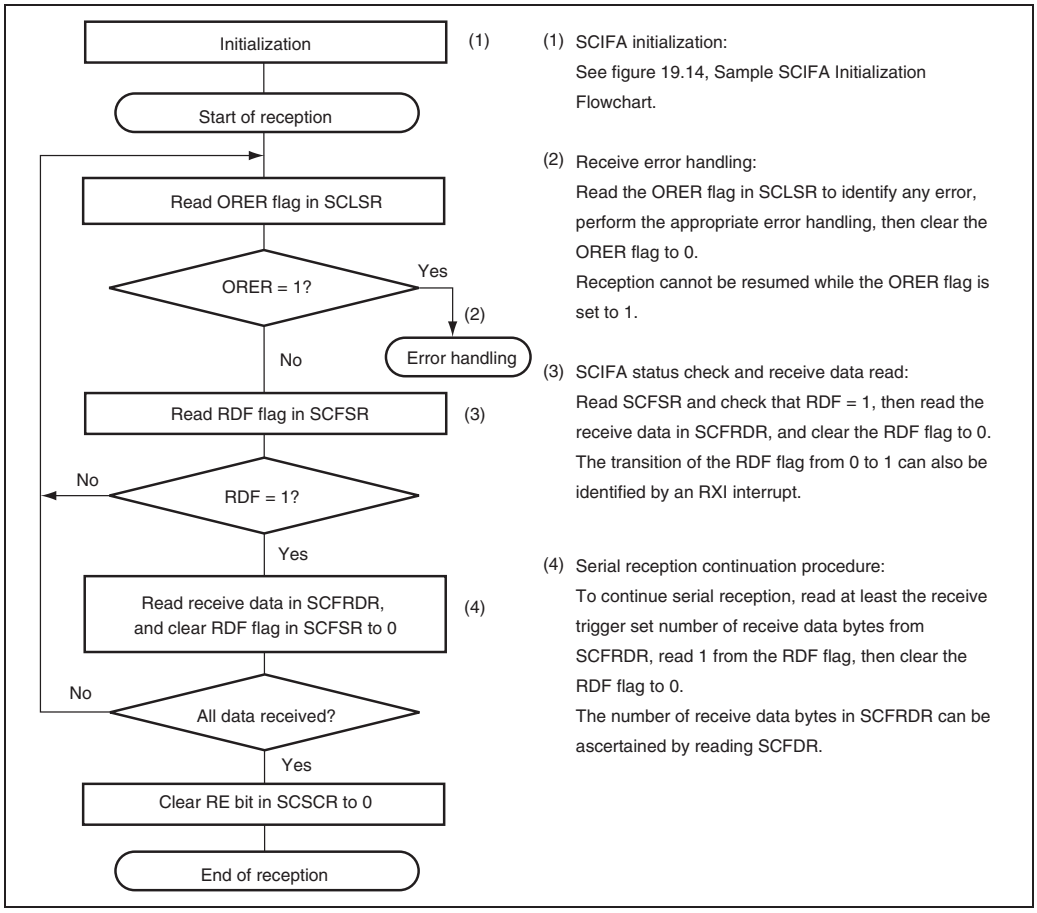

Figure 21.17 Sample Serial Reception Flowchart (1)

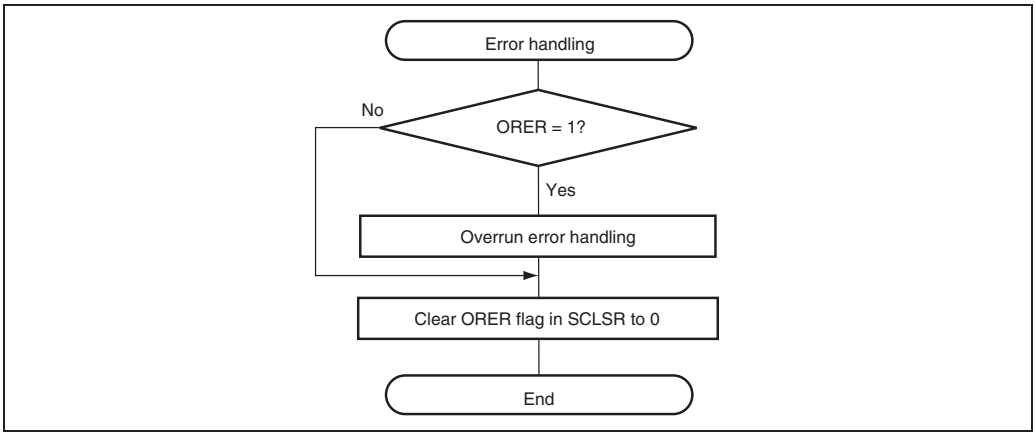

Figure 21.18 Sample Serial Reception Flowchart (2)

In serial reception, SCIFA operates as described below.

1. SCIFA is initialized internally in synchronization with the output of the synchronization clock.
2. The received data is stored in SCRSR in LSB-to-MSB order.
   After receiving the data, SCIFA checks whether the receive data can be transferred from SCRSR to SCFRDR. If this check is passed, the receive data is stored in SCFRDR. If an overrun error is detected in the error check, reception cannot continue.
3. If the RIE bit in SCSCR is set to 1 when the RDF flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.
   If the RIE or REIE bit in SCSCR is set to 1 when the ORER flag changes to 1, a break interrupt (BRI) request is generated.

Figure 21.19 shows an example of the operation for reception in clocked synchronous mode.

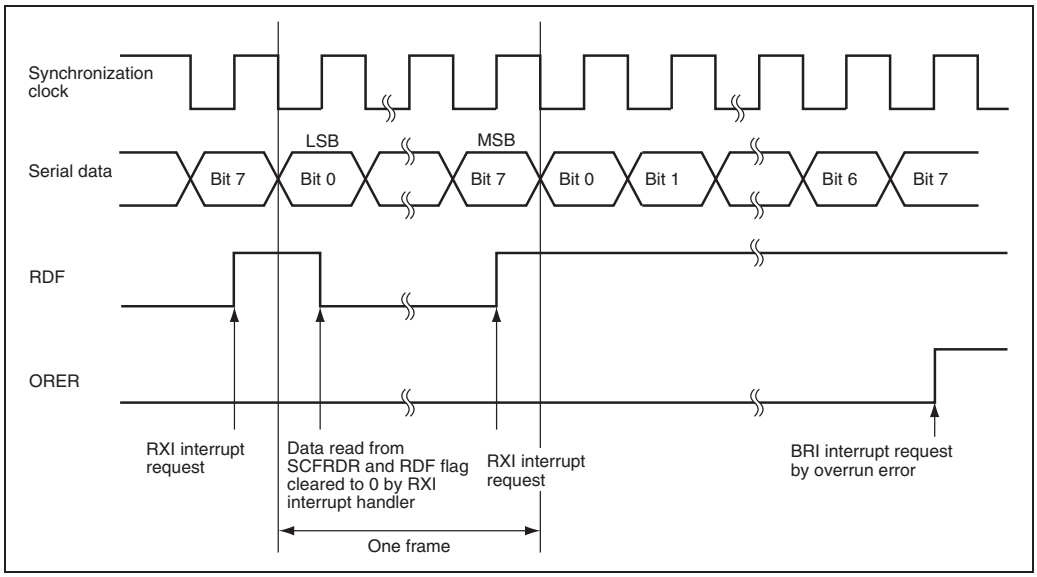

Figure 21.19 Sample SCIFA Reception Operation in Clocked Synchronous Mode

(6) Simultaneous Serial Data Transmission and Reception (Clocked Synchronous Mode)

Figure 21.20 shows a sample flowchart for simultaneous serial data transmission and reception.

Use the following procedure for simultaneous serial transmission and reception after enabling SCIFA for both the transmission and reception.

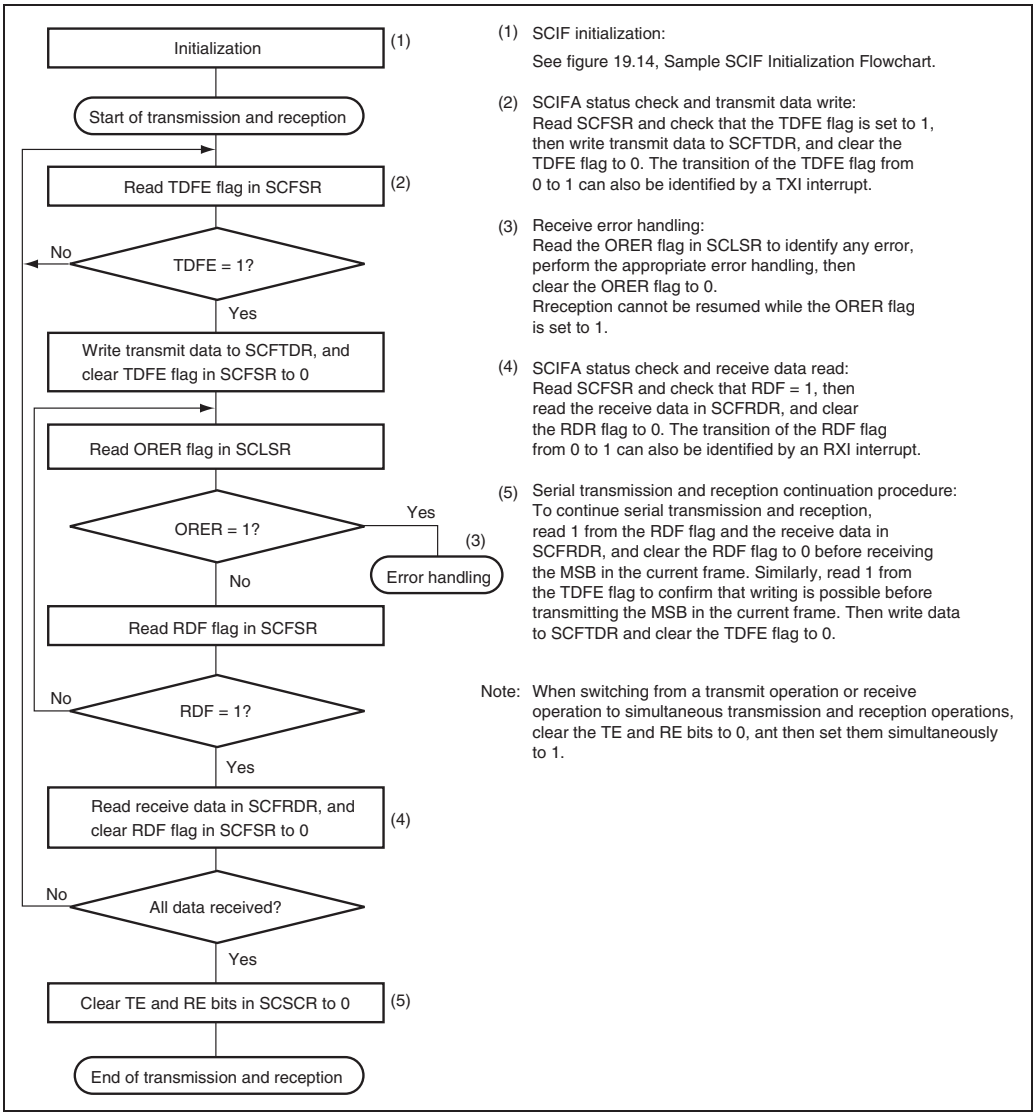

Figure 21.20 Sample Simultaneous Serial Transmission and Reception Flowchart

21.5 SCIFA Interrupt Sources and DMAC

SCIFA supports seven interrupts: transmit-FIFO-data-empty (TXI), transmit-data-stop (TDI), receive-error (ERI), receive-FIFO-data-full (RXI), break (BRI), receive-data-ready (DRI),and transmit-end(TEND). The vectors of each interrupt source are the same.

Table 21.7 shows the interrupt sources. The TIE, RIE, ERIE, BRIE, DRIE, TSIE,and TENDE bits in SCASCR are used to enable or disable the respective interrupt sources.

If the TDFE flag in SCASSR is set to 1, a TXI interrupt request is generated. When the TSF flag in SCASSR is set to 1, a TDI interrupt request is generated. The DMAC can be activated and data transfer performed on generation of TXI and TDI interrupt requests. When data exceeding the transmit trigger set number is written to SCAFTDR by the DMAC, the DMAC transfer request is automatically cleared to 0. The DMAC requests of TXI and TDI are the same.

When the RDF flag in SCASSR is set to 1, an RXI interrupt request is generated. The DMAC can be activated and data transfer performed on generation of an RXI interrupt request. When receive data in SCAFRDR is read by the DMAC until the amount left is less than the receive trigger set number, the DMAC transfer request is automatically cleared to 0.

When using the DMAC for transmission/reception, set the DMAC to the DMAC transfer enabled state before making the SCIFA settings. Transmission/reception is complete when the DMA transfer is terminated.

When the TEND flag in SCASSR is set to 1,the ER flag in SCASSR is set to 1, the BRK flag in SCASSR is set to 1, the DR flag in SCASSR is set to 1, or the TSF flag in SCASSR is set to 1, an interrupt request is generated. Note that the vectors of each interrupt source are the same.

Table 21.7 SCIFA Interrupt Sources

Interrupt Source Type	DMAC Activation
Interrupt initiated by receive error flag (ER) break flag (BRK) or transmit-end(TEND)	Not possible
Interrupt initiated by receive FIFO data full flag (RDF) or receive data ready flag (DR)	Possible*1
Interrupt initiated by transmit FIFO data empty flag (TDFE) or transmit data stop flag (TSF)	Possible*2

Notes: 1. The DMAC can only be activated by an interrupt request initiated by the receive FIFO data full flag (RDF).
2. The DMAC can only be activated by an interrupt request initiated by the transmit FIFO data empty flag (TDFE).

21.6 Usage Notes

Note the following when using SCIFA.

(1) SCAFTDR Writing and the TDFE Flag

The TDFE flag in SCASSR is set when the number of transmit data bytes written in SCAFTDR has fallen to or below the transmit trigger number set by bits TTRG1 and TTRG0 in SCAFCR. After TDFE is set, transmit data up to the number of empty bytes in SCAFTDR can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in SCAFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again after being read as 1 and cleared to 0. TDFE clearing should therefore be carried out when SCAFTDR contains more than the transmit trigger number of transmit data bytes.

The number of transmit data bytes in SCAFTDR can be found from the T6 to T0 bits in SCAFDR.

(2) SCAFRDR Reading and the RDF Flag

The RDF flag in SCASSR is set when the number of receive data bytes in SCAFRDR has become equal to or greater than the receive trigger number set by bits RTRG1 and RTRG0 in SCAFCR. After RDF is set, receive data equivalent to the trigger number can be read from SCAFRDR, allowing efficient continuous reception.

However, if the number of data bytes in SCAFRDR is still equal to or greater than the trigger number after a read, the RDF flag will be set to 1 again if it is cleared to 0. RDF should therefore be cleared to 0 after being read as 1 after all receive data has been read.

The number of receive data bytes in SCAFRDR can be found from the R6 to R0 bits in SCAFDR.

(3) Break Detection and Processing

Break signals can be detected by reading the RxD pin directly when a framing error (FER) is detected. In the break state the input from the RxD pin consists of all 0s, so the FER flag is set and the parity error flag (PER) may also be set.

Although SCIFA stops transferring receive data to SCAFRDR after receiving a break, the receive operation continues.

(4) Receive Data Sampling Timing and Receive Margin

As an example, when the sampling rate is 1/16, SCIFA operates on a base clock with a frequency of 8 times the transfer rate.

In reception, SCIFA synchronizes internally with the fall of the start bit, which it samples on the base clock. Receive data is latched at the rising edge of the eighth base clock pulse (when the sampling rate is 1/16).

The timing is shown in Figure 21.21.

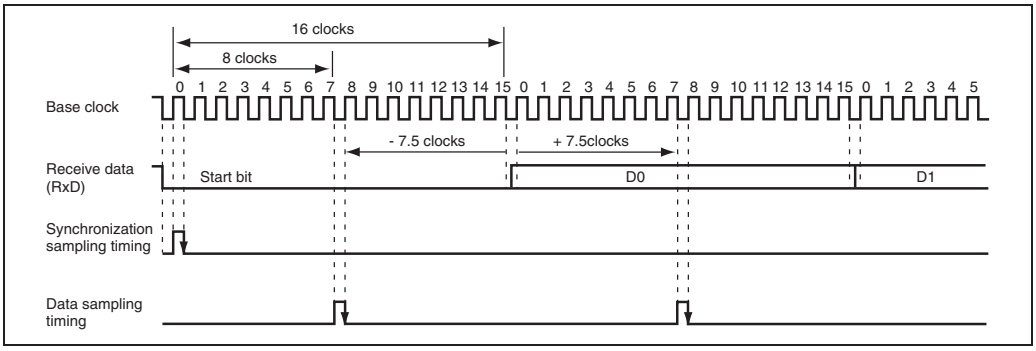

Figure 21.21 Receive Data Sampling Timing

The receive margin can therefore be expressed as shown in equation (1).

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\% \ldots\ldots (1)$$

M: Receive margin (%)
N: Ratio of clock frequency to bit rate (N = 16)
D: Clock duty cycle (D = 0 to 1.0)
L: Frame length (L = 9 to 12)
F: Absolute deviation of clock frequency

From equation (1), if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation (2).

When D = 0.5 and F = 0:

$$M = (0.5 - 1/(2 \times 16)) \times 100\% = 46.875\% \ldots\ldots (2)$$

This is a theoretical value. A reasonable margin to allow in system designs is the value above (46.875%) plus 20% to 30%.

(5) PAD Pin when the Pin for SCIF Is Selected

The table below shows the PAD pin state when the pin for SCIF is selected.

When the pin for SCIF is selected	TXD	RXD	RTS_N	CTS_N	SCK
PAD enable	1 (enable)	1 (enable)	SCAFCR.MCE (Initial value: 0, disable)	SCAFCR.MCE (Initial value: 0, disable)	SCASCR.CKE0 (Initial value: 0, disable)
Pin state	Output (initial value: 1)	Input	Hi-Z	Input	Hi-Z
Pull-up/-down	—	Pull-up required	—	Pull-up required	—
Remarks	—	SCIF fixes RXD to 1 internally when SCASCR.RE = 0.	—	SCIF fixes CTS_N to 1 internally when SCAFCR.MCE = 0.	—

Section 22 Serial Communications Interface with FIFO B (SCIFB)

This LSI has a serial communications interface incorporating FIFO buffers (Serial Communications Interface with FIFO B: SCIFB) that can perform both asynchronous and clocked synchronous serial communications.

Each interface includes two 256-stage buffers, one for the transmit FIFO register and one for the receive FIFO register, enabling fast, efficient, and continuous communications.

22.1 Features

- One channel installed in the system domain
- Asynchronous mode

  Serial data communications are executed using an asynchronous system in which synchronization is achieved character by character. Serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA).

  There is a choice of eight serial data communication formats.

  — Data length: 7 or 8 bits

  — Stop bit length: 1 or 2 bits

  — Parity: Even/odd/none

  — LSB-first transfer

  — Receive error detection: Parity, framing, and overrun errors

  — Break detection: If a framing error is followed by at least one frame at the space "0" (low level), a break is detected.
- Clocked synchronous mode

  Serial data communications in synchronization with a clock can be carried out with other LSIs that have a clocked synchronous communications function.

  — Data length: 8 bits

  — Receive error detection: Overrun error

  — A rising or falling edge of a clock is selectable as the data transmit/receive timing.
- On-chip baud-rate generator allows any bit rate to be selected.

  — Minimum: SUBϕ/5 bps, maximum: SUBϕ/(27 × 256 × 64) bps (asynchronous)

— Minimum: SUBϕ/(2 × 2) bps, maximum: SUBϕ/(2 × 256 × 64) bps (clocked synchronous)

- Serial clock source: Internal clock signal generated by the baud-rate generator.
- Six interrupt sources

  There are six interrupt sources — transmit-data-stop, transmit-FIFO-data-empty, receive-FIFO-data-full, receive-error (framing/parity error), break-receive, and receive-data-ready interrupts. The vectors of each interrupt source are the same.
- The DMA controller (DMAC) can be activated to execute a data transfer in the event of a transmit-FIFO-data-empty, transmit-data-stop, or receive-FIFO-data-full interrupt. The DMAC requests of transmit-FIFO-data-empty and transmit-data-stop interrupts are the same.
- Supports multibyte DMA transfers.
- On-chip modem control functions (CTS_N and RTS_N)
- On-chip transmit-data-stop function
- When not in use, the SCIFB can be stopped by halting its clock supply to reduce power consumption.
- The amount of data in the transmit/receive FIFO registers, and the number of receive errors in the receive data in the receive FIFO register, can be ascertained.

Figure 22.1 shows a block diagram of SCIFB.

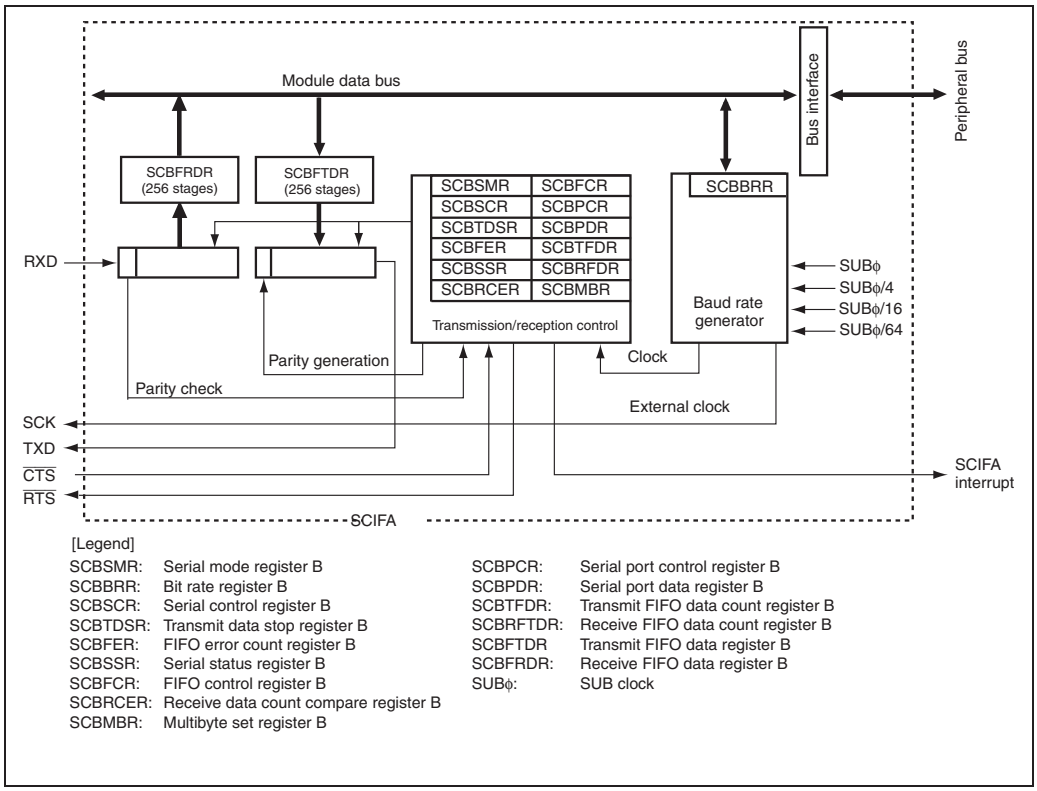

Figure 22.1 Block Diagram of SCIFB

22.2 Input/Output Pins

Table 22.1 shows the SCIFB pin configuration.

Table 22.1 Pin Configuration

Channel	Abbreviation	Input/output	Description
0	SCIFB_SCK	Output	Clock output
	SCIFB_RXD	Input	Receive data
	SCIFB_TXD	Output	Transmit data
	SCIFB_CTS_N	Input	Clear to send
	SCIFB_RTS_N	Output	Request to send

Note: The channel number is omitted, and SCK, RxD, TxD, CTS_N, and RTS_N are used as generic terms in the following descriptions.

22.3 Register Descriptions

Table 22.2 shows the SCIFB registers. Table 22.3 shows the register states in the respective processing modes.

Table 22.2 Register Configuration

Register Name	Register Abbreviation	R/W	Address		Access Size
			Regular	Shadow	
Serial mode register B	SCBSMR	R/W	H'E6C3 0000	H'E7C3 0000	16
Bit rate register B	SCBBRR	R/W	H'E6C3 0004	H'E7C3 0004	8

22.3.1 Serial Mode Register (SCBSMR)

SCBSMR is a 16-bit readable/writable register used to set SCIFB's serial transfer format and select the baud-rate generator clock source and the sampling rate.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	CKEDG	—	SRC[2:0]			C/$\overline{A}$	CHR	PE	O/E	STOP	—	CKS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	CKEDG	0	R/W	Transmit/Receive Clock Edge Select Selects the clock edge at which the serial data is output in clocked synchronous mode. 0: Serial data is transmitted at the falling edge of output clock. Serial data is received at the rising edge of output clock. 1: Serial data is transmitted at the rising edge of output clock. Serial data is received at the falling edge of output clock.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	SRC[2:0]	000	R/W	Sampling Control These bits select the sampling rate. 000: Sampling rate 1/16 001: Sampling rate 1/5 010: Sampling rate 1/7 011: Sampling rate 1/11 100: Sampling rate 1/13 101: Sampling rate 1/17 110: Sampling rate 1/19 111: Sampling rate 1/27
7	C/$\overline{A}$	0	R/W	Communication Mode Selects asynchronous mode or clocked synchronous mode as the SCIFB operating mode. 0: Asynchronous mode 1: Clocked synchronous mode
6	CHR	0	R/W	Character Length Selects 7 or 8 bits as the data length. 0: 8-bit data 1: 7-bit data* Note: * When the 7-bit character is selected, the MSB (bit 7) in SCBFTDR is not transmitted.
5	PE	0	R/W	Parity Enable Selects whether or not parity bit addition is performed in transmission, and parity bit checking in reception. 0: Parity bit addition and checking disabled 1: Parity bit addition and checking enabled* Note: * When the PE bit is set to 1, the parity (even or odd) specified by the O/E bit is added to transmit data before transmission. In reception, the parity bit is checked for the parity (even or odd) specified by the O/E bit.

Bit	Bit Name	Initial Value	R/W	Description
4	O/E	0	R/W	Parity Mode Selects either even or odd parity for use in parity addition and checking. The O/E bit setting is only valid when the PE bit is set to 1, enabling parity bit addition and checking. The O/E bit setting is invalid when parity addition and checking is disabled. 0: Even parity*[1] 1: Odd parity*[2] Notes: 1. When even parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is even. 2. When odd parity is set, parity bit addition is performed in transmission so that the total number of 1-bits in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is odd.
3	STOP	0	R/W	Stop Bit Length Selects 1 or 2 bits as the stop bit length. In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit; if it is 0, it is treated as the start bit of the next transmit character. 0: 1 stop bit*[1] 1: 2 stop bits*[2] Notes: 1. In transmission, a single logic-1 bit (stop bit) is added to the end of a transmit character before it is sent. 2. In transmission, two logic-1 bits (stop bits) are added to the end of a transmit character before it is sent.

Bit	Bit Name	Initial Value	R/W	Description
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	CKS[1:0]	00	R/W	Clock Select Select the clock source of the internal baud-rate generator. 00: SUBϕ 01: SUBϕ/4 10: SUBϕ/16 11: SUBϕ/64 Note: SUBϕ: SUB clock

22.3.2 Bit Rate Register (SCBBRR)

SCBBRR is an 8-bit readable/writable register that sets the serial transfer bit rate in accordance with the baud-rate generator operating clock selected by bits CKS1 and CKS0 in SCBSMR.

Bit:	7	6	5	4	3	2	1	0
	SCBRD[7:0]							
Initial value:	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCBRD[7:0]	H'FF	R/W	Bit Rate 0 ≤ SCBRD ≤ 255 (Asynchronus) 1 ≤ SCBRD ≤ 255 (Clocked synchronous)

The SCBBRR setting is found by using the following equations.

(1) Asynchronous Mode:

- When the sampling rate is 1/16,
  $N = \{ SUB\phi/(16 \times 2^{2n} \times B) \} \times 10^6 - 1$
- When the sampling rate is 1/5,
  $N = \{ SUB\phi/(5 \times 2^{2n} \times B) \} \times 10^6 - 1$

- When the sampling rate is 1/11,
  $N = \{ SUB\phi / (11 \times 2^{2n} \times B) \} \times 10^6 - 1$
- When the sampling rate is 1/13,
  $N = \{ SUB\phi / (13 \times 2^{2n} \times B) \} \times 10^6 - 1$
- When the sampling rate is 1/27,
  $N = \{ SUB\phi / (27 \times 2^{2n} \times B) \} \times 10^6 - 1$

(2) Clocked Synchronous Mode:

$$N = \{ SUB\phi / (2 \times 2^{2n} \times B) \} \times 10^6 - 1$$

Where B: Bit rate (bits/s)
N: SCBBRR setting for baud-rate generator
Asynchronous mode ($0 \le N \le 255$)
Clocked synchronous mode ($1 \le N \le 255$)

SUBϕ: Subclock frequency (MHz)

n: Baud-rate generator input clock (n = 0 to 3)
(See the table below for the relation between n and the clock.)

Table 22.4 SCBSMR Setting

		SCBSMR Setting
n	**Clock**	**CKS[1:0]**
0	SUBϕ	00
1	SUBϕ/4	01
2	SUBϕ/16	10
3	SUBϕ/64	11

The bit rate error in asynchronous mode is found by using the following equations.

When the sampling rate is 1/16,

$$\text{Error (\%)} = \{ \{ \text{SUB}\phi / ((N + 1) \times 16 \times 2^{2n} \times B) \} \times 10^{6} - 1 \} \times 100$$

When the sampling rate is 1/5,

$$\text{Error (\%)} = \{ \{ \text{SUB}\phi / ((N + 1) \times 5 \times 2^{2n} \times B) \} \times 10^{6} - 1 \} \times 100$$

When the sampling rate is 1/11,

$$\text{Error (\%)} = \{ \{ \text{SUB}\phi / ((N + 1) \times 11 \times 2^{2n} \times B) \} \times 10^{6} - 1 \} \times 100$$

When the sampling rate is 1/13,

$$\text{Error (\%)} = \{ \{ \text{SUB}\phi / ((N + 1) \times 13 \times 2^{2n} \times B) \} \times 10^{6} - 1 \} \times 100$$

When the sampling rate is 1/27,

$$\text{Error (\%)} = \{ \{ \text{SUB}\phi / ((N + 1) \times 27 \times 2^{2n} \times B) \} \times 10^{6} - 1 \} \times 100$$

22.3.3 Serial Control Register (SCBSCR)

SCBSCR is a 16-bit readable/writable register that performs enabling or disabling of SCIFB transfer operations and interrupt requests, and selection of the serial clock source.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TDRQE	RDRQE	RCEE	—	TSIE	ERIE	BRIE	DRIE	TIE	RIE	TE	RE	—	—	—	CKE0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	TDRQE	0	R/W	Transmit Data Transfer Request Enable Switches the transmit FIFO empty interrupt or DMA transfer request when TIE = 1 and the transmit FIFO empty occurs. 0: Interrupt request to CPU is issued. 1: Transmit data transfer request to DMAC is issued.
14	RDRQE	0	R/W	Receive Data Transfer Request Enable Switches the receive FIFO-data-full interrupt or DMA transfer request when RIE = 1 and the receive FIFO-data-full occurs. 0: Interrupt request to CPU is issued. 1: Receive data transfer request to DMAC is issued.
13	RCEE	0	R/W	Receive Data Count Compare Interrupt Enable Generates an interrupt when the receive data count comparison counter matches the current receive data count. 0: Receive data count compare interrupt disabled* 1: Receive data count compare interrupt enabled Note: * This interrupt request is cleared by clearing the RCEF flag to 0 after reading 1 from it or clearing the RCEE bit to 0.
12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11	TSIE	0	R/W	Transmit Data Stop Interrupt Enable Enables or disables generation of a transmit-data-stop interrupt when the TSE bit in SCBFCR is enabled and the TSF flag in SCBSSR is set to 1. 0: Transmit-data-stop interrupt disabled* 1: Transmit-data-stop interrupt enabled Note: * The TDI interrupt request is cleared by clearing the TSF flag to 0 after reading 1 from it or clearing the TSIE bit to 0.
10	ERIE	0	R/W	Receive Error Interrupt Enable Enables or disables generation of a receive-error (framing or parity error) interrupt when the ER flag in SCBSSR is set to 1. 0: Receive-error interrupt disabled* 1: Receive-error interrupt enabled Note: * The ERI interrupt request is cleared by clearing the ER flag to 0 after reading 1 from it or clearing the ERIE bit to 0.
9	BRIE	0	R/W	Break Interrupt Enable Enables or disables generation of a break-receive interrupt when the BRK flag in SCBSSR is set to 1. 0: Break-receive interrupt disabled* 1: Break-receive interrupt enabled Note: * The BRI interrupt request is cleared by clearing the BRK flag to 0 after reading 1 from it or clearing the BRIE bit to 0.
8	DRIE	0	R/W	Receive Data Ready Interrupt Enable Enables or disables generation of a receive-data-ready interrupt when the DR flag in SCBSSR is set to 1. 0: Receive-data-ready interrupt disabled* 1: Receive-data-ready interrupt enabled Note: * The DRI interrupt request is cleared by clearing the DR flag to 0 after reading 1 from it or clearing the DRIE bit to 0.

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	Transmit Interrupt Enable Enables or disables generation of a transmit-FIFO-data-empty interrupt request when the TDFE flag in SCBSSR is set to 1. 0: Transmit-FIFO-data-empty interrupt request disabled* 1: Transmit-FIFO-data-empty interrupt request enabled Note: * This interrupt request is cleared by writing transmit data exceeding the transmit trigger set number to SCBFTDR, reading 1 from the TDFE flag, then clearing it to 0, or by clearing the TIE bit to 0.
6	RIE	0	R/W	Receive Interrupt Enable Enables or disables generation of a receive-FIFO-data-full interrupt request when the RDF flag in SCBSSR is set to 1. 0: Receive-FIFO-data-full interrupt request disabled* 1: Receive-FIFO-data-full interrupt request enabled Note: * This interrupt request is cleared by reading 1 from the RDF flag, then clearing the flag to 0, or by clearing the RIE bit to 0.
5	TE	0	R/W	Transmit Enable Enables or disables the start of serial transmission by SCIFB. 0: Transmission disabled 1: Transmission enabled* Note: * Make SCBSMR and SCBFCR settings, decide the transmit format, and reset the transmit FIFO before setting the TE bit to 1.

Bit	Bit Name	Initial Value	R/W	Description
4	RE	0	R/W	Receive Enable Enables or disables the start of serial reception by SCIFB. 0: Reception disabled*[1] 1: Reception enabled*[2] Notes: 1. Clearing the RE bit to 0 does not affect the DR, ER, BRK, RDF, FER, PER, and ORER flags, which retain their state. 2. Make SCBSMR and SCBFCR settings, decide the receive format, and reset the receive FIFO before setting the RE bit to 1.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CKE0	0	R/W	Clock Enable Enables or disables the clock output from the SCK pin. The CKE0 bit must be set before determining the SCIFB operating mode with SCBSMR. 0: SCK pin disabled 1: Clock output from SCK* Note: * In clocked synchronous mode, the SCK pin outputs a clock with the same frequency as the bit rate.

22.3.4 Transmit Data Stop Register (SCBTDSR)

SCBTDSR is a 16-bit readable/writable register that sets the number of transmit data bytes. SCBTDSR is valid only when the TSE bit in SCBFCR is enabled. Transmit operation is stopped when the number of data bytes set in SCBTDSR is transmitted. The setting value should be H'0000 (one byte) to H'FFFF (65536 bytes). SCBTDSR is initialized to H'FFFF.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TDSRD[15:0]															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TDSRD[15:0]	H'FFFF	R/W	Transmit Data Stop Setting

22.3.5 FIFO Error Count Register (SCBFER)

SCBFER is a 16-bit read-only register that indicates the number of receive errors (framing errors and parity errors).

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PER[7:0]								FER[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	PER[7:0]	000000	R	Parity Error Count These bits indicate the number of data in which parity errors are generated, in receive data stored in SCBFRDR. After the ER bit in SCBSSR is set, the value of bits PER7 to PER0 indicates the number of data in which parity errors are generated. When all 256 bytes of receive data in SCBFRDR have parity errors, these bits indicate 0.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	FER[7:0]	000000	R	Framing Error Count These bits indicate the number of data in which framing errors are generated, in receive data stored in SCBFRDR. After the ER bit in SCBSSR is set, the value of bits FER7 to FER0 indicates the number of data in which framing errors are generated. When all 256 bytes of receive data in SCBFRDR have framing errors, these bits indicate 0.

22.3.6 Serial Status Register (SCBSSR)

SCBSSR is a 16-bit readable/writable register that indicates the SCIFB status.

However, 1 cannot be written to the ORER, TSF, ER, TDFE, BRK, RDF, and DR flags. Before these flags can be cleared to 0, they must first be read as 1. The TEND, FER, and PER flags are read-only flags and cannot be modified.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RCEF	—	—	—	ORER	TSF	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R/(W)*	R	R	R	R/(W)*	R/(W)*	R/(W)*	R	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
15 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
13	RCEF	0	R/(W)*	Receive Data Count Match Indicates that the receive data count matches the receive data count comparison counter. 0: Receive data count does not match the receive data count comparison counter. [Clearing conditions] Power-on reset or manual reset When 0 is written to RCEF after reading RCEF = 1 1: Receive data count matches the receive data count comparison counter.*[2] [Setting condition] When the receive data count matches the counter value
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	ORER	0	R/(W)*	Overrun Error Indicates that an overrun error occurred during reception. This bit is valid only in asynchronous mode. 0: Reception is in progress or has completed normally.*[1] [Clearing conditions] Power-on reset or manual reset When 0 is written to ORER after reading ORER = 1 1: An overrun error occurred during reception.*[2] [Setting condition] When serial data reception is completed while the receive FIFO is full Notes: 1. The ORER flag is not affected and retains its previous state when the RE bit in SCBSCR is cleared to 0. 2. The receive data prior to the overrun error is retained in SCBFRDR, and the data received subsequently is lost. Serial data reception cannot be continued with the ORER flag set to 1.
8	TSF	0	R/(W)*	Transmit Data Stop Indicates that the number of transmit data matches the value of SCBTDSR. This bit is valid only in asynchronous mode. 0: The number of transmit data does not match the SCBTDSR value. [Clearing conditions] Power-on reset or manual reset When 0 is written to TSF after reading TSF = 1 1: The number of transmit data matches the SCBTDSR value.

Bit	Bit Name	Initial Value	R/W	Description
7	ER	0	R/(W)*	Receive Error Indicates that a framing error or parity error occurred during reception.*[1] This bit is valid only in asynchronous mode. 0: No framing error or parity error occurred during reception. [Clearing conditions] Power-on reset or manual reset When 0 is written to ER after reading ER = 1 1: A framing error or parity error occurred during reception. [Setting conditions] When the SCIFB checks whether the stop bit at the end of the receive data is 1 when reception ends, and the stop bit is 0*[2] When, in reception, the number of logic-1 bits in the receive data and in the parity bit does not match the parity setting (even or odd) specified by the O/E bit in SCBSMR Notes: 1. The ER flag is not affected and retains its previous state when the RE bit in SCBSCR is cleared to 0. When a receive error occurs, the receive data is still transferred to SCBFRDR, and reception continues. The FER and PER bits in SCBSSR can be used to determine whether there is a receive error in the data read from SCBFRDR. 2. When the stop-bit length is 2 bits, only the first stop bit is checked for a value of 1 and the second stop bit is not checked.

Bit	Bit Name	Initial Value	R/W	Description
6	TEND	1	R	Transmission End Indicates that there is no valid data in SCBFTDR when the last bit of the transmit character is sent and that transmission has been completed. 0: Transmission is in progress. [Clearing condition] When data is written to SCBFTDR 1: Transmission has been completed. [Setting condition] When there is no transmit data in SCBFTDR during transmission of a 1-byte serial transmit character
5	TDFE	1	R/(W)*	Transmit FIFO Data Empty Indicates that data has been transferred from SCBFTDR to SCBTSR, the number of data bytes in SCBFTDR has fallen to or below the transmit trigger data number set by bits TTRG1 and TTRG0 in SCBFCR, and new transmit data can be written to SCBFTDR. 0: A number of transmit data bytes exceeding the transmit trigger set number have been written to SCBFTDR. [Clearing condition] When transmit data exceeding the transmit trigger set number is written to SCBFTDR, and 0 is written to TDFE after reading TDFE = 1 1: The number of transmit data bytes in SCBFTDR is equal to or less than the transmit trigger set number. [Setting conditions] Power-on reset or manual reset When the number of SCBFTDR transmit data bytes falls to or below the transmit trigger set number after a transmit operation* Note: * As SCBFTDR is a 256-byte FIFO register, the maximum number of bytes that can be written when TDFE = 1 is 256 – (transmit trigger set number). Data written in excess of this will be ignored. The number of data bytes in SCBFTDR is indicated by SCBTFDR.

Bit	Bit Name	Initial Value	R/W	Description
4	BRK	0	R/(W)*	Break Detect Indicates that a receive data break signal has been detected. This bit is valid only in asynchronous mode. 0: A break signal has not been received. [Clearing conditions] Power-on reset or manual reset When 0 is written to BRK after reading BRK = 1 1: A break signal has been received.* [Setting condition] When data with a framing error is received, followed by the space 0 level (low level) for at least one frame length Note: * When a break is detected, the receive data (H'00) following the detection is not transferred to SCBFRDR. When the break ends and the receive signal returns to mark 1, receive data transfer is resumed.
3	FER	0	R	Framing Error Indicates a framing error in the data read from SCBFRDR. This bit is valid only in asynchronous mode. 0: There is no framing error in the receive data read from SCBFRDR. [Clearing conditions] Power-on reset or manual reset When there is no framing error in SCBFRDR read data 1: There is a framing error in the receive data read from SCBFRDR. [Setting condition] When there is a framing error in SCBFRDR read data

Bit	Bit Name	Initial Value	R/W	Description
2	PER	0	R	Parity Error Indicates a parity error in the data read from SCBFRDR. This bit is valid only in asynchronous mode. 0: There is no parity error in the receive data read from SCBFRDR. [Clearing conditions] Power-on reset or manual reset When there is no parity error in SCBFRDR read data 1: There is a parity error in the receive data read from SCBFRDR. [Setting condition] When there is a parity error in SCBFRDR read data
1	RDF	0	R/(W)*	Receive FIFO Data Full Indicates that the received data has been transferred from SCBRSR to SCBFRDR, and the number of receive data bytes in SCBFRDR is equal to or greater than the receive trigger number set by bits RTRG1 and RTRG0 in SCBFCR. 0: The number of receive data bytes in SCBFRDR is less than the receive trigger set number. [Clearing conditions] Power-on reset or manual reset When SCBFRDR is read until the number of receive data bytes in SCBFRDR falls below the receive trigger set number, and 0 is written to RDF after reading RDF = 1 1: The number of receive data bytes in SCBFRDR is equal to or greater than the receive trigger set number. [Setting condition] When SCBFRDR contains at least the receive trigger set number of receive data bytes* Note: * SCBFRDR is a 256-byte FIFO register. When RDF = 1, at least the receive trigger set number of data bytes can be read. If data is read when SCBFRDR is empty, an undefined value will be returned. The number of receive data bytes in SCBFRDR is indicated by the lower bits of SCBRFDR.

Bit	Bit Name	Initial Value	R/W	Description
0	DR	0	R/(W) *	Receive Data Ready Indicates that there are data bytes fewer than the receive trigger set number in SCBFRDR, and no further data will arrive at least 15 etu after the stop bit of the last data received. This bit is valid only in asynchronous mode. 0: Reception is in progress or has ended normally and no receive data is left in SCBFRDR. [Clearing conditions] (initial value) Power-on reset or manual reset When all the receive data in SCBFRDR has been read, and 0 is written to DR after reading DR = 1 1: No further receive data has arrived. [Setting condition] When SCBFRDR contains data bytes fewer than the receive trigger set number, and no further data will arrive at least 15 etu after the stop bit of the last data received* Note: * Corresponds to 1.5 frame time in 8-bit one-stop-bit format. etu: Elementary time unit (time for transfer of 1 bit)

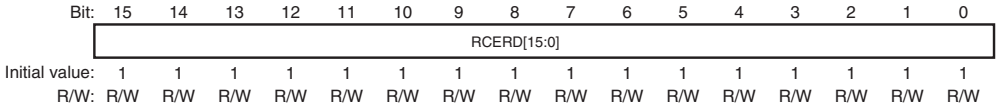
Note: * Only 0 can be written for flag clearing.

22.3.7 FIFO Control Register (SCBFCR)

SCBFCR is a 16-bit readable/writable register that clears all data and sets the trigger data number for the transmit and receive FIFO registers. The register also contains a loopback test enable bit.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSE	TCRST	RCE	RCRST	—	RSTRG[2:0]			RTRG[1:0]		TTRG[1:0]		MCE	TFRST	RFRST	LOOP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	TSE	0	R/W	Transmit Data Stop Enable Enables or disables the transmit data stop function. 0: Transmit data stop function disabled 1: Transmit data stop function enabled
14	TCRST	0	R/W	Transmit Count Reset Clears the transmit count to 0. This bit is valid only when the transmit data stop function is used. 0: Transmit count reset disabled* 1: Transmit count reset enabled (clearing to 0) Note: * The transmit count is reset (clearing to 0) by a power-on reset or manual reset.
13	RCE	0	R/W	Receive Data Count Comparison Enable Enables or disables the comparison of receive data count. 0: Comparison of receive data count disabled 1: Comparison of receive data count enabled
12	RCRST	0	R/W	Receive Count Reset Clears the receive count to 0. This bit is valid only when the receive data count comparison function is used. 0: Receive count reset disabled* 1：Receive count reset enabled (clearing to 0) Note：* The receive count is reset (clearing to 0) by a power-on reset or manual reset.



Bit	Bit Name	Initial Value	R/W	Description
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10 to 8	RSTRG[2:0]	000	R/W	RTS_N Output Active Trigger The $\overline{\text{RTS}}$ signal becomes high when the number of receive data stored in SCBFRDR reaches the trigger set number shown below. 000: 255 001: 1 010: 32 011: 64 100: 128 101: 192 110: 224 111: 240
7, 6	RTRG[1:0]	00	R/W	Receive FIFO Data Number Trigger Set the number of receive data bytes that sets the RDF flag in SCBSSR. The RDF flag is set when the number of receive data bytes in SCBFRDR reaches the trigger set number shown below. 00: 1 01: 16 10: 32 11: 48 In multibyte transfer mode, a transfer request is made to the DMAC when the number of receive data bytes in SCBFRDR reaches the trigger set number shown below. (The RDF flag is undefined.) 00: Reserved 01: 32 10: 16 11: 1

Bit	Bit Name	Initial Value	R/W	Description
5, 4	TTRG[1:0]	00	R/W	Transmit FIFO Data Number Trigger Set the number of remaining transmit data bytes that sets the TDFE flag in SCBSSR. The TDFE flag is set when, as the result of a transmit operation, the number of transmit data bytes in SCBFTDR falls to or below the trigger set number shown below. 00: 32 (32) 01: 16 (48) 10: 2 (62) 11: 0 (64) In multibyte transfer mode, a transfer request is made to the DMAC when the number of transmit data bytes in SCBFTDR falls to or below the trigger set number shown below. (The TDFE flag is undefined.) 00: Reserved 01: 224 (32) 10: 240 (16) 11: 255 (1) Note: The values in parentheses are the number of empty bytes in SCBFTDR when the flag is set.
3	MCE	0	R/W	Modem Control Enable Enables the CTS_N and RTS_N modem control signals. 0：Modem signals disabled* 1：Modem signals enabled Note: * CTS_N is fixed at active-0 regardless of the input value, and RTS_N output is also fixed at 0.
2	TFRST	0	R/W	Transmit FIFO Data Register Reset Invalidates the transmit data in SCBFTDR and resets it to the empty state. 0: Reset operation disabled* 1: Reset operation enabled Note: * A reset operation is performed at a power-on reset or manual reset.

Bit	Bit Name	Initial Value	R/W	Description
1	RFRST	0	R/W	Receive FIFO Data Register Reset Invalidates the receive data in SCBFRDR and resets it to the empty state. 0: Reset operation disabled* 1: Reset operation enabled Note: * A reset operation is performed at a power-on reset or manual reset.
0	LOOP	0	R/W	Loopback Test Internally connects the transmit output pin (TxD) to receive input pin (RxD) and RTS_N pin to CTS_N pin, enabling loopback testing. 0: Loopback test disabled 1: Loopback test enabled

22.3.8 Receive Data Count Compare Register (SCBRCER)

SCBRCER is a 16-bit readable/writable register that sets the number of receive data bytes. SCBRCER is valid only when the RCE bit in SCBFCR is set to 1 (enabled). The data reception stops when the number of receive data bytes reaches the value of this register. A value between H'0000 (1 byte) to H'FFFF (65536 bytes) can be set. SCBRCER is initialized to H'FFFF.

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	RCERD[15:0]	H'FFFF	R/W	Receive Data Stop

22.3.9 Multibyte Set Register (SCBMBR)

SCBMBR is a 16-bit readable/writable register for multibyte transfer setting. Settings for transmission in SCBMBR is valid when the TDRQE bit in SCBSCR is set to 1, and settings for reception is valid when the RDRQE bit in SCBSCR is set to 1.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADD REQ	—	—	—	—	—	—	—	—	—	—	—	RCECR ON	—	MBRON	MBTON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	ADDREQ	0	R/W	Enables or disables receive data transfer until the receive FIFO data count is decreased to 0. 0: Receive data transfer disabled until the receive FIFO data count is decreased to 0 1: Receive data transfer enabled until the receive FIFO data count is decreased to 0
14 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	RCECRON	0	R/W	Enables or disables receive data transfer in conjunction with the RCEF bit in SCBSSR. Receive data transfer requests are made until the receive FIFO data count is decreased to 0. 0: Receive data transfer in conjunction with RCEF in SCBSSR enabled 1: Receive data transfer in conjunction with RCEF in SCBSSR disabled

Bit	Bit Name	Initial Value	R/W	Description
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1	MBRON	0	R/W	Enables or disables multibyte receive data transfer 0: Multibyte receive data transfer disabled 1: Multibyte receive data transfer enabled
0	MBTON	0	R/W	Enables or disables multibyte transmit data transfer 0: Multibyte transmit data transfer disabled 1: Multibyte transmit data transfer enabled

22.3.10 Serial Port Control Register (SCBPCR)

SCBPCR is a 16 bit readable/writable register. This register specifies whether the TXD, SCK and RTS_N pins function as output ports or the TXD, SCK and RTS_N pins, respectively. It also specifies whether the RXD and CTS_N pins function as input ports or the RXD and CTS_N pins, respectively.

SCBPCR is initialized to H'0000. This register function is valid only when the SCIFB pin function is selected through the pin function controller (PFC).

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	RTSC	CTSC	SCKC	RXDC	TXDC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	H'000	R	Reserved These bits are always read as 0. The write value should always be 0.
4	RTSC	0	R/W	Selects the RTS_N pin function. 0: The RTS_N pin functions as the RTS_N pin. 1: The RTS_N pin functions as an output port.
3	CTSC	0	R/W	Selects the CTS_N pin function. 0: The CTS_N pin functions as the CTS_N pin. 1: The CTS_N pin functions as an input port.
2	SCKC	0	R/W	Selects the SCK pin function. 0: The SCK pin functions as the SCK pin. 1: The SCK pin functions as an output port.
1	RXDC	0	R/W	Selects the RXD pin function. 0: The RXD pin functions as the RXD pin. 1: The RXD pin functions as an input port.
0	TXDC	0	R/W	Selects the TXD pin function. 0: The TXD pin functions as the TXD pin. 1: The TXD pin functions as an output port.

22.3.11 Serial Port Data Register (SCBPDR)

SCBPDR is a 16 bit readable/writable register. This register specifies data output to the TXD, SCK and RTS_N pins when the SCIFB pin function is selected by SCBPCR. It also specifies the pin level of the RXD and CTS_N pins.

SCBPDR is initialized to H'0000. This register function is valid only when the SCIFB pin function is selected through the pin function controller (PFC).

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	RTSD	CTSD	SCKD	RXDD	TXDD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	—	0	—	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	W	R	W	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	H'000	R	Reserved These bits are always read as 0. The write value should always be 0.
4	RTSD	0	W	Specifies data output to the RTS_N pin. 0: Outputs 0. 1: Outputs 1.

Bit	Bit Name	Initial Value	R/W	Description
3	CTSD	Undefined	R	Specifies the CTS_N pin level. 0: CTS_N pin level is 0. 1: CTS_N pin level is 1.
2	SCKD	0	W	Specifies data output to the SCK pin. 0: Outputs 0. 1: Outputs 1.
1	RXDD	Undefined	R	Specifies the RXD pin level. 0: RXD pin level is 0. 1: RXD pin level is 1.
0	TXDD	0	R/W	Specifies data output to the TXD pin. 0: Outputs 0. 1: Outputs 1.

22.3.12 Transmit FIFO Data Count Register (SCBTFDR)

SCBTFDR is a 16-bit read-only register that indicates the number of data bytes stored in SCBFTDR.

The T8 to T0 bits indicate the number of transmit data bytes in SCBFTDR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	T[8:0]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 0	T[8:0]	H'000	R	Indicate the number of data bytes remaining in SCBFTDR. H'000 shows that SCBFTDR contains no transmit data, and H'100 shows that SCBFTDR is filled with transmit data.

22.3.13 Receive FIFO Data Count Register (SCBRFDR)

SCBRFDR is a 16-bit read-only register that indicates the number of data bytes stored in SCBFRDR.

The R8 to R0 bits indicate the number of receive data in SCBFRDR.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	R[8:0]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 0	R[8:0]	H'000	R	Indicate the number of data bytes remaining in SCBFRDR. H'000 shows that SCBFRDR contains no receive data, and H'100 shows that SCBFRDR is filled with receive data.

22.3.14 Transmit FIFO Data Register (SCBFTDR)

SCBFTDR is an 8-bit 256-stage FIFO data register that stores data for serial transmission.

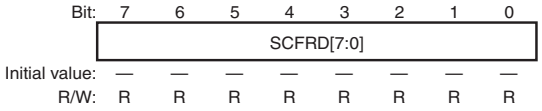
If SCBTSR is empty when transmit data has been written to SCBFTDR, the SCIFB transfers the transmit data written in SCBFTDR to SCBTSR and starts serial transmission.

SCBFTDR is a write-only register, and cannot be read by the CPU.

The next data cannot be written when SCBFTDR is filled with 256 bytes of transmit data. Data written in this case is ignored.

Bit:	7	6	5	4	3	2	1	0
	SCFTD[7:0]							
Initial value:	—	—	—	—	—	—	—	—
R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFTD[7:0]	Undefined	W	Serial transmit data FIFO



22.3.15 Receive FIFO Data Register (SCBFRDR)

SCBFRDR is a 256-stage FIFO register that stores received serial data.

When the SCIFB has received one byte of serial data, it transfers the received data from SCBRSR to SCBFRDR where it is stored, and completes the receive operation. SCBRSR is then enabled for reception, and consecutive receive operations can be performed until SCBFRDR is full (256-byte data).

SCBFRDR is a read-only register, and cannot be written to by the CPU.

If a read is performed when there is no receive data in SCBFRDR, an undefined value will be returned. When SCBFRDR is full of receive data, subsequent serial data is lost.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SCFRD[7:0]	Undefined	R	Serial receive data FIFO

22.4 Operation

22.4.1 Overview

The SCIFB supports serial communications in asynchronous mode, in which synchronization is achieved character by character, and in clocked synchronous mode, in which synchronization is achieved with clock pulses. 256-stage FIFO buffers are provided for both transmission and reception, reducing the CPU overhead and enabling high-speed continuous communications.

22.4.2 Asynchronous Mode

In the asynchronous mode , the transfer format is selected by the setting in SCBSMR as shown in Table 22.5. Features in this mode are as follows.

- Data length: 7 or 8 bits
- The addition of parity (even, odd or none) and the choice of stop-bit length (1 or 2 bits), along with the data length, determine the transfer format and character length.
- Receive error detection: Framing, parity, and overrun errors, receive-FIFO-data-full, receive-data-ready, and breaks.
- Independent indications of the number of data stored in the transmit and receive FIFO registers.
- Serial clock source: Internal clock signal generated by the baud-rate generator.

Table 22.5 SCBSMR Settings for Serial Transfer Format Selection

SCBSMR Setting					SCIFB Transfer Format		
Bit 7	Bit 6	Bit 5	Bit 3		Data Length	Parity Bit	Stop Bit Length
C/A	CHR	PE	STOP	Mode			
0	0	0	0	Asynchronous mode	8-bit data	None	1 bits
			1				2 bits
		1	0			Provided	1 bits
			1				2 bits
	1	0	0		7-bit data	None	1 bits
			1				2 bits
		1	0			Provided	1 bits
			1				2 bits
1	*	*	*	Clocked synchronous mode	8-bit data	None	None

Note: * Don't care

22.4.3 Serial Operation in Asynchronous Mode

(1) Data Transfer Format

Table 22.6 shows the transfer formats that can be used in asynchronous mode. Any of eight transfer formats can be selected according to the SCBSMR settings.

Table 22.6 Serial Transfer Formats

SCBSMR setting			Serial transfer format and frame length
CHR	PE	STOP	1 2 3 4 5 6 7 8 9 10 11 12
0	0	0	START 8 bit data STOP
		1	START 8 bit data STOP STOP
	1	0	START 8 bit data P STOP
		1	START 8 bit data P STOP STOP
1	0	0	START 7 bit data STOP
		1	START 7 bit data STOP STOP
	1	0	START 7 bit data P STOP
		1	START 7 bit data P STOP STOP

(2) Clock

An internal clock signal generated by the on-chip baud-rate generator provides the transfer clock for SCIFB.

(3) Data Transfer Operations:

1. SCIFB initialization

   Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCBSCR to 0, and then initialize the SCIFB as described below.

   When the transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, SCBTSR is initialized. Note that clearing the TE and RE bits to 0 does not change the contents of SCBSSR, SCBFTDR, or SCBFRDR. The TE bit should be cleared to 0 after all transmit data has been sent and the TEND bit in SCBSSR has been set to 1. Clearing to 0 can also be performed during transmission, but the data lines that transmit the data will go to the high-impedance state after the clearance. Before setting TE to 1 again to start transmission, the TFRST bit in SCBFCR should first be set to 1 to reset SCBFTDR.

   Figure 22.2 shows a sample SCIFB initialization flowchart.

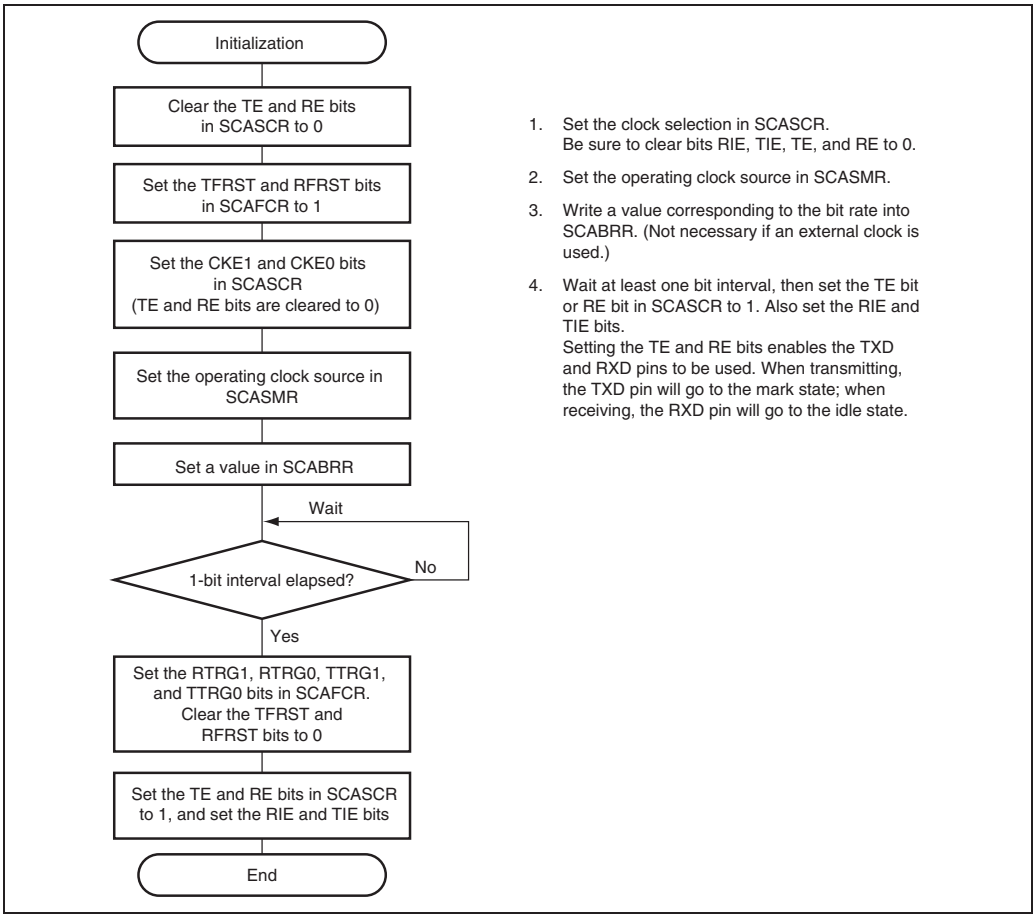


Figure 22.2 Sample SCIFB Initialization Flowchart

2. Serial data transmission

   Figure 22.3 shows a sample flowchart for serial transmission.

   Use the following procedure for serial data transmission after enabling the SCIFB for transmission.

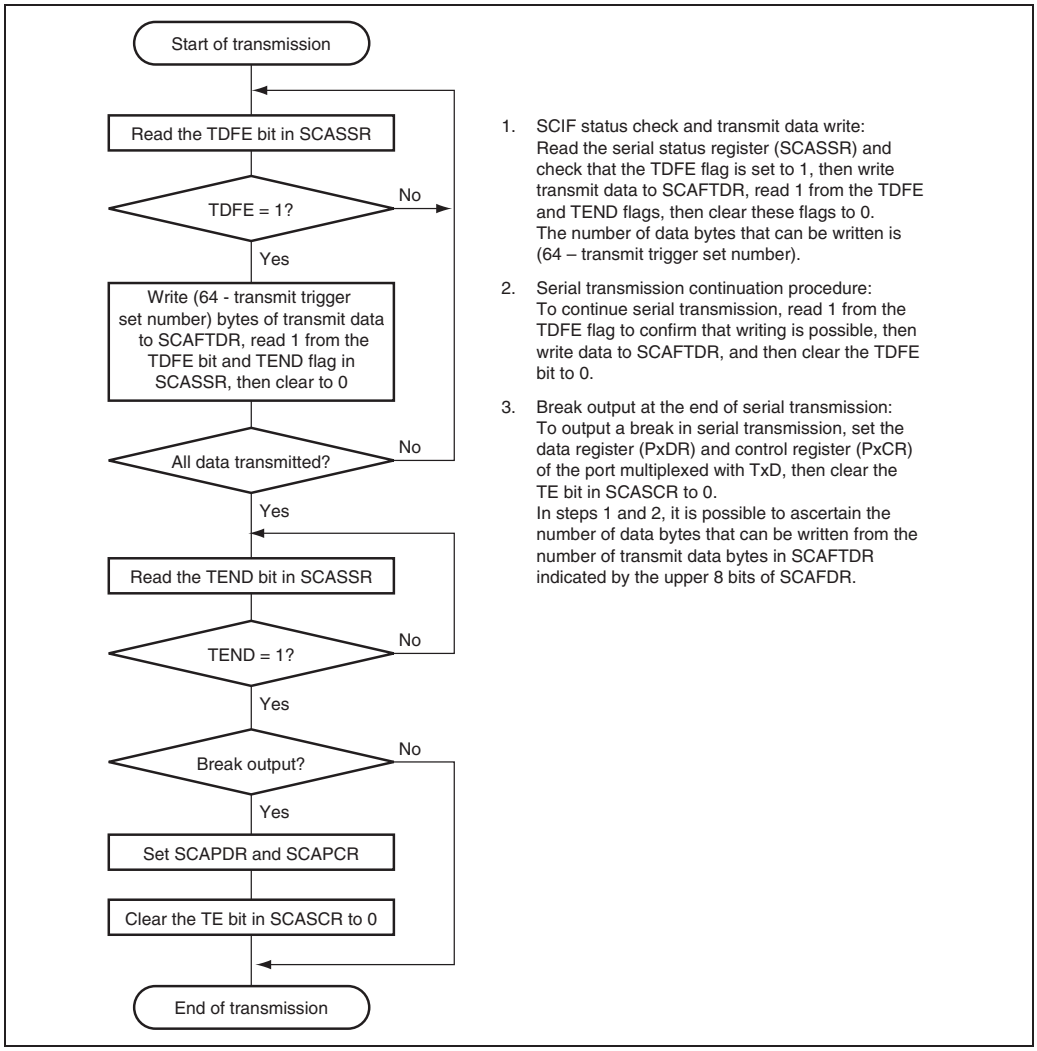

Figure 22.3 Sample Serial Transmission Flowchart

In serial transmission, the SCIFB operates as described below.

A. When data is written into SCBFTDR, the SCIFB transfers the data from SCBFTDR to SCBTSR and starts transmitting. Confirm that the TDFE flag in SCBSSR is set to 1 before writing transmit data to SCBFTDR. The number of data bytes that can be written is not less than (256 – transmit trigger set number).

B. When data is transferred from SCBFTDR to SCBTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCBFTDR. When the number of transmit data bytes in SCBFTDR falls to or below the transmit trigger number set in SCBFCR, the TDFE flag is set. If the TIE bit in SCBSCR is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

When the transmit data stop function is used and the number of data bytes set in SCBTDSR is matched, transmit operation is stopped and the TSF flag in SCBSSR is set. If the TSIE bit in SCBSCR is set to 1, a transmit-data-stop-interrupt (TDI) request is generated. The vectors of TXI and TDI are the same.

The serial transmit data is sent from the TxD pin in the following order.

a. Start bit: One logic-0 bit is output.
b. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
c. Parity bit: One parity bit (even or odd parity) is output.
d. A format in which a parity bit is not output can also be selected.
e. Stop bit(s): One or two logic-1 bits (stop bits) are output.
f. Mark state: Output of 1 is continued until the start bit is sent to start the next transmission.

C. The SCIFB checks the SCBFTDR transmit data at the timing for sending the stop bit. If data is present, the data is transferred from SCBFTDR to SCBTSR, the stop bit is sent, and then serial transmission of the next frame is started.

If there is no transmit data, the TEND flag in SCBSSR is set to 1, the stop bit is sent, and then the line goes to the mark state in which 1 is output.

Figure 22.4 shows an example of the operation for transmission in asynchronous mode.

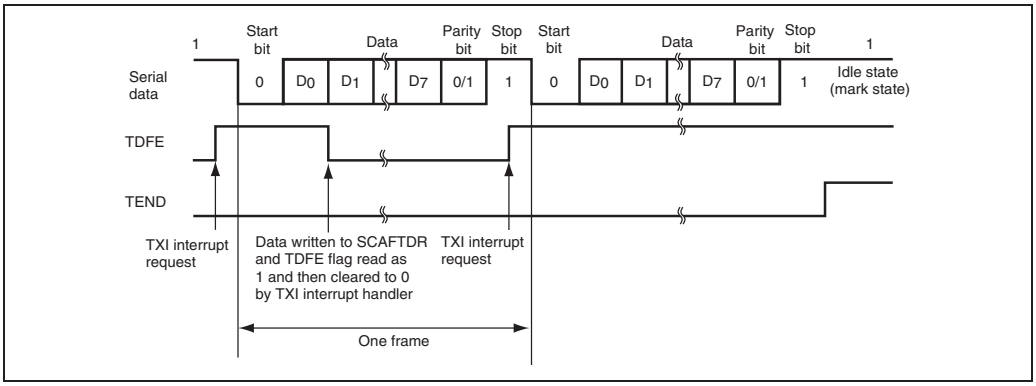

Figure 22.4 Example of Transmit Operation (Example with 8-Bit Data, Parity, One Stop Bit)

- Transmit data stop function

  When the value in SCBTDSR equals the number of transmitted data bytes, this function stops the transmit operation. Interrupts can be generated and the DMAC can be activated by setting the TSIE bit (interrupt enable bit) to 1.

  Figure 22.5 shows an example of operation for the transmit data stop function.

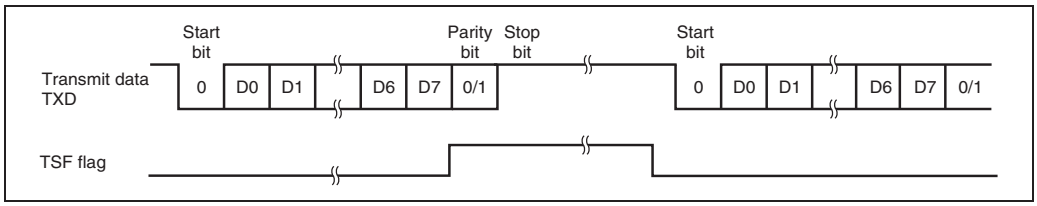

Figure 22.5 Example of Transmit Data Stop Function

Figure 22.6 shows a flowchart for the transmit data stop function.

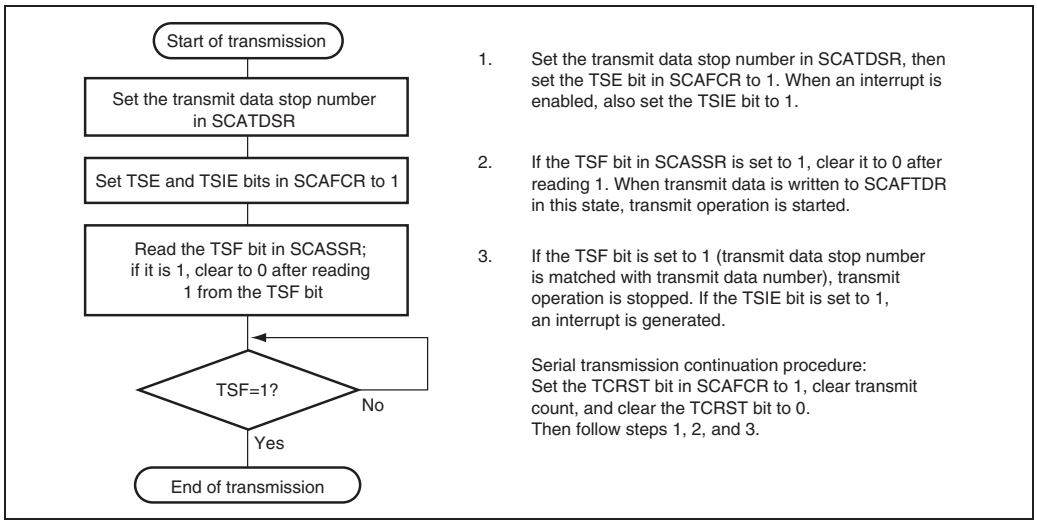

Figure 22.6 Transmit Data Stop Function Flowchart

3. Serial data reception

Figures 20.7 and 20.8 show sample flowcharts for serial reception.

Use the following procedure for serial data reception after enabling the SCIFB for reception.

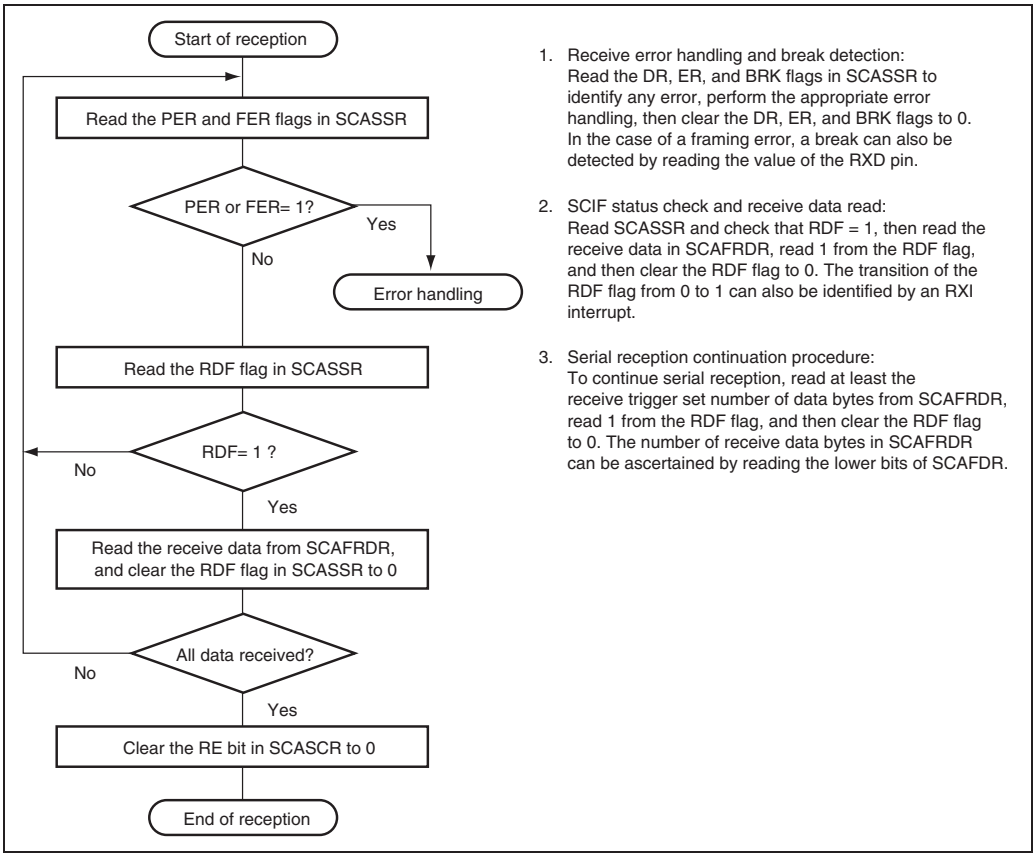

Figure 22.7 Sample Serial Reception Flowchart (1)

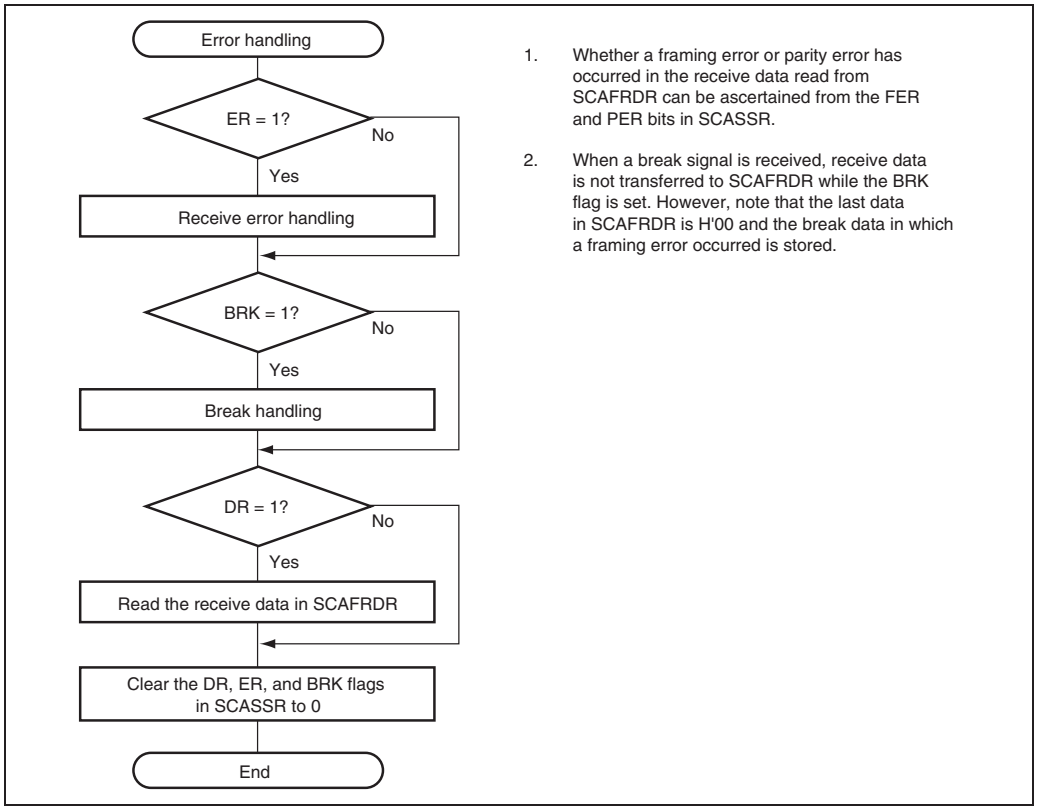

Figure 22.8 Sample Serial Reception Flowchart (2)

In serial reception, the SCIFB operates as described below.

A. The SCIFB monitors the communication line, and if a 0 start bit is detected, performs internal synchronization and starts reception.

B. The received data is stored in SCBRSR in LSB-to-MSB order.

C. The parity bit and stop bit are received.

After receiving these bits, the SCIFB carries out the following checks.

a. Stop bit check: The SCIFB checks to see if the value in the stop bit position is 1. If the two-stop-bit setting has been made, only the value in the first stop-bit position is checked.

b. The SCIFB checks whether received data can be transferred from SCBRSR to SCBFRDR.

c. Break check: The SCIFB checks to confirm that the BRK flag is 0, indicating that the SCIFB is not in the break state.

If all the above checks are passed, the receive data is stored in SCBFRDR.

Note: Reception continues when a receive error (framing error or parity error) occurs.

D. If the RIE bit in SCBSCR is set to 1 when the RDF flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.

If the ERIE bit in SCBSCR is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated.

If the BRIE bit in SCBSCR is set to 1 when the BRK flag changes to 1, a break reception interrupt (BRI) request is generated.

If the DRIE bit in SCBSCR is set to 1 when the DR flag changes to 1, a receive-data-ready interrupt (DRI) request is generated.

The vectors of each interrupt source are the same.

Figure 22.9 shows an example of the operation for reception in asynchronous mode.

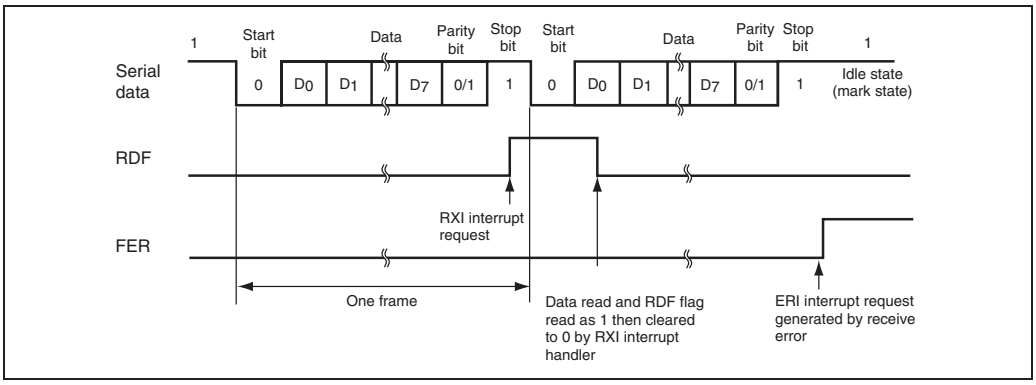

Figure 22.9 Example of SCIFB Receive Operation (Example with 8-Bit Data, Parity, One Stop Bit)

The SCIFB has a modem function that allows the stoppage and resumption of transmission according to the input value of CTS_N. Setting CTS_N to 1 places the transmission line in the mark state after transmission of the current frame. When CTS_N is set to 0, the next frame for transmission is output, with a start bit as its leader.

Figure 22.10 shows an example of the operation of CTS_N control.

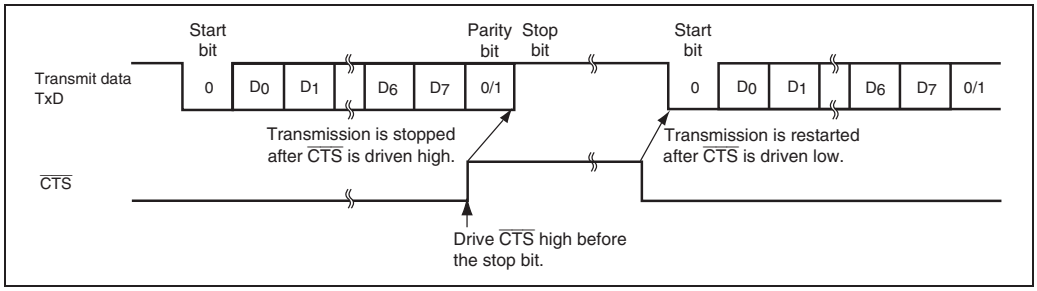

Figure 22.10 Example of CTS_N Control Operation

The RTS_N signal is driven high when the modem function is in use and the received data stored in the receive FIFO register (SCBFRDR) equals or exceeds the number of the RTS_N output triggers.

Figure 22.11 shows an example of the operation for RTS_N control.

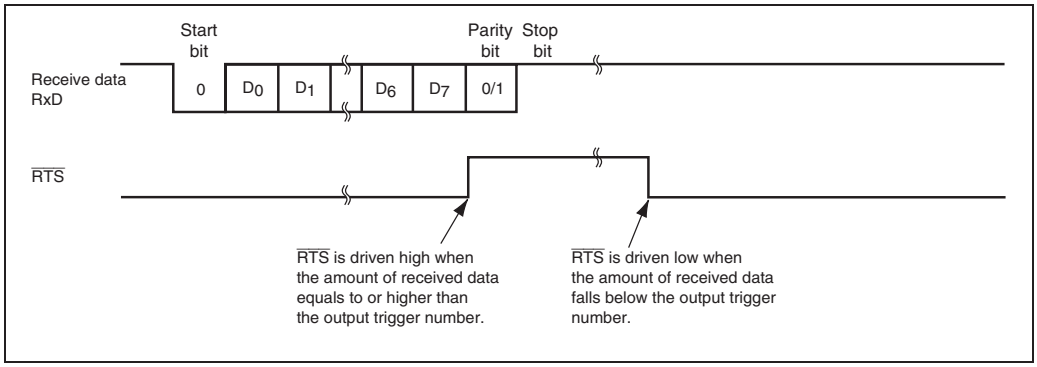

Figure 22.11 Example of RTS_N Control Operation

22.4.4 Operation in Clocked Synchronous Mode

Clocked synchronous mode, in which data is transmitted or received in synchronization with clock pulses, is suitable for fast serial communications.

Since the transmitter and receiver are independent units in SCIFB, full-duplex communications can be achieved by sharing the clock. Both the transmitter and receiver have a 256-stage FIFO buffer structure, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

Through the setting of the CKEDG bit, the format for clocked synchronous communications can be selected.

Figures 20.12 and 20.13 show the format for clocked synchronous communications.

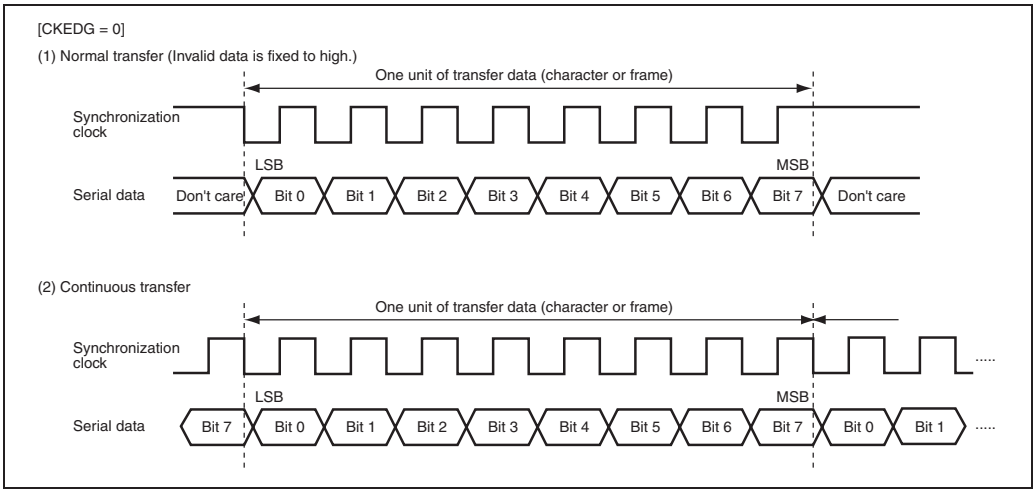

Figure 22.12 Data Format in Clocked Synchronous Communications (CKEDG = 0)

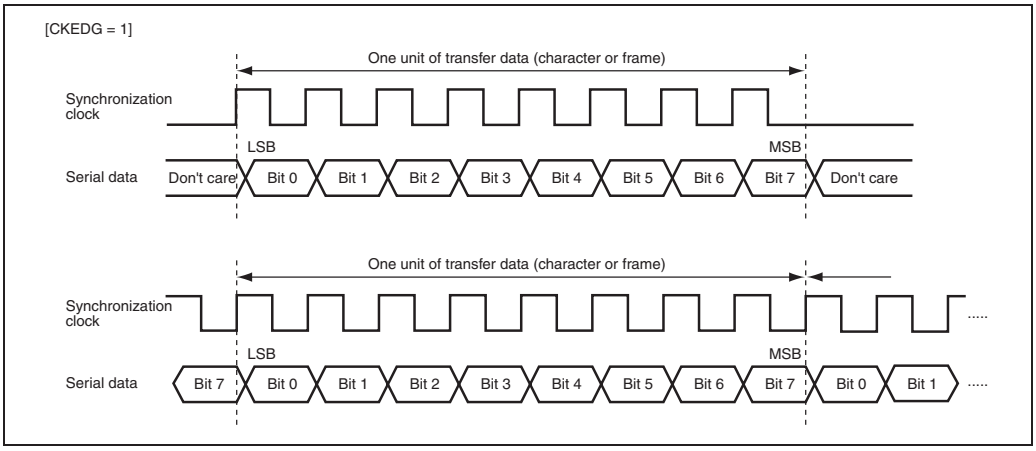

Figure 22.13 Data Format in Clocked Synchronous Communications (CKEDG = 1)

In clock synchronous serial communications, the data on the communications line is latched on one edge selected by the CKEDG bit in SCBSMR and is output until the next edge. Accuracy of data is guaranteed on the next edge (i.e. that in the opposite direction to the latching edge).

In serial communications, each character is output starting with the LSB and ending with the MSB. After the MSB is output, the communications line remains in the state of the last bit.

Data is received on the opposite edge to that on which data is output.

(1) Data Transfer Format

A fixed 8-bit data format is used. No parity bit can be added.

(2) Clock

An internal clock signal generated by the on-chip baud-rate generator provides the transfer clock for SCIFB. For details on SCIFB clock source selection, see Table 22.5.

(3) SCIFB Initialization (Clocked Synchronous Mode)

Before transmitting and receiving data, it is necessary to clear the TE and RE bits in SCBSCR to 0, and then initialize the SCIFB as described below.

When changing the operating mode or transfer format, etc., the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, SCBTSR is initialized. Note that clearing the RE bit to 0 does not initialize the RDF, PER, FER, or ORER flag state or change the contents of SCBFRDR.

Figure 22.14 shows a sample SCIFB initialization flowchart.

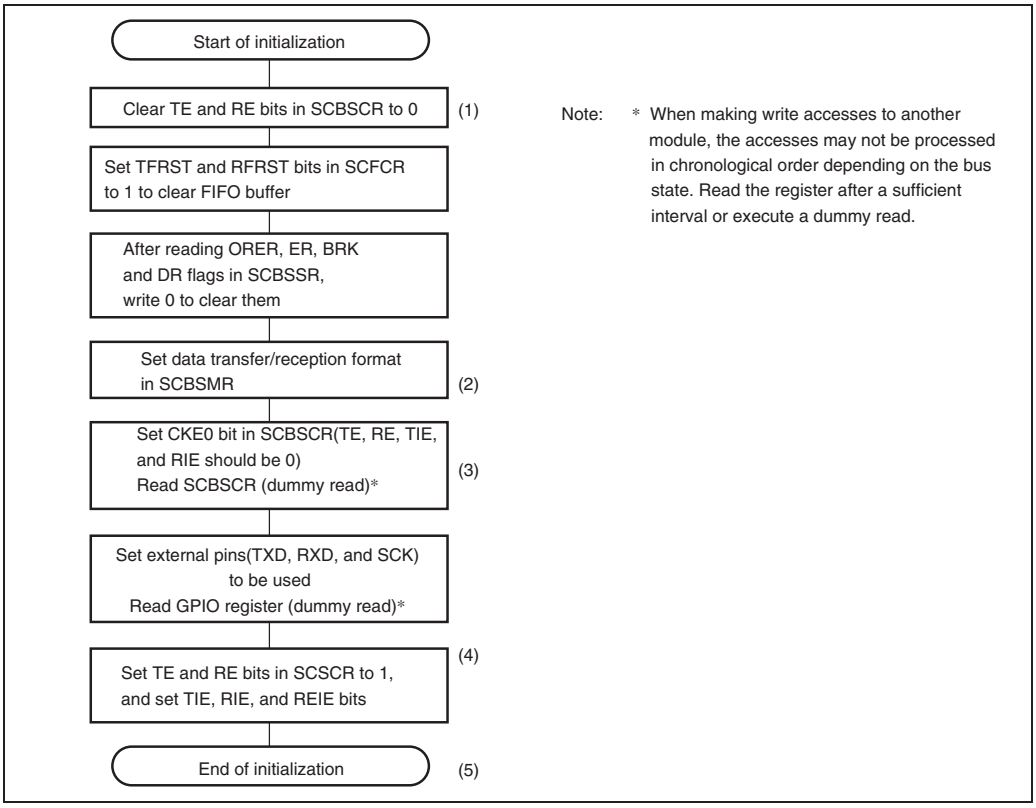

Figure 22.14 Sample SCIFB Initialization Flowchart

(4) Serial Data Transmission (Clocked Synchronous Mode)

Figure 22.15 shows a sample flowchart for serial transmission.

Use the following procedure for serial data transmission after enabling the SCIFB for transmission.

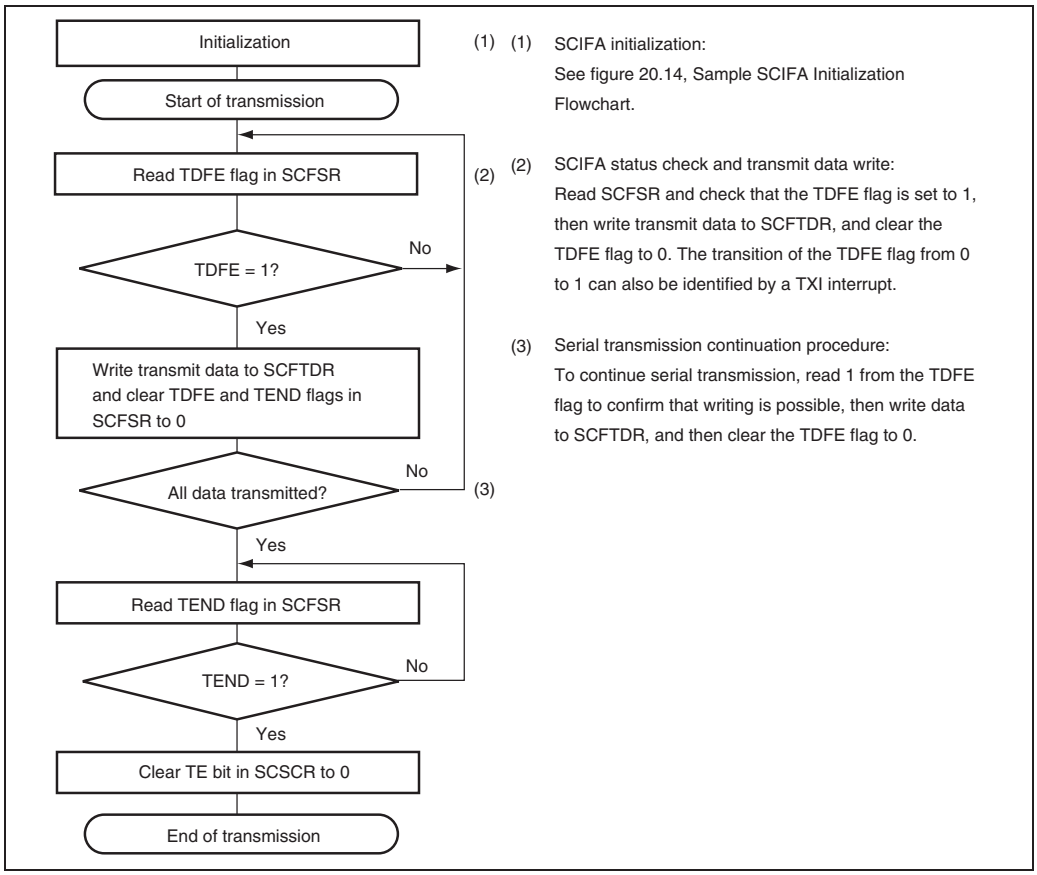

Figure 22.15 Sample Serial Transmission Flowchart

In serial transmission, the SCIFB operates as described below.

1. When data is written into SCBFTDR, the SCIFB transfers data from SCBFTDR to SCTSR and starts transmitting. Confirm that the TDFE flag in SCBSSR is set to 1 before writing transmit data to SCBFTDR. The number of data bytes that can be written is at least 16 – (transmit trigger set number).
2. When data is transferred from SCBFTDR to SCTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCBFTDR. When the number of transmit data bytes in SCBFTDR falls to or below the transmit trigger number set in SCBFCR, the TDFE flag is set. If the TIE bit in SCBSCR is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

   The SCIFB outputs data in synchronization with the input clock.

   The serial transmit data is sent from the TXD pin in the LSB-first order.
3. The SCIFB checks the SCBFTDR transmit data at the timing for sending the last bit. If data is present, the data is transferred from SCBFTDR to SCTSR, and then serial transmission of the next frame is started. If there is no transmit data, the TEND flag in SCBSSR is set to 1 after the last bit is sent, and the transmit data pin (TXD pin) retains the output state of the last bit.

Figure 22.16 shows an example of the SCIFB operation for transmission in clocked synchronous mode.

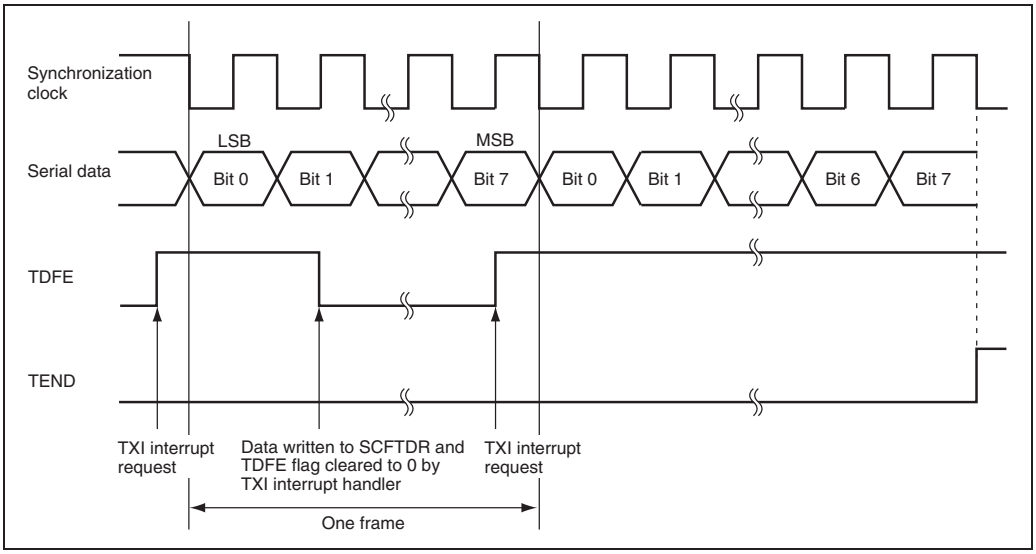

Figure 22.16 Sample SCIFB Transmission Operation in Clocked Synchronous Mode

(5) Serial Data Reception (Clocked Synchronous Mode)

Figures 20.17 and 20.18 show sample flowcharts for serial reception.

Use the following procedure for serial data reception after enabling the SCIFB for reception.

When switching the operating mode from asynchronous mode to clocked synchronous mode without initializing SCIFB, make sure that the ORER flag in SCBSSR, and PERC and FERC flags in SCLSR are cleared to 0.

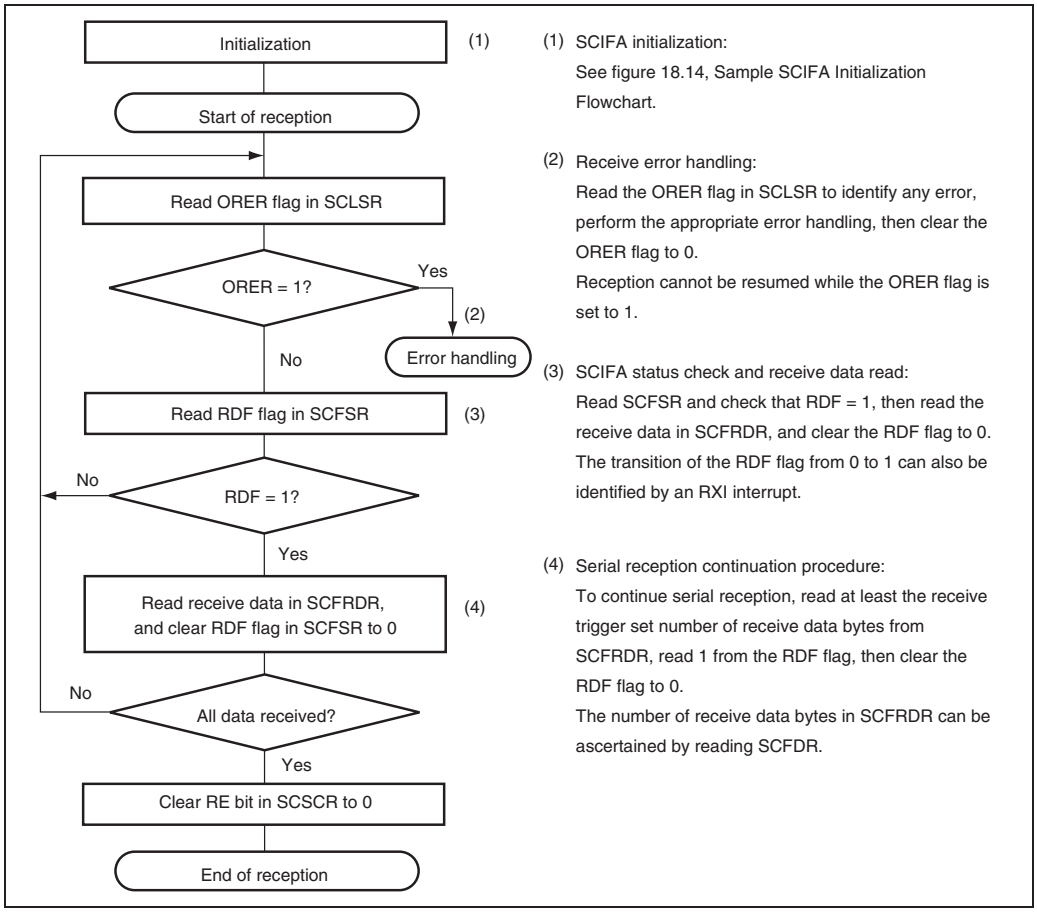

Figure 22.17 Sample Serial Reception Flowchart (1)

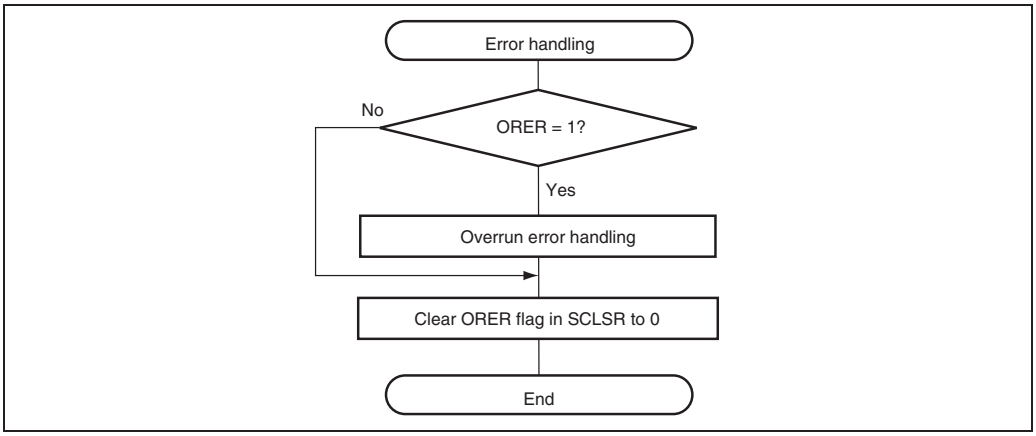

Figure 22.18 Sample Serial Reception Flowchart (2)

In serial reception, the SCIFB operates as described below.

1. The SCIFB starts reception in synchronization with the output of the synchronization clock.
2. The received data is stored in SCRSR in LSB-to-MSB order.
   After receiving the data, the SCIFB checks whether the receive data can be transferred from SCRSR to SCBFRDR. If this check is passed, the receive data is stored in SCBFRDR. If an overrun error is detected in the error check, reception cannot continue.
3. If the RIE bit in SCBSCR is set to 1 when the RDF flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated.
   If the RIE or ERIE bit in SCBSCR is set to 1 when the ORER flag changes to 1, a break interrupt (BRI) request is generated.

Figure 22.19 shows an example of the operation for reception in clocked synchronous mode.

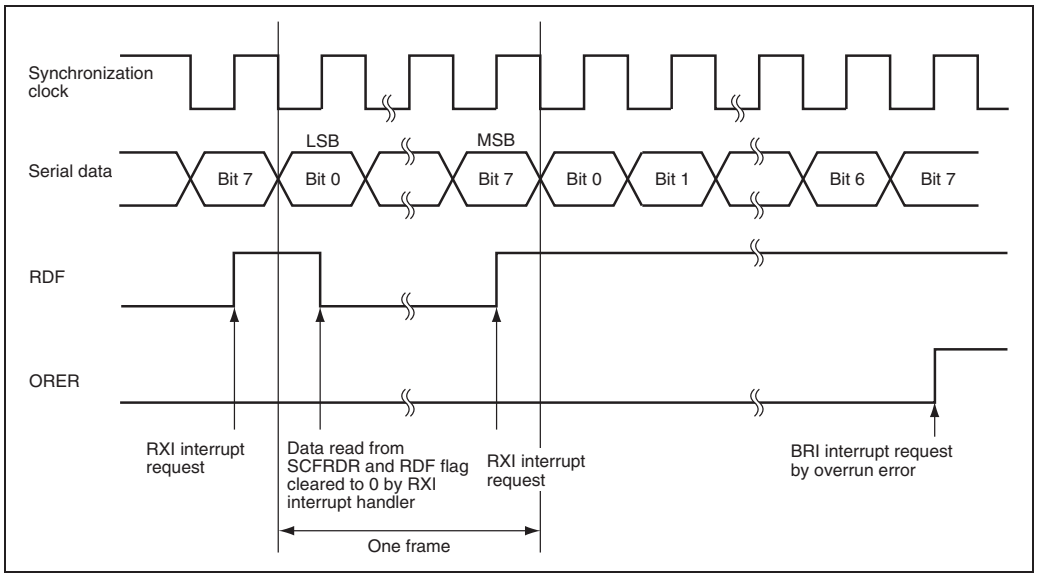

Figure 22.19 Sample SCIFB Reception Operation in Clocked Synchronous Mode

(6) Simultaneous Serial Data Transmission and Reception (Clocked Synchronous Mode)

Figure 22.20 shows a sample flowchart for simultaneous serial data transmission and reception.

Use the following procedure for simultaneous serial transmission and reception after enabling the SCIFB for both the transmission and reception.

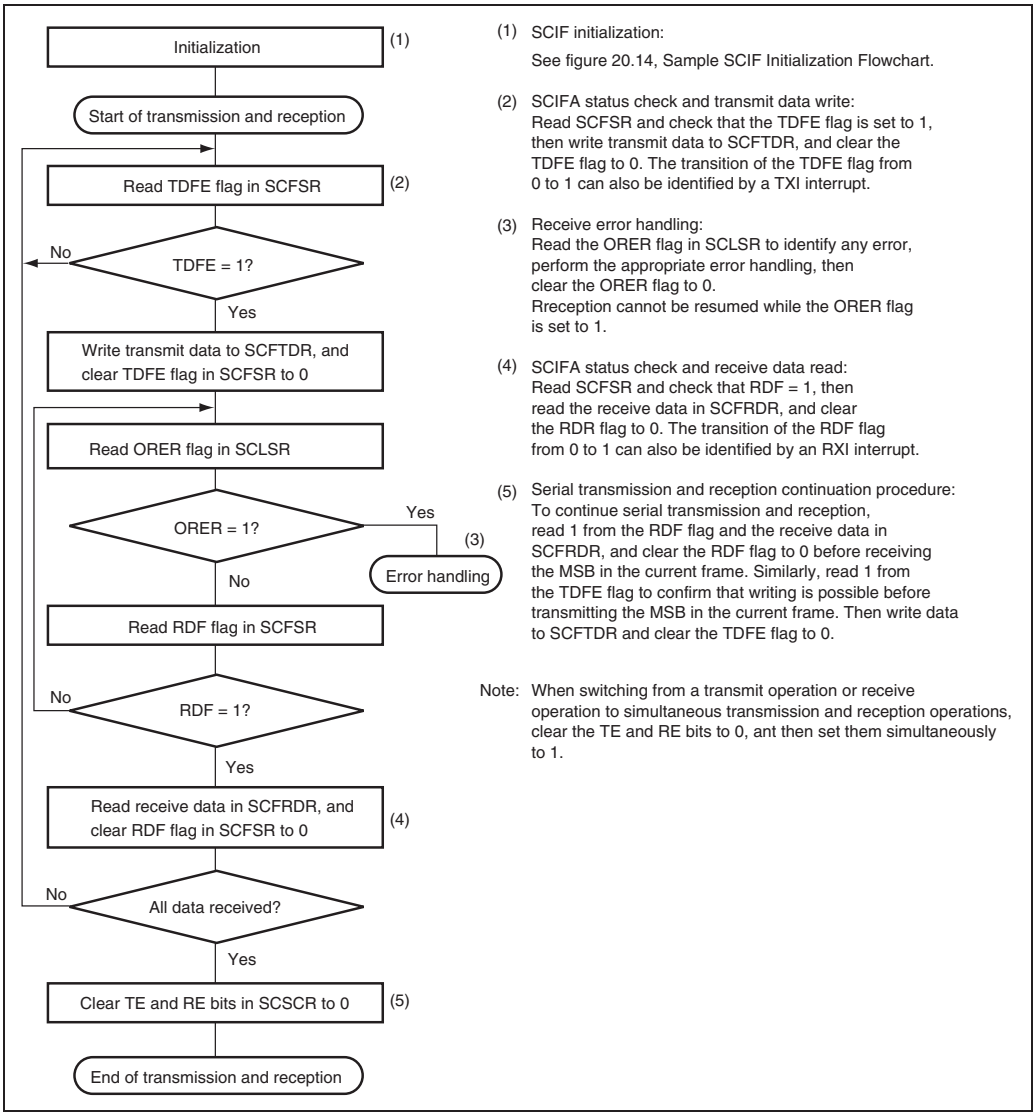

Figure 22.20 Sample Simultaneous Serial Transmission and Reception Flowchart

22.5 SCIFB Interrupt Sources and DMAC

The SCIFB supports six interrupts: transmit-FIFO-data-empty (TXI), transmit-data-stop (TDI), receive-error (ERI), receive-FIFO-data-full (RXI), break (BRI), and receive-data-ready (DRI). The vectors of each interrupt source are the same.

Table 22.7 shows the interrupt sources. The TIE, RIE, ERIE, BRIE, DRIE, and TSIE bits in SCBSCR are used to enable or disable the respective interrupt sources.

If the TDFE flag in SCBSSR is set to 1, a TXI interrupt request is generated. When the TSF flag in SCBSSR is set to 1, a TDI interrupt request is generated. The DMAC can be activated for data transfer on generation of TXI and TDI interrupt requests. When data exceeding the transmit trigger set number is written to SCBFTDR by the DMAC, the DMAC transfer request is automatically cleared to 0. The DMAC requests of TXI and TDI are the same.

When the RDF flag in SCBSSR is set to 1, an RXI interrupt request is generated. The DMAC can be activated for data transfer on generation of an RXI interrupt request. When receive data in SCBFRDR is read by the DMAC until the amount left is less than the receive trigger set number, the DMAC transfer request is automatically cleared to 0.

When using the DMAC for transmission/reception, set the DMAC to the DMAC transfer enabled state before making the SCIFB settings. Transmission/reception is complete when the DMA transfer is terminated.

When the ER, BRK, DR, or TSF flag in SCBSSR is set to 1, an interrupt request is generated. Note that the vectors of each interrupt source are the same.

Table 22.7 SCIFB Interrupt Sources

Interrupt Source Type	DMAC Activation
Interrupt initiated by receive error (ER) or break (BRK) flag	Not possible
Interrupt initiated by receive-FIFO-data-full (RDF) or receive-data-ready (DR) flag	Possible*[1]
Interrupt initiated by transmit-FIFO-data-empty (TDFE) or transmit-data-stop (TSF) flag	Possible*[2]

Notes: 1. The DMAC can only be activated by an interrupt request initiated by the receive-FIFO-data-full (RDF) flag.
2. The DMAC can only be activated by an interrupt request initiated by the transmit-FIFO-data-empty (TDFE) flag.

22.6 Multibyte Transfer

22.6.1 Basic Multibyte Settings

Table 22.8 shows the SCIFB settings and DMA settings for multibyte transfer.

Table 22.8 SCIFB Settings and DMA Settings for Multibyte Transfer

		SCIFB				DMA	
		SCBMBR		SCBFCR		DMACHCR	DMATCR
Transfer Mode	Transmission/ Reception	MBTON	MBRON	RTRG [1:0]	TTRG [1:0]	TS[3:0]	TCR[31:0]
1-byte transfer	Transmission	1	—	B'11	—	B'0000	Transfer count
	Reception	—	1	—	B'11	B'0000	Transfer count
16-byte transfer	Transmission	1	—	B'10	—	B'1010	Transfer count/16 (roundup)
	Reception	—	1	—	B'10	B'1010	Transfer count/16 (roundup)
32-byte transfer	Transmission	1	—	B'01	—	B'1101	Transfer count/32 (roundup)
	Reception	—	1	—	B'01	B'1101	Transfer count/32 (roundup)

22.6.2 Transfer Count Definition

(1) Number of Transfer Data Bytes for Transmission

In 16-byte or 32-byte transfer mode, data more than the transfer count is transferred to the transmit FIFO buffer. Therefore, define the transfer count in SCBTDSR, and set the TSE bit in SCBFCR to 1 to enable the transmit data stop function before starting DMA transfer.

(2) Number of Transfer Data Bytes for Reception

In 16-byte or 32-byte transfer mode, when the receive data remaining in the receive FIFO buffer is less than 16 bytes (or 32 bytes), the data is still left in the FIFO buffer. When the RCEF bit in SCBSSR is set to 1 by setting the RCE bit in SCBFCR and the RCECRON bit in SCBMBR to 1, 16-byte (or 32-byte) transfer requests are made continuously to the DMAC until the receive FIFO buffer becomes empty. In this case, the DMAC attempts to transfer data more than the number of received data bytes, causing an underflow error.

When the ADDREQ bit in SCBMBR is set to 1 after the reception is completed, 16-byte (or 32-byte) transfer requests are made to the DMAC until the receive FIFO buffer becomes empty.

22.7 Usage Notes

Note the following when using SCIFB.

(1) Writing Data to SCBFTDR and TDFE Flag

The TDFE flag in SCBSSR is set when the number of transmit data bytes written in SCBFTDR has fallen to or below the transmit trigger number set by bits TTRG1 and TTRG0 in SCBFCR. After TDFE is set, transmit data up to the number of empty bytes in SCBFTDR can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in SCBFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again after being read as 1 and cleared to 0. TDFE should therefore be cleared when SCBFTDR contains transmit data more than the transmit trigger number bytes.

The number of transmit data bytes in SCBFTDR is indicated by the T8 to T0 bits in SCBTFDR.

(2) Reading Data from SCBFRDR and RDF Flag

The RDF flag in SCBSSR is set when the number of receive data bytes in SCBFRDR has become equal to or greater than the receive trigger number set by bits RTRG1 and RTRG0 in SCBFCR. After RDF is set, receive data equivalent to the trigger number can be read from SCBFRDR, allowing efficient continuous reception.

However, if the number of data bytes in SCBFRDR is still equal to or greater than the trigger number after a read, the RDF flag will be set to 1 again if it is cleared to 0. RDF should therefore be cleared to 0 after being read as 1 after all receive data has been read.

The number of receive data bytes in SCBFRDR is indicated by the R8 to R0 bits in SCBRFDR.

(3) Break Detection and Processing

Break signals can be detected by reading the RxD pin directly when a framing error (FER) is detected. Since the input from the RxD pin is always 0 in the break state, the FER flag is set and the parity error (PER) flag may also be set.

Although the SCIFB stops transferring receive data to SCBFRDR after receiving a break, it continues the receive operation.

(4) Receive Data Sampling Timing and Receive Margin

As an example, when the sampling rate is 1/16, the SCIFB operates on a base clock with a frequency of 8 times the transfer rate.

In reception, the SCIFB synchronizes internally by sampling the fall of the start bit with the base clock. Receive data is latched at the rising edge of the eighth base clock pulse (when the sampling rate is 1/16).

The receive data sampling timing is shown in Figure 22.21.

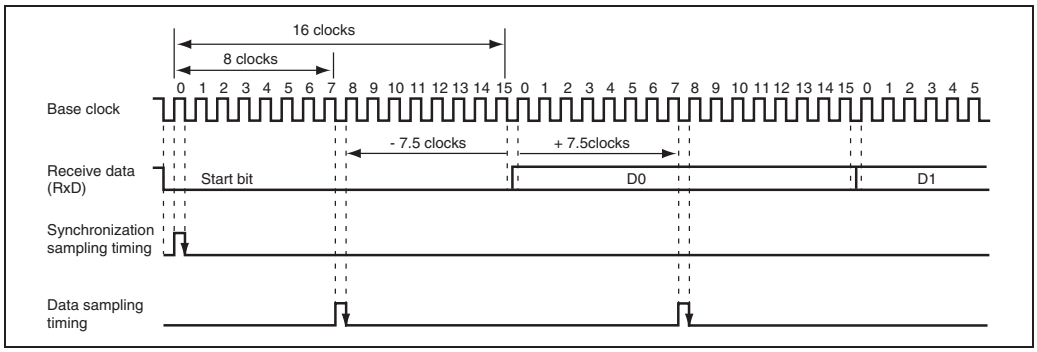

Figure 22.21 Receive Data Sampling Timing

The receive margin can therefore be expressed as shown in equation (1).

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\% \ldots\ldots (1)$$

M: Receive margin (%)

N: Ratio of clock frequency to bit rate (N = 16)

D: Clock duty cycle (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute deviation of clock frequency

From equation (1), if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation (2).

When D = 0.5 and F = 0:

$M = (0.5 - 1/(2 \times 16)) \times 100\% = 46.875\% \ldots\ldots (2)$

This is a theoretical value. A reasonable margin to allow in system designs is the value above (46.875%) plus 20 to 30%.

(5) PAD Pin when the Pin for SCIFB Is Selected

The table below shows the PAD pin state when the pin for the SCIFB is selected.

When the pin for SCIFB is selected	TXD	RXD	RTS_N	CTS_N	SCK
PAD enable	1 (enable)	1 (enable)	MCE in SCBFCR (Initial value: 0, disable)	MCE in SCBFCR (Initial value: 0, disable)	CKE0 in SCBSCR (Initial value: 0, disable)
Pin state	Output (initial value: 1)	Input	Hi-Z	Input	Hi-Z
Pull Up/Down	—	Pull-up required	—	Pull-up required	—
Remarks	—	SCIF fixes RXD to 1 internally when RE in SCBSCR = 0.	—	SCIF fixes CTS_N to 0 internally when MCE in SCBFCR = 0	—

Section 23 Clock-Synchronized Serial Interface with FIFO (MSIOF0, MSIOF1 and MSIOF2)

This LSI includes three-channel clock-synchronized serial I/O module with FIFO (MSIOF0/MSIOF1/MSIOF2).

23.1 Features

- MSIOF0 in the realtime domain and MSIOF1/2 in the system domain

- FIFO capacity: 32 bits × 64 stages for transmission and 32 bits × 256 stages for reception
- MSB first or LSB first selectable for data transmission and reception
- Synchronization by frame synchronization pulse, level, or left/right channel switch
- Supports both master and slave modes
- Independent clock and synchronization signals for transmission and reception (common clock and synchronization signals are also selectable)
- Supports multiple-channel communication
  - Transfers multiple groups or words of data in one frame.
  - The word data size for each group can be selected from eight to 32 bits
  - Up to 256 words can be transferred in each group when one or two groups are used, or up to 16 words can be transferred in each group when three or four groups are used.
- Interrupts: One type
- Serial clock

  The internal clock (SUBϕ) or external pin input (MSIOF_MCK0 or MSIOF_MCK1) can be selected as the clock source.
- DMA transfer

  Supports multibyte DMA transfer.
  Supports DMA transfer by a transfer request for transmission and reception
- Serial format

  Supports serial formats such as IIS, SPI (for both master and slave modes), and μWIRE.
- CLK/SYNC in independent transmit/receive mode
  - Up to 12 MHz for both transmission and reception
- CLK/SYNC (SPI) in common transmit/receive mode
  - Up to 12 MHz for transmission alone
  - Up to 6 MHz for reception

Figure 23.1 shows a block diagram of the MSIOF.

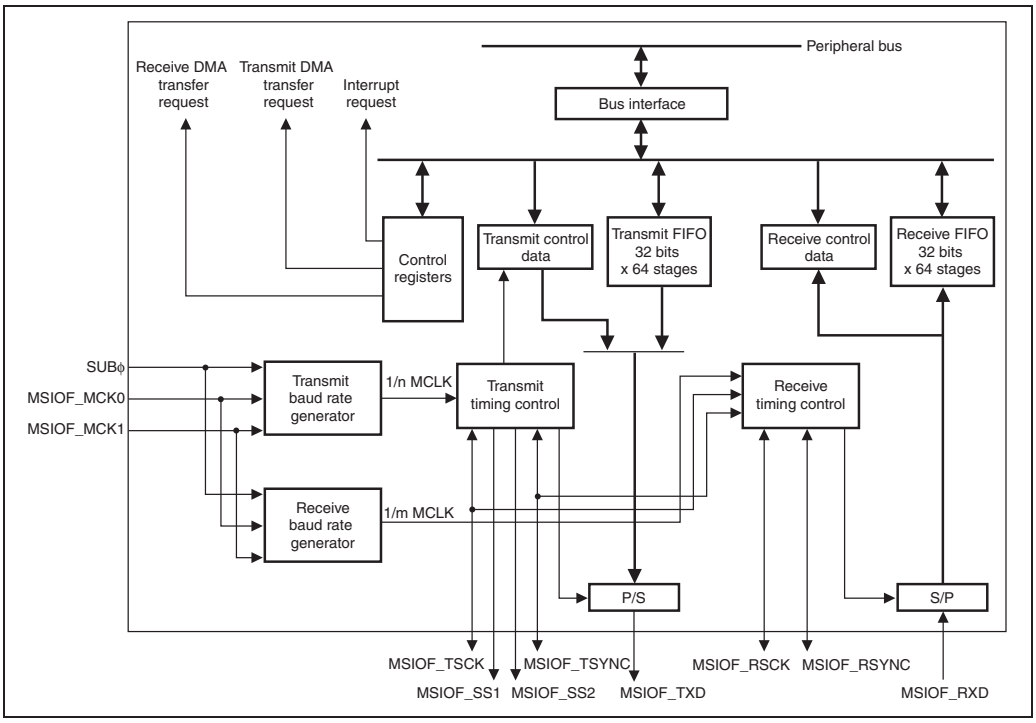

Figure 23.1 Block Diagram of MSIOF

23.2 Input/Output Pins

The pin configuration in this module is shown in table 23.1.

Table 23.1 Pin Configuration

Name	Abbreviation*	I/O	Function
MSIOF0_MCK0 MSIOF0L_MCK0		Input	MSIOF0 master clock input 0
MSIOF0_MCK1 MSIOF0L_MCK1		Input	MSIOF0 master clock input 1
MSIOF0_TSCK (MSIOFSCK) (SCK) MSIOF0L_TSCK (MSIOFSCK) (SCK)	SCK	I/O	MSIOF0 serial clock for transmission Works as SCK when a common clock is used for transmission and reception.
MSIOF0_TSYNC (SS0) MSIOF0L_TSYNC (SS0)	$\overline{\text{SS0}}$	I/O	MSIOF0 frame synchronization signal channel 0 for transmission Works as SYNC when a common synchronization signal is used for transmission and reception.
MSIOF0_SS1 (SS1) MSIOF0L_SS1 (SS1)	$\overline{\text{SS1}}$	Output	MSIOF0 frame synchronization signal channel 1 for transmission This signal works only master transmission mode.
MSIOF0_SS2 (SS2) MSIOF0L_SS2 (SS2)	$\overline{\text{SS2}}$	Output	MSIOF0 frame synchronization signal channel 2 for transmission This signal works only master transmission mode.
MSIOF0_RSCK MSIOF0L_RSCK		I/O	MSIOF0 serial clock for reception
MSIOF0_RSYNC MSIOF0L_RSYNC		I/O	MSIOF0 frame synchronization signal for reception

Name	Abbreviation*	I/O	Function
MSIOF0_TXD (MOSI/MISO)	MOSI/MISO	Output	MSIOF0 transmit data
MSIOF0L_TXD (MOSI/MISO)			
MSIOF0_RXD (MISO/MOSI)	MISO/MOSI	Input	MSIOF0 receive data
MSIOF0L_RXD (MISO/MOSI)			
MSIOF1_MCK0		Input	MSIOF0 master clock input 0
MSIOF1_MCK1		Input	MSIOF0 master clock input 1
MSIOF1_TSCK (MSIOFSCK) (SCK)	SCK	I/O	MSIOF0 serial clock for transmission Works as SCK when a common clock is used for transmission and reception.
MSIOF1_TSYNC (SS0)	$\overline{SS0}$	I/O	MSIOF0 frame synchronization signal channel 0 for transmission Works as SYNC when a common synchronization signal is used for transmission and reception.
MSIOF1_SS1 (SS1)	$\overline{SS1}$	Output	MSIOF0 frame synchronization signal channel 1 for transmission This signal works only master transmission mode.
MSIOF1_SS2 (SS2)	$\overline{SS2}$	Output	MSIOF0 frame synchronization signal channel 2 for transmission This signal works only master transmission mode.
MSIOF1_RSCK		I/O	MSIOF0 serial clock for reception
MSIOF1_RSYNC		I/O	MSIOF0 frame synchronization signal for reception
MSIOF1_TXD (MOSI/MISO)	MOSI/MISO	Output	MSIOF0 transmit data
MSIOF1_RXD (MISO/MOSI)	MISO/MOSI	Input	MSIOF0 receive data
MSIOF2_MCK0		Input	MSIOF2 master clock input 0

Name	Abbreviation*	I/O	Function
MSIOF2_MCK1		Input	MSIOF2 master clock input 1
MSIOF2_TSCK (MSIOFSCK) (SCK)	SCK	I/O	MSIOF2 serial clock for transmission Works as SCK when a common clock is used for transmission and reception.
MSIOF2_TSYNC (SS0)	$\overline{SS0}$	I/O	MSIOF2 frame synchronization signal channel 0 for transmission Works as SYNC when a common synchronization signal is used for transmission and reception.
MSIOF2_SS1 (SS1)	$\overline{SS1}$	Output	MSIOF2 frame synchronization signal channel 1 for transmission This signal works only master transmission mode.
MSIOF2_SS2 (SS2)	$\overline{SS2}$	Output	MSIOF2 frame synchronization signal channel 2 for transmission This signal works only master transmission mode.
MSIOF2_RSCK		I/O	MSIOF2 serial clock for reception
MSIOF2_RSYNC		I/O	MSIOF2 frame synchronization signal for reception
MSIOF2_TXD (MOSI/MISO)	MOSI/MISO	Output	MSIOF2 transmit data
MSIOF2_RXD (MISO/MOSI)	MISO/MOSI	Input	MSIOF2 receive data

Note: * In SPI mode, the pins are called SCK, $\overline{SS0}$, $\overline{SS1}$, $\overline{SS2}$, MOSI, and MISO.
The GPIO register can be used to switch between MSIOF0_**** and MSIOF0L_**** and switch between MSIOF2_****.

23.3 Register Descriptions

Table 23.2 shows the MSIOF0/MSIOF1/MSIOF2 register configuration and table 23.3 shows the register state in each processing mode.

Table 23.2 Register Configuration

Name	Abbreviation	R/W	Address	Access Size
MSIOF0 transmit mode register 1	SI0TMDR1	R/W	H'FFF1 0000	32
MSIOF0 transmit mode register 2	SI0TMDR2	R/W	HFFF1 0004	32

23.3.1 MSIOF Transmit Mode Register 1 (SITMDR1)

SITMDR1 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. 0: Slave mode 1: Master mode
30	PCON	0	R/W	Transfer Signal Connection When the TXRST bit is valid when PCON = 1, the RXRST bit is also valid at the same time. When PCON = 1, the receiver should be set to slave mode. 0: MSIOF_TSCK and MSIOF_TSYNC are used only for transmission. 1: MSIOF_TSCK and MSIOF_TSYNC are used as common signals for transmission and reception (MSIOF_SCK and MSIOF_SYNC).
29, 28	SYNCMD [1:0]	00	R/W	SYNC Mode These bits specify the mode for the MSIOF_TSYNC signal. 00: Frame start synchronization pulse 01: 1-bit synchronization pulse for last data in slot 10: Level mode/SPI 11: L/R mode

Bit	Bit Name	Initial Value	R/W	Descriptions
27, 26	SYNCCH [1:0]	00	R/W	Synchronization Signal Channel Select These bits are valid only in master mode. 00: The frame synchronization signal is output from MSIOF_TSYNC. 01: The frame synchronization signal is output from MSIOF_SS1. 10: The frame synchronization signal is output from MSIOF_SS2. 11: Setting prohibited
25	SYNCAC	0	R/W	MSIOF_TSYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	DTDL[2:0]	001	R/W	Data Pin Bit Delay for MSIOF_TSYNC Pin B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Descriptions
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	SYNCDL [2:0]	000	R/W	Frame Synchronization Signal Timing Delay These bits are invalid when SYNCMD[1:0] = B'01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. When L/R mode , these bits should always be set to 000. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 011: 3-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
15 to 12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
11 to 8	DIV[3:0]	0000	R/W	Word Division One 32-bit data stored in the transmit FIFO can be transmitted as two separate 16-bit words through two groups. The word count in each group must be set to 1. In this case, data of groups other than word division target groups must be handled as control data. This setting is valid only in LR mode. 0000: Not divided 0001: Upper word in group 1 and lower word in group 2 0100: Upper word in group 2 and lower word in group 1 Other than above: Setting prohibited
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3, 2	FLD[1:0]	00	R/W	Frame Synchronization Signal Interval Specify the minimum idle time between frames in the number of serial clock cycles. This setting is valid only in master mode. When Level mode, set the FLD bits in SITMDR1 for at least 4 cycles of SUBϕ. When L/R mode , these bits should always be set to 00. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay

1	CONT	0	R/W	Continuous Frame Transmission Specifies continuous transmission of multiple frames of data within one frame. This setting is valid when SYNCMD[1:0] = B'00 or B'10 When the TFSE bit in SICTR is set to 0 in master mode, transmission is stopped after one-frame data is transmitted. 0: Does not perform continuous transmission. 1: Performs continuous transmission.
0	TXSTP	0	R/W	Transmission Stop Specifies the processing performed when the remaining number of transmit FIFO stages becomes smaller than the total number of words in the transmit frame. This setting is valid only in master mode. When transmission is continued, the value specified with TXDIZ is output as transmit data. If, with TXSTP = 1, the remaining number of transmit FIFO stages becomes smaller than the total number of words in the transmit frame, transmission is stopped temporarily. After this, however, transmission is automatically restarted if writing into the transmit FIFO causes the remaining number to become larger than the total number of words in the transmit frame. 0: Continues transmission when the transmit FIFO is empty. (The frame synchronization signal is output.) 1: Temporarily stops transmission when the remaining number of transmit FIFO stages becomes smaller than the total number of words in the transmit frame. (The frame synchronization signal is not output.)

23.3.2 MSIOF Transmit Mode Register 2 (SITMDR2)

SITMDR2 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GRP[1:0]		—	BITLEN1[4:0]					WDLEN1[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL1[1:0]		GRPDL3[1:0]		CRDE4	CRDE3	CRDE2	CRDE1	CRDNUM4	CRDNUM3	CRDNUM2	CRDNUM1	GRPMASK4	GRPMASK3	GRPMASK2	GRPMASK1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	GRP[1:0]	00	R/W	Group Count The number of groups is set to the value specified in these bits + 1. When three or more groups are specified, the data size (BITLEN) is set to 16 bits or less.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0] (BITLEN3)	01111	R/W	Data Size (8 to 32 bits) The word size (bits) of groups 1 and 3 is set to the value specified in these bits + 1. (BITLEN1 = BITLEN3) Eight bits or a larger size should be specified. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored).
23 to 16	WDLEN1[7:0] (WDLEN1[3:0], WDLEN3[3:0])	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 1 and 3 are set to WDLEN1 + 1 and WDLEN3 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN1. When three or four groups are used, the upper 4-bit value is set to WDLEN1, and the lower 4-bit value is set to WDLEN3.

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	GRPDL1[1:0]	00	R/W	Group 1 Data Transmission Delay Specify the number of blank bits to be inserted before transmission of group 1. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
13, 12	GRPDL3[1:0]	00	R/W	Group 3 Data Transmission Delay Specify the number of blank bits to be inserted before transmission of group 3. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
11	CRDE4	0	R/W	Control Data Enable
10	CRDE3	0	R/W	“x” in CRDEx represents a group. Each of these bits specifies whether the group transmits FIFO data or control data. 0: The specified group transmits FIFO data. 1: The specified group transmits control data.
9	CRDE2	0	R/W	
8	CRDE1	0	R/W	
7	CRDNUM4	0	R/W	Control Data Transmit Count
6	CRDNUM3	0	R/W	“x” in CRDNUMx represents a group. Each of these bits specifies the transmission count of control data when multiple words are set for a control data group. Each bit is valid only when the corresponding CRDEx bit is 1. When CRDNUMx = 1, control data is transmitted only for the first word, and the value specified with TXDIZ is output for remaining words. 0: Transmits control data continuously. 1: Transmits control data only once.
5	CRDNUM2	0	R/W	
4	CRDNUM1	0	R/W	

Bit	Bit Name	Initial Value	R/W	Descriptions
3	GRPMASK4	0	R/W	Group Output Mask
2	GRPMASK3	0	R/W	“x” in GRPMASKx represents a group. When GRPMASKx = 1, the group outputs the value specified with TXDIZ.
1	GRPMASK2	0	R/W	
0	GRPMASK1	0	R/W	

23.3.3 MSIOF Transmit Mode Register 3 (SITMDR3)

SITMDR3 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	BITLEN2[4:0]					WDLEN2[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL2[1:0]		GRPDL4[1:0]		—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0] (BITLEN4)	01111	R/W	Word Size (8 to 32 bits) The word size is set to the value specified in these bits + 1. Eight bits or a larger size should be specified. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored).
23 to 16	WDLEN2[7:0] (WDLEN2[3:0], WDLEN4[3:0])	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 2 and 4 are set to WDLEN2 + 1 and WDLEN4 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN2. When three or four groups are used, the upper 4-bit value is set to WDLEN2, and the lower 4-bit value is set to WDLEN4.

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	GRPDL2[1:0]	00	R/W	Group 2 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 2. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
13, 12	GRPDL4[1:0]	00	R/W	Group 4 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 4. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
11 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

23.3.4 MSIOF Receive Mode Register 1 (SIRMDR1)

SIRMDR1 is a 32-bit readable/writable register that specifies the MSIOF receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRMD	PCON	SYNCMD[1:0]		SYNCCH[1:0]		SYNC AC	BITLSB	—	DTDL[2:0]			—	SYNCDL[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MRG[3:0]				—	—	—	—	FLD[1:0]		CONT	RXSTP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. This bit should be set to 0 (slave mode) when setting the PCON bit in SITMDR1 to 1. 0: Slave mode 1: Master mode
30	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
29, 28	SYNCMD [1:0]	00	R/W	SYNC Mode These bits specify the mode for the MSIOF_RSYNC signal. 00: Frame start synchronization pulse 01: 1-bit synchronization pulse for last data in slot 10: Level mode/SPI 11: L/R mode
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	SYNCAC	0	R/W	MSIOF_RSYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode

Bit	Bit Name	Initial Value	R/W	Descriptions
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	DTDL[2:0]	001	R/W	Data Pin Bit Delay for MSIOF_RSYNC Pin B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
18 to 16	SYNCDL [2:0]	000	R/W	MSIOF_RSYNC Timing Delay The synchronization signal is extended for the clock cycles specified in these bits. These bits are invalid when SYNCMD[1:0] = B'01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. When L/R mode , these bits should always be set to 000. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 011: 3-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
15 to 12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
11 to 8	MRG[3:0]	0000	R/W	Word Merge The data received as 16-bit words of two groups can be merged into one 32-bit word and the 32-bit word is stored in the receive FIFO. The word count of the two groups to be merged must be set to 1. In this case, data of groups other than word merging target groups must be handled as control data. This setting is valid only in LR mode. 0000: Not merged 0001: Upper word in group 1 and lower word in group 2 0100: Upper word in group 2 and lower word in group 1 Other than above: Setting prohibited
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3, 2	FLD[1:0]	00	R/W	Frame Synchronization Signal Interval These bits specify the minimum idle time between frames in the number of serial clock cycles. This setting is valid only in master mode. When Level mode, set the FLD bits in SIRMDR1 for at least 4 cycles of SUBϕ. When L/R mode , these bits should always be set to 00. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay

Bit	Bit Name	Initial Value	R/W	Descriptions
1	CONT	0	R/W	Continuous Frame Reception Specifies continuous reception of multiple frames of data within one frame. This setting is valid when SYNCMD[1:0] =B'00 or B'10 When the RFSE bit in SICTR is set to 0 in master mode, reception is terminated after one-frame data is received. 0: Does not perform continuous reception. 1: Performs continuous reception.
0	RXSTP	0	R/W	Reception Stop with Receive FIFO Full Specifies the processing when the receive FIFO becomes full. This setting is valid only in master mode. 0: Continues reception when the receive FIFO is full. (The receive frame synchronization signal is output.) 1: Terminates reception when the receive FIFO is full. (The receive frame synchronization signal is not output.)

23.3.5 MSIOF Receive Mode Register 2 (SIRMDR2)

SIRMDR2 is a 32-bit readable/writable register that specifies the MSIOF receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GRP[1:0]		—	BITLEN1[4:0]					WDLEN1[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL1[1:0]		GRPDL3[1:0]		CRDE4	CRDE3	CRDE2	CRDE1	CRDNUM4	CRDNUM3	CRDNUM2	CRDNUM1	GRPMASK4	GRPMASK3	GRPMASK2	GRPMASK1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	GRP[1:0]	00	R/W	Group Count The number of groups is set to the value specified in these bits + 1. When three or more groups are specified, the word size (BITLEN) is set to 16 bits or less. When using transfer signal connection (PCON = 1), set the same value as the value specified by the GRP bits in SITMDR2.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0] (BITLEN3)	01111	R/W	Word Size (8 to 32 bits) The word size (bits) of groups 1 and 3 is set to the value specified in these bits + 1. (BITLEN1 = BITLEN3) Eight bits or a larger size should be specified. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored). When using transfer signal connection (PCON = 1), set the same value as the value specified by the BITLEN1 bits in SITMDR2.

Bit	Bit Name	Initial Value	R/W	Descriptions
23 to 16	WDLEN1[7:0] (WDLEN1[3:0] WDLEN3[3:0])	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 1 and 3 are set to WDLEN1 + 1 and WDLEN3 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN1. When three or four groups are used, the upper 4-bit value is set to WDLEN1, and the lower 4-bit value is set to WDLEN3. When using transfer signal connection (PCON = 1), set the same value as the value specified by the WDLEN1 bits in SITMDR2.
15, 14	GRPDL1[1:0]	00	R/W	Group 1 Data Reception Delay These bits specify the delay in data reception of group 1. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay When using transfer signal connection (PCON = 1), set the same value as the value specified by the GRPDL1 bits in SITMDR2.
13, 12	GRPDL3[1:0]	00	R/W	Group 3 Data Reception Delay These bits specify the delay in data reception of group 3. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay When using transfer signal connection (PCON = 1), set the same value as the value specified by the GRPDL3 bits in SITMDR2.

Bit	Bit Name	Initial Value	R/W	Descriptions
11	CRDE4	0	R/W	Control Data Enable
10	CRDE3	0	R/W	"x" in CRDEx represents a group. Each of these bits specifies whether the group receives FIFO data or control data. 0: The specified group receives FIFO data. 1: The specified group receives control data.
9	CRDE2	0	R/W	
8	CRDE1	0	R/W	
7	CRDNUM4	0	R/W	Control Data Reception Count
6	CRDNUM3	0	R/W	"x" in CRDNUMx represents a group. Each of these bits specifies the reception count of control data when multiple words are set for a control data group. Each bit is valid only when the corresponding CRDEx bit is 1. When CRDNUMx = 1, only the first word is received as control data, and the other words are discarded as invalid data. 0: Receives control data continuously. 1: Receives control data only once in a frame.
5	CRDNUM2	0	R/W	
4	CRDNUM1	0	R/W	
3	GRPMASK4	0	R/W	Group Input Mask
2	GRPMASK3	0	R/W	"x" in GRPMASKx represents a group. When GRPMASKx = 1, inputs of the group are masked and discarded as invalid data.
1	GRPMASK2	0	R/W	
0	GRPMASK1	0	R/W	

23.3.6 MSIOF Receive Mode Register 3 (SIRMDR3)

SIRMDR3 is a 32-bit readable/writable register that specifies the MSIOF receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	BITLEN2[4:0]					WDLEN2[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL2[1:0]		GRPDL4[1:0]		—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0] (BITLEN4)	01111	R/W	Word Size (8 to 32 bits) The word size is set to the value specified in these bits + 1. Eight bits or a larger size should be specified. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored). When using transfer signal connection (PCON = 1), set the same value as the value specified by the BITLEN2 bits in SITMDR3.
23 to 16	WDLEN2[7:0] (WDLEN4)	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 2 and 4 are set to WDLEN2 + 1 and WDLEN4 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN2. When three or four groups are used, the upper 4-bit value is set to WDLEN2, and the lower 4-bit value is set to WDLEN4. When using transfer signal connection (PCON = 1), set the same value as the value specified by the WDLEN2 bits in SITMDR3.

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	GRPDL2[1:0]	00	R/W	Group 2 Data Reception Delay These bits specify the delay in data reception of group 2. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay When using transfer signal connection (PCON = 1), set the same value as the value specified by the GRPDL2 bits in SITMDR3.
13, 12	GRPDL4[1:0]	00	R/W	Group 4 Data Reception Delay These bits specify the delay in data reception of group 4 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay When using transfer signal connection (PCON = 1), set the same value as the value specified by the GRPDL4 bits in SITMDR3.
11 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

23.3.7 MSIOF Control Register (SICTR)

SICTR is a 32-bit readable/writable register that specifies the MSIOF operating state.

The values written to the TXE, RXE, TFSE, RFSE, TSCKE, and RSCKE bits become valid (can be read from the bits) several cycles after writing. These bits should not be modified together; modify one bit at a time, check that the new value can be read from the bit, and then modify another bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSCKIZ[1:0]		RSCKIZ[1:0]		TEDG	REDG	—	—	TXDIZ[1:0]		—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSCKE	TFSE	RSCKE	RFSE	—	—	TXE	RXE	—	—	—	—	—	—	TXRST	RXRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	TSCKIZ[1:0]	00	R/W	Transmit Clock Input/Output Polarity Select in SPI Mode When Transmission is Disabled When SPI mode is not used, these bits must always be set to 00. These bits must always be set 10 or 11 when SPI mode. [Master mode] 00: Outputs MSIOF_TSCK when transmission is disabled. 01: Setting prohibited 10: Outputs 0. 11: Outputs 1. [Slave mode] 00: Inputs MSIOF_TSCK when transmission is disabled. 01: Setting prohibited 10: Inputs 0 through MSIOF_TSCK when transmission is disabled. 11: Inputs 1 through MSIOF_TSCK when transmission is disabled.

Bit	Bit Name	Initial Value	R/W	Descriptions
29, 28	RSCKIZ[1:0]	00	R/W	Receive Clock Input/Output Polarity Select in SPI Mode In SPI mode, set these bits to the TSCKIZ value. [Master mode] 00: Outputs MSIOF_RSCK when transmission is disabled. 01: Setting prohibited 10: Outputs 0. 11: Outputs 1. [Slave mode] 00: Inputs MSIOF_RSCK when transmission is disabled. 01: Setting prohibited 10: Inputs 0 through MSIOF_RSCK when transmission is disabled. 11: Inputs 1 through MSIOF_RSCK when transmission is disabled.
27	TEDG	0	R/W	Transmit Timing 0: Outputs transmit data at the rising edge of the clock. 1: Outputs transmit data at the falling edge of the clock.
26	REDG	0	R/W	Receive Timing 0: Samples receive data at the falling edge of the clock. 1: Samples receive data at the rising edge of the clock.
25, 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23, 22	TXDIZ[1:0]	00	R/W	Pin Output When Transmission is Disabled These bits specify the MSIOF_TXD pin output state when transmission is disabled. 00: Outputs 0. 01: Outputs 1. 10: Output is in high-impedance state. 11: Setting prohibited
21 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
15	TSCKE	0	R/W	Transmit Serial Clock Output Enable This bit is valid in master mode. When this bit is set to 1, the MSIOF initializes the baud rate generator and initiates the operation. At the same time, the MSIOF outputs the clock generated by the baud rate generator to the MSIOF_TSCK pin. After the clock is output, 1 can be read. When transmitting data, set this bit to 1 before setting the TFSE and TXE bits. After data transmission, clear the TFSE and TXE bits and then clear this bit to 0. [Write data] 0: Disables the MSIOF_TSCK output. (Outputs the value specified with TSCKIZ.) 1: Enables the MSIOF_TSCK output. [Read data] 0: Does not output MSIOF_TSCK. (Outputs the value specified with TSCKIZ.) 1: Outputs MSIOF_TSCK.
14	TFSE	0	R/W	Transmit Frame Synchronization Signal Output Enable This bit is valid in master mode. When this bit is set to 1, the MSIOF initializes the frame counter and initiates the operation. After the transmit frame synchronization signal is output, 1 can be read. When 0 is written to this bit, 0 is set after transmission of the frame. [Write data] 0: Disables the MSIOF_TSYNC output. (Outputs the value specified with SYNCAC.) 1: Enables the MSIOF_TSYNC output. [Read data] 0: Does not output MSIOF_TSYNC. (Outputs the value specified with SYNCAC.) 1: Outputs MSIOF_TSYNC.

Bit	Bit Name	Initial Value	R/W	Descriptions
13	RSCKE	0	R/W	Receive Serial Clock Output Enable This bit is valid in master mode. When this bit is set to 1, the MSIOF initializes the baud rate generator and initiates the operation. At the same time, the MSIOF outputs the clock generated by the baud rate generator to the MSIOF_RSCK pin. After the clock is output, 1 can be read. When receiving data, set this bit to 1 before setting the RFSE and RXE bits. After data reception, clear the RFSE and RXE bits and then clear this bit to 0. [Write data] 0: Disables the MSIOF_RSCK output. (Outputs the value specified with RSCKIZ.) 1: Enables the MSIOF_RSCK output. [Read data] 0: Does not output MSIOF_RSCK. (Outputs the value specified with RSCKIZ.) 1: Outputs MSIOF_RSCK.
12	RFSE	0	R/W	Receive Frame Synchronization Signal Output Enable This bit is valid in master mode. When this bit is set to 1, the MSIOF initializes the frame counter and initiates the operation. After the receive frame synchronization signal is output, 1 can be read. When 0 is written to this bit, 0 is set after reception of the frame. [Write data] 0: Disables the MSIOF_RSYNC output. (Outputs the value specified with SYNCAC.) 1: Enables the MSIOF_RSYNC output. [Read data] 0: Does not output MSIOF_RSYNC. (Outputs the value specified with SYNCAC.) 1: Outputs MSIOF_RSYNC.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

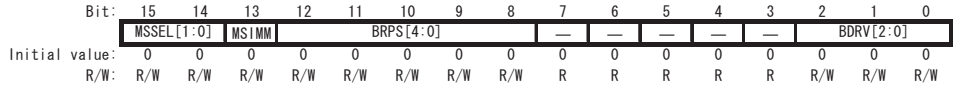
Bit	Bit Name	Initial Value	R/W	Descriptions
9	TXE	0	R/W	Transmit Enable When this bit is set to 1, the MSIOF starts data transmission from the beginning of the next frame (at the rising edge of the frame synchronization signal). After the valid data is output, 1 can be read. When value 1 set to this bit becomes valid, the MSIOF issues a transmit data transfer request according to the setting of the TFWM bits in SIFCTR. When transmit data is stored in the transmit FIFO, transmission of data from the MSIOF_TXD pin begins. When 0 is written to this bit, 0 is set after transmission of the frame. This bit is initialized upon a transmit reset. [Write data] 0: Disables the MSIOF_TXD output. (Outputs the value specified with TXDIZ.) 1: Enables the MSIOF_TXD output. [Read data] 0: Does not output MSIOF_TXD. (Outputs the value specified with TXDIZ.) 1: Outputs MSIOF_TXD.
8	RXE	0	R/W	Receive Enable When this bit is set to 1, the MSIOF starts data reception from the beginning of the next frame (at the rising edge of the frame synchronization signal). When value 1 set to this bit becomes valid, the MSIOF starts receiving data through the MSIOF_RXD pin. When receive data is stored in the receive FIFO, the MSIOF issues a receive data transfer request according to the setting of the RFWM bits in SIFCTR. This bit is initialized upon a receive reset. [Write data] 0: Disables data reception through MSIOF_RXD. 1: Enables data reception through MSIOF_RXD. [Read data] 0: Data is not received through MSIOF_RXD. 1: Data can be received through MSIOF_RXD.

Bit	Bit Name	Initial Value	R/W	Descriptions
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	TXRST	0	R/W	Transmit Reset When value 1 set to this bit becomes valid, the MSIOF immediately sets transmit data through the MSIOF_TXD pin to 0, and initializes the transmit data registers and transmit-related status. When value 1 set to this bit becomes valid when PCON = 1, the RXRST bit is also becomes valid. The following registers and bits are initialized. SITDR1 and SITDR2 SITFDR Transmit FIFO write pointer TCRDY, TFEMP, and TDREQ bits in SISTR TXE bit This bit is read as 1 until the reset operation is completed for about SUBϕ20 cycles. No data should be written to SICTR or the transmit FIFO during this time period. [Write data] 0: Does not reset transmit operation. 1: Resets transmit operation. [Read data] 0: Transmit operation reset is completed. 1: Transmit operation is being reset.

Bit	Bit Name	Initial Value	R/W	Descriptions
0	RXRST	0	R/W	Receive Reset When value 1 set to this bit becomes valid, the MSIOF immediately disables reception through the MSIOF_RXD pin, and initializes the receive data registers and receive-related status. The following registers and bits are initialized. SIRDR1 and SIRDR2 SIRFDR Receive FIFO read pointer RCRDY, RFFUL, and RDREQ bits in SISTR RXE bit This bit is read as 1 until the reset operation is completed for about SUBϕ20 cycles. No data should be written to SICTR or read the receive FIFO during this time period. [Write data] 0: Does not reset receive operation. 1: Resets receive operation. [Read data] 0: Receive operation reset is completed. 1: Receive operation is being reset.

23.3.8 MSIOF Transmit Clock Select Register (SITSCR)

SITSCR is a 16-bit readable/writable register that specifies the conditions for generating the transmit serial clock in master mode. SITSCR can be specified when the TRMD bit in SITMDR1 is set to B'1.



Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSSEL[1:0]		MSIMM	BRPS[4:0]					—	—	—	—	—	BDRV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	MSSEL[1:0]	00	R/W	Master Clock Source Select The master clock is the clock input to the baud rate generator. 00: Selects SUBϕ as the master clock. 01: Selects the signal input from the MSIOF_MCK0 pin as the master clock. 10: Selects the signal input from the MSIOF_MCK1 pin as the master clock. 11: Setting prohibited
13	MSIMM	0	R/W	Master Clock Direct Select When setting MSIMM = 1, the master clock source should be set to 24 MHz or lower. Set 0 when MSSEL = 2’b00. 0: Selects the clock output from the baud rate generator as the serial clock. 1: Selects the master clock itself as the serial clock.
12 to 8	BRPS[4:0]	00000	R/W	Prescalar Setting These bits specify the master clock division ratio in the count value of the prescalar in the baud rate generator. The specifiable value is from B'00000 (× 1/1) to B'11111 (× 1/32).
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
2 to 0	BRDV[2:0]	000	R/W	Baud Rate Generator's Division Ratio These bits specify the frequency division ratio for the output stage of the baud rate generator. The final frequency division ratio of the baud rate generator is determined as BRPS × BRDV (1/1024 max.). 000: Prescalar output × 1/2 001: Prescalar output × 1/4 010: Prescalar output × 1/8 011: Prescalar output × 1/16 100: Prescalar output × 1/32 101: Setting prohibited 110: Setting prohibited 111: Prescalar output × 1/1 Note: B'111 is valid only when the BRPS[4:0] bits are set to B'00000 or B'00001.

23.3.9 MSIOF Receive Clock Select Register (SIRSCR)

SIRSCR is a 16-bit readable/writable register that specifies the conditions for generating the receive serial clock in master mode. SIRSCR can be specified when the TRMD bit in SIRMDR1 is set to B'1.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSSEL[1:0]		MSIMM	BRPS[4:0]					—	—	—	—	—	BDRV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	MSSEL[1:0]	00	R/W	Master Clock Source Select The master clock is the clock input to the baud rate generator. 00: Selects SUBϕ as the master clock. 01: Selects the signal input from the MSIOF_MCK0 pin as the master clock. 10: Selects the signal input from the MSIOF_MCK1 pin as the master clock. 11: Setting prohibited
13	MSIMM	0	R/W	Master Clock Direct Select When setting MSIMM = 1, the master clock source should be set to 24 MHz or lower. Set 0 when MSSEL = 2'b00. 0: Selects the clock output from the baud rate generator as the serial clock. 1: Selects the master clock itself as the serial clock.
12 to 8	BRPS[4:0]	00000	R/W	Prescalar Setting These bits specify the master clock division ratio in the count value of the prescalar in the baud rate generator. The specifiable value is from B'00000 (× 1/1) to B'11111 (× 1/32).
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
2 to 0	BRDV[2:0]	000	R/W	Baud Rate Generator's Division Ratio These bits specify the frequency division ratio for the output stage of the baud rate generator. The final frequency division ratio of the baud rate generator is determined as BRPS × BRDV (1/1024 max.). 000: Prescalar output × 1/2 001: Prescalar output × 1/4 010: Prescalar output × 1/8 011: Prescalar output × 1/16 100: Prescalar output × 1/32 101: Setting prohibited 110: Setting prohibited 111: Prescalar output × 1/1 Note: B'111 is valid only when the BRPS[4:0] bits are set to B'00000 or B'00001.

23.3.10 MSIOF Transmit Control Data Register 1 (SITDR1)

SITDR1 is a 32-bit write-only register that specifies the transmit control data of the MSIOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCRD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCRD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	TCRD1[15:0]	H'0000	W	When one or two groups are used: These bits specify the transmit control data for the upper 16 bits of a word in group 1 When three or four groups are used: These bits specify the transmit control data for a word in group 1.
15 to 0	TCRD2[15:0]	H'0000	W	When one or two groups are used: These bits specify the transmit control data for the lower 16 bits of a word in group 1 when the word size is larger than 16 bits. When three or four groups are used: These bits specify the transmit control data for a word in group 3.

23.3.11 MSIOF Transmit Control Data Register 2 (SITDR2)

SITDR2 is a 32-bit write-only register that specifies the transmit control data of the MSIOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCRD3[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCRD4[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	TCRD3[15:0]	H'0000	W	When one or two groups are used: These bits specify the transmit control data for the upper 16 bits of a word in group 2. When three or four groups are used: These bits specify the transmit control data for a word in group 2.
15 to 0	TCRD4[15:0]	H'0000	W	When one or two groups are used: These bits specify the transmit control data for the lower 16 bits of a word in group 2 when the word size is larger than 16 bits. When three or four groups are used: These bits specify the transmit control data for a word in group 4.

23.3.12 MSIOF Transmit FIFO Data Register (SITFDR)

SITFDR is a 32-bit write-only register that specifies the transmit FIFO data of the MSIOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SITFD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SITFD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SITFD1[15:0]	H'0000	W	These bits specify the upper 16 bits of the FIFO data to be output through MSIOF_TXD.
15 to 0	SITFD2[15:0]	H'0000	W	These bits specify the lower 16 bits of the FIFO data to be output through MSIOF_TXD.

23.3.13 MSIOF Receive Control Data Register 1 (SIRDR1)

SIRDR1 is a 32-bit read-only register that stores the receive control data of the MSIOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RCRD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCRD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	RCRD1[15:0]	H'0000	R	When one or two groups are used: Store the receive control data for the upper 16 bits of a word in group 1. When three or four groups are used: Store the receive control data for a word in group 1.
15 to 0	RCRD2[15:0]	H'0000	R	When one or two groups are used: Store the receive control data for the lower 16 bits of a word in group 1 when the word size is larger than 16 bits. When three or four groups are used: Store the receive control data for a word in group 3.

23.3.14 MSIOF Receive Control Data Register 2 (SIRDR2)

SIRDR2 is a 32-bit read-only register that stores the receive control data of the MSIOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RCRD3[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCRD4[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	RCRD3[15:0]	H'0000	R	When one or two groups are used: Store the receive control data for the upper 16 bits of a word in group 2. When three or four groups are used: Store the receive control data for a word in group 2.
15 to 0	RCRD4[15:0]	H'0000	R	When one or two groups are used: Store the receive control data for the lower 16 bits of a word in group 2 when the word size is larger than 16 bits. When three or four groups are used: Store the receive control data for a word in group 4.

23.3.15 MSIOF Receive FIFO Data Register (SIRFDR)

SIRFDR is a 32-bit read-only register that stores the receive FIFO data of the MSIOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SIRFD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SIRFD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SIRFD1[15:0]	Undefined	R	Store the upper 16 bits of the FIFO data received through MSIOF_RXD.
15 to 0	SIRFD2[15:0]	Undefined	R	Store the lower 16 bits of the FIFO data received through MSIOF_RXD.

23.3.16 MSIOF Status Register (SISTR)

Each bit in SISTR becomes an MSIOF interrupt source when the corresponding bit in SIIER is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	TCRDY	TFEMP	TDREQ	—	—	—	—	TEOF	—	TFSERR	TFOVF	TFUDF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R
Bit:																
	—	RCRDY	RFFUL	RDREQ	—	—	—	—	REOF	—	RFSERR	RFUDF	RFOVF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	TCRDY	0	R/W	Transmit Control Data Ready If SITDR1 or SITDR2 is written while this bit is cleared to 0, SICTR is overwritten and the previous contents are not output through the MSIOF_TXD pin. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. When this bit is set to 1, the contain is cleared. Write 0 to this bit is invalid. 0: SITDR1 and SITDR2 are not ready to be written. 1: SITDR1 and SITDR2 are ready to be written.

Bit	Bit Name	Initial Value	R/W	Descriptions
29	TFEMP	0	R/W	Transmit FIFO Empty This bit is valid when the TXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: Transmit FIFO is not empty. 1: Transmit FIFO is empty.
28	TDREQ	0	R	Transmit Data Transfer Request A transmit data transfer request is issued when the empty space in the transmit FIFO exceeds the size specified by the TFWM bits in SIFCTR. When transferring transmit data through the DMAC, this bit is always cleared after one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the MSIOF again sets this bit to 1. This bit is valid when the TXE bit in SICTR is 1. This bit indicates a state; if the size of empty space in the transmit FIFO becomes less than the size specified by the TFWM bits in SIFCTR, the MSIOF clears this bit. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. However, when the TDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of empty space in the transmit FIFO has not exceeded the size specified by the TFWM bits in SIFCTR. 1: The size of empty space in the transmit FIFO has exceeded the size specified by the TFWM bits in SIFCTR.
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
23	TEOF	0	R/W	Frame Transmission End The MSIOF issues the frame transmission end flag upon completion of one-frame data transmission. This bit is valid when the TXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: One-frame transmission end is not detected. 1: One-frame transmission end is detected.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERR	0	R/W	Transmit Frame Synchronization Error A transmit frame synchronization error occurs when the next transmit frame synchronization timing arrives before the previous data or control data transmission has been completed. If a transmit frame synchronization error occurs, the MSIOF performs transmission only for the slots that can be transferred. This bit is valid when the TXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No transmit frame synchronization error has occurred. 1: A transmit frame synchronization error has occurred.

Bit	Bit Name	Initial Value	R/W	Descriptions
20	TFOVF	0	R/W	Transmit FIFO Overflow A transmit FIFO overflow means that there has been an attempt to write to SITFDR when the transmit FIFO is full. If a transmit FIFO overflow occurs, the MSIOF ignores the write operation causing the overflow. This bit is valid when the TXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No transmit FIFO overflow has occurred. 1: A transmit FIFO overflow has occurred.
19	TFUDF	0	R/W	Transmit FIFO Underflow A transmit FIFO underflow means that loading for transmission has occurred when the transmit FIFO is empty. This bit is valid when the TXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No transmit FIFO underflow has occurred. 1: A transmit FIFO underflow has occurred.
18 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
14	RCRDY	0	R/W	Receive Control Data Ready When data different from the previous data is stored during reception of control data, this bit is set to 1 indicating that valid data was written. When the first data that is not 0 is stored, this bit is set to 1. If valid data is written to SIRDR1 or SIRDR2 when this bit is set to 1, SIRDR1 or SIRDR2 is overwritten with the latest data. This bit is valid when the RXE bit in SICTR is 1. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. When this bit is set to 1, the contain is cleared. Write 0 to this bit is invalid. 0: SIRDR1 and SIRDR2 store no valid data. 1: SIRDR1 and SIRDR2 store valid data.
13	RFFUL	0	R/W	Receive FIFO Full This bit is valid when the RXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: Receive FIFO is not full. 1: Receive FIFO is full.

Bit	Bit Name	Initial Value	R/W	Descriptions
12	RDREQ	0	R	Receive Data Transfer Request A receive data transfer request is issued when the valid data space in the receive FIFO exceeds the size specified by the RFWM bits in SIFCTR. When transferring receive data through the DMAC, this bit is always cleared by one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the MSIOF again sets this bit to 1. This bit is valid when the RXE bit in SICTR is 1. This bit indicates a state; if the size of valid data space in the receive FIFO becomes less than the size specified by the RFWM bits in SIFCTR, the MSIOF clears this bit. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. However, when the RDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of valid data space in the receive FIFO has not exceeded the size specified by the RFWM bits in SIFCTR. 1: The size of valid data space in the receive FIFO has exceeded the size specified by the RFWM bits in SIFCTR.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOF	0	R/W	Frame Reception End The MSIOF issues the frame reception end flag upon completion of one-frame data reception. This bit is valid when the RXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: One-frame reception end is not detected. 1: One-frame reception end is detected.

Bit	Bit Name	Initial Value	R/W	Descriptions
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	RFSERR	0	R/W	Receive Frame Synchronization Error A receive frame synchronization error occurs when the next receive frame synchronization timing arrives before the previous data or control data reception has been completed. If a receive frame synchronization error occurs, the MSIOF performs reception only for the slots that can be transferred. This bit is valid when the RXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No receive frame synchronization error has occurred 1: A receive frame synchronization error has occurred
4	RFUDF	0	R/W	Receive FIFO Underflow A receive FIFO underflow means that reading of SIRFDR has occurred when the receive FIFO is empty. If a receive FIFO underflow occurs, the value read from SIRFDR is not guaranteed. This bit is valid when the RXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No receive FIFO underflow has occurred. 1: A receive FIFO underflow has occurred.

Bit	Bit Name	Initial Value	R/W	Descriptions
3	RFOVF	0	R/W	Receive FIFO Overflow A receive FIFO overflow means that writing has been caused by receiving operation when the receive FIFO is full. If a receive FIFO overflow occurs, the receive data causing the overflow is lost. This bit is valid when the RXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No receive FIFO overflow has occurred. 1: A receive FIFO overflow has occurred.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

23.3.17 MSIOF Interrupt Enable Register (SIIER)

SIIER is a 32-bit readable/writable register that enables the issue of MSIOF interrupts. When each bit in this register is set to 1 and the corresponding bit in SISTR is set to 1, the MSIOF issues an interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TDMAE	TCRDYE	TFEMPE	TDREQE	—	—	—	—	TEOFE	—	TFSERRE	TFOVFE	TFUDFE	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDMAE	RCRDYE	RFFULE	RDREQE	—	—	—	—	REOFE	—	RFSERRE	RFUDFE	RFOVFE	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TDMAE	0	R/W	Transmit Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The TDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.
30	TCRDYE	0	R/W	Transmit Control Data Ready Enable 0: Disables interrupts due to transmit control data ready. 1: Enables interrupts due to transmit control data ready.
29	TFEMPE	0	R/W	Transmit FIFO Empty Enable 0: Disables interrupts due to transmit FIFO empty. 1: Enables interrupts due to transmit FIFO empty.
28	TDREQE	0	R/W	Transmit Data Transfer Request Enable 0: Disables interrupts due to transmit data transfer requests. 1: Enables interrupts due to transmit data transfer requests.

Bit	Bit Name	Initial Value	R/W	Descriptions
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23	TEOFE	0	R/W	Frame Transmission End Enable 0: Disables a frame transmission end interrupt. 1: Enables a frame transmission end interrupt.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERRE	0	R/W	Transmit Frame Synchronization Error Enable 0: Disables interrupts due to transmit frame synchronization errors. 1: Enables interrupts due to transmit frame synchronization errors.
20	TFOVFE	0	R/W	Transmit FIFO Overflow Enable 0: Disables interrupts due to transmit FIFO overflow. 1: Enables interrupts due to transmit FIFO overflow.
19	TFUDFE	0	R/W	Transmit FIFO Underflow Enable 0: Disables interrupts due to transmit FIFO underflow. 1: Enables interrupts due to transmit FIFO underflow.
18 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	RDMAE	0	R/W	Receive Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The RDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.

Bit	Bit Name	Initial Value	R/W	Descriptions
14	RCRDYE	0	R/W	Receive Control Data Ready Enable 0: Disables interrupts due to receive control data ready. 1: Enables interrupts due to receive control data ready.
13	RFFULE	0	R/W	Receive FIFO Full Enable 0: Disables interrupts due to receive FIFO full. 1: Enables interrupts due to receive FIFO full.
12	RDREQE	0	R/W	Receive Data Transfer Request Enable 0: Disables interrupts due to receive data transfer requests. 1: Enables interrupts due to receive data transfer requests.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOFE	0	R/W	Frame Reception End Enable 0: Disables a frame reception end interrupt. 1: Enables a frame reception end interrupt.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	RFSERRE	0	R/W	Receive Frame Synchronization Error Enable 0: Disables interrupts due to receive frame synchronization errors. 1: Enables interrupts due to receive frame synchronization errors.
4	RFUDFE	0	R/W	Receive FIFO Underflow Enable 0: Disables interrupts due to receive FIFO underflow. 1: Enables interrupts due to receive FIFO underflow.

Bit	Bit Name	Initial Value	R/W	Descriptions
3	RFOVFE	0	R/W	Receive FIFO Overflow Enable 0: Disables interrupts due to receive FIFO overflow. 1: Enables interrupts due to receive FIFO overflow.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

23.3.18 MSIOF FIFO Control Register (SIFCTR)

SIFCTR is a 32-bit readable/writable register that indicates the area available for the transmit/receive FIFO transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TFWM[2:0]			-	-	TFUA[6:0]							-	-	-	-
Initial value	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFWM[2:0]			RFUA[8:0]									-	-	-	-
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	TFWM[2:0]	000	R/W	Transmit FIFO Watermark A transfer request of the transmit FIFO is issued by the TDREQE bit in SIIER. The transmit FIFO always operates as a 64-stage FIFO regardless of these bit settings. 000: Issues a transfer request when 64 stages of the transmit FIFO are empty. 001: Issues a transfer request when 32 or more stages of the transmit FIFO are empty. 010: Issues a transfer request when 24 or more stages of the transmit FIFO are empty. 011: Issues a transfer request when 16 or more stages of the transmit FIFO are empty. 100: Issues a transfer request when 12 or more stages of the transmit FIFO are empty. 101: Issues a transfer request when 8 or more stages of the transmit FIFO are empty. 110: Issues a transfer request when 4 or more stages of the transmit FIFO are empty. 111: Issues a transfer request when 1 or more stages of transmit FIFO are empty.

Bit	Bit Name	Initial Value	R/W	Descriptions
28, 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 20	TFUA[6:0]	H'40	R	Transmit FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'0000000 (full) to B'1000000 (empty).
19 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 13	RFWM[2:0]	000	R/W	Receive FIFO Watermark A transfer request of the receive FIFO is issued by the RDREQE bit in SIIER. The receive FIFO always operates as a 256-stage FIFO regardless of these bit settings. 000: Issues a transfer request when 1 stage or more of the receive FIFO are valid. 001: Issues a transfer request when 4 or more stages of the receive FIFO are valid. 010: Issues a transfer request when 8 or more stages of the receive FIFO are valid. 011: Issues a transfer request when 16 or more stages of the receive FIFO are valid. 100: Issues a transfer request when 32 or more stages of the receive FIFO are valid. 101: Issues a transfer request when 64 or more stages of the receive FIFO are valid. 110: Issues a transfer request when 128 or more stages of the receive FIFO are valid. 111: Issues a transfer request when 256 stages of the receive FIFO are valid.
12, 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
10 to 4	RFUA[8:0]	H'00	R	Receive FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'000000000 (empty) to B'100000000 (full).
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

23.4 Operation

23.4.1 Operating Mode

(1) Independent Transmit/Receive Mode

Dedicated clock and frame synchronization signals can be specified each for transmission and reception.

Master mode: MSIOF_TSCK, MSIOF_TSYNC, MSIOF_RSCK, and MSIOF_RSYNC are output.

Slave mode: MSIOF_TSCK, MSIOF_TSYNC, MSIOF_RSCK, and MSIOF_RSYNC are input.

(2) Common Transmit/Receive Mode

Common clock and frame synchronization signals are used for transmission and reception.

Master mode: MSIOF_TSCK (MSIOF_SCK) and MSIOF_TSYNC (MSIOF_SYNC) are output.

Slave mode: MSIOF_TSCK (MSIOF_SCK) and MSIOF_TSYNC (MSIOF_SYNC) are input.

23.4.2 Serial Clocks

(1) Clock Output in Master Mode

In master mode, the baud rate generator is used to generate the serial clock. The division ratio is from 1/1 to 1/1024.

(2) Clock Input in Slave Mode

In slave mode, the clock input for transmission and reception is used as the serial clock.

(3) Multiple Channel Function

This module provides the multiple channel function as shown in figure 23.2.

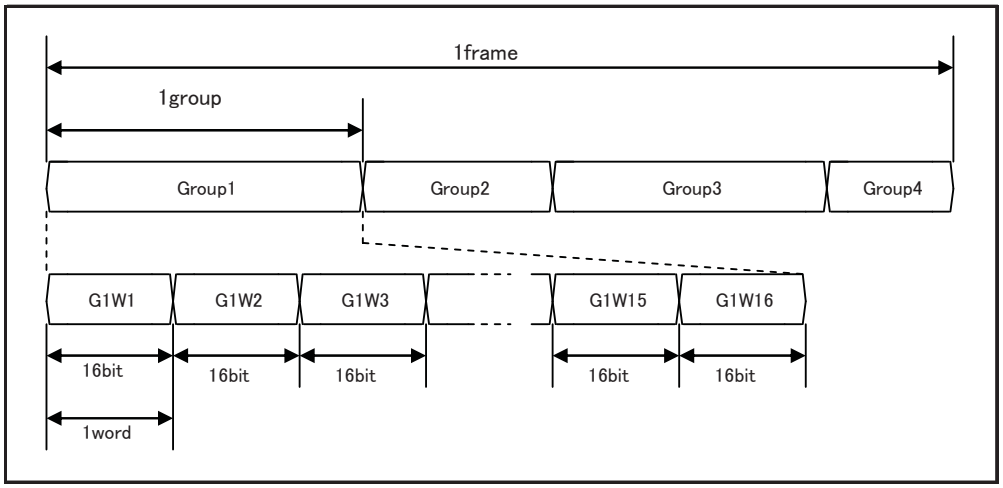


Figure 23.2 Multiple Channel Structure

The following conditions can be specified for the multiple channel function.

- Up to four groups in one frame
- Up to 256 words in one group
- Eight bits to 32 bits in one word
- Up to three blank bits can be inserted between groups

Note the following limitations by the number of groups.

Table 23.4 Maximum Word Size and Group Size Limited by Number of Groups

Number of Groups	Maximum Word Size	Maximum Group Size
One or two	32 bits	256 words
Three or four	16 bits	16 words

23.4.3 Serial Timing

(1) MSIOF_TSYNC, MSIOF_RSYNC

The MSIOF_TSYNC and MSIOF_RSYNC are frame synchronization signals. The following four modes are available.

- Frame start synchronization pulse: 1-bit-width pulse indicating the start of a frame
- Last bit synchronization pulse: 1-bit-width pulse indicating the last bit in a word
- Level/SPI: Level signal asserted during frame transmission
- L/R: 1/2-frame-width pulse indicating the first-half groups in a high level and the last-half groups in a low level

Figures 23.3 to 23.6 show the synchronization timing in these modes using the MSIOF_TSYNC and MSIOF_RSYNC signals.

(a) Frame Start Synchronization Pulse

The rising edge of the synchronization pulse indicates the start of a frame.

The delay between the rising edge of the synchronization signal and the start of data transmission or reception can be specified with the DTDL bits. The width of the synchronization pulse can be extended through the SYNCDL bit setting.

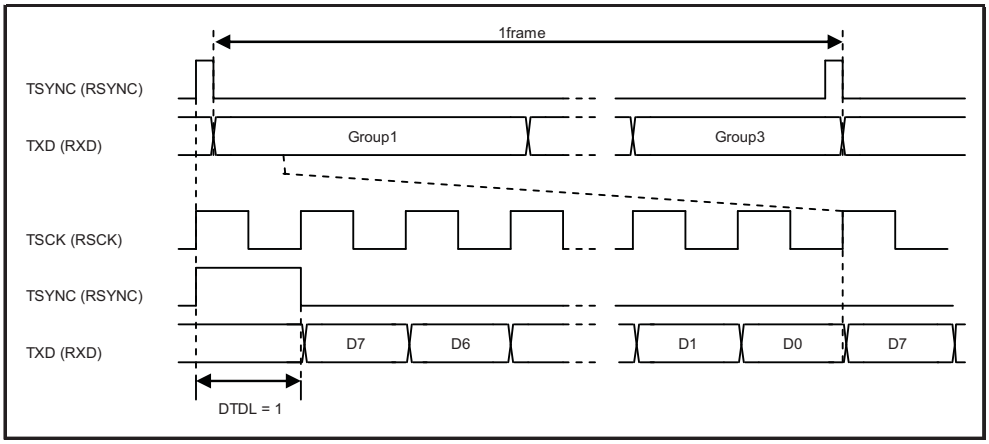

Figure 23.3 Synchronization Timing in Start Frame Synchronization Pulse Mode

(b) Last Bit Synchronization Pulse

The rising edge of the synchronization pulse indicates the last bit of each word.

The delay between the last bit of a word and the synchronization pulse can be specified with the DTDL bits.

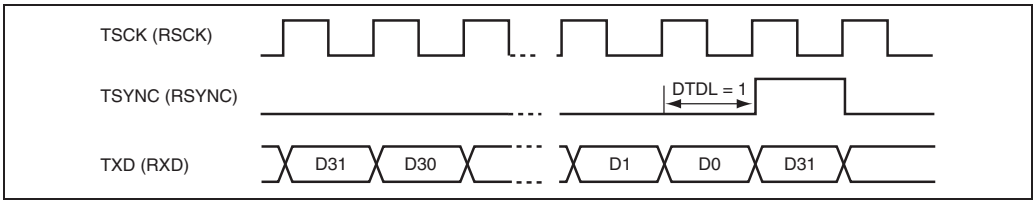

Figure 23.4 Synchronization Timing in Last Bit Synchronization Pulse Mode

(c) Level Synchronization

The synchronization signal is driven high for the frame length.

The delay between the rising edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits and the delay between the end of transmission or reception and the falling edge of the synchronization signal can be specified with the SYNCDL bits (DTDL = 0 to 2 and SYNCDL = 0 to 3). This mode is available for the SPI master or slave operation.

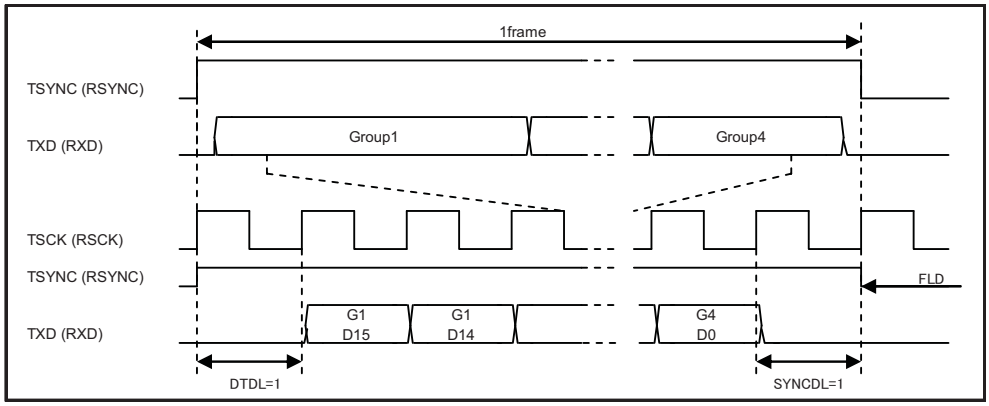

Figure 23.5 Synchronization Timing in Level Synchronization Mode

(d) L/R Synchronization

A high level in the synchronization signal indicates the first-half groups and a low level indicates the last-half groups.

The delay between the rising or falling edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits and the delay between the end of transmission or reception and the falling or rising edge of the synchronization signal can be specified with the SYNCDL bits (DTDL = 0 to 2 and SYNCDL = 0 to 3).

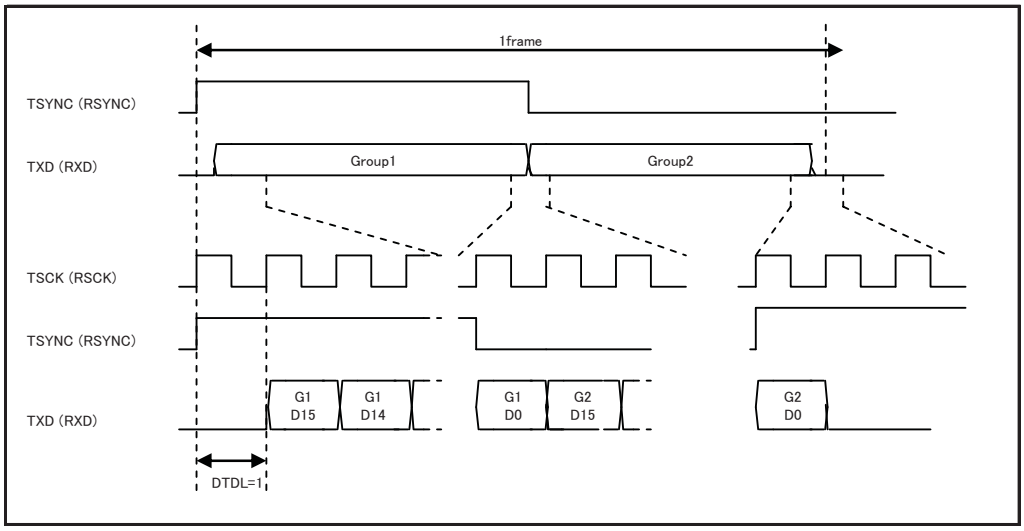

Figure 23.6 Synchronization Timing in L/R Synchronization Mode

(2) Transmit/Receive Timing

The timing of MSIOF_TXD transmission relative to MSIOF_TSCK and of MSIOF_RXD reception relative to MSIOF_RSCK can be specified as sampling on either edge, as listed below. The respective settings are made in TEDG and REDG bits of SICTR.

- Falling-edge sampling
- Rising-edge sampling

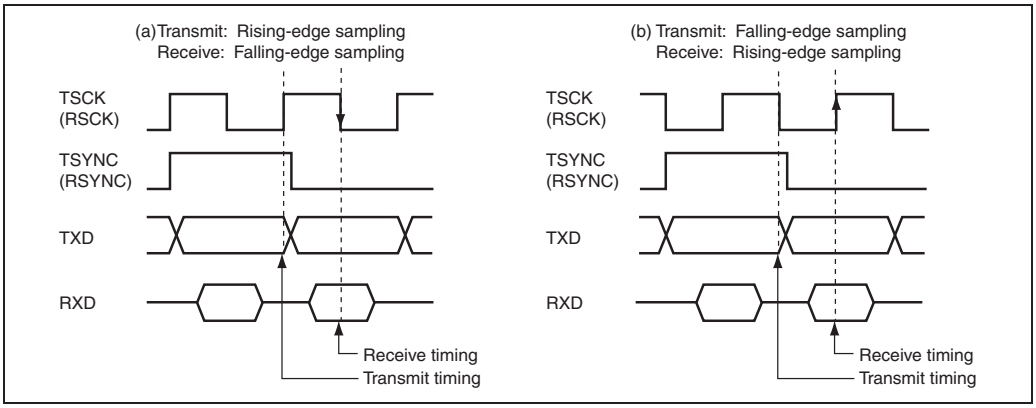

Figure 23.7 Transmit/Receive Timing.

23.4.4 Control Data Interface

For the groups specified with the CRDE bits in SITMDR2 and SIRMDR2, data is not stored in the FIFOs but handled as control data to be stored in SITDR1/SITDR2 and SIRDR1/SIRDR2.

Control data is transferred in the following two ways, which can be selected through the CRDNUM bits in SITMDR2 and SIRMDR2, as shown in figure 23.8.

- Only the first word in the group is transferred as valid data.
- All words in the group is transferred as valid data.

For the invalid data period during transmission, the value specified in the TXDIZ bit is output. The invalid receive data is not stored in SIRDR1 or SIRDR2.

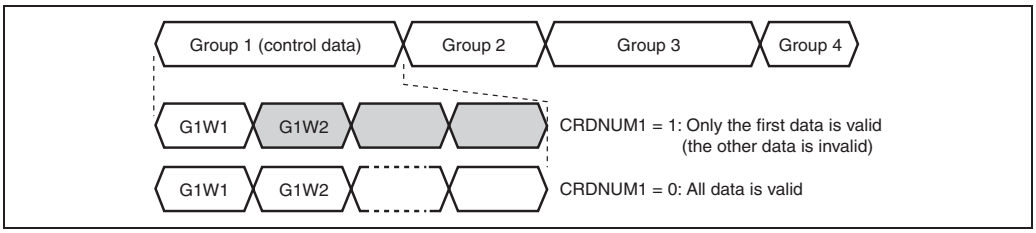

Figure 23.8 Control Data Allocation

23.4.5 Transfer Data Allocation to Registers

(1) Transmit/Receive Data

Transmit/receive data (FIFO data and control data) should be written to or read from the following registers.

- Transmit FIFO data writing: SITFDR (32-/16-/8-bit access)
- Control data writing: SITDR1 and SITDR2 (32-/16-bit access)
- Receive FIFO data reading: SIRFDR (32-/16-/8-bit access)
- Control data reading: SIRDR1 and SIRDR2 (32-/16-bit access)

Only 16-bit access to FIFO data is allowed. However, both upper 16-bit access and lower 16-bit access are possible to control data.

When the word size is smaller than the transmit FIFO data access size, the upper bits are transmitted as valid data. For example, when writing data to the transmit FIFO by 32-bit access and transmitting a16-bit word, the upper 16 bits are transmitted and the lower 16 bits are discarded as invalid data.

In the same way, when the word size is larger than the receive FIFO data access size, the upper bits are received as valid data. For example, when 32-bit data is stored in the receive FIFO and the data is read by 16-bit access, the lower 16 bits are discarded as invalid data.

Figure 23.9 shows the bit alignment of these registers.

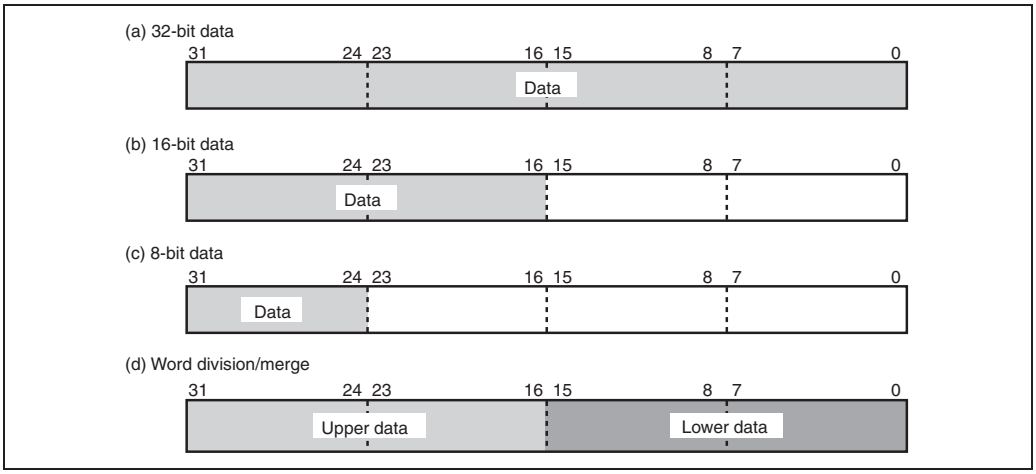

Figure 23.9 Transmit/Receive Data Bit Alignment

23.4.6 FIFO

(1) Overview

The transmit and receive FIFOs of the MSIOF have the following features.

- 32 bits × 64 stages for transmission and 32 bits × 256 stages for reception
- The FIFO pointer is updated in one read or write cycle regardless of the access size of the CPU or DMAC. (One access cannot be divided into multiple accesses.)

(2) Transfer Request

A request for FIFO data transfer can be issued to the CPU or DMAC as the following interrupt sources.

- FIFO transmit request: TDREQ (interrupt source for transmission)
- FIFO receive request: RDREQ (interrupt source for reception)

The conditions for requesting FIFO data transfer can be specified separately for transmission and reception. The conditions for the transmit FIFO and receive FIFO are specified in the TFWM[2:0] bits and RFWM[2:0] bits in SIFCTR, respectively.

Table 23.5 Condition for Issuing Transmit Request

TFWM[2:0]	Number of Requested Stages	Condition for Transmit Request	Areas Used
000	1	64 stages of empty area	Smallest
001	32	32 or more stages of empty area	↑
010	40	24 or more stages of empty area	↑
011	48	16 or more stages of empty area	↑
100	52	12 or more stages of empty area	↑
101	56	8 or more stages of empty area	↑
110	60	4 or more stages of empty area	↑
111	64	1 or more stages of empty area	Largest

Table 23.6 Condition for Issuing Receive Request

RFWM[2:0]	Number of Requested Stages	Condition for Receive Request	Areas Used
000	1	1 or more stages of valid data	Smallest
001	4	4 or more stages of valid data	
010	8	8 or more stages of valid data	
011	16	16 or more stages of valid data	
100	32	32 or more stages of valid data	
101	64	64 or more stages of valid data	
110	128	128 or more stages of valid data	
111	256	256 stages of valid data	Largest

The maximum FIFO stages are always available even if the data area or empty area exceeds the size specified for the transfer condition. Accordingly, an overflow error or an underflow error occurs if the data area or empty area exceeds the maximum number of FIFO stages.

The FIFO transfer request is canceled when the specified condition is not satisfied even if the FIFO does not become empty or full.

(3) Number of FIFOs

The number of transmit and receive FIFO stages used are indicated by the following registers.

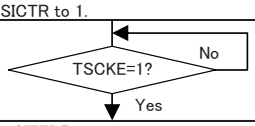
- Transmit FIFO: The number of empty FIFO stages is indicated by the TFUA[6:0] bits in SIFCTR.
- Receive FIFO: The number of valid data stages is indicated by the RFUA[8:0] bits in SIFCTR.

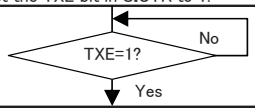
These registers show the number of data stages that can be transferred by the CPU or DMAC.

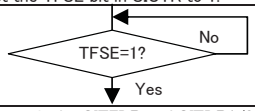
23.4.7 Transmit and Receive Procedures

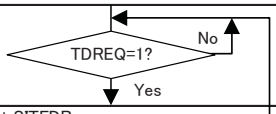
(1) Transmission in Master Mode

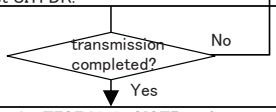
Figure 23.10 shows an example of settings and operation for transmission in master mode.

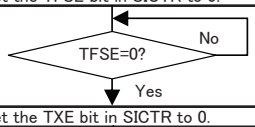


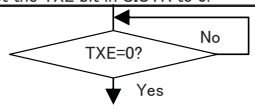










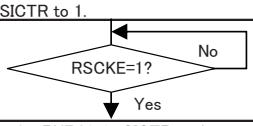


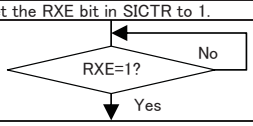
No.	Flow chart	Setting	operation
1	Set SITMDR1/2/3 SITSCR , SIFCTR , and SIIER.	Set the operating mode, serial clock , and FIFO threshold value, and enable interrupts.	
2	Set the TSCKE bit in SICTR to 1.	Set output sampling and start the baud rate generator.	Outputs the serial clock.
3		Read 1 from TSCKE bit in SICTR.	
4	Set SITFDR, SITDR1/2.	Set transmit data.	
5	Set the TXE bit in SICTR to 1.	Enable transmittion.	
6		Read 1 from TXE bit in SICTR.	
7	Set the TFSE bit in SICTR to 1.	Starting output frame of synchronization signal.	Outputs the frame syncronization signal.
8		Read 1 from TFSE bit in SICTR.	
9	Transmit the SITFDR and SITDR1/2 contents through TXD in synchronization with		Transmit data.
10			Assert transmit data transfer request according to the FIFO threshold valu
11	Set SITFDR.	Set transfer data.	
12		Read 1 from TFEMP bit in SICTR.	
13	Set the TFSE bit in SICTR to 0.	Disable output frame of synchronization signal.	
14		Read 0 from TFSE bit in SICTR.	
15	Set the TXE bit in SICTR to 0.	Disable transmit enable.	
16	 Transmission complete.	Read 0 from TXE bit in SICTR.	

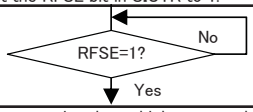
Figure 23.10 Example of Transmit Procedure in Master Mode

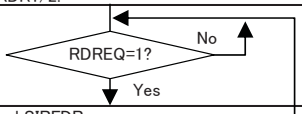
(2) Reception in Master Mode with SITMDR1.PCON=0

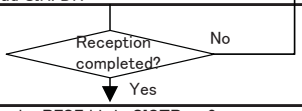
Figure 23.11 shows an example of settings and operation for reception in master mode with SITMDR1.PCON=0.

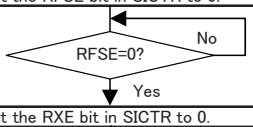


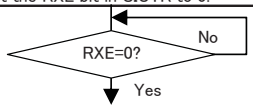










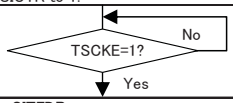


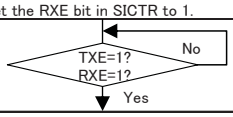
No.	Flow chart	Setting	operating
1	Set SIRMDR1/2/3 SITMDR1/2/3 SIRSCR , SIFCTR and SIIER.	Set the operating mode serial clock FIFO threshold value, and enable interrupts.	
2	Set the RSCKE bit in SICTR to 1.	Set output sampling and start the baud rate generator.	Outputs the serial clock.
3		Read 1 from RSCKE bit in SICTR.	
4	Set the RXE bit in SICTR to 1.	Enable reception.	
5		Read 1 from RXE bit in SICTR.	
6	Set the RFSE bit in SICTR to 1.	Starting output frame of synchronization signal.	Outputs the frame syncronization signal.
7		Read 1 from RFSE bit in SICTR.	
8	The reception data which was synchronized with RSYNC are stored to SIRFDR or SIRDR1/2.		Data Reception.
10			Assert receiving data transfer enable according to the FIFO threshold valu
11	Read SIRFDR	Read reception data.	
12			
13	Set the RFSE bit in SICTR to 0.	Disable output frame of synchronization signal.	
14		Read 0 from RFSE bit in SICTR.	
15	Set the RXE bit in SICTR to 0.	Disable receive enable.	
16	 Receiving data complete.	Read0 from RXE bit in SICTR	

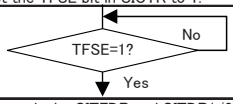
Figure 23.11 Example of Receive Procedure in Master Mode(SITMDR1.PCON=0)

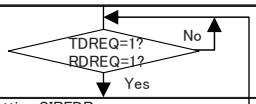
(3) Reception in Master Mode with SITMDR1.PCON=1

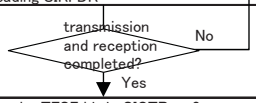
Figure 23.12 shows an example of settings and operation for reception in master mode with SITMDR1.PCON=1.

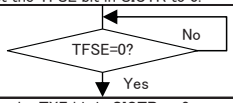


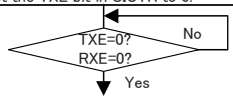










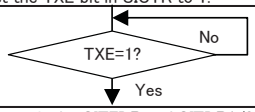


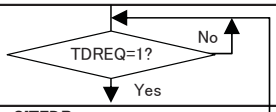
No.	Flow chart	Setting	operation
1	Set SIRMDR1/2/3 SITMDR1/2/3 SIRSCR , SIFCTR and SIIER.	Set the operating mode with dummy transmit when SPI mode. serial clock FIFO threshold value, and enable interrupts.	
2	Set the TSCKE bit in SICTR to 1.	Set output sampling and start the baud rate generator.	Outputs the serial clock.
3		Read 1 from TSCKE bit in SICTR.	
4	Set SITFDR, SITDR1/2.	Set transmit dummy data. Dummy write need same size as required receiving data.	
5	Set the TXE bit in SICTR to 1. Set the RXE bit in SICTR to 1.	Enable transmittion. Enable reception.	
6		Read 1 from TXE bit in SICTR. Read 1 from RXE bit in SICTR.	
7	Set the TFSE bit in SICTR to 1.	Starting output frame of synchronization signal.	Outputs the frame syncronization signal.
8		Read 1 from TFSE bit in SICTR.	
9	Transmit the SITFDR and SITDR1/2 contents through TXD in synchronization with Receiving data was stored to SIRFDR and SIRDR1/2 in synchronization with MSIOF_TSYNC.		Transmit and reception.
10			Assert transmit data transfer request and reception data transfer request according to the FIFO threshold valu
11	Setting SIRFDR Reading SIRFDR	Writing transmit data. Reading receiving data.	
12			
13	Set the TFSE bit in SICTR to 0.	Disable output frame of synchronization signal.	
14		Read 0 from TFSE bit in SICTR.	
15	Set the TXE bit in SICTR to 0.	Disable transmit enable.	
16	 Transmission complete.	Read 0 from TXE bit in SICTR. Read 0 from RXE bit in SICTR.	

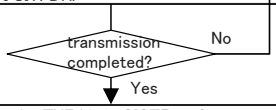
Figure 23.12 Example of Receive Procedure in Master Mode(SITMDR1.PCON=1)

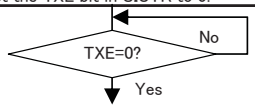
(4) Transmission in Slave Mode

Figure 23.13 shows an example of settings and operation for transmission in slave mode.







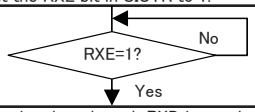


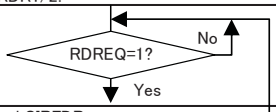
No.	Flow chart	Setting	operation
1	Setting master device polarity	Depend on master device.	Decide SYNC/SCK polarity
2	Set SITMDR1/2/3 SIFCTR and SIIER.	Set operating mode FIFO threshold value and enable interrupts.	
3	Set SITFDR, SITDR1/2.	Set transmit data.	
4	Set the TXE bit in SICTR to 1.	Enable transmittion.	
5		Read 1 from TXE bit in SICTR.	
6	Transmit the SITFDR and SITDR1/2 contents through TXD in synchronization with		Data transmit
7			Assert transmit data transfer request according to the FIFO threshold valu
8	Set SITFDR.	Set transfer data.	
9			
10	Set the TXE bit in SICTR to 0.	Disable transmit enable.	
11	 Transmission complete.	Read 0 from TXE bit in SICTR.	

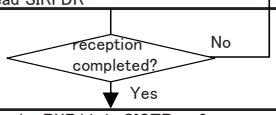
Figure 23.13 Example of Transmit Procedure in Slave Mode

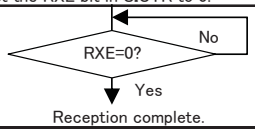
(5) Reception in Slave Mode

Figure 23.14 shows an example of settings and operation for reception in slave mode.









No.	Flow chart	Setting	operation
1	Setting master device polarity	Depend on master device.	Decide SYNC/SCK polarity
2	Set SIRMDR1/2/3 SIFCTR and SIIER.	Set operating mode FIFO threshold value and enable interrupts.	
3	Set the RXE bit in SICTR to 1.	Enable reception.	
4		Read 1 from RXE bit in SICTR.	
5	Receive data through RXD in synchronization with MSIOF_RSYNC and store it in SIRFDR and SIRDR1/2.		Data receive
6			Assert reception data transfer request according to the FIFO threshold valu
7	Read SIRFDR	Read reception data.	
8			
9	Set the RXE bit in SICTR to 0.	Disable reception enable	
10		Read 0 from RXE bit in SICTR.	

Figure 23.14 Example of Receive Procedure in Slave Mode

(6) Reset

After a power-on reset is applied, module stop state is canceled, or a reset signal is asserted through the TXRST or RXRST setting in SICTR, it takes about SUBϕ20 cycles to complete the internal reset of the module. During a period from the beginning of reset until the TXRST or RXRST value is read as 0, do not modify the control register or access the FIFOs.

The MSIOF can separately reset the transmit and receive units by setting the following bits to 1.

- Transmit reset: TXRST bit in SICTR
- Receive reset: RXRST bit in SICTR

Table 23.7 Transmit and Receive Reset

Type	Objects Initialized
Transmit reset	SITDR1, SITDR2, and SITFDR
	Transmit FIFO write pointer
	TCRDY, TFEMP, and TDREQ bits in SISTR
	TXE bit in SICTR
Receive reset	SIRDR1, SIRDR2, and SIRFDR
	Receive FIFO read pointer
	RCRDY, RFFUL, and RDREQ bits in SISTR
	RXE bit in SICTR

(7) Initial Operating Mode

After a power-on reset, both the transmit and receive units are initialized to master mode (0 is output through CLK and SYNC). When using slave mode, keep the connected device outputting 0 until the operating mode setting is completed.

23.4.8 Interrupts

The MSIOF has one type of interrupt.

(1) Interrupt Sources

Interrupts can be generated by several sources. Each source is shown as an MSIOF status in SISTR. Table 23.8 lists the MSIOF interrupt sources.

Table 23.8 MSIOF Interrupt Sources

No.	Classification	Bit Name	Function Name	Description
1	Transmission	TDREQ	Transmit FIFO transfer request	The transmit FIFO has empty space of specified size or more.
2		TFEMP	Transmit FIFO empty	The transmit FIFO is empty.
3		TEOF	Frame Transmission End	Transmission of data with a length of one frame is completed.
4	Reception	RDREQ	Receive FIFO transfer request	The receive FIFO stores data of specified size or more.
5		RFFUL	Receive FIFO full	The receive FIFO is full.
6		REOF	Frame reception end	Reception of data with a length of one frame is completed.
7	Control	TCRDY	Transmit control data ready	The transmit control data register is ready to be written.
8		RCRDY	Receive control data ready	The receive control data register stores valid data.
9	Error	TFUDF	Transmit FIFO underflow	Serial data transmit timing has arrived while the transmit FIFO is empty.
10		TFOVF	Transmit FIFO overflow	The transmit FIFO is written to while it is full.
11		RFOVF	Receive FIFO overflow	Serial data is received while the receive FIFO is full.
12		RFUDF	Receive FIFO underflow	The receive FIFO is read while the receive FIFO is empty.
13		TFSERR	Transmit FS error	A transmit frame synchronization signal is input before the specified number of bits has been reached (in slave mode).
14		RFSERR	Receive FS error	A receive frame synchronization signal is input before the specified number of bits has been reached (in slave mode).

Whether an interrupt is issued from an interrupt source is determined by the SIIER settings. If an interrupt source bit is set to 1 and the corresponding bit in SIIER is set to 1, an MSIOF interrupt is issued.

(2) TDREQ and RDREQ

The transmit FIFO transfer request (TDREQ) and receive FIFO transfer request (RDREQ) are signals indicating the state. If the state changes after TDREQ or RDREQ is set, it is automatically cleared by the MSIOF.

When the DMA transfer is used, a DMA transfer request signal is pulled low for one cycle at the end of DMA transfer.

(3) Processing when Errors Occur

- Transmit FIFO underflow (TFUDF)
  The value specified with TXDIZ in SICTR is output.
- Transmit FIFO overflow (TFOVF)
  The contents of the transmit FIFO are protected, and the write operation causing the overflow is ignored.
- Receive FIFO overflow (RFOVF)
  Data causing the overflow is discarded and lost.
- Receive FIFO underflow (RFUDF)
  An undefined value is output on the bus.
- Transmit FS error (TFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.
- Receive FS error (RFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.

23.4.9 Transmit and Receive Timing

Examples of the MSIOF serial transmission and reception are shown in figures 23.14 and 23.15.

(1) 16-Bit Synchronization Pulse

Synchronization pulse method, one group, one word, 16 bits in a word, no bit delay

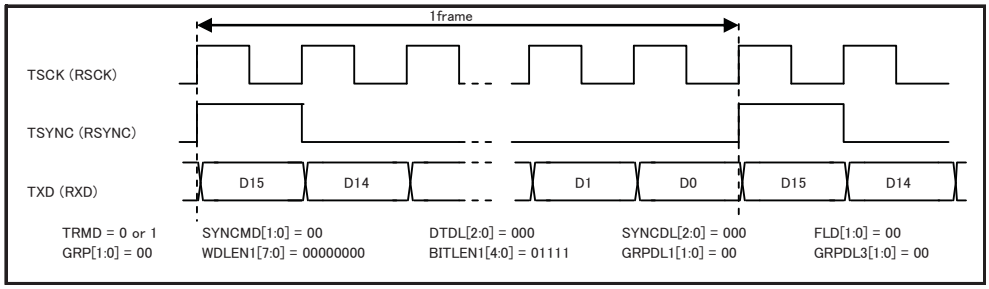


Figure 23.15 Transmit and Receive Timing (16 Bits)

(2) 32-Bit Synchronization Pulse

Synchronization pulse method, one group, 32 words, 32 bits in a word, 1-bit delay

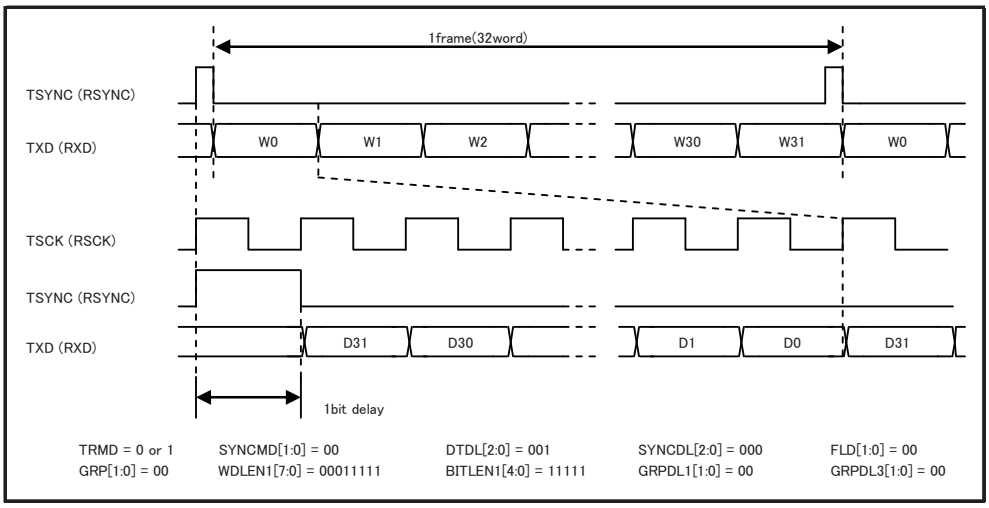

Figure 23.16 Transmit and Receive Timing (32 Bits)

(3) 24-Bit IIS Transmission

L/R mode, 2 groups, 1 word for each group, 24-bit word for each group, 1-bit delay

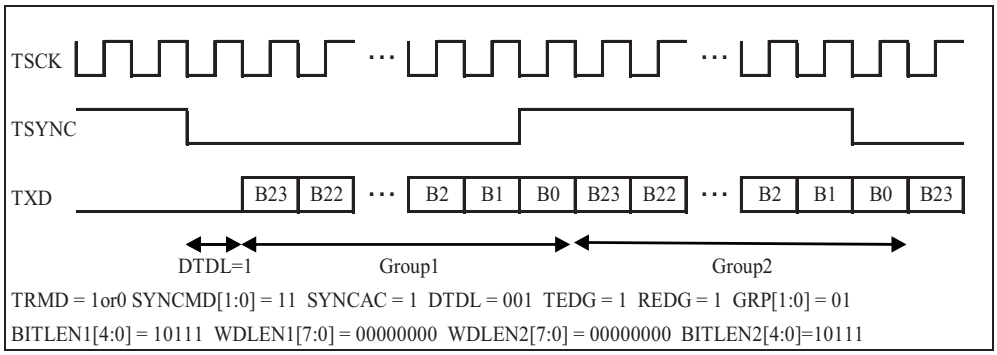

Figure 23.17 Transmit Timing(24-Bit IIS)

(4) μ-WIRE (Transmission Only)

Level mode, 2 groups, 1 word for each group, 8-bit/16-bit words, 1-bit delay

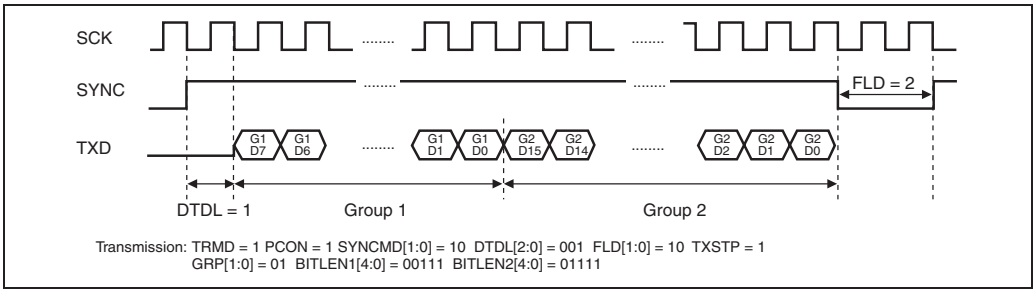

Figure 23.18 Transmit Timing (μ-WIRE Transmission)

(5) μ-WIRE (Transmission/Reception Switching)

Level mode, 2 groups, 1 word for each group, 16-bit/32-bit words, 1-bit delay

Transmit group 1 output masking, and receive group 2 input masking

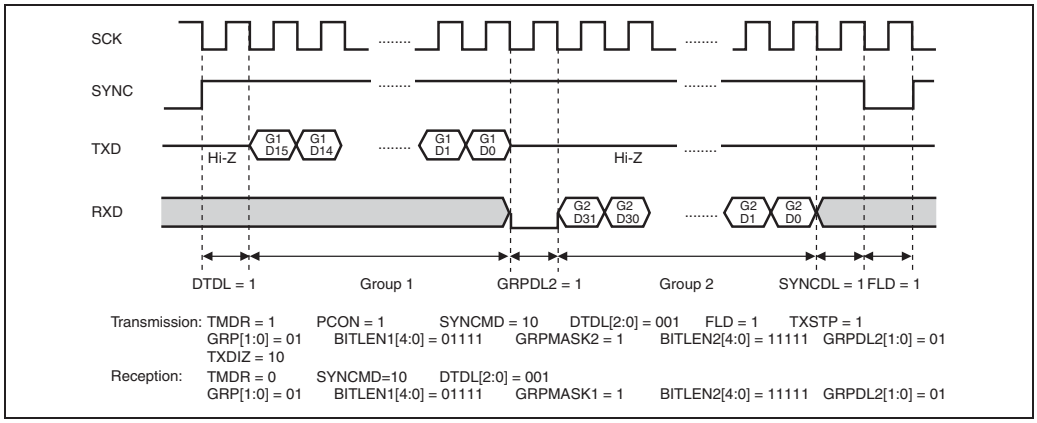

Figure 23.19 Transmit and Receive Timing (μ-WIRE)

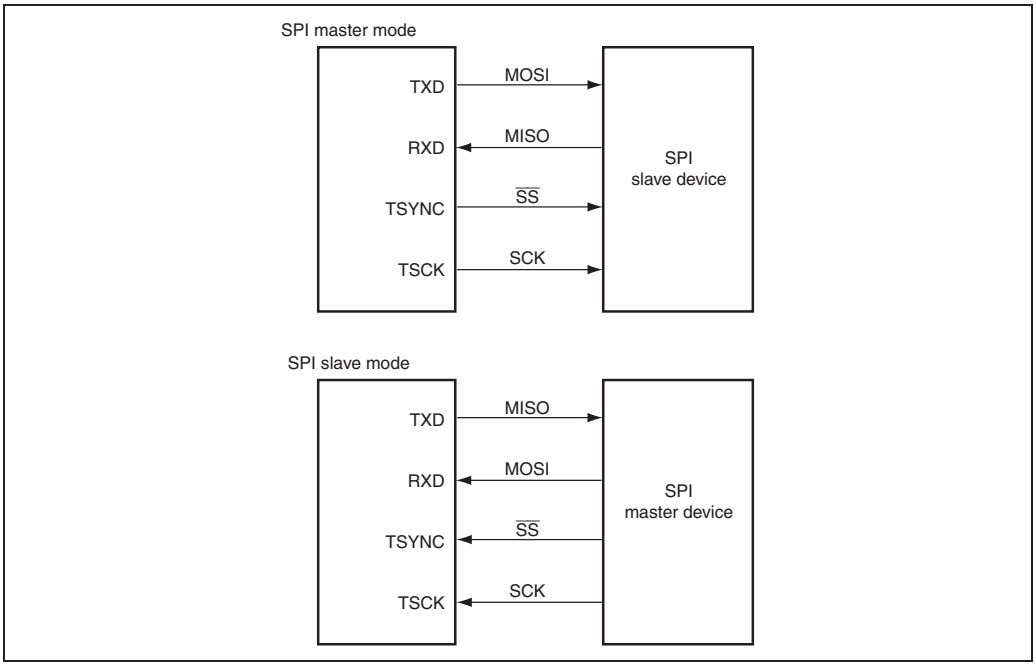
23.4.10 SPI

With the appropriate register settings, the MSIOF can be used as an SPI device.

(1) Example of SPI Device Connection

Figure 23.19 shows an example of connection with an SPI device.



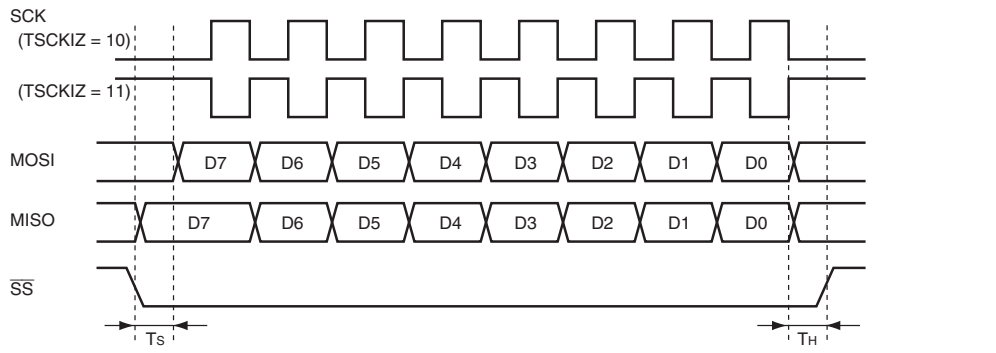


Figure 23.20 Example of SPI Device Connection

(2) SPI Serial Clock Timing

Figures 23.20 and 23.21 show the data and clock timing in SPI mode. As shown in the figures, four types of serial transfer formats can be used.

Transmit: TRMD = 1 (master) or 0 (slave) PCON = 1 SYNCMD[1:0] = 10 SYNCAC = 1
GRP[1:0] = 00 BITLEN1[4:0] = 00111 WDLEN1[7:0] = 00000000 GRPDL1[1:0] = 00 GRPDL3[1:0] = 00

Receive: TRMD = 0 SYNCMD[1:0] = 10 SYNCAC = 1
GRP[1:0] = 00 BITLEN1[4:0] = 00111 WDLEN1[7:0] = 00000000 GRPDL1[1:0] = 00 GRPDL3[1:0] = 00

Set DTDL to satisfy T_S (0 to 2 can be specified in 0.5-clock-cycle units)
Set SYNCDL to satisfy T_H (0 to 2 can be specified in 0.5-clock-cycle units)
The sum of DTDL and SYNCDL settings should be an integer.

SICTR: Upper: TSCKIZ[1:0] = 10, RSCKIZ[1:0] = 10, TEDG = 1, REDG = 1
Lower: TSCKIZ[1:0] = 11, RSCKIZ[1:0] = 11, TEDG = 0, REDG = 0

Figure 23.21 SPI Clock and Data Timing 1

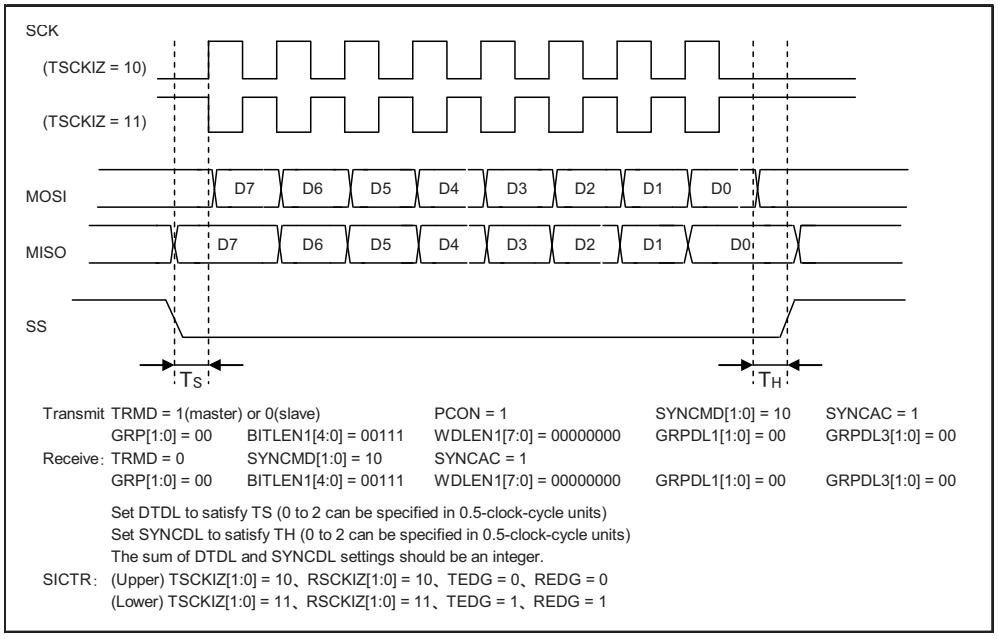

Figure 23.22 SPI Clock and Data Timing 2

23.4.11 Notes for Using SPI Mode

- When the module stop release or software reset is performed in SPI mode, set the control register (SICTR) again with each of the receive-setting bits (RSCKIZ/REDG) being 0.
- For SPI master mode operation, set the FLD bits in SITMDR1 for at least 4 cycles of SUBϕ.
- For SPI slave mode operation, set the frame synchronization signal interval to at least 4 cycles of SUBϕ.
- For SPI slave mode operation, The setting for data delay should always set 0.
- For SPI slave mode operation, TXDIZ bits work on SS signal invalid state.

23.4.12 IIS

This module can support IIS format with following setting which is shown Figure 23.23 and Figure 23.24.BITLEN1/2 bit will change by usage.

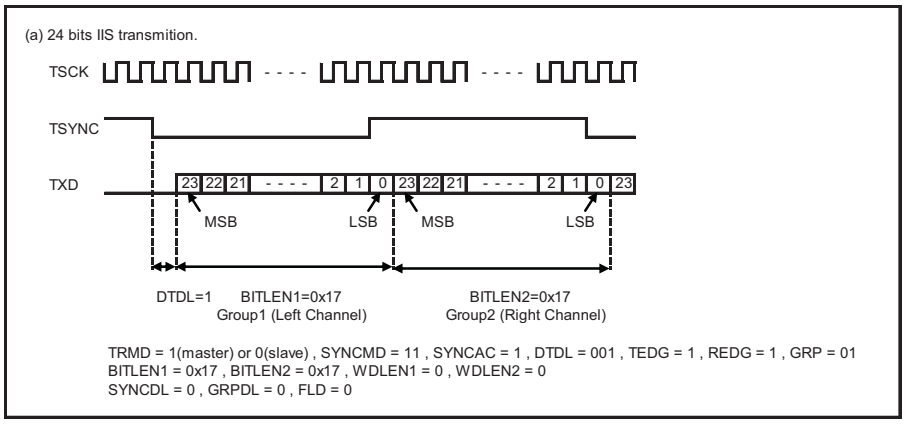

Figure 23.23 24 bits IIS transmition

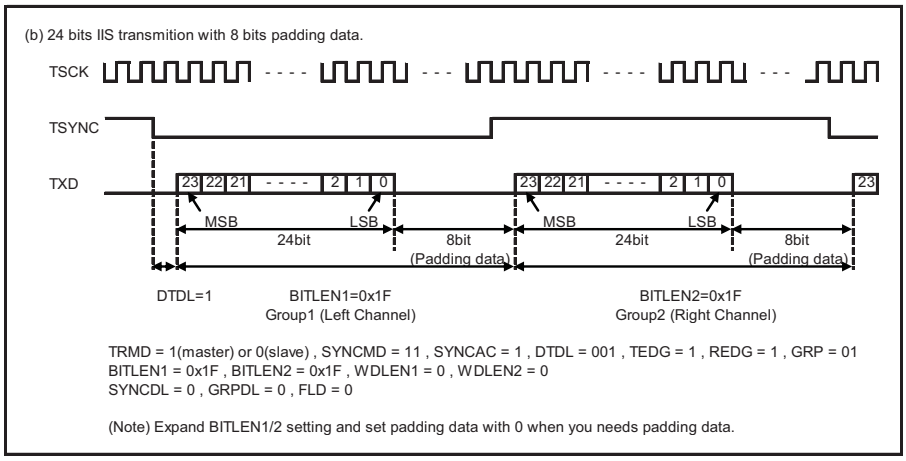

Figure 23.24 24 bits IIS transmition with 8 bits padding data

Section 24 Baseband Interface (BBIF1)

This LSI includes one channel of clock-synchronized serial I/O module (BBIF1) with FIFO, which can be connected to the BB domain MMIF.

24.1 Features

- Secure read processing from the MMIF to BBIF1 using the flow control pin.
- FIFO capacity: 32 bits × 64 stages for transmission and 32 bits × 256 stages for reception
- MSB first or LSB first selectable for data transmission and reception
- Synchronization in frame synchronization pulse, level, or left/right channel switch mode
- Supports both transmit master mode and receive slave mode (fixed).
- Independent clock and synchronization signals for transmission and reception
- Supports multiple-channel communication
  - Transfers multiple groups or words in one frame.
  - The word size for each group can be selected from eight to 32 bits.
  - Up to 256 words can be transferred in each group when one or two groups are used, or up to 16 words can be transferred in each group when three or four groups are used.
- Interrupts: One type
- Serial clock

  The internal clock (SUBϕ) is used as the serial clock source for transmission, and the receive serial clock input is used for reception.
- DMA transfer

  Supports multibyte DMA transfer.
  Supports DMA transfer by a transfer request for transmission and reception
- Serial format

  Supports the IIS and SPI serial formats (for master mode).

Figure 24.1 shows a block diagram of the BBIF1.

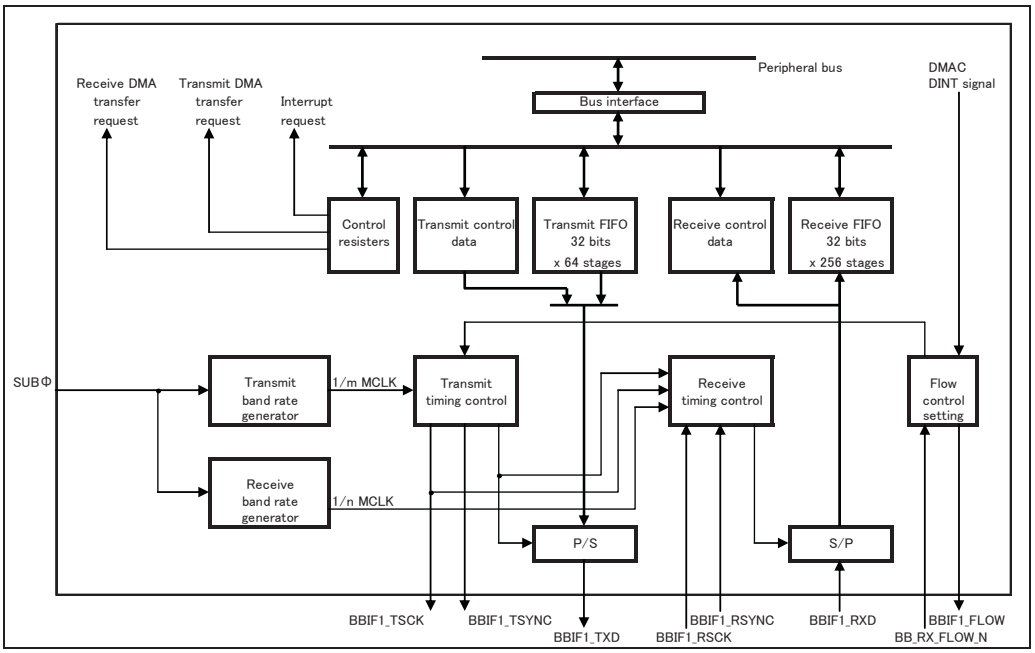

Figure 24.1 Block Diagram of BBIF1

24.2 Input/Output Pins

The pin configuration in this module is shown in Table 24.1.

Table 24.1 Pin Configuration

Name	I/O	Function
BBIF1_TSCK	Output	Serial clock for transmission
BBIF1_TSYNC	Output	Frame synchronization signal for transmission
BBIF1_RSCK	Input	Serial clock for reception
BBIF1_RSYNC	Input	Frame synchronization signal for reception
BBIF1_TXD	Output	Transmit data
BBIF1_RXD	Input	Receive data
BBIF1_FLOW	Output	APL Flow control signal
BB_RX_FLOW_N	Input	BB Flow control signal

24.3 Register Descriptions

Table 24.2 shows the register configuration of the BBIF1. Table 22.3 shows the register state in each processing mode.

Table 24.2 BBIF1 Register Configuration

Name	Abbreviation	R/W	Address	Access Size
BBIF1 transmit mode register 1	SITMDR1	R/W	H'E6C90000 H'E7C90000	32

24.3.1 BBIF1 Transmit Mode Register 1 (SITMDR1)

SITMDR1 is a 32-bit readable/writable register that specifies the BBIF1 transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRMD	—	SYNCMD[1:0]		SYNCCH[1:0]		SYNCA0	BITLSB	—	DTDL[2:0]			—	SYNCDL[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	DIV[3:0]				—	—	—	—	FLD[1:0]		CONT	TXSTP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. 0: Setting prohibited 1: Master mode
30	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
29, 28	SYNCMD [1:0]	00	R/W	SYNC Mode These bits specify the mode for the BBIF1_TSYNC signal. 00: Frame start synchronization pulse 01: 1-bit synchronization pulse for last data in slot 10: Level mode/SPI 11: L/R mode
27, 26	SYNCCH [1:0]	00	R/W	Synchronization Signal Channel Select 00: The frame synchronization signal is output from BBIF1_TSYNC. Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Descriptions
25	SYNCAC	0	R/W	BBIF1_TSYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	DTDL[2:0]	001	R/W	Data Pin Bit Delay for BBIF1_TSYNC Pin B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through the DTDL[2:0] and SYNCDL[2:0] bits becomes an integer value. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
18 to 16	SYNCDL [2:0]	000	R/W	Frame Synchronization Signal Timing Delay These bits extend the transmit frame synchronization signal. This setting is invalid when SYNCMD[1:0] = B'01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through the DTDL[2:0] and SYNCDL[2:0] bits becomes an integer value. When L/R mode , these bits should always be set to 000. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 011: 3-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
15 to 12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
11 to 8	DIV[3:0]	0000	R/W	Word Division One 32-bit word stored in the transmit FIFO can be transmitted as two separate 16-bit words through two groups. The word count in each group must be set to 1. In this case, data of groups other than word division target groups must be handled as control data. This setting is valid only in LR mode. 0000: Not divided 0001: Upper word in group 1 and lower word in group 2 0100: Upper word in group 2 and lower word in group 1 Other than above: Setting prohibited
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3, 2	FLD[1:0]	00	R/W	Frame Synchronization Signal Interval These bits specify the minimum idle time between frames in the number of serial clock cycles. When Level mode, set the FLD bits in SIRMDR1 for at least 4 cycles of SUBφ When L/R mode , these bits should always be set to 00. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay

Bit	Bit Name	Initial Value	R/W	Descriptions
1	CONT	0	R/W	Continuous Frame Transmission Specifies continuous transmission of multiple frames of data within one frame. This setting is valid when SYNCMD[1:0] = B'00 or B'10. When the TFSE bit in SICTR is set to 0, transmission is terminated after one-frame data is transmitted. 0: Does not perform continuous transmission. 1: Performs continuous transmission.
0	TXSTP	0	R/W	Transmission Stop Specifies the processing performed when the remaining number of stages in the transmit FIFO becomes smaller than the total number of words in the transmit frame. This setting is valid only in master mode. When transmission is continued, the value specified with TXDIZ is output as transmit data. If, with TXSTP = 1, the remaining number of stages in the transmit FIFO becomes smaller than the total number of words in the transmit frame, transmission is stopped temporarily. After this, however, transmission is automatically restarted if writing into the transmit FIFO causes the remaining number to become larger than the total number of words in the transmit frame. 0: Continues transmission when the transmit FIFO is empty. (The frame synchronization signal is output.) 1: Temporarily stops transmission when the remaining number of stages in the transmit FIFO becomes smaller than the total number of words in the transmit frame. (The frame synchronization signal is not output.)

24.3.2 BBIF1 Transmit Mode Register 2 (SITMDR2)

SITMDR2 is a 32-bit readable/writable register that specifies the BBIF1 transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GRP[1:0]		—	BITLEN1[4:0]					WDLEN1[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL1[1:0]		GRPDL3[1:0]		CRDE4	CRDE3	CRDE2	CRDE1	CRDNUM4	CRDNUM3	CRDNUM2	CRDNUM1	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	GRP[1:0]	00	R/W	Group Count The number of groups is set to the value specified in these bits + 1. When three or more groups are specified, the word size (BITLEN) is set to 16 bits or less.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0] (BITLEN3)	01111	R/W	Word Size (8 to 32 bits) The word size (bits) of groups 1 and 3 is set to the value specified in these bits + 1. (BITLEN1 = BITLEN3) Eight bits or a larger size should be specified. When three or four groups are used, the word size is set to 16 bits or less. (the highest bit is ignored).
23 to 16	WDLEN1[7:0] (WDLEN1[3:0] WDLEN3[3:0])	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 1 and 3 are set to WDLEN1 + 1 and WDLEN3 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN1. When three or four groups are used, the upper 4-bit value is set to WDLEN1, and the lower 4-bit value is set to WDLEN3.

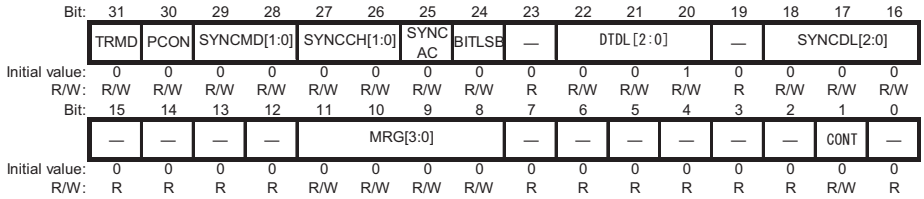
Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	GRPDL1[1:0]	00	R/W	Group 1 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 1. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
13, 12	GRPDL3[1:0]	00	R/W	Group 3 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 3. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
11	CRDE4	0	R/W	Control Data Enable "x" in CRDEx represents a group. Each of these bits specifies whether the group transmits FIFO data or control data. 0: The specified group transmits FIFO data. 1: The specified group transmits control data.
10	CRDE3	0	R/W	
9	CRDE2	0	R/W	
8	CRDE1	0	R/W	
7	CRDNUM4	0	R/W	Control Data Transmit Count "x" in CRDNUMx represents a group. Each of these bits specifies the transmission count of control data when multiple words are set for a control data group. Each bit is valid only when the corresponding CRDE bit is 1. When CRDNUMx = 1, control data is transmitted only for the first word, and the value specified with TXDIZ is output for other words. 0: Transmits control data continuously. 1: Transmits control data only once.
6	CRDNUM3	0	R/W	
5	CRDNUM2	0	R/W	
4	CRDNUM1	0	R/W	

Bit	Bit Name	Initial Value	R/W	Descriptions
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

24.3.3 BBIF1 Transmit Mode Register 3 (SITMDR3)

SITMDR3 is a 32-bit readable/writable register that specifies the BBIF1 transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	BITLEN2[4:0]					WDLEN2[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0] (BITLEN4)	01111	R/W	Word Size (8 to 32 bits) The word size is set to the value specified in these bits + 1. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored). Eight bits or a larger size should be specified.
23 to 16	WDLEN2[7:0] (WDLEN2[3:0] WDLEN4[3:0]	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 2 and 4 are set to WDLEN2 + 1 and WDLEN4 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN2. When three or four groups are used, the upper 4-bit value is set to WDLEN2, and the lower 4-bit value is set to WDLEN4.

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	GRPDL2[1:0]	00	R/W	Group 2 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 2. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
13, 12	GRPDL4[1:0]	00	R/W	Group 4 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 4. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
11 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

24.3.4 BBIF1 Receive Mode Register 1 (SIRMDR1)

SIRMDR1 is a 32-bit readable/writable register that specifies the BBIF1 receive mode.

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. 0: Slave mode 1: Master mode
30	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
29, 28	SYNCMD [1:0]	00	R/W	SYNC Mode These bits specify the mode for the BBIF1_RSYNC signal. 00: Frame start synchronization pulse 01: 1-bit synchronization pulse for last data in slot 10: Level mode/SPI 11: L/R mode
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	SYNCAC	0	R/W	BBIF1_RSYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode

Bit	Bit Name	Initial Value	R/W	Descriptions
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	DTDL[2:0]	001	R/W	Data Pin Bit Delay for BBIF1_RSYNC Pin B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through the DTDL[2:0] and SYNCDL[2:0] bits becomes an integer value. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

18 to 16	SYNCDL [2:0]	000	R/W	BBIF1_RSYNC Timing Delay The synchronization signal is extended for the clock cycles specified in these bits. This setting is invalid when SYNCMD[1:0] = B'01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through the DTDL[2:0] and SYNCDL[2:0] bits becomes an integer value. When L/R mode , these bits should always be set to 000. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 011: 3-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
15 to 12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
11 to 8	MRG[3:0]	0000	R/W	Word Merge The data received as 16-bit words of two groups can be merged into one 32-bit word and the 32-bit word is stored in the receive FIFO. The word count in the groups to be merged must be set to 1. In this case, data of groups other than word merging target groups must be handled as control data. This setting is valid only in LR mode. 0000: Not merged 0001: Upper word in group 1 and lower word in group 2 0100: Upper word in group 2 and lower word in group 1 Other than above: Setting prohibited
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	CONT	0	R/W	Continuous Frame Reception Specifies continuous reception of multiple frames of data within one frame. This setting is valid when SYNCMD[1:0] = B'00 or B'10. When the RFSE bit in SICTR is set to 0 in master mode, reception is terminated after one-frame data is received. 0: Does not perform continuous reception. 1: Performs continuous reception.
0	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

24.3.5 BBIF1 Receive Mode Register 2 (SIRMDR2)

SIRMDR2 is a 32-bit readable/writable register that specifies the BBIF1 receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GRP[1:0]		—	BITLEN1[4:0]					WDLEN1[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL1[1:0]		GRPDL3[1:0]		CRDE4	CRDE3	CRDE2	CRDE1	CRDNUM4	CRDNUM3	CRDNUM2	CRDNUM1	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	GRP[1:0]	00	R/W	Group Count The number of groups is set to the value specified in these bits + 1. When three or more groups are specified, the word size (BITLEN) is set to 16 bits or less.

Bit	Bit Name	Initial Value	R/W	Descriptions
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0] (BITLEN3)	01111	R/W	Word Size (8 to 32 bits) The word size (bits) of groups 1 and 3 is set to the value specified in these bits + 1 (BITLEN1 = BITLEN3). Eight bits or a larger size should be specified. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored).
23 to 16	WDLEN1[7:0] (WDLEN1[3:0] WDLEN3[3:0])	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 1 and 3 are set to WDLEN1 + 1 and WDLEN3 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN1. When three or four groups are used, the upper 4-bit value is set to WDLEN1, and the lower 4-bit value is set to WDLEN3.
15, 14	GRPDL1[1:0]	00	R/W	Group 1 Data Reception Delay These bits specify the delay in data reception of group 1. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
13, 12	GRPDL3[1:0]	00	R/W	Group 3 Data Reception Delay These bits specify the delay in data reception of group 3. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay

Bit	Bit Name	Initial Value	R/W	Descriptions
11	CRDE4	0	R/W	Control Data Enable
10	CRDE3	0	R/W	“x” in CRDEx represents a group. Each of these bits specifies whether the group receives FIFO data or control data.
9	CRDE2	0	R/W	
8	CRDE1	0	R/W	0: The specified group receives FIFO data.
				1: The specified group receives control data.
7	CRDNUM4	0	R/W	Control Data Reception Count
6	CRDNUM3	0	R/W	“x” in CRDNUMx represents a group. Each of these bits specifies the reception count of control data when multiple words are set for a control data group. When CRDNUMx = 1, only the first word is received as control data, and the other words are discarded as invalid data.
5	CRDNUM2	0	R/W	
4	CRDNUM1	0	R/W	0: Receives control data continuously.
				1: Receives only one word of control data.
3 to 0	—	All 0	R	Reserved
				These bits are always read as 0. The write value should always be 0.

24.3.6 BBIF1 Receive Mode Register 3 (SIRMDR3)

SIRMDR3 is a 32-bit readable/writable register that specifies the BBIF1 receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	BITLEN2[4:0]					WDLEN2[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0] (BITLEN4)	01111	R/W	Word Size (8 to 32 bits) The word size is set to the value specified in these bits + 1. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored). These bits should be set to eight bits or more.
23 to 16	WDLEN2[7:0] (WDLEN4)	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 2 and 4 are set to WDLEN2 + 1 and WDLEN4 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN2. When three or four groups are used, the upper 4-bit value is set to WDLEN2, and the lower 4-bit value is set to WDLEN4.
15, 14	GRPDL2[1:0]	00	R/W	Group 2 Data Reception Delay These bits specify the delay in data reception of group 2. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
13, 12	GRPDL4[1:0]	00	R/W	Group 4 Data Reception Delay These bits specify the delay in data reception of group 4. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
11 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

24.3.7 BBIF1 Control Register (SICTR)

SICTR is a 32-bit readable/writable register that specifies the BBIF1 operating state.

The values written to the TXE, RXE, TFSE, RFSE, TSCKE, and RSCKE bits become valid (can be read from the bits) several cycles after writing. These bits should not be modified together; modify one bit at a time, check that the new value can be read from the bit, and then modify another bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSCKIZ[1:0]		RSCKIZ[1:0]		TEDG	REDG	—	—	TXDIZ[1:0]		—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSCKE	TFSE	—	—	—	—	TXE	RXE	—	—	—	—	—	—	TXRST	RXRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	TSCKIZ[1:0]	00	R/W	Transmit Clock Output Polarity Select in SPI Mode When Transmission is Invalid When SPI mode is not used, these bits should always be set to 00. 00: Outputs BBIF1_TSCK when transmission is invalid. 01: Setting prohibited 10: Outputs 0. 11: Outputs 1.

Bit	Bit Name	Initial Value	R/W	Descriptions
29, 28	RSCKIZ[1:0]	00	R/W	Receive Clock Input Polarity Select in SPI Mode In SPI mode, set these bits to the TSCKIZ value. 00: Inputs BBIF1_RSCK when transmission is invalid 01: Setting prohibited 10: Inputs 0 through BBIF1_RSCK when transmission is invalid. 11: Inputs 1 through BBIF1_RSCK when transmission is invalid.
27	TEDG	0	R/W	Transmit Timing 0: Outputs transmit data at the rising edge of the clock. 1: Outputs transmit data at the falling edge of the clock.
26	REDG	0	R/W	Receive Timing 0: Samples receive data at the falling edge of the clock. 1: Samples receive data at the rising edge of the clock.
25, 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23, 22	TXDIZ[1:0]	00	R/W	Pin Output When Transmission is Invalid These bits specify the BBIF1_TXD pin output state when transmission is invalid. 00: Outputs 0. 01: Outputs 1. 10: Setting prohibited 11: Setting prohibited
21 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
15	TSCKE	0	R/W	Transmit Serial Clock Output Enable This bit is valid in master mode. When this bit is set to 1, the BBIF1 initializes the baud rate generator and initiates the operation. At the same time, the BBIF1 outputs the clock generated by the baud rate generator to the BBIF1_TSCK pin. After the clock is output, 1 can be read. When transmitting data, set this bit to 1 before setting the TFSE and TXE bits. After data transmission, clear the TFSE and TXE bits and then clear this bit to 0. [Write data] 0: Disables the BBIF1_TSCK output. (Outputs the value specified with TSCKIZ.) 1: Enables the BBIF1_TSCK output. [Read data] 0: Does not output BBIF1_TSCK. (Outputs the value specified with TSCKIZ.) 1: Outputs BBIF1_TSCK.
14	TFSE	0	R/W	Transmit Frame Synchronization Signal Output Enable This bit is valid in master mode. When this bit is set to 1, the BBIF1 initializes the frame counter and initiates the operation. After the transmit frame synchronization signal is output, 1 can be read. When 0 is written to this bit, 0 is set after transmission of the frame. [Write data] 0: Disables the BBIF1_TSYNC output. (Outputs the value specified with SYNCAC.) 1: Enables the BBIF1_TSYNC output. [Read data] 0: Does not output BBIF1_TSYNC. (Outputs the value specified with SYNCAC.) 1: Outputs BBIF1_TSYNC.

Bit	Bit Name	Initial Value	R/W	Descriptions
13 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	TXE	0	R/W	Transmit Enable When this bit is set to 1, the BBIF1 starts data transmission from the beginning of the next frame (at the rising edge of the frame synchronization signal). When value 1 set to this bit becomes valid, the BBIF1 issues a transmit data transfer request according to the setting of the TFWM bits in SIFCTR. When transmit data is stored in the transmit FIFO, transmission of data from the BBIF1_TXD pin begins. When 0 is written to this bit, 0 is set after transmission of the frame. This bit is initialized upon a transmit reset. [Write data] 0: Disables the BBIF1_TXD output. (Outputs the value specified with TXDIZ.) 1: Enables the BBIF1_TXD output. [Read data] 0: Does not output BBIF1_TXD. (Outputs the value specified with TXDIZ.) 1: Outputs BBIF1_TXD.

Bit	Bit Name	Initial Value	R/W	Descriptions
8	RXE	0	R/W	Receive Enable When this bit is set to 1, the BBIF1 starts data reception from the beginning of the next frame (at the rising edge of the frame synchronization signal). When value 1 set to this bit becomes valid, the BBIF1 begins reception of data through the BBIF1_RXD pin. When receive data is stored in the receive FIFO, the BBIF1 issues a receive data transfer request according to the setting of the RFWM bits in SIFCTR. This bit is initialized upon a receive reset. [Write data] 0: Disables data reception through BBIF1_RXD. 1: Enables data reception through BBIF1_RXD. [Read data] 0: Data is not received through BBIF1_RXD. 1: Data can be received through BBIF1_RXD.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
1	TXRST	0	R/W	Transmit Reset When value 1 set to this bit becomes valid, the BBIF1 immediately sets transmit data through the BBIF1_TXD pin to 0, and initializes the transmit data registers and transmit-related status. The following registers and bits are initialized. • SITDR1 and SITDR2 • SITFDR • Transmit FIFO write pointer • TCRDY, TFEMP, and TDREQ bits in SISTR • TXE bit This bit is read as 1 until the reset operation is completed for about 20 cycles. No data should be written to SICTR or the transmit FIFO during this time period. [Write data] 0: Does not reset transmit operation. 1: Resets transmit operation. [Read data] 0: Transmit operation reset is completed. 1: Transmit operation is being reset.

Bit	Bit Name	Initial Value	R/W	Descriptions
0	RXRST	0	R/W	Receive Reset When value 1 set to this bit becomes valid, the BBIF1 immediately disables reception through the BBIF1_RXD pin, and initializes the receive data registers and receive-related status. The following registers and bits are initialized. • SIRDR1 and SIRDR2 • SIRFDR • Receive FIFO read pointer • RCRDY, RFFUL, and RDREQ bits in SISTR • RXE bit This bit is read as 1 until the reset operation is completed for about 20 cycles. No data should be written to SICTR or read the receive FIFO during this time period. [Write data] 0: Does not reset receive operation. 1: Resets receive operation. [Read data] 0: Receive operation reset is completed. 1: Receive operation is being reset.

24.3.8 BBIF1 Transmit Clock Select Register (SITSCR)

SITSCR is a 16-bit readable/writable register that specifies the conditions for generating the transmit serial clock in master mode. SITSCR can be specified when the TRMD bit in SITMDR1 is set to B'1.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSSEL[1:0]		MSIMM	BRPS[4:0]					—	—	—	—	—	BRDV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	MSSEL[1:0]	00	R/W	Master Clock Source Select The master clock is the clock input to the baud rate generator. 00: Selects SUBϕ as the master clock. Other than above: Setting prohibited
13	MSIMM	0	R/W	Master Clock Direct Select 0: Selects the clock output from the baud rate generator as the serial clock. 1: Selects the master clock itself as the serial clock.
12 to 8	BRPS[4:0]	00000	R/W	Prescalar Setting These bits specify the master clock division ratio in the count value of the prescalar in the baud rate generator. The specifiable value is from B'00000 ($\times$ 1/1) to B'11111 ($\times$ 1/32).
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
2 to 0	BRDV[2:0]	000	R/W	Baud Rate Generator's Division Ratio These bits specify the frequency division ratio for the output stage of the baud rate generator. The final frequency division ratio of the baud rate generator is determined as BRPS × BRDV (1/1024 max.). 000: Prescalar output × 1/2 001: Prescalar output × 1/4 010: Prescalar output × 1/8 011: Prescalar output × 1/16 100: Prescalar output × 1/32 101: Setting prohibited 110: Setting prohibited 111: Prescalar output × 1/1 Note: B'111 is valid only when the BRPS[4:0] bits are set to B'00000 or B'00001.

24.3.9 BBIF1 Transmit Control Data Register 1 (SITDR1)

SITDR1 is a 32-bit write-only register that specifies the transmit control data of the BBIF1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCRD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCRD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	TCRD1[15:0]	H'0000	W	• When one or two groups are used: These bits specify the transmit control data for the upper 16 bits of a word in group 1 • When three or four groups are used: These bits specify the transmit control data for a word in group 1.
15 to 0	TCRD2[15:0]	H'0000	W	• When one or two groups are used: These bits specify the transmit control data for the lower 16 bits of a word in group 1 when the word size is larger than 16 bits. • When three or four groups are used: These bits specify the transmit control data for a word in group 3.

24.3.10 BBIF1 Transmit Control Data Register 2 (SITDR2)

SITDR2 is a 32-bit write-only register that specifies the transmit control data of the BBIF1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCRD3[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCRD4[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	TCRD3[15:0]	H'0000	W	• When one or two groups are used: These bits specify the transmit control data for the upper 16 bits of a word in group 2. • When three or four groups are used: These bits specify the transmit control data for a word in group 2.
15 to 0	TCRD4[15:0]	H'0000	W	• When one or two groups are used: These bits specify the transmit control data for the lower 16 bits of a word in group 2 when the word size is larger than 16 bits. • When three or four groups are used: These bits specify the transmit control data for a word in group 4.

24.3.11 BBIF1 Transmit FIFO Data Register (SITFDR)

SITFDR is a 32-bit write-only register that specifies the transmit FIFO data of the BBIF1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SITFD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SITFD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SITFD1[15:0]	H'0000	W	These bits specify the upper 16 bits of the FIFO data to be output through BBIF1_TXD.
15 to 0	SITFD2[15:0]	H'0000	W	These bits specify the lower 16 bits of the FIFO data to be output through BBIF1_TXD.

24.3.12 BBIF1 Receive Control Data Register 1 (SIRDR1)

SIRDR1 is a 32-bit read-only register that stores the receive control data of the BBIF1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RCRD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCRD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	RCRD1[15:0]	H'0000	R	• When one or two groups are used: Store the receive control data for the upper 16 bits of a word in group 1 • When three or four groups are used: Store the receive control data for a word in group 1.
15 to 0	RCRD2[15:0]	H'0000	R	• When one or two groups are used: Store the receive control data for the lower 16 bits of a word in group 1 when the word size is larger than 16 bits. • When three or four groups are used: Store the receive control data for a word in group 3.

24.3.13 BBIF1 Receive Control Data Register 2 (SIRDR2)

SIRDR2 is a 32-bit read-only register that stores the receive control data of the BBIF1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RCRD3[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCRD4[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	RCRD3[15:0]	H'0000	R	• When one or two groups are used: Store the receive control data for the upper 16 bits of a word in group 2 • When three or four groups are used: Store the receive control data for a word in group 2.
15 to 0	RCRD4[15:0]	H'0000	R	• When one or two groups are used: Store the receive control data for the lower 16 bits of a word in group 2 when the word size is larger than 16 bits. • When three or four groups are used: Store the receive control data for a word in group 4.

24.3.14 BBIF1 Receive FIFO Data Register (SIRFDR)

SIRFDR is a 32-bit read-only register that stores the receive FIFO data of the BBIF1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SIRFD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SIRFD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SIRFD1[15:0]	Undefined	R	Store the upper 16 bits of the FIFO data received through BBIF1_RXD.
15 to 0	SIRFD2[15:0]	Undefined	R	Store the lower 16 bits of the FIFO data received through BBIF1_RXD.

24.3.15 BBIF1 Status Register (SISTR)

Each bit in SISTR becomes a BBIF1 interrupt source when the corresponding bit in SIIER is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	TCRDY	TFEMP	TDREQ	—	—	—	—	TEOF	—	TFSERR	TFOVF	TFUDF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	RCRDY	RFFUL	RDREQ	—	—	—	—	REOF	—	RFSERR	RFUDF	RFOVF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	TCRDY	0	R/W	Transmit Control Data Ready If SITDR1 or SITDR2 is written while this bit is cleared to 0, SICTR is overwritten and the previous contents are not output through the BBIF1_TXD pin. This bit is valid when the TXE bit in SICTR is 1. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: SITDR1 and SITDR2 are not ready to be written. 1: SITDR1 and SITDR2 are ready to be written.

Bit	Bit Name	Initial Value	R/W	Descriptions
29	TFEMP	0	R/W	Transmit FIFO Empty This bit is valid when the TXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: Transmit FIFO is not empty. 1: Transmit FIFO is empty.
28	TDREQ	0	R	Transmit Data Transfer Request A transmit data transfer request is issued when the empty space in the transmit FIFO exceeds the size specified by the TFWM bits in SIFCTR. When transferring transmit data through the DMAC, this bit is always cleared after one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the BBIF1 again sets this bit to 1. This bit is valid when the TXE bit in SICTR is 1. This bit indicates a state; if the size of empty space in the transmit FIFO becomes less than the size specified by the TFWM bits in SIFCTR, the BBIF1 clears this bit. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. However, when the TDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of empty space in the transmit FIFO has not exceeded the size specified by the TFWM bits in SIFCTR. 1: The size of empty space in the transmit FIFO has exceeded the size specified by the TFWM bits in SIFCTR.
27 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
23	TEOF	0	R/W	Frame Transmission End The BBIF1 issues the frame transmission end flag upon completion of one-frame data transmission. This bit is valid when the TXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: One-frame transmission end is not detected. 1: One-frame transmission end is detected.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERR	0	R/W	Transmit Frame Synchronization Error A transmit frame synchronization error occurs when the next transmit frame synchronization timing arrives before the previous data or control data transmission has been completed. If a transmit frame synchronization error occurs, the BBIF1 performs transmission only for the slots that can be transferred. This bit is valid when the TXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: No transmit frame synchronization error has occurred. 1: A transmit frame synchronization error has occurred.

Bit	Bit Name	Initial Value	R/W	Descriptions
20	TFOVF	0	R/W	Transmit FIFO Overflow A transmit FIFO overflow means that there has been an attempt to write to SITFDR when the transmit FIFO is full. If a transmit FIFO overflow occurs, the BBIF1 ignores the write operation causing the overflow. This bit is valid when the TXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: No transmit FIFO overflow has occurred. 1: A transmit FIFO overflow has occurred.
19	TFUDF	0	R/W	Transmit FIFO Underflow A transmit FIFO underflow means that loading for transmission has occurred when the transmit FIFO is empty. This bit is valid when the TXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: No transmit FIFO underflow has occurred. 1: A transmit FIFO underflow has occurred.
18 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
14	RCRDY	0	R/W	Receive Control Data Ready When data different from the previous data is stored during reception of control data, this bit is set to 1 indicating that valid data was written. When the first data that is not 0 is stored, this bit is set to 1. If valid data is written to SIRDR1 or SIRDR2 when this bit is set to 1, SIRDR1 or SIRDR2 is overwritten with the latest data. This bit is valid when the RXE bit in SICTR is 1. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: SIRDR1 and SIRDR2 store no valid data. 1: SIRDR1 and SIRDR2 store valid data.
13	RFFUL	0	R/W	Receive FIFO Full This bit is valid when the RXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: Receive FIFO is not full. 1: Receive FIFO is full.

Bit	Bit Name	Initial Value	R/W	Descriptions
12	RDREQ	0	R	Receive Data Transfer Request A receive data transfer request is issued when the valid data space in the receive FIFO exceeds the size specified by the RFWM bits in SIFCTR. When transferring transmit data through the DMAC, this bit is always cleared by one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the BBIF1 again sets this bit to 1. This bit is valid when the RXE bit in SICTR is 1. This bit indicates a state; if the size of valid data space in the receive FIFO becomes less than the size specified by the RFWM bits in SIFCTR, the BBIF1 clears this bit. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. However, when the RDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of valid data space in the receive FIFO has not exceeded the size specified by the RFWM bits in SIFCTR. 1: The size of valid data space in the receive FIFO has exceeded the size specified by the RFWM bits in SIFCTR.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
7	REOF	0	R/W	Frame Reception End The BBIF1 issues the frame reception end flag upon completion of one-frame data reception. This bit is valid when the RXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: One-frame reception end is not detected. 1: One-frame reception end is detected.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	RFSERR	0	R/W	Receive Frame Synchronization Error A receive frame synchronization error occurs when the next receive frame synchronization timing arrives before the previous data or control data reception has been completed. If a receive frame synchronization error occurs, the BBIF1 performs reception only for the slots that can be transferred. This bit is valid when the RXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: No receive frame synchronization error has occurred. 1: A receive frame synchronization error has occurred.

Bit	Bit Name	Initial Value	R/W	Descriptions
4	RFUDF	0	R/W	Receive FIFO Underflow A receive FIFO underflow means that reading of SIRFDR has occurred when the receive FIFO is empty. If a receive FIFO underflow occurs, the value read from SIRFDR is not guaranteed. This bit is valid when the RXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: No receive FIFO underflow has occurred. 1: A receive FIFO underflow has occurred.
3	RFOVF	0	R/W	Receive FIFO Overflow A receive FIFO overflow means that writing has been caused by receiving operation when the receive FIFO is full. If a receive FIFO overflow occurs, the receive data causing the overflow is lost. This bit is valid when the RXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF1 interrupt is issued. 0: No receive FIFO overflow has occurred. 1: A receive FIFO overflow has occurred.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

24.3.16 BBIF1 Interrupt Enable Register (SIIER)

SIIER is a 32-bit readable/writable register that enables the issue of BBIF1 interrupts. When each bit in this register is set to 1 and the corresponding bit in SISTR is set to 1, the BBIF1 issues an interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TDMAE	TCRDYE	TFEMPE	TDREQE	—	—	—	—	TEOFE	—	TFSERRE	TFOVFE	TFUDFE	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDMAE	RCRDYE	RFFULE	RDREQE	—	—	—	—	REOFE	—	RFSERRE	RFUDFE	RFOVFE	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TDMAE	0	R/W	Transmit Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The TDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.
30	TCRDYE	0	R/W	Transmit Control Data Ready Enable 0: Disables interrupts due to transmit control data ready. 1: Enables interrupts due to transmit control data ready.
29	TFEMPE	0	R/W	Transmit FIFO Empty Enable 0: Disables interrupts due to transmit FIFO empty 1: Enables interrupts due to transmit FIFO empty
28	TDREQE	0	R/W	Transmit Data Transfer Request Enable 0: Disables interrupts due to transmit data transfer requests. 1: Enables interrupts due to transmit data transfer requests.

Bit	Bit Name	Initial Value	R/W	Descriptions
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23	TEOFE	0	R/W	Frame Transmission End Enable 0: Disables a frame transmission end interrupt. 1: Enables a frame transmission end interrupt.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERRE	0	R/W	Transmit Frame Synchronization Error Enable 0: Disables interrupts due to transmit frame synchronization errors. 1: Enables interrupts due to transmit frame synchronization errors.
20	TFOVFE	0	R/W	Transmit FIFO Overflow Enable 0: Disables interrupts due to transmit FIFO overflow. 1: Enables interrupts due to transmit FIFO overflow.
19	TFUDFE	0	R/W	Transmit FIFO Underflow Enable 0: Disables interrupts due to transmit FIFO underflow. 1: Enables interrupts due to transmit FIFO underflow.
18 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	RDMAE	0	R/W	Receive Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The RDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.

Bit	Bit Name	Initial Value	R/W	Descriptions
14	RCRDYE	0	R/W	Receive Control Data Ready Enable 0: Disables interrupts due to receive control data ready. 1: Enables interrupts due to receive control data ready.
13	RFFULE	0	R/W	Receive FIFO Full Enable 0: Disables interrupts due to receive FIFO full. 1: Enables interrupts due to receive FIFO full.
12	RDREQE	0	R/W	Receive Data Transfer Request Enable 0: Disables interrupts due to receive data transfer requests. 1: Enables interrupts due to receive data transfer requests.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOFE	0	R/W	Frame Reception End Enable 0: Disables a frame reception end interrupt. 1: Enables a frame reception end interrupt.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	RFSERRE	0	R/W	Receive Frame Synchronization Error Enable 0: Disables interrupts due to receive frame synchronization errors. 1: Enables interrupts due to receive frame synchronization errors.
4	RFUDFE	0	R/W	Receive FIFO Underflow Enable 0: Disables interrupts due to receive FIFO underflow. 1: Enables interrupts due to receive FIFO underflow.

Bit	Bit Name	Initial Value	R/W	Descriptions
3	RFOVFE	0	R/W	Receive FIFO Overflow Enable 0: Disables interrupts due to receive FIFO overflow. 1: Enables interrupts due to receive FIFO overflow.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

24.3.17 BBIF1 FIFO Control Register (SIFCTR)

SIFCTR is a 32-bit readable/writable register that indicates the area available for the transmit/receive FIFO transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TFWM[2:0]			—	—	TFUA[6:0]							—	—	—	—
Initial value:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFWM[2:0]			RFUA[8:0]									—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	TFWM[2:0]	000	R/W	Transmit FIFO Watermark A transfer request of the transmit FIFO is issued by the TDREQE bit in SIIER. The transmit FIFO always operates as a 64-stage FIFO regardless of these bit settings. 000: Issues a transfer request when 64 stages of the transmit FIFO are empty. 001: Issues a transfer request when 32 or more stages of the transmit FIFO are empty. 010: Issues a transfer request when 24 or more stages of the transmit FIFO are empty. 011: Issues a transfer request when 16 or more stages of the transmit FIFO are empty. 100: Issues a transfer request when 12 or more stages of the transmit FIFO are empty. 101: Issues a transfer request when 8 or more stages of the transmit FIFO are empty. 110: Issues a transfer request when 4 or more stages of the transmit FIFO are empty. 111: Issues a transfer request when 1 or more stages of transmit FIFO are empty.

Bit	Bit Name	Initial Value	R/W	Descriptions
28, 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 20	TFUA[6:0]	H'40	R	Transmit FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'0000000 (full) to B'1000000 (empty).
19 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 13	RFWM[2:0]	000	R/W	Receive FIFO Watermark A transfer request of the receive FIFO is issued by the RDREQE bit in SIIER. The receive FIFO always operates as a 256-stage FIFO regardless of these bit settings. 000: Issues a transfer request when 1 stage or more of the receive FIFO are valid. 001: Issues a transfer request when 4 or more stages of the receive FIFO are valid. 010: Issues a transfer request when 8 or more stages of the receive FIFO are valid. 011: Issues a transfer request when 16 or more stages of the receive FIFO are valid. 100: Issues a transfer request when 32 or more stages of the receive FIFO are valid. 101: Issues a transfer request when 64 or more stages of the receive FIFO are valid. 110: Issues a transfer request when 128 or more stages of the receive FIFO are valid. 111: Issues a transfer request when 256 stages of the receive FIFO are valid.
12 to 4	RFUA[8:0]	H'000	R	Receive FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'000000000 (empty) to B'100000000 (full).

Bit	Bit Name	Initial Value	R/W	Descriptions
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

24.3.18 BBIF1 Flow Control Register (SIFLCTR)

SIFLCTR is a 32-bit readable/writable register that controls the output of the flow control pin.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	APFLE	APFLMASK	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BBFLE	BBFLMASK	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	APFLE	0	R/W	AP-Flow Control Pin Forcible Output 0: Does not forcibly assert the flow control pin. (Outputs the DINT signal.) 1: Forcibly asserts the flow control pin.
30	APFLMASK	0	R/W	AP-Flow Control Pin Output Mask 0: Does not mask the flow control pin output. 1: Masks the flow control pin output. Setting this bit to 1 takes precedence over the APFLE bit.
29 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	BBFLE	0	R/W	BB-Flow Control Pin Forcible Input 0: Does not forcibly assert the flow control pin. (Inputs the BB_RX_FLOW signal.) 1: Forcibly asserts the flow control pin.
14	BBFLMASK	0	R/W	BB-Flow Control Pin Input Mask 0: Does not mask the flow control pin input. 1: Masks the flow control pin output. Setting this bit to 1 takes precedence over the BBFLE bit.
13 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

24.4 Operation

24.4.1 Operating Mode

(1) Independent Transmit/Receive Mode

Dedicated clock and frame synchronization signals can be specified each for transmission and reception.

Master mode: BBIF1_TSCK and BBIF1_TSYNC (BBIF1_RSCK and BBIF1_RSYNC) are output.

Slave mode: BBIF1_TSCK and BBIF1_TSYNC (BBIF1_RSCK and BBIF1_RSYNC) are input.

(2) Common Transmit/Receive Mode

Common clock and frame synchronization signals are used for transmission and reception.

Master mode: BBIF1_TSCK (BBIF1_SCK) and BBIF1_TSYNC (BBIF1_SYNC) are output.

Slave mode: BBIFTSCK (BBIF1_SCK) and BBIF1_TSYNC (BBIF1_SYNC) are input.

24.4.2 Serial Clocks

(1) Clock Output in Master Mode

In master mode, the baud rate generator is used to generate the serial clock. The division ratio is from 1/1 to 1/1024.

(2) Clock Input in Slave Mode

In slave mode, the clock input for transmission and reception is used as the serial clock.

(3) Multiple Channel Function

This module provides the multiple channel function as shown in Figure 24.2.

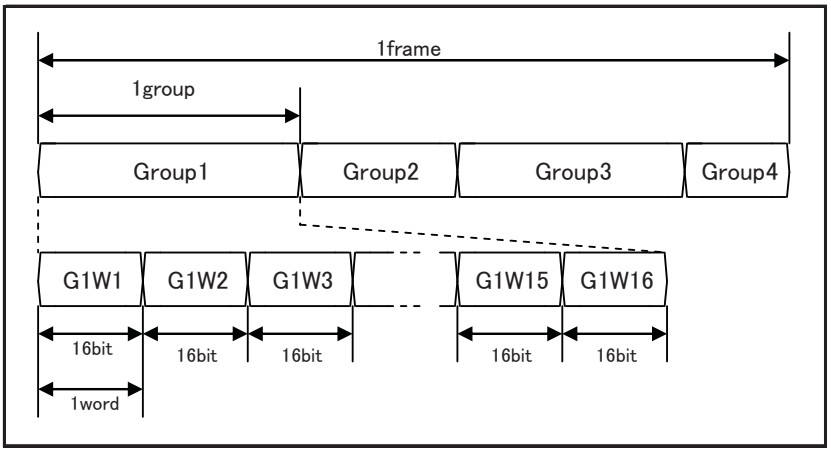

Figure 24.2 Multiple Channel Structure

The following conditions can be specified for the multiple channel function.

- Up to four groups in one frame
- Up to 256 words in one group
- Eight bits to 32 bits in one word
- Up to three blank bits can be inserted between groups

Note the following limitations by the number of groups.

Table 24.4 Maximum Word Size and Group Size Limited by Number of Groups

Number of Groups	Maximum Word Size	Maximum Group Size
One or two	32 bits	256 words
Three or four	16 bits	16 words

24.4.3 Serial Timing

(1) BBIF1_TSYNC, BBIF1_RSYNC

The BBIF1_TSYNC and BBIF1_RSYNC are frame synchronization signals. The following four modes are available.

- Frame start synchronization pulse: 1-bit-width pulse indicating the start of a frame
- Last bit synchronization pulse: 1-bit-width pulse indicating the last bit in a word
- Level/SPI: Level signal asserted during frame transmission
- L/R: 1/2-frame-width pulse indicating the first-half groups in a high level and the last-half groups in a low level

Figure 24.3 to 24.6 show the BBIF1_SYNC synchronization timing in these modes.

(2) Frame Start Synchronization Pulse

The rising edge of the synchronization pulse indicates the start of a frame.

The delay between the rising edge of the synchronization signal and the start of data transmission or reception can be specified with the DTDL bits. The width of the synchronization pulse can be extended through the SYNCDL bit setting.

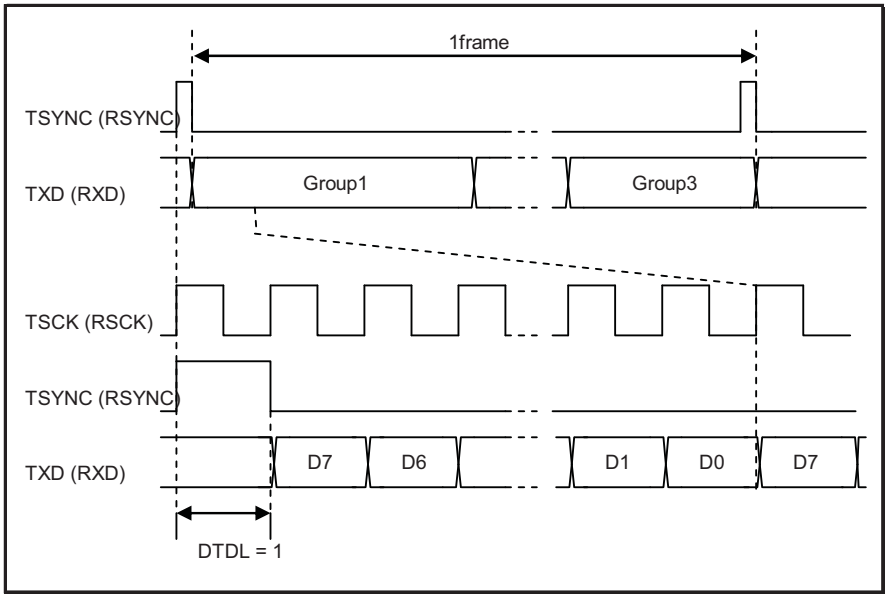

Figure 24.3 Synchronization Timing in Start Frame Synchronization Pulse Mode

(3) Last Bit Synchronization Pulse

The rising edge of the synchronization pulse indicates the last bit of each word.

The delay between the last bit of a word and the synchronization pulse can be specified with the DTDL bits.

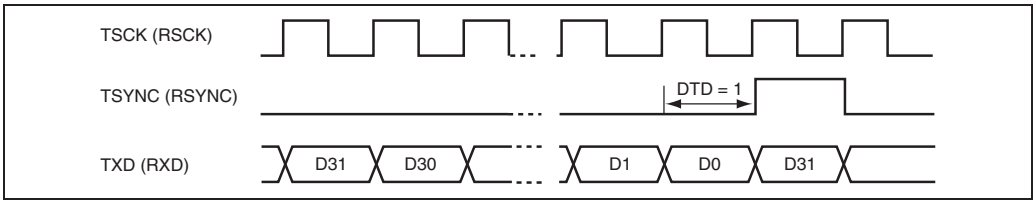

Figure 24.4 Synchronization Timing in Last Bit Synchronization Pulse Mode

(4) Level Synchronization

The synchronization signal is driven high for the frame length.

The delay between the rising edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits and the delay between the end of transmission or reception and the falling edge of the synchronization signal can be specified with the SYNCDL bits (DTDL = 0 to 2 and SYNCDL = 0 to 3). This mode is available for the SPI master or slave operation.

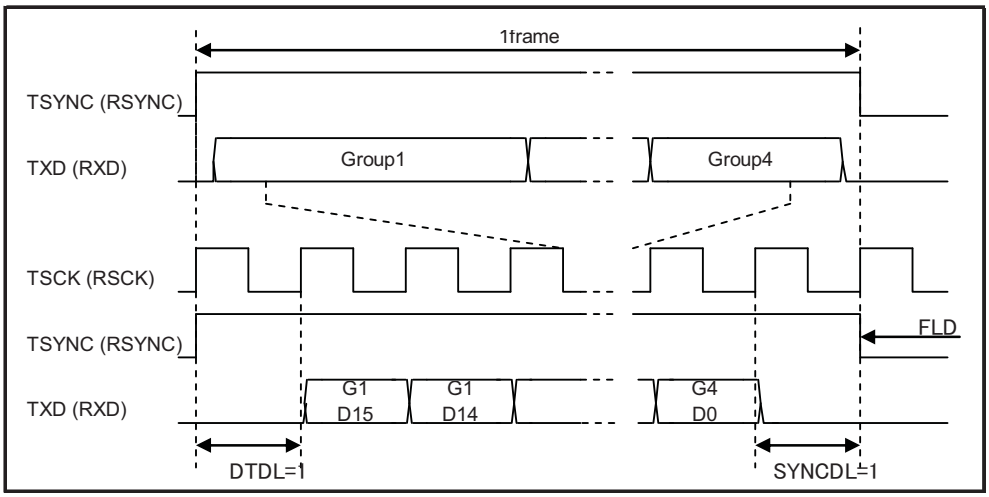

Figure 24.5 Synchronization Timing in Level Synchronization Mode

(5) L/R Synchronization

A high level in the synchronization signal indicates the first-half groups and a low level indicates the last-half groups.

The delay between the rising or falling edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits and the delay between the end of transmission or reception and the falling or rising edge of the synchronization signal can be specified with the SYNCDL bits (DTDL = 0 to 2 and SYNCDL = 0 to 3).

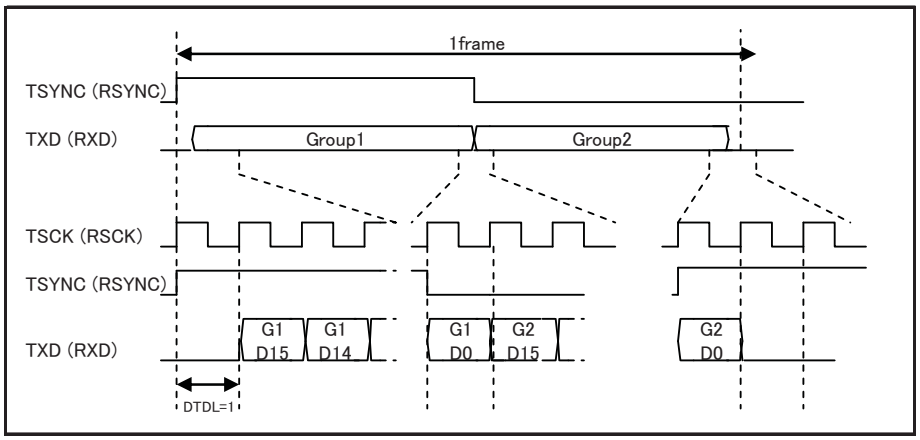

Figure 24.6 Synchronization Timing in L/R Synchronization Mode

(6) Transmit/Receive Timing

The BBIF1_TXD transmit timing and BBIF1_RXD receive timing relative to the BBIF1_TSCK and BBIF1_RSCK can be specified as the sampling timing in the following two ways through the TEDG and REDG bits in SIMDR.

- Falling-edge sampling
- Rising-edge sampling

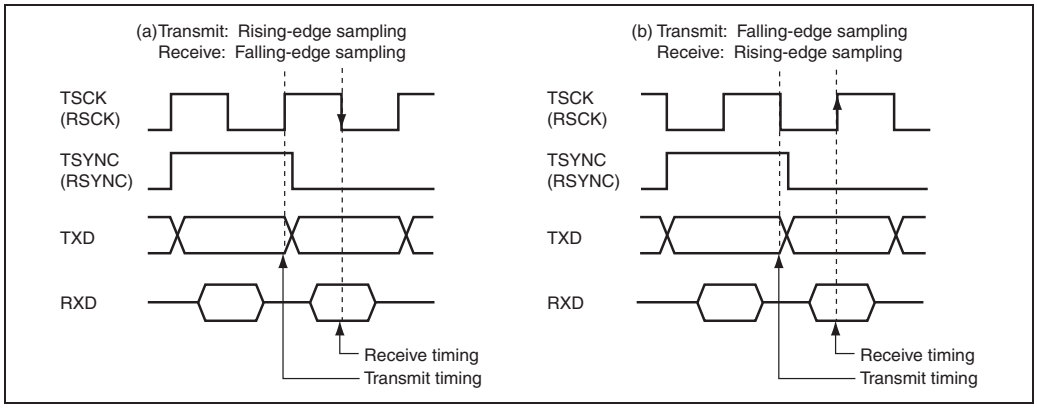

Figure 24.7 Transmit/Receive Timing.

24.4.4 Control Data Interface

For the groups specified with the CRDE bits in SITMDR2 and SIRMDR2, data is not stored in the FIFOs but handled as control data to be stored in SITDR1/SITDR2 and SIRDR1/SIRDR2.

Control data is transferred in the following two ways, which can be selected through the CRDNUM bits in SITMDR2 and SIRMDR2, as shown in figure 22.8.

- Only the first word in the group is transferred as valid data.
- All words in the group is transferred as valid data.

For the invalid data period during transmission, the value specified in the TXDIZ bit is output. The invalid receive data is not stored in SIRDR1 or SIRDR2.

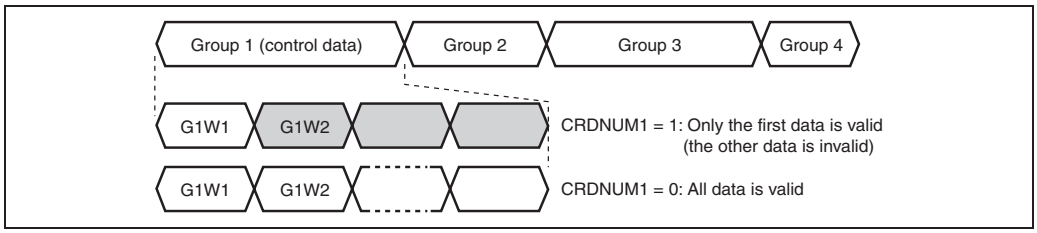

Figure 24.8 Control Data Allocation

24.4.5 Transfer Data Allocation to Registers

(1) Transmit/Receive Data

Transmit/receive data (FIFO data and control data) should be written to or read from the following registers.

- Transmit FIFO data writing: SITFDR (32/16-bit access)
- Control data writing: SITDR1 and SITDR2 (32/16-bit access)
- Receive FIFO data reading: SIRFDR (32/16-bit access)
- Control data reading: SIRDR1 and SIRDR2 (32/16-bit access)

When making a 16-bit access, only upper 16 bits of FIFO data is accessible. However, both upper 16 bits and lower 16 bits of control data are accessible.

When the word size is smaller than the transmit FIFO data access size, the upper bits are transmitted as valid data. For example, when writing data to the transmit FIFO by 32-bit access and transmitting a16-bit word, the upper 16 bits are transmitted and the lower 16 bits are discarded as invalid data.

In the same way, when the word size is larger than the receive FIFO data access size, the upper bits are received as valid data. For example, when 32-bit data is stored in the receive FIFO and the data is read by 16-bit access, the lower 16 bits are discarded as invalid data.

Figure 24.9 shows the bit alignment of these registers.

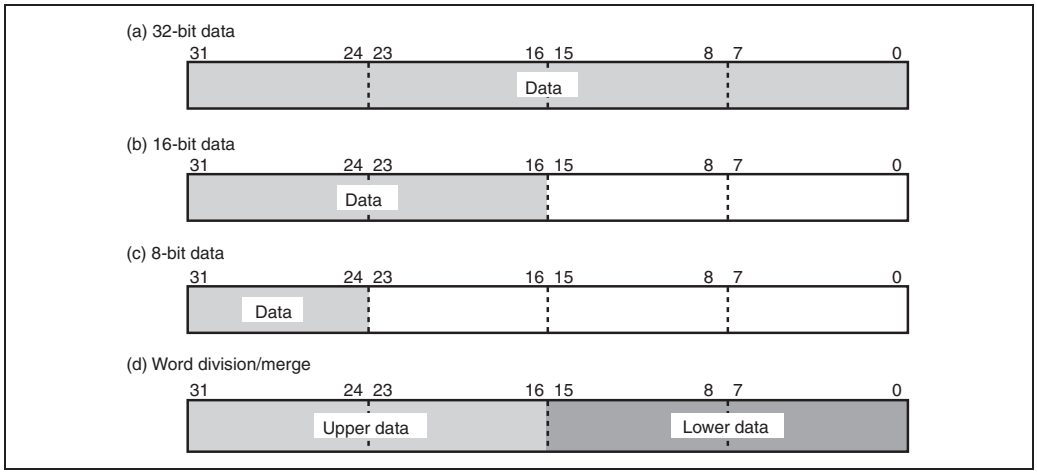

Figure 24.9 Transmit/Receive Data Bit Alignment

24.4.6 FIFO

(1) Overview

The transmit and receive FIFOs of the BBIF1 have the following features.

- 32 bits × 64 stages for transmission and 32 bits × 256 stages for reception
- The FIFO pointer is updated in one read or write cycle regardless of the access size of the CPU or DMAC. (One access cannot be divided into multiple accesses.)

(2) Transfer Request

A request for FIFO data transfer can be issued to the CPU or DMAC as the following interrupt sources.

- FIFO transmit request: TDREQ (interrupt source for transmission)
- FIFO receive request: RDREQ (interrupt source for reception)

The conditions for requesting FIFO data transfer can be specified separately for transmission and reception. The conditions for the transmit FIFO and receive FIFO are specified in the TFWM[2:0] bits and RFWM[2:0] bits in SIFCTR, respectively.

Table 24.5 Condition for Issuing Transmit Request

TFWM[2:0]	Number of Requested Stages	Condition for Transmit Request	Areas Used
000	1	64 stages of empty area	Smallest
001	32	32 or more stages of empty area	↕
010	40	24 or more stages of empty area	
011	48	16 or more stages of empty area	
100	52	12 or more stages of empty area	
101	56	8 or more stages of empty area	
110	60	4 or more stages of empty area	
111	64	1 or more stages of empty area	Largest

Table 24.6 Condition for Issuing Receive Request

RFWM[2:0]	Number of Requested Stages	Condition for Receive Request	Areas Used
000	1	1 or more stages of valid data	Smallest
001	4	4 or more stages of valid data	
010	8	8 or more stages of valid data	
011	16	16 or more stages of valid data	
100	32	32 or more stages of valid data	
101	64	64 or more stages of valid data	
110	128	128 or more stages of valid data	
111	256	256 stages of valid data	Largest

The maximum FIFO stages are always available even if the data area or empty area exceeds the size specified for the transfer condition. Accordingly, an overflow error or an underflow error occurs if the data area or empty area exceeds the maximum number of FIFO stages.

The FIFO transfer request is canceled when the specified condition is not satisfied even if the FIFO does not become empty or full.

(3) Number of FIFOs

The number of transmit and receive FIFO stages used are indicated by the following registers.

- Transmit FIFO: The number of empty FIFO stages is indicated by the TFUA[6:0] bits in SIFCTR.
- Receive FIFO: The number of valid data stages is indicated by the RFUA[8:0] bits in SIFCTR.

These registers show the number of data stages that can be transferred by the CPU or DMAC.

24.4.7 MMIF Transmission Flow Control

(1) Overview

The BBIF1_FLOW signal is a flow control output generated from the DMAC interrupt (DINT) signal as the input. While the BBIF1_FLOW output is active low indicating the flow state, data transmission from the MMIF is suspended, which allows secure reading of receive data during this time period. Table 22.7 shows the BBIF1_FLOW output state according to the values of the SIFLCTR register.

Table 24.7 BBIF1_FLOW Output State

State	DINT	FLE Bit	FLMASK Bit	BBIF1_FLOW
During transfer	H	0	0	H
During DMAC interrupt processing	L	0	0	L
FLE bit forcible flow	*	1	0	L
Flow output mask	*	*	1	H

Note: * Don't care

(2) Flow Control Procedure (when two buffers are used)

The following shows an example of DMAC setting to set two buffers (side A and side B) in the SDRAM for BBIF1 receive data (when using channel 1 of DMAC1, for example).

DMA1SAR_1 in DMAC1 = SIRFDR in BBIF1 (or BB1PKDATAR1 in DREQPAK)
DMA1DAR_1 in DMAC1 = Start address of side A buffer
DMA1TCR_1 in DMAC1 = Transfer count of side A/side B total buffer size
DMA1CHCR_1 in DMAC1 = (HIE = 1 and IE = 1)
DMA1DMICR in DMAC1 = H'00000091

When a DMA transfer starts, a half end interrupt or a transfer end interrupt is output upon completion of the transfer of side A or side B. The DINT signal is also asserted at the same time, and the BBIF1_FLOW output turns low indicating the flow state.

This automatically suspends the MMIF transmit data output. Setting the APFLE bit in BBIF1 to 1 within the DMAC1 interrupt handler maintains the flow state until the buffer read operation is completed. Clearing the APFLE bit to 0 automatically restarts transfer of the transmit data from the suspended position.

Figure 24.10 shows the overview of receive data read processing.

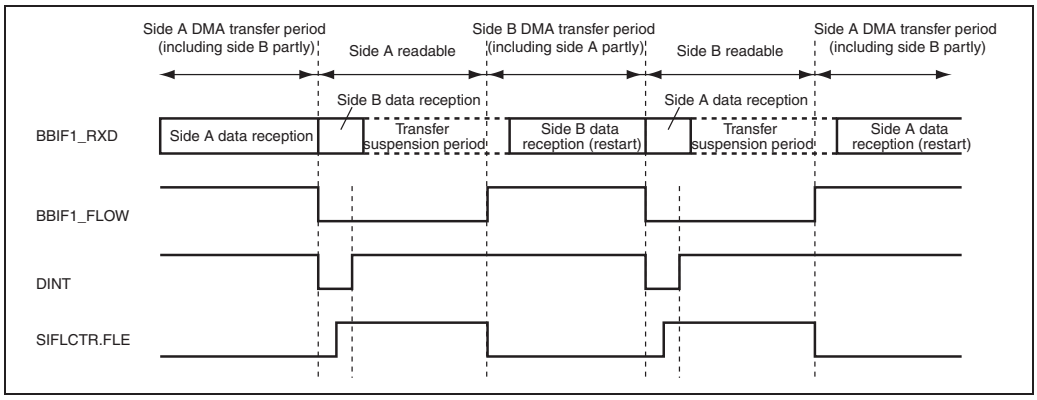

Figure 24.10 Receive Data Read Using BBIF1_FLOW

24.4.8 BBIF transmit flow control

BBIF1 can dynamic control the transmission of a message data output for MMIF with BB_RX_FLOW_N. MMIF can read data safty when BB_RX_FLOW_N is low level. Because BBIF1 doen't transmit data.

BBIF1 stop transmission when detect BBFLE = 1 or flow signal asserted if BBFLMASK bit set 0.BBIF1 stop till BB_RX_FLOW_N negate.

BBIF1 re-start transmit when detect BB_FLOW_N negated and BBFLE=0.The value of BB_RX_FLOW_N and BBFLE is masked when BBFLMASK=1.

The transmition was expanded after BB_RX_FLOW_N asserted.Because BBIF1 need least 2 cycle of BBIF1_TSCK for detection BB_RX_FLOW_N for synchronization.Fig24.11 shown timing chart of RX_FLOW_N.

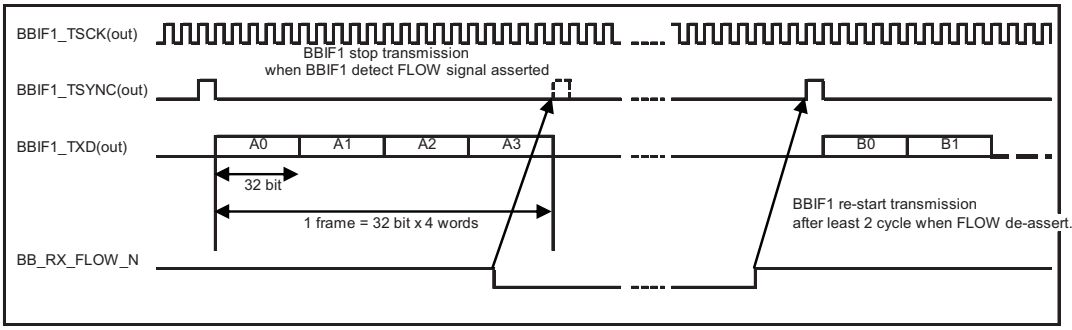

Figure 24.11 Timing chart of BB_RX_FLOW_N

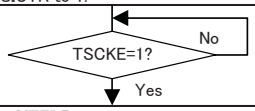
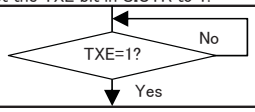
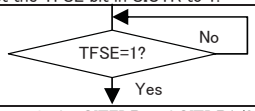
24.4.9 Transmit and Receive Procedures

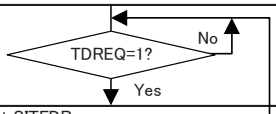
(1) Transmission in Master Mode

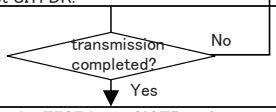
Figure 24.12 shows an example of settings and operation for transmission in master mode.

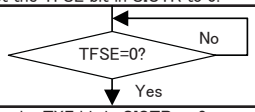


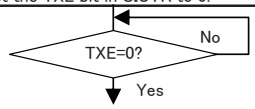










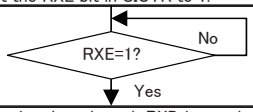


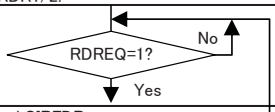
No.	Flow chart	Setting	operation
1	Set SITMDR1/2/3 SITSCR , SIFCTR , and SIIER.	Set the operating mode, serial clock , and FIFO threshold value, and enable interrupts.	
2	Set the TSCKE bit in SICTR to 1.	Set output sampling and start the baud rate generator.	Outputs the serial clock.
3		Read 1 from TSCKE bit in SICTR.	
4	Set SITFDR, SITDR1/2.	Set transmit data.	
5	Set the TXE bit in SICTR to 1.	Enable transmittion.	
6		Read 1 from TXE bit in SICTR.	
7	Set the TFSE bit in SICTR to 1.	Starting output frame of synchronization signal.	Outputs the frame syncronization signal.
8		Read 1 from TFSE bit in SICTR.	
9	Transmit the SITFDR and SITDR1/2 contents through TXD in synchronization with		Transmit data.
10			Assert transmit data transfer request according to the FIFO threshold valu
11	Set SITFDR.	Set transfer data.	
12		Read 1 from TFEMP bit in SICTR.	
13	Set the TFSE bit in SICTR to 0.	Disable output frame of synchronization signal.	
14		Read 0 from TFSE bit in SICTR.	
15	Set the TXE bit in SICTR to 0.	Disable transmit enable.	
16	 Transmission complete.	Read 0 from TXE bit in SICTR.	

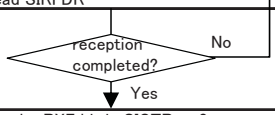
Figure 24.12 Example of Transmit Procedure in Master Mode

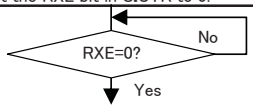
(2) Reception in Slave Mode

Figure 24.13 shows an example of settings and operation for reception in slave mode.









No.	Flow chart	Setting	operation
1	Setting master device polarity	Depend on master device.	Decide SYNC/SCK polarity
2	Set SIRMDR1/2/3 SIFCTR and SIIER.	Set operating mode FIFO threshold value and enable interrupts.	
3	Set the RXE bit in SICTR to 1.	Enable reception.	
4		Read 1 from RXE bit in SICTR.	
5	Receive data through RXD in synchronization with MSIOF_RSYNC and store it in SIRFDR and SIRDR1/2.		Receive data
6			Assert reception data transfer request according to the FIFO threshold valu
7	Read SIRFDR	Read reception data.	
8			
9	Set the RXE bit in SICTR to 0.	Disable reception enable	
10	 Reception complete.	Read 0 from RXE bit in SICTR.	

Figure 24.13 Example of Receive Procedure in Slave Mode

(3) Reset

After a power-on reset is applied, module stop state is canceled, or a reset signal is asserted through the TXRST or RXRST setting in SICTR, it takes about SUBϕ20 cycles to complete the internal reset of the module. During a period from the beginning of reset until the TXRST or RXRST value is read as 0, do not modify the control register or access the FIFOs.

The BBIF1 can separately reset the transmit and receive units by setting the following bits to 1.

- Transmit reset: TXRST bit in SICTR
- Receive reset: RXRST bit in SICTR

Table 24.8 Transmit and Receive Reset

Type	Objects Initialized
Transmit reset	SITDR1, SITDR2, and SITFDR
	Transmit FIFO write pointer
	TCRDY, TFEMP, and TDREQ bits in SISTR
	TXE bit in SICTR
Receive reset	SIRDR1, SIRDR2, and SIRFDR
	Receive FIFO read pointer
	RCRDY, RFFUL, and RDREQ bits in SISTR
	RXE bit in SICTR

(4) Initial Operating Mode

After a power-on reset, both the transmit and receive units are initialized to master mode (0 is output through CLK and SYNC). When using slave mode, keep the connected device outputting 0 until the operating mode setting is completed.

24.4.10 Interrupts

The BBIF1 has one type of interrupt.

(1) Interrupt Sources

Interrupts can be issued by several sources. Each source is shown as a BBIF1 status in SISTR. Table 24.9 lists the BBIF1 interrupt sources.

Table 24.9 BBIF1 Interrupt Sources

No.	Classification	Bit Name	Function Name	Description
1	Transmission	TDREQ	Transmit FIFO transfer request	The transmit FIFO has empty space of specified size or more.
2		TFEMP	Transmit FIFO empty	The transmit FIFO is empty.
3		TEOF	Frame transmission end	Transmission of data with a length of one frame is completed.
4	Reception	RDREQ	Receive FIFO transfer request	The receive FIFO stores data of specified size or more.
5		RFFUL	Receive FIFO full	The receive FIFO is full.
6		REOF	Frame reception end	Reception of data with a length of one frame is completed.
7	Control	TCRDY	Transmit control data ready	The transmit control data register is ready to be written.
8		RCRDY	Receive control data ready	The receive control data register stores valid data.
9	Error	TFUDF	Transmit FIFO underflow	Serial data transmit timing has arrived while the transmit FIFO is empty.
10		TFOVF	Transmit FIFO overflow	The transmit FIFO is written to while it is full.
11		RFOVF	Receive FIFO overflow	Serial data is received while the receive FIFO is full.
12		RFUDF	Receive FIFO underflow	The receive FIFO is read while the receive FIFO is empty.
13		TFSERR	Transmit FS error	A transmit frame synchronization signal is input before the specified number of bits has been reached (in slave mode).
14		RFSERR	Receive FS error	A receive frame synchronization signal is input before the specified number of bits has been reached (in slave mode).

Whether an interrupt is issued from an interrupt source is determined by the SIIER settings. If an interrupt source bit is set to 1 and the corresponding bit in SIIER is set to 1, a BBIF1 interrupt is issued.

(2) TDREQ and RDREQ

The transmit FIFO transfer request (TDREQ) and receive FIFO transfer request (RDREQ) are signals indicating the state. If the state changes after TDREQ or RDREQ is set, it is automatically cleared by the BBIF1.

When the DMA transfer is used, a DMA transfer request signal is pulled low for one cycle at the end of DMA transfer.

(3) Processing when Errors Occur

- Transmit FIFO underflow (TFUDF)
  The value specified with TXDIZ in SICTR is output.
- Transmit FIFO overflow (TFOVF)
  The contents of the transmit FIFO are protected, and the write operation causing the overflow is ignored.
- Receive FIFO overflow (RFOVF)
  Data causing the overflow is discarded and lost.
- Receive FIFO underflow (RFUDF)
  An undefined value is output on the bus.
- Transmit FS error (TFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.
- Receive FS error (RFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.

24.4.11 Transmit and Receive Timing

Examples of the BBIF1 serial transmission and reception are shown in Figure 24.14 and 24.15.

(1) 16-Bit Synchronization Pulse

Synchronization pulse method, one group, one word, 16 bits in a word, no bit delay

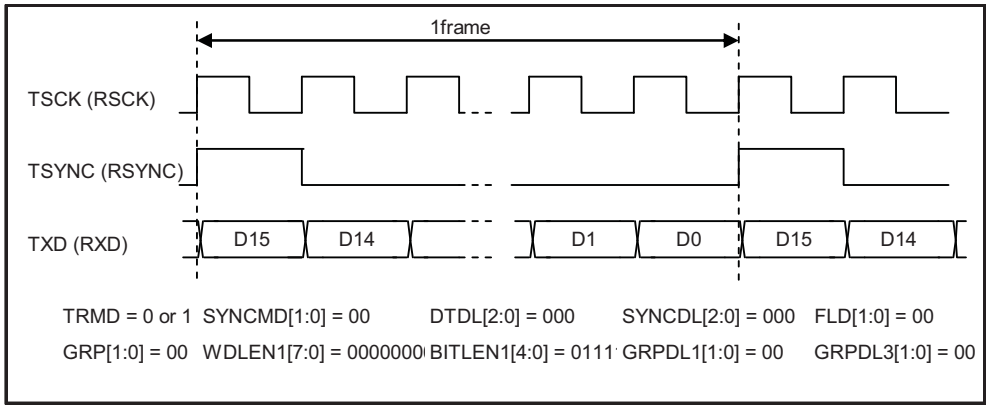


Figure 24.14 Transmit and Receive Timing (16 Bits)

(2) 32-Bit Synchronization Pulse

Synchronization pulse method, one group, 32 words, 32 bits in a word, 1-bit delay

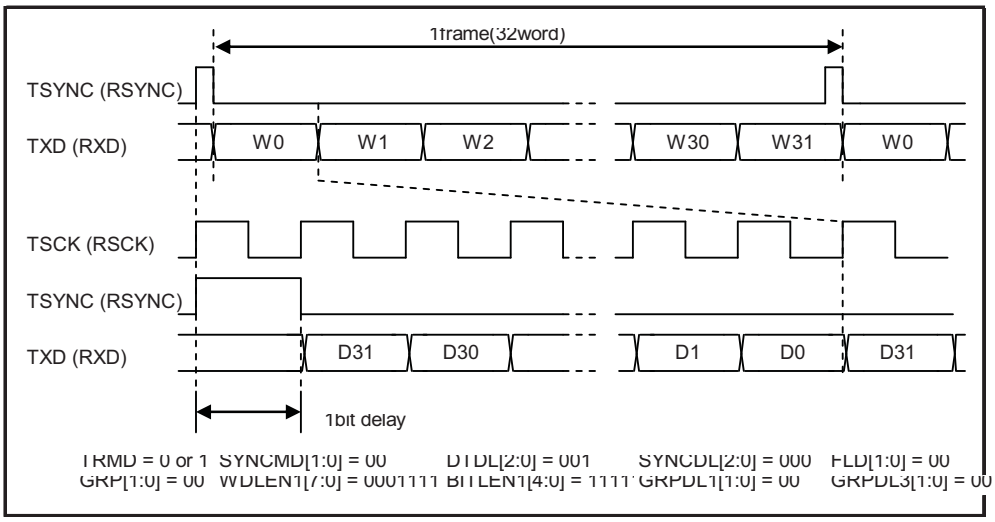

Figure 24.15 Transmit and Receive Timing (32 Bits)

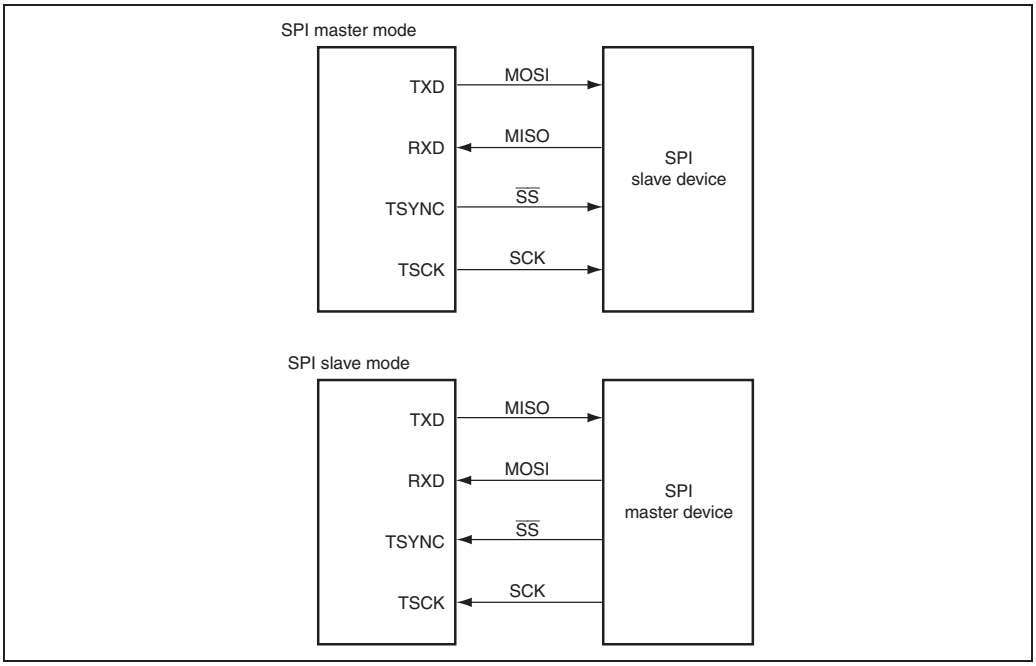
24.4.12 SPI

The BBIF can be used as an SPI device by setting the registers appropriately.

(1) Example of SPI Device Connection

Figure 24.16 shows an example of connection with an SPI device.



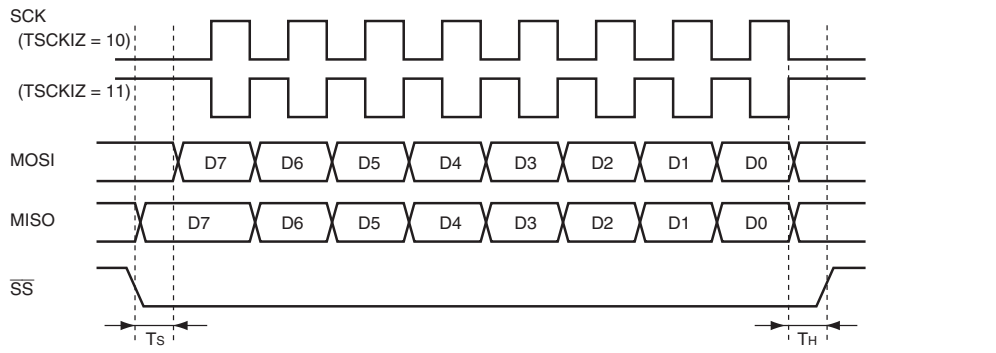


Figure 24.16 Example of SPI Device Connection

(2) SPI Serial Clock Timing

Figure 24.17 and 24.18 show the data and clock timing in SPI mode. As shown in the figures, four types of serial transfer formats can be used.

Transmit: TRMD = 1 (master) or 0 (slave) PCON = 1 SYNCMD[1:0] = 10 SYNCAC = 1
GRP[1:0] = 00 BITLEN1[4:0] = 00111 WDLEN1[7:0] = 00000000 GRPDL1[1:0] = 00 GRPDL3[1:0] = 00

Receive: TRMD = 0 SYNCMD[1:0] = 10 SYNCAC = 1
GRP[1:0] = 00 BITLEN1[4:0] = 00111 WDLEN1[7:0] = 00000000 GRPDL1[1:0] = 00 GRPDL3[1:0] = 00

Set DTDL to satisfy TS (0 to 2 can be specified in 0.5-clock-cycle units)
Set SYNCDL to satisfy TH (0 to 2 can be specified in 0.5-clock-cycle units)
The sum of DTDL and SYNCDL settings should be an integer.

SICTR: Upper: TSCKIZ[1:0] = 10, RSCKIZ[1:0] = 10, TEDG = 1, REDG = 1
Lower: TSCKIZ[1:0] = 11, RSCKIZ[1:0] = 11, TEDG = 0, REDG = 0

Figure 24.17 SPI Clock and Data Timing 1

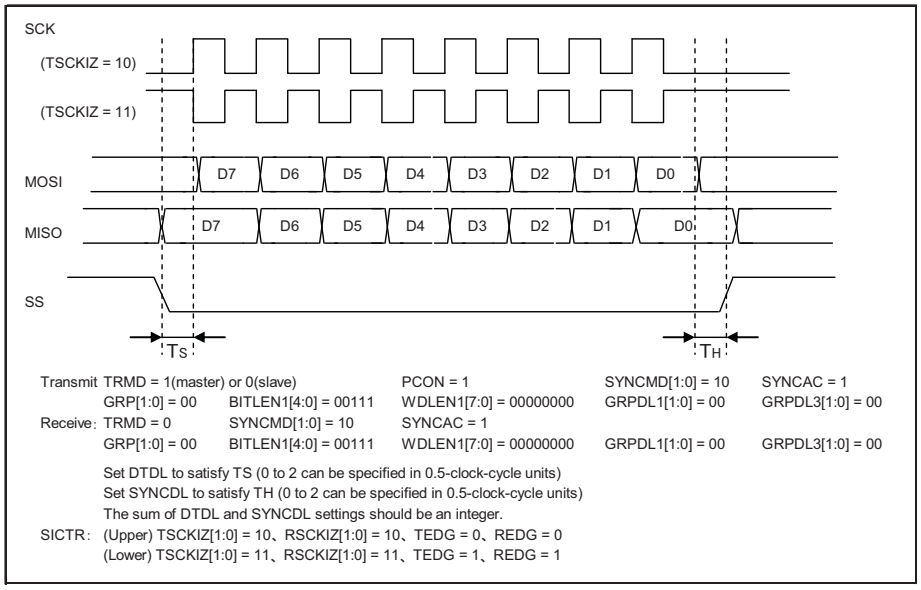

Figure 24.18 SPI Clock and Data Timing 2

24.4.13 Notes on Using SPI Mode

When the module stop release or software reset is performed in SPI mode, set the control register (SICTR) again with each of the receive-setting bits (RSCKIZ/REDG) being 0.

When using SPI master mode, set the FLD bits in SITMDR1 to ensure four SUBϕ cycles or more.

24.4.14 IIS

This module can support IIS format with following setting which is shown Figure 23.22 and Figure 23.23.BITLEN1/2 bit will change by usage.

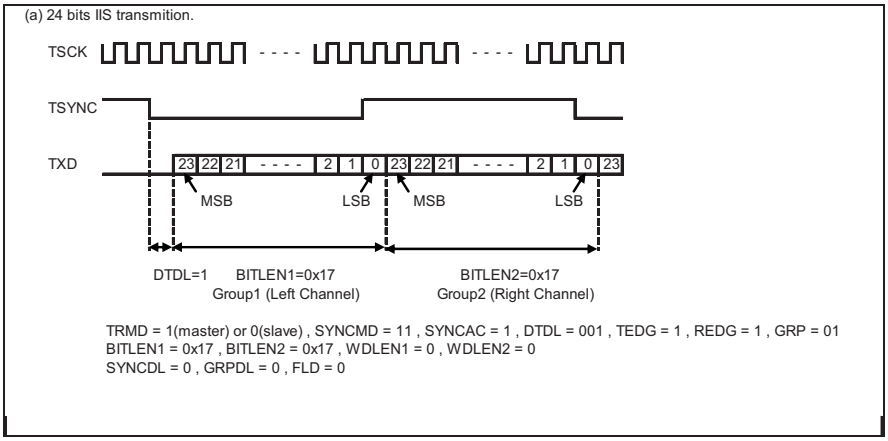

Figure 24.19 24 bits IIS transmition

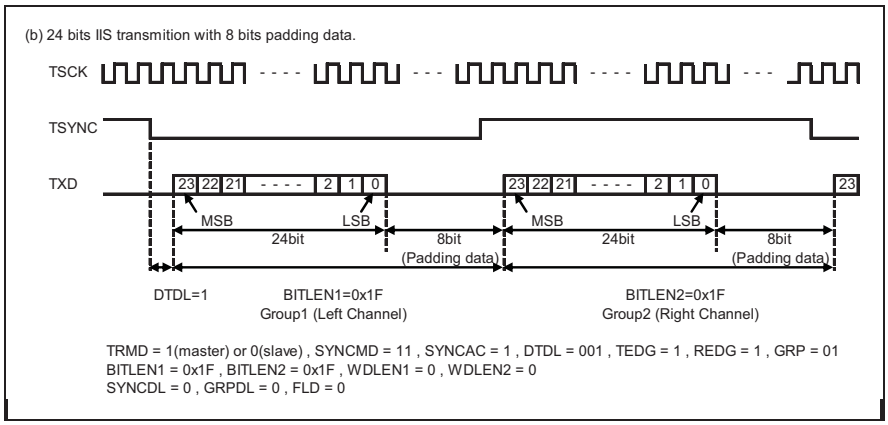

Figure 24.20 24 bits IIS transmition with 8 bits padding data

Section 25 Baseband Interface 2 (BBIF2)

This LSI includes one channel of clock-synchronized serial I/O module (BBIF2) with FIFO, which can be connected to the BB-domain PCMSEL.

25.1 Features

- FIFO capacity: 32 bits × 64 stages for transmission and 32 bits × 256 stages for reception
- MSB first or LSB first selectable for data transmission and reception
- Synchronization in frame synchronization pulse, level, or left/right channel switch mode
- Supports both transmit master/slave modes and receive slave mode.
- Common clock and synchronization signals for transmission and reception
- Supports multiple-channel communication
  - Transfers multiple groups or words data in one frame.
  - The word size for each group can be selected from eight to 32 bits.
  - Up to 256 words can be transferred in each group when one or two groups are used, or up to 16 words can be transferred in each group when three or four groups are used.
- Interrupts: One type
- Serial clock

  Internal clock SUBϕ, FSIϕ, or FMSOϕ is selectable as the master clock source.
- DMA transfer

  Supports DMA transfer by a transfer request for transmission and reception.

  Supports multibyte DMA transfer.
- Serial format

  Supports serial formats such as IIS (transmission only) and SPI (for master and slave modes).

Figure 25.1 shows a block diagram of the BBIF2.

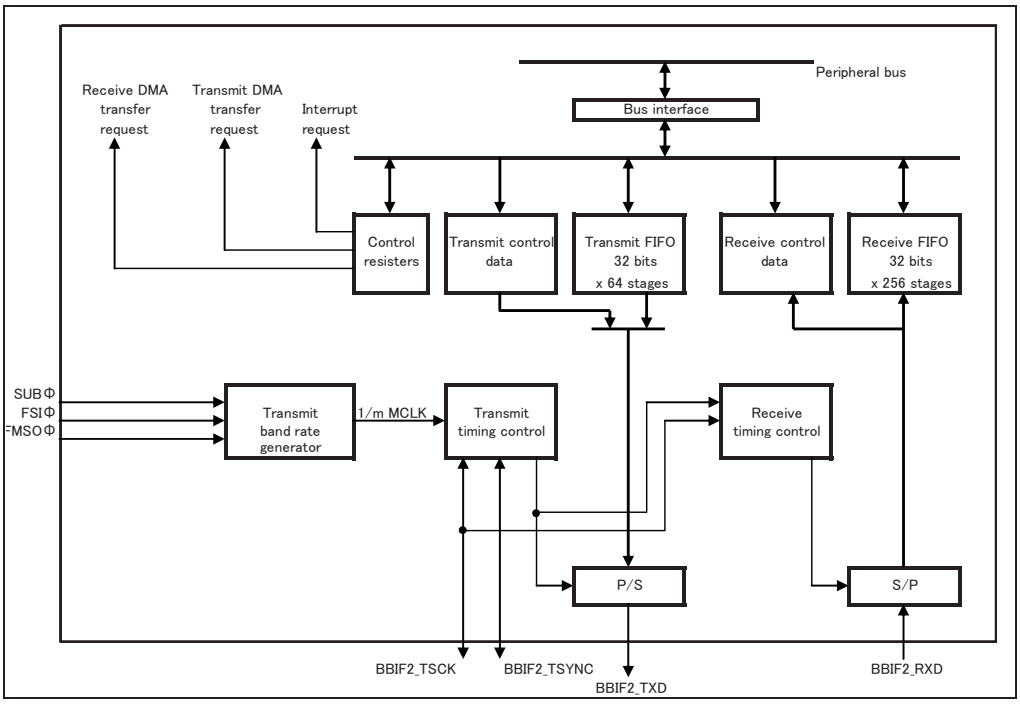

Figure 25.1 Block Diagram of BBIF2

25.2 Input/Output Pins

The pin configuration in this module is shown in Table 25.1.

Table 25.1 Pin Configuration

Name	Abbreviation*	I/O	Function
BBIF2_TSCK	SCK	I/O	BBIF2 serial clock input/output Used as BBIF2_SCK when the clock common to transmission and reception is used.
BBIF2_TSYNC($\overline{SS0}$)	$\overline{SS0}$	I/O	BBIF2 frame synchronization signal channel-0 input/output Used as BBIF2_SYNC when the synchronization signal common to transmission and reception is used.
BBIF2_TXD(MOSI/MISO)	MOSI/MISO	Output	BBIF2 transmit data
BBIF2_RXD(MISO/MOSI)	MISO/MOSI	Input	BBIF2 receive data

Note: * In SPI mode, names SCK, $\overline{SS0}$, $\overline{SS1}$, $\overline{SS2}$, MOSI, and MISO are used.

25.3 Register Descriptions

Table 25.2 shows the register configuration of the BBIF2. Table 25.3 shows the register state in each processing mode.

Table 25.2 BBIF2 Register Configuration

Name	Abbreviation	R/W	Address	Access Size
BBIF2 transmit mode register 1	SITMDR1	R/W	H'E6CA0000 H'E7CA0000 H'FFFA0000	32

R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. 0: Slave mode 1: Master mode
30	PCON	0	R/W	Transfer Signal Connection 0: Setting prohibited 1: Uses BBIF2_TSCK and BBIF2_TSYNC for transmission and reception (BBIF2_SCK and BBIF2_SYNC). When value 1 set to the TXRST bit becomes valid, the RXRST bit becomes valid at the same time.
29, 28	SYNCMD [1:0]	00	R/W	SYNC Mode These bits specify the mode for the BBIF2_TSYNC signal. 00: Frame start synchronization pulse 01: 1-bit synchronization pulse for last data in slot 10: Level mode/SPI 11: L/R mode

27, 26	SYNCCH [1:0]	00	R/W	Synchronization Signal Channel Select 00: The frame synchronization signal is output from BBIF2_TSYNC. Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Descriptions
25	SYNCAC	0	R/W	BBIF2_TSYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	DTDL[2:0]	001	R/W	Data Pin Bit Delay for BBIF2_TSYNC Pin B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through the DTDL[2:0] and SYNCDL[2:0] bits becomes an integer value. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
18 to 16	SYNCDL [2:0]	000	R/W	Frame Synchronization Signal Timing Delay These bits extend the transmit frame synchronization signal. This setting is invalid when SYNCMD[1:0] = 01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through the DTDL[2:0] and SYNCDL[2:0] bits becomes an integer value. When L/R mode , these bits should always be set to 000. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 011: 3-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
15 to 12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
11 to 8	DIV[3:0]	0000	R/W	Word Division One 32-bit word stored in the transmit FIFO can be transmitted as two separate 16-bit words through two groups. The word count in each group must be set to 1. In this case, data of groups other than word division target groups must be handled as control data. This setting is valid only in LR mode. 0000: Not divided 0001: Upper word in group 1 and lower word in group 2 Other than above: Setting prohibited
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
3, 2	FLD[1:0]	00	R/W	Frame Synchronization Signal Interval These bits specify the minimum idle time between frames in the number of serial clock cycles. This setting is valid only in master mode. When Level mode, set the FLD bits in SIRMDR1 for at least 4 cycles of SUBφ. When L/R mode , these bits should always be set to 00. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
1	CONT	0	R/W	Continuous Frame Transmission Specifies continuous transmission of multiple frames of data within one frame. This setting is valid when SYNCMD[1:0] = 00 or 10. When the TFSE bit in SICTR is set to 0 in master mode, transmission is terminated after one-frame data is transmitted. 0: Does not perform continuous transmission. 1: Performs continuous transmission.

0	TXSTP	0	R/W	Transmission Stop Specifies the processing performed when the remaining number of stages in the transmit FIFO becomes smaller than the total number of words in the transmit frame. This setting is valid only in master mode. When transmission is continued, the value specified with TXDIZ is output as transmit data. If, with TXSTP = 1, the remaining number of stages in the transmit FIFO becomes smaller than the total number of words in the transmit frame, transmission is stopped temporarily. After this, however, transmission is automatically restarted if writing into the transmit FIFO causes the remaining number to become larger than the total number of words in the transmit frame. 0: Continues transmission when the transmit FIFO is empty. (The frame synchronization signal is output.) 1: Temporarily stops transmission when the remaining number of stages in the transmit FIFO becomes smaller than the total number of words in the transmit frame. (The frame synchronization signal is not output.)

25.3.2 Transmit Mode Register 2 (SITMDR2)

SITMDR2 is a 32-bit readable/writable register that specifies the BBIF2 transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GRP[1:0]		—	BITLEN1[4:0]					WDLEN1[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL1[1:0]		GRPDL3[1:0]		CRDE4	CRDE3	CRDE2	CRDE1	CRDNUM4	CRDNUM3	CRDNUM2	CRDNUM1	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	GRP[1:0]	00	R/W	Group Count The number of groups is set to the value specified in these bits + 1. When three or more groups are specified, the word size (BITLEN) is set to 16 bits or less.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0] (BITLEN3)	01111	R/W	Word Size (8 to 32 bits) The word size (bits) of groups 1 and 3 is set to the value specified in these bits + 1 (BITLEN1 = BITLEN3). Eight bits or a larger size should be specified. When three or four groups are used, the word size is set to 16 bits or less. (the highest bit is ignored).
23 to 16	WDLEN1[7:0] (WDLEN1[3:0] WDLEN3[3:0])	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 1 and 3 are set to WDLEN1 + 1 and WDLEN3 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN1. When three or four groups are used, the upper 4-bit value is set to WDLEN1, and the lower 4-bit value is set to WDLEN3.

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	GRPDL1[1:0]	00	R/W	Group 1 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 1. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
13, 12	GRPDL3[1:0]	00	R/W	Group 3 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 3. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
11	CRDE4	0	R/W	Control Data Enable
10	CRDE3	0	R/W	"x" in CRDEx represents a group. Each of these bits specifies whether the group transmits FIFO data or control data. 0: The specified group transmits FIFO data. 1: The specified group transmits control data.
9	CRDE2	0	R/W	
8	CRDE1	0	R/W	
7	CRDNUM4	0	R/W	Control Data Transmit Count
6	CRDNUM3	0	R/W	"x" in CRDNUMx represents a group. Each of these bits specifies the transmission count of control data when multiple words are set for a control data group. Each bit is valid only when the corresponding CRDE bit is 1. When CRDNUMx = 1, control data is transmitted only for the first word, and the value specified with TXDIZ is output for other words. 0: Transmits control data continuously. 1: Transmits control data only once.
5	CRDNUM2	0	R/W	
4	CRDNUM1	0	R/W	

Bit	Bit Name	Initial Value	R/W	Descriptions
3 to 0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

25.3.3 Transmit Mode Register 3 (SITMDR3)

SITMDR3 is a 32-bit readable/writable register that specifies the BBIF2 transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	BITLEN2[4:0]					WDLEN2[7:0]

R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL2[1:0]		GRPDL4[1:0]		—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0] (BITLEN4)	01111	R/W	Word Size (8 to 32 bits) The word size is set to the value specified in these bits + 1. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored).

Bit	Bit Name	Initial Value	R/W	Descriptions
23 to 16	WDLEN2[7:0] (WDLEN2[3:0] WDLEN4[3:0]	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 2 and 4 are set to WDLEN2 + 1 and WDLEN4 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN2. When three or four groups are used, the upper 4-bit value is set to WDLEN2, and the lower 4-bit value is set to WDLEN4.
15, 14	GRPDL2[1:0]	00	R/W	Group 2 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 2. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
13, 12	GRPDL4[1:0]	00	R/W	Group 4 Data Transmission Delay These bits specify the number of blank bits to be inserted before transmission of group 4. The value specified with TXDIZ in SICTR is output during transmission. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
11 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

25.3.4 Receive Mode Register 1 (SIRMDR1)

SIRMDR1 is a 32-bit readable/writable register that specifies the BBIF2 receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRMD	PCON	SYNCMD[1:0]		SYNCCH[1:0]		SYNC AC	BITLSB	—	DTDL[2:0]			—	SYNCDL[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MRG[3:0]				—	—	—	—	—	—	CONT	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. Set the PCON bit in SITMDR1 to 1. 0: Slave mode 1: Master mode
30	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
29, 28	SYNCMD [1:0]	00	R/W	SYNC Mode These bits specify the mode for the BBIF2_SYNC signal. Set these bits to the same value as SYNCMD[1:0] in SITMDR1. 00: Frame start synchronization pulse 01: 1-bit synchronization pulse for last data in slot 10: Level mode/SPI 11: L/R mode
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
25	SYNCAC	0	R/W	BBIF2_SYNC Polarity Set this bit to the same value as SYNCAC in SITMDR1. 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
22 to 20	DTDL[2:0]	001	R/W	Data Pin Bit Delay for BBIF2_SYNC Pin B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through the DTDL[2:0] and SYNCDL[2:0] bits becomes an integer value. Set these bits to the same value as DTDL in SITMDR1. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
18 to 16	SYNCDL [2:0]	000	R/W	BBIF2_SYNC Timing Delay The synchronization signal is extended for the clock cycles specified in these bits. This setting is invalid when SYNCMD[1:0] = 01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through the DTDL[2:0] and SYNCDL[2:0] bits becomes an integer value. Set these bits to the same value as SYNCDL in SITMDR1. When L/R mode , these bits should always be set to 000. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 011: 3-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
15 to 12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
11 to 8	MRG[3:0]	0000	R/W	Word Merge The data received as 16-bit words of two groups can be merged into one 32-bit word and the merged data is stored in the receive FIFO. The word count in the groups to be merged must be set to 1. In this case, data of groups other than word merging target groups must be handled as control data. This setting is valid only in LR mode. 0000: Not merged 0001: Upper word in group 1 and lower word in group 2 0100: Upper word in group 2 and lower word in group 1 Other than above: Setting prohibited
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
1	CONT	0	R/W	Continuous Frame Reception Specifies continuous reception of multiple frames of data within one frame. This setting is valid when SYNCMD[1:0] =00 or 10. When the RFSE bit in SICTR is set to 0 in master mode, reception is terminated after one-frame data is received. 0: Does not perform continuous reception. 1: Performs continuous reception.
0	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

25.3.5 Receive Mode Register 2 (SIRMDR2)

SIRMDR2 is a 32-bit readable/writable register that specifies the BBIF2 receive mode. Set this register so that the frame size equals the value specified in SITMDR2 and SITMDR3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GRP[1:0]		—	BITLEN1[4:0]					WDLEN1[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL1[1:0]		GRPDL3[1:0]		CRDE4	CRDE3	CRDE2	CRDE1	CRDNUM4	CRDNUM3	CRDNUM2	CRDNUM1	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	GRP[1:0]	00	R/W	Group Count The number of groups is set to the value specified in these bits + 1. When three or more groups are specified, the word size (BITLEN) is set to 16 bits or less. When using transfer signal connection (PCON = 1), set the same value as the GRP bits in SITMDR2.

Bit	Bit Name	Initial Value	R/W	Descriptions
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0] (BITLEN3)	01111	R/W	Word Size (8 to 32 bits) The word size (bits) of groups 1 and 3 is set to the value specified in these bits + 1 (BITLEN1 = BITLEN3). Eight bits or a larger size should be specified. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored). When using transfer signal connection (PCON = 1), set the same value as the BITLEN1 bits in SITMDR2.
23 to 16	WDLEN1[7:0] (WDLEN1[3:0] WDLEN3[3:0])	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 1 and 3 are set to WDLEN1 + 1 and WDLEN3 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN1. When three or four groups are used, the upper 4-bit value is set to WDLEN1, and the lower 4-bit value is set to WDLEN3. When using transfer signal connection (PCON = 1), set the same value as the WDLEN1 bits in SITMDR2.
15, 14	GRPDL1[1:0]	00	R/W	Group 1 Data Reception Delay These bits specify the delay in data reception of group 1. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay When using transfer signal connection (PCON = 1), set the same value as the GRPDL1 bits in SITMDR2.

Bit	Bit Name	Initial Value	R/W	Descriptions
13, 12	GRPDL3[1:0]	00	R/W	Group 3 Data Reception Delay These bits specify the delay in data reception of group 3. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay When using transfer signal connection (PCON = 1), set the same value as the GRPDL3 bits in SITMDR2.
11	CRDE4	0	R/W	Control Data Enable
10	CRDE3	0	R/W	"x" in CRDEx represents a group. Each of these bits specifies whether the group receives FIFO data or control data. 0: The specified group receives FIFO data. 1: The specified group receives control data.
9	CRDE2	0	R/W	
8	CRDE1	0	R/W	
7	CRDNUM4	0	R/W	Control Data Reception Count
6	CRDNUM3	0	R/W	"x" in CRDNUMx represents a group. Each of these bits specifies the reception count of control data when multiple words are set for a control data group. Each bit is valid only when the corresponding CRDE bit is 1. When CRDNUMx = 1, only the first word is received as control data, and the other words are discarded as invalid data. 0: Receives control data continuously. 1: Receives only one word of control data.
5	CRDNUM2	0	R/W	
4	CRDNUM1	0	R/W	
3 to 0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

25.3.6 Receive Mode Register 3 (SIRMDR3)

SIRMDR3 is a 32-bit readable/writable register that specifies the BBIF2 receive mode. Set this register so that the frame size equals the value specified in SITMDR2 and SITMDR3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	BITLEN2[4:0]					WDLEN2[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRPDL2[1:0]		GRPDL4[1:0]		—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0] (BITLEN4[3:0])	01111	R/W	Word Size (8 to 32 bits) The word size is set to the value specified in these bits + 1. When three or four groups are used, the word size is set to 16 bits or less (the highest bit is ignored). Set the word size to eight bits or more. When using transfer signal connection (PCON = 1), set the same value as the BITLEN2 bits in SITMDR3.
23 to 16	WDLEN2[7:0] (WDLEN4[3:0])	H'00	R/W	Word Count (1 to 256 words) The word counts of groups 2 and 4 are set to WDLEN2 + 1 and WDLEN4 + 1 respectively. When one or two groups are used, the 8-bit value is set to WDLEN2. When three or four groups are used, the upper 4-bit value is set to WDLEN2, and the lower 4-bit value is set to WDLEN4. When using transfer signal connection (PCON = 1), set the same value as the WDLEN2 bits in SITMDR3.

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	GRPDL2[1:0]	00	R/W	Group 2 Data Reception Delay These bits specify the delay in data reception of group 2. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay When using transfer signal connection (PCON = 1), set the same value as the GRPDL2 bits in SITMDR3.
13, 12	GRPDL4[1:0]	00	R/W	Group 4 Data Reception Delay These bits specify the delay in data reception of group 4. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay When using transfer signal connection (PCON = 1), set the same value as the GRPDL4 bits in SITMDR3.
11 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

25.3.7 Control Register (SICTR)

SICTR is a 32-bit readable/writable register that specifies the BBIF2 operating state.

The values written to the TXE, RXE, TFSE, and, TSCKE bits become valid (can be read from the bits) several cycles after writing. These bits should not be modified together; modify one bit at a time, check that the new value can be read from the bit, and then modify another bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSCKIZ[1:0]		RSCKIZ[1:0]		TEDG	REDG	—	—	TXDIZ[1:0]		—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R

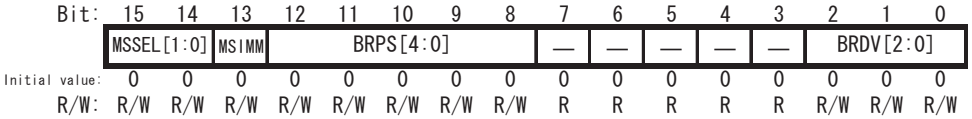
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSCKE	TFSE	—	—	—	—	TXE	RXE	—	—	—	—	—	—	TXRST	RXRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	TSCKIZ[1:0]	00	R/W	Transmit Clock Input/Output Polarity Select in SPI Mode When Transmission is Invalid When SPI mode is not used, these bits should always be set to 00. [Master mode] 00: Outputs BBIF2_TSCK when transmission is invalid. 01: Setting prohibited 10: Outputs 0. 11: Outputs 1. [Slave mode] 00: Inputs BBIF2_TSCK when transmission is invalid. 01: Setting prohibited 10: Inputs 0 through BBIF2_TSCK when transmission is invalid. 11: Inputs 1 through BBIF2_TSCK when transmission is invalid.

Bit	Bit Name	Initial Value	R/W	Descriptions
29, 28	RSCKIZ[1:0]	00	R/W	Receive Clock Input Polarity Select in SPI Mode In SPI mode, set these bits to the TSCKIZ value. 00: Inputs BBIF2_SCK when transmission is invalid. 01: Setting prohibited 10: Inputs 0 through BBIF2_SCK when transmission is invalid. 11: Inputs 1 through BBIF2_SCK when transmission is invalid.
27	TEDG	0	R/W	Transmit Timing 0: Outputs transmit data at the rising edge of the clock. 1: Outputs transmit data at the falling edge of the clock.
26	REDG	0	R/W	Receive Timing 0: Samples receive data at the falling edge of the clock. 1: Samples receive data at the rising edge of the clock.
25, 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23, 22	TXDIZ[1:0]	00	R/W	Pin Output When Transmission is Invalid These bits specify the BBIF2_TXD pin output state when transmission is invalid. 00: Outputs 0. 01: Outputs 1. 10: Output is in high-impedance state. 11: Setting prohibited
21 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
15	TSCKE	0	R/W	Transmit Serial Clock Output Enable This bit is valid in master mode. When this bit is set to 1, the BBIF2 initializes the baud rate generator and initiates the operation. At the same time, the BBIF outputs the clock generated by the baud rate generator to the BBIF2_TSCK pin. After the clock is output, 1 can be read. When transmitting data, set this bit to 1 before setting the TFSE and TXE bits. After data transmission, clear the TFSE and TXE bits and then clear this bit to 0. [Write data] 0: Disables the BBIF2_TSCK output. (Outputs the value specified with TSCKIZ.) 1: Enables the BBIF2_TSCK output. [Read data] 0: Does not output BBIF2_TSCK. (Outputs the value specified with TSCKIZ.) 1: Outputs BBIF2_TSCK.
14	TFSE	0	R/W	Transmit Frame Synchronization Signal Output Enable This bit is valid in master mode. When this bit is set to 1, the BBIF2 initializes the frame counter and initiates the operation. After the transmit frame synchronization signal is output, 1 can be read. When 0 is written to this bit, 0 is set after transmission of the frame. [Write data] 0: Disables the BBIF2_TSYNC output. (Outputs the value specified with SYNCAC.) 1: Enables the BBIF2_TSYNC output. [Read data] 0: Does not output BBIF2_TSYNC. (Outputs the value specified with SYNCAC.) 1: Outputs BBIF2_TSYNC.

Bit	Bit Name	Initial Value	R/W	Descriptions
13 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	TXE	0	R/W	Transmit Enable When this bit is set to 1, the BBIF2 starts data transmission from the beginning of the next frame (at the rising edge of the frame synchronization signal). After valid data is output, 1 can be read. When value 1 set to this bit becomes valid, the BBIF2 issues a transmit data transfer request according to the setting of the TFWM bits in SIFCTR. When transmit data is stored in the transmit FIFO, transmission of data from the BBIF2_TXD pin begins. When 0 is written to this bit, 0 is set after transmission of the frame. This bit is initialized upon a transmit reset. [Write data] 0: Disables the BBIF2_TXD output. (Outputs the value specified with TXDIZ.) 1: Enables the BBIF2_TXD output. [Read data] 0: Does not output BBIF2_TXD. (Outputs the value specified with TXDIZ.) 1: Outputs BBIF2_TXD.



Bit	Bit Name	Initial Value	R/W	Descriptions
8	RXE	0	R/W	Receive Enable When this bit is set to 1, the BBIF2 starts data reception from the beginning of the next frame (at the rising edge of the frame synchronization signal). When value 1 set to this bit becomes valid, the BBIF2 begins reception of data through the BBIF2_RXD pin. When receive data is stored in the receive FIFO, the BBIF issues a receive data transfer request according to the setting of the RFWM bits in SIFCTR. This bit is initialized upon a receive reset. [Write data] 0: Disables data reception through BBIF2_RXD. 1: Enables data reception through BBIF2_RXD. [Read data] 0: Data is not received through BBIF2_RXD. 1: Data can be received through BBIF2_RXD.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
1	TXRST	0	R/W	Transmit Reset When value 1 set to this bit becomes valid, the BBIF2 immediately sets transmit data through the BBIF2_TXD pin to 0, and initializes the transmit data registers and transmit-related status. When value 1 set to this bit becomes valid with PCON = 1, the RXRST bit is also becomes valid. The following registers and bits are initialized. • SITDR1 and SITDR2 • SITFDR • Transmit FIFO write pointer • TCRDY, TFEMP, and TDREQ bits in SISTR • TXE bit This bit is read as 1 until the reset operation is completed for about SUBϕ20 cycles. No data should be written to SICTR or the transmit FIFO during this time period. [Write data] 0: Does not reset transmit operation. 1: Resets transmit operation. [Read data] 0: Transmit operation reset is completed. 1: Transmit operation is being reset.

Bit	Bit Name	Initial Value	R/W	Descriptions
0	RXRST	0	R/W	Receive Reset When value 1 set to this bit becomes valid, the BBIF2 immediately disables reception through the BBIF2_RXD pin, and initializes the receive data registers and receive-related status. The following registers and bits are initialized. • SIRDR1 and SIRDR2 • SIRFDR • Receive FIFO read pointer • RCRDY, RFFUL, and RDREQ bits in SISTR • RXE bit This bit is read as 1 until the reset operation is completed for about SUBϕ20 cycles. No data should be written to SICTR or read the receive FIFO during this time period. [Write data] 0: Does not reset receive operation. 1: Resets receive operation. [Read data] 0: Receive operation reset is completed. 1: Receive operation is being reset.

25.3.8 Transmit Clock Select Register (SITSCR)

SITSCR is a 16-bit readable/writable register that specifies the conditions for generating the transmit serial clock in master mode. SITSCR can be specified when the TRMD bit in SITMDR1 is set to B'1.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSSEL[1:0]		MSIMM	BRPS[4:0]					—	—	—	—	—	BRDV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	MSSEL[1:0]	00	R/W	Master Clock Source Select The master clock is the clock input to the baud rate generator. 00: Selects SUBCKϕ as the master clock. 01: Selects FSIϕ as the master clock. 10: Selects FMSOϕ as the master clock. 11: Setting prohibited
13	MSIMM	0	R/W	Master Clock Direct Select 0: Selects the clock output from the baud rate generator as the serial clock. 1: Selects the master clock itself as the serial clock. To set MSIMM = 1, set the master clock source to 24 MHz or less.
12 to 8	BRPS[4:0]	00000	R/W	Prescalar Setting These bits specify the master clock division ratio in the count value of the prescalar in the baud rate generator. The specifiable value is from B'00000 (× 1/1) to B'11111 (× 1/32).
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
2 to 0	BRDV[2:0]	000	R/W	Baud Rate Generator's Division Ratio These bits specify the frequency division ratio for the output stage of the baud rate generator. The final frequency division ratio of the baud rate generator is determined as BRPS × BRDV (1/1024 max.). 000: Prescalar output × 1/2 001: Prescalar output × 1/4 010: Prescalar output × 1/8 011: Prescalar output × 1/16 100: Prescalar output × 1/32 101: Setting prohibited 110: Setting prohibited 111: Prescalar output × 1/1 Note: 111 is valid only when the BRPS[4:0] bits are set to 00000 or 00001.

25.3.9 Transmit Control Data Register 1 (SITDR1)

SITDR1 is a 32-bit readable/writable register that specifies the transmit control data of the BBIF2.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCRD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCRD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	TCRD1[15:0]	H'0000	W	• When one or two groups are used: These bits specify the transmit control data for the upper 16 bits of a word in group 1. • When three or four groups are used: These bits specify the transmit control data for a word in group 1.
15 to 0	TCRD2[15:0]	H'0000	W	• When one or two groups are used: These bits specify the transmit control data for the lower 16 bits of a word in group 1 when the word size is larger than 16 bits. • When three or four groups are used: These bits specify the transmit control data for a word in group 3.

25.3.10 Transmit Control Data Register 2 (SITDR2)

SITDR2 is a 32-bit readable/writable register that specifies the transmit control data of the BBIF2.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCRD3[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCRD4[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	TCRD3[15:0]	H'0000	W	• When one or two groups are used: These bits specify the transmit control data for the upper 16 bits of a word in group 2. • When three or four groups are used: These bits specify the transmit control data for a word in group 2.
15 to 0	TCRD4[15:0]	H'0000	W	• When one or two groups are used: These bits specify the transmit control data for the lower 16 bits of a word in group 2 when the word size is larger than 16 bits. • When three or four groups are used: These bits specify the transmit control data for a word in group 4.

25.3.11 Transmit FIFO Data Register (SITFDR)

SITFDR is a 32-bit write-only register that specifies the transmit FIFO data of the BBIF2.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SITFD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SITFD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SITFD1[15:0]	H'0000	W	These bits specify the upper 16 bits of the FIFO data to be output through BBIF2_TXD.
15 to 0	SITFD2[15:0]	H'0000	W	These bits specify the lower 16 bits of the FIFO data to be output through BBIF2_TXD.

25.3.12 Receive Control Data Register 1 (SIRDR1)

SIRDR1 is a 32-bit read-only register that stores the receive control data of the BBIF2.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RCRD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCRD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	RCRD1[15:0]	H'0000	R	• When one or two groups are used: Store the receive control data for the upper 16 bits of a word in group 1. • When three or four groups are used: Store the receive control data for a word in group 1.
15 to 0	RCRD2[15:0]	H'0000	R	• When one or two groups are used: Store the receive control data for the lower 16 bits of a word in group 1 when the word size is larger than 16 bits. • When three or four groups are used: Store the receive control data for a word in group 3.

25.3.13 Receive Control Data Register 2 (SIRDR2)

SIRDR2 is a 32-bit read-only register that stores the receive control data of the BBIF2.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RCRD3[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCRD4[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	RCRD3[15:0]	H'0000	R	• When one or two groups are used: Store the receive control data for the upper 16 bits of a word in group 2. • When three or four groups are used: Store the receive control data for a word in group 2.
15 to 0	RCRD4[15:0]	H'0000	R	• When one or two groups are used: Store the receive control data for the lower 16 bits of a word in group 2 when the word size is larger than 16 bits. • When three or four groups are used: Store the receive control data for a word in group 4.

25.3.14 Receive FIFO Data Register (SIRFDR)

SIRFDR is a 32-bit read-only register that stores the receive FIFO data of the BBIF2.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SIRFD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SIRFD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SIRFD1[15:0]	H'00	R	Store the upper 16 bits of the FIFO data received through BBIF2_RXD.
15 to 0	SIRFD2[15:0]	H'00	R	Store the lower 16 bits of the FIFO data received through BBIF2_RXD.

25.3.15 Status Register (SISTR)

Each bit in SISTR becomes a BBIF2 interrupt source when the corresponding bit in SIIER is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	TCRDY	TFEMP	TDREQ	—	—	—	—	TEOF	—	TFSERR	TFOVF	TFUDF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	RCRDY	RFFUL	RDREQ	—	—	—	—	REOF	—	RFSERR	RFUDF	RFOVF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	TCRDY	0	R/W	Transmit Control Data Ready If SITDR1 or SITDR2 is written while this bit is cleared to 0, SICTR is overwritten and the previous contents are not output through the BBIF2_TXD pin. This bit is valid when the TXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: SITDR1 and SITDR2 are not ready to be written. 1: SITDR1 and SITDR2 are ready to be written.

Bit	Bit Name	Initial Value	R/W	Descriptions
29	TFEMP	0	R/W	Transmit FIFO Empty This bit is valid when the TXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: Transmit FIFO is not empty. 1: Transmit FIFO is empty.
28	TDREQ	0	R	Transmit Data Transfer Request A transmit data transfer request is issued when the empty space in the transmit FIFO exceeds the size specified by the TFWM bits in SIFCTR. When transferring transmit data through the DMAC, this bit is always cleared after one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the BBIF2 again sets this bit to 1. This bit is valid when the TXE bit in SICTR is 1. This bit indicates a state; if the size of empty space in the transmit FIFO becomes less than the size specified by the TFWM bits in SIFCTR, the BBIF2 clears this bit. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. However, when the TDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of empty space in the transmit FIFO has not exceeded the size specified by the TFWM bits in SIFCTR. 1: The size of empty space in the transmit FIFO has exceeded the size specified by the TFWM bits in SIFCTR.
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
23	TEOF	0	R/W	Frame Transmission End The BBIF2 issues the frame transmission end flag upon completion of one-frame data transmission. This bit is valid when the TXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: One-frame transmission end is not detected. 1: One-frame transmission end is detected.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERR	0	R/W	Transmit Frame Synchronization Error A transmit frame synchronization error occurs when the next transmit frame synchronization timing arrives before the previous data or control data transmission has been completed. If a transmit frame synchronization error occurs, the BBIF2 performs transmission only for the slots that can be transferred. This bit is valid when the TXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: No transmit frame synchronization error has occurred. 1: A transmit frame synchronization error has occurred.

Bit	Bit Name	Initial Value	R/W	Descriptions
20	TFOVF	0	R/W	Transmit FIFO Overflow A transmit FIFO overflow means that there has been an attempt to write to SITFDR when the transmit FIFO is full. If a transmit FIFO overflow occurs, the BBIF2 ignores the write operation causing the overflow. This bit is valid when the TXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: No transmit FIFO overflow has occurred. 1: A transmit FIFO overflow has occurred.
19	TFUDF	0	R/W	Transmit FIFO Underflow A transmit FIFO underflow means that loading for transmission has occurred when the transmit FIFO is empty. This bit is valid when the TXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: No transmit FIFO underflow has occurred. 1: A transmit FIFO underflow has occurred.
18 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
14	RCRDY	0	R/W	Receive Control Data Ready When data different from the previous data is stored during reception of control data, this bit is set to 1 indicating that valid data was written. When the first data that is not 0 is stored, this bit is set to 1. If valid data is written to SIRDR1 or SIRDR2 when this bit is set to 1, SIRDR1 or SIRDR2 is overwritten with the latest data. This bit is valid when the RXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: SIRDR1 and SIRDR2 store no valid data. 1: SIRDR1 and SIRDR2 store valid data.
13	RFFUL	0	R/W	Receive FIFO Full This bit is valid when the RXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: Receive FIFO is not full. 1: Receive FIFO is full.

Bit	Bit Name	Initial Value	R/W	Descriptions
12	RDREQ	0	R	Receive Data Transfer Request A receive data transfer request is issued when the valid data space in the receive FIFO exceeds the size specified by the RFWM bits in SIFCTR. When transferring transmit data through the DMAC, this bit is always cleared by one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the BBIF2 again sets this bit to 1. This bit is valid when the RXE bit in SICTR is 1. This bit indicates a state; if the size of valid data space in the receive FIFO becomes less than the size specified by the RFWM bits in SIFCTR, the BBIF2 clears this bit. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. However, when the RDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of valid data space in the receive FIFO has not exceeded the size specified by the RFWM bits in SIFCTR. 1: The size of valid data space in the receive FIFO has exceeded the size specified by the RFWM bits in SIFCTR.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOF	0	R/W	Frame Reception End The BBIF2 issues the frame reception end flag upon completion of one-frame data reception. This bit is valid when the RXE bit in SICTR is 1. When this bit is set to 1, the content is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: One-frame reception end is not detected. 1: One-frame reception end is detected.

Bit	Bit Name	Initial Value	R/W	Descriptions
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	RFSERR	0	R/W	Receive Frame Synchronization Error A receive frame synchronization error occurs when the next receive frame synchronization timing arrives before the previous data or control data reception has been completed. If a receive frame synchronization error occurs, the BBIF2 performs reception only for the slots that can be transferred. This bit is valid when the RXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: No receive frame synchronization error has occurred. 1: A receive frame synchronization error has occurred.
4	RFUDF	0	R/W	Receive FIFO Underflow A receive FIFO underflow means that reading of SIRFDR has occurred when the receive FIFO is empty. If a receive FIFO underflow occurs, the value read from SIRFDR is not guaranteed. This bit is valid when the RXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: No receive FIFO underflow has occurred. 1: A receive FIFO underflow has occurred.

Bit	Bit Name	Initial Value	R/W	Descriptions
3	RFOVF	0	R/W	Receive FIFO Overflow A receive FIFO overflow means that writing has been caused by receiving operation when the receive FIFO is full. If a receive FIFO overflow occurs, the receive data causing the overflow is lost. This bit is valid when the RXE bit in SICTR is 1. When 1 is written to this bit, it is cleared. Writing 0 to this bit is invalid. If the interrupt request from this bit is enabled, a BBIF2 interrupt is issued. 0: No receive FIFO overflow has occurred. 1: A receive FIFO overflow has occurred.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

25.3.16 Interrupt Enable Register (SIIER)

SIIER is a 32-bit readable/writable register that enables the issue of BBIF2 interrupts. When each bit in this register is set to 1 and the corresponding bit in SISTR is set to 1, the BBIF2 issues an interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TDMAE	TCRDYE	TFEMPE	TDREQE	—	—	—	—	TEOFE	—	TFSERRE	TFOVFE	TFUDFE	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDMAE	RCRDYE	RFFULE	RDREQE	—	—	—	—	REOFE	—	RFSERRE	RFUDFE	RFOVFE	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TDMAE	0	R/W	Transmit Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The TDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.
30	TCRDYE	0	R/W	Transmit Control Data Ready Enable 0: Disables interrupts due to transmit control data ready. 1: Enables interrupts due to transmit control data ready.
29	TFEMPE	0	R/W	Transmit FIFO Empty Enable 0: Disables interrupts due to transmit FIFO empty. 1: Enables interrupts due to transmit FIFO empty.
28	TDREQE	0	R/W	Transmit Data Transfer Request Enable 0: Disables interrupts due to transmit data transfer requests. 1: Enables interrupts due to transmit data transfer requests.

Bit	Bit Name	Initial Value	R/W	Descriptions
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23	TEOFE	0	R/W	Frame Transmission End Enable 0: Disables a frame transmission end interrupt. 1: Enables a frame transmission end interrupt.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERRE	0	R/W	Transmit Frame Synchronization Error Enable 0: Disables interrupts due to transmit frame synchronization errors. 1: Enables interrupts due to transmit frame synchronization errors.
20	TFOVFE	0	R/W	Transmit FIFO Overflow Enable 0: Disables interrupts due to transmit FIFO overflow 1: Enables interrupts due to transmit FIFO overflow
19	TFUDFE	0	R/W	Transmit FIFO Underflow Enable 0: Disables interrupts due to transmit FIFO underflow. 1: Enables interrupts due to transmit FIFO underflow.
18 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	RDMAE	0	R/W	Receive Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The RDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.

Bit	Bit Name	Initial Value	R/W	Descriptions
14	RCRDYE	0	R/W	Receive Control Data Ready Enable 0: Disables interrupts due to receive control data ready. 1: Enables interrupts due to receive control data ready.
13	RFFULE	0	R/W	Receive FIFO Full Enable 0: Disables interrupts due to receive FIFO full. 1: Enables interrupts due to receive FIFO full.
12	RDREQE	0	R/W	Receive Data Transfer Request Enable 0: Disables interrupts due to receive data transfer requests. 1: Enables interrupts due to receive data transfer requests.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOFE	0	R/W	Frame Reception End Enable 0: Disables a frame reception end interrupt. 1: Enables a frame reception end interrupt.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	RFSERRE	0	R/W	Receive Frame Synchronization Error Enable 0: Disables interrupts due to receive frame synchronization errors. 1: Enables interrupts due to receive frame synchronization errors.
4	RFUDFE	0	R/W	Receive FIFO Underflow Enable 0: Disables interrupts due to receive FIFO underflow. 1: Enables interrupts due to receive FIFO underflow.

Bit	Bit Name	Initial Value	R/W	Descriptions
3	RFOVFE	0	R/W	Receive FIFO Overflow Enable 0: Disables interrupts due to receive FIFO overflow. 1: Enables interrupts due to receive FIFO overflow.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

25.3.17 FIFO Control Register (SIFCTR)

SIFCTR is a 32-bit readable/writable register that indicates the area available for the transmit/receive FIFO transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TFWM[2:0]			—	—	TFUA[6:0]							—	—	—	—
Initial value:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFWM[2:0]			RFUA[8:0]									—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	TFWM[2:0]	0	R/W	Transmit FIFO Watermark A transfer request of the transmit FIFO is issued by the TDREQE bit in SIIER. The transmit FIFO always operates as a 64-stage FIFO regardless of these bit settings. 000: Issues a transfer request when 64 stages of the transmit FIFO are empty. 001: Issues a transfer request when 32 or more stages of the transmit FIFO are empty. 010: Issues a transfer request when 24 or more stages of the transmit FIFO are empty. 011: Issues a transfer request when 16 or more stages of the transmit FIFO are empty. 100: Issues a transfer request when 12 or more stages of the transmit FIFO are empty. 101: Issues a transfer request when 8 or more stages of the transmit FIFO are empty. 110: Issues a transfer request when 4 or more stages of the transmit FIFO are empty. 111: Issues a transfer request when 1 or more stages of transmit FIFO are empty.
28 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 20	TFUA[6:0]	H'40	R	Transmit FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'0000000 (full) to B'1000000 (empty).
19 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 13	RFWM[2:0]	000	R/W	Receive FIFO Watermark A transfer request of the receive FIFO is issued by the RDREQE bit in SIIER. The receive FIFO always operates as a 256-stage FIFO regardless of these bit settings. 000: Issues a transfer request when 1 stage or more of the receive FIFO are valid. 001: Issues a transfer request when 4 or more stages of the receive FIFO are valid. 010: Issues a transfer request when 8 or more stages of the receive FIFO are valid. 011: Issues a transfer request when 16 or more stages of the receive FIFO are valid. 100: Issues a transfer request when 32 or more stages of the receive FIFO are valid. 101: Issues a transfer request when 64 or more stages of the receive FIFO are valid. 110: Issues a transfer request when 128 or more stages of the receive FIFO are valid. 111: Issues a transfer request when 256 stages of the receive FIFO are valid.
12 to 4	RFUA[8:0]	H'000	R	Receive FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'000000000 (empty) to B'100000000 (full).
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

25.4 Operation

25.4.1 Operating Mode

(a) Common Transmit/Receive Mode

BBIF2 uses common clock and frame synchronization signals for transmission and reception.

Master mode: BBIF2_TSCK (BBIF2_SCK) and BBIF2_TSYNC (BBIF2_SYNC) are output.

Slave mode: BBIF2_TSCK (BBIF2_SCK) and BBIF2_TSYNC (BBIF2_SYNC) are input.

25.4.2 Serial Clocks

(a) Clock Output in Master Mode

In master mode, the baud rate generator is used to generate the serial clock. The division ratio is from 1/1 to 1/1024.

(b) Clock Input in Slave Mode

In slave mode, the clock input for transmission and reception is used as the serial clock.

(c) Multiple Channel Function

This module provides the multiple channel function as shown in figure 25.2.

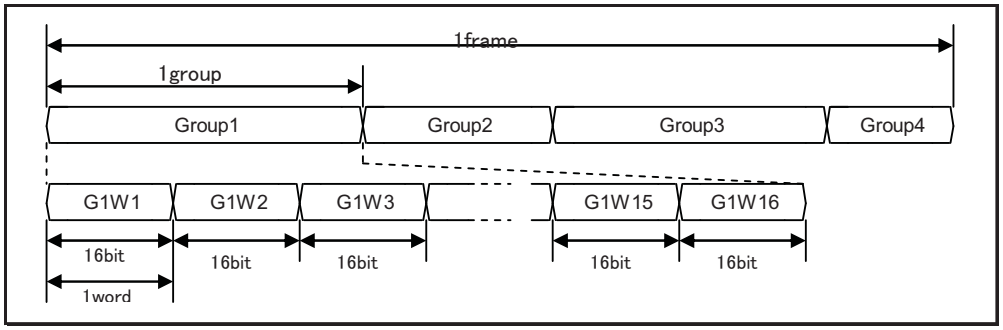


Figure 25.2 Multiple Channel Structure

The following conditions can be specified for the multiple channel function.

- Up to four groups in one frame
- Up to 256 words in one group
- Eight bits to 32 bits in one word
- Up to three blank bits can be inserted between groups

Note the following limitations by the number of groups.

Table 25.4 Maximum Word Size and Group Size Limited by Number of Groups

Number of Groups	Maximum Word Size	Maximum Group Size
One or two	32 bits	256 words
Three or four	16 bits	16 words

25.4.3 Serial Timing

(a) BBIF2_SYNC

The BBIF2_SYNC is a frame synchronization signal. The following four transfer modes are available.

- Frame start synchronization pulse: 1-bit-width pulse indicating the start of a frame
- Last bit synchronization pulse: 1-bit-width pulse indicating the last bit in a word
- Level/SPI: Level signal asserted during frame transmission
- L/R: 1/2-frame-width pulse indicating the first-half groups in a high level and the last-half groups in a low level

Figure 25.3 to 25.6 show the BBIF2_SYNC synchronization timing in these modes.

- Frame Start Synchronization Pulse

The rising edge of the synchronization pulse indicates the start of a frame.

The delay between the rising edge of the synchronization signal and the start of data transmission or reception can be specified with the DTDL bits. The width of the synchronization pulse can be extended through the SYNCDL bit setting.

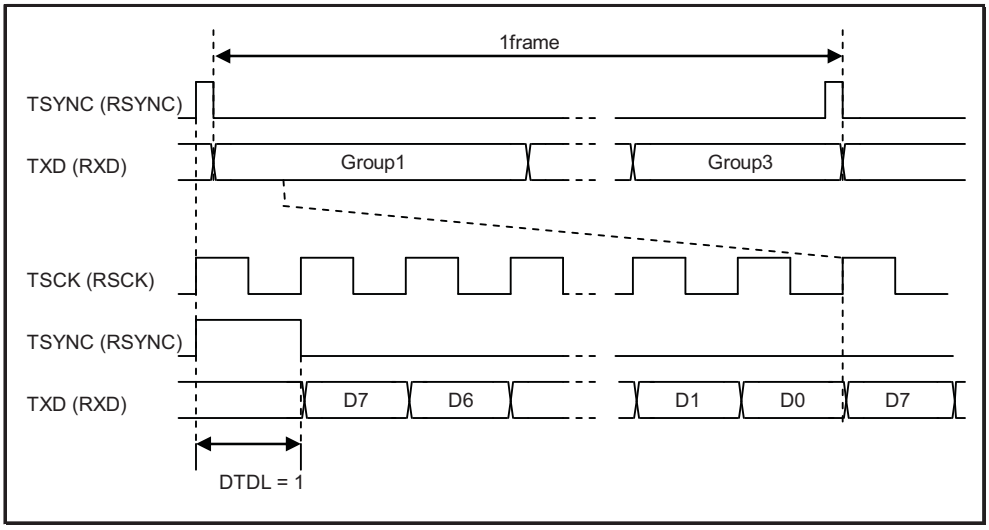

Figure 25.3 Synchronization Timing in Start Frame Synchronization Pulse Mode

- Last Bit Synchronization Pulse

The rising edge of the synchronization pulse indicates the last bit of each word.

The delay between the last bit of a word and the synchronization pulse can be specified with the DTDL bits.

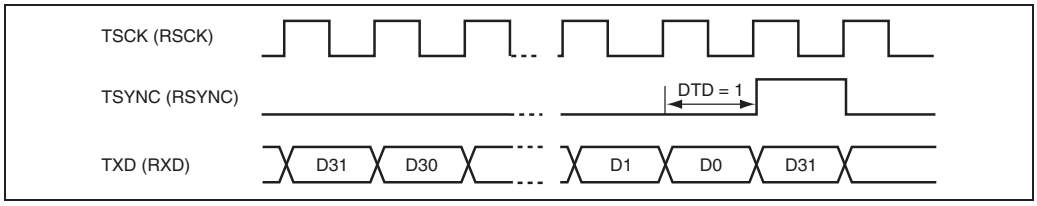

Figure 25.4 Synchronization Timing in Last Bit Synchronization Pulse Mode

- Level Synchronization

The synchronization signal is driven high for the frame length.

The delay between the rising edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits and the delay between the end of transmission or reception and the falling edge of the synchronization signal can be specified with the SYNCDL bits (DTDL = 0 to 2 and SYNCDL = 0 to 3). This mode is available for the SPI master or slave operation.

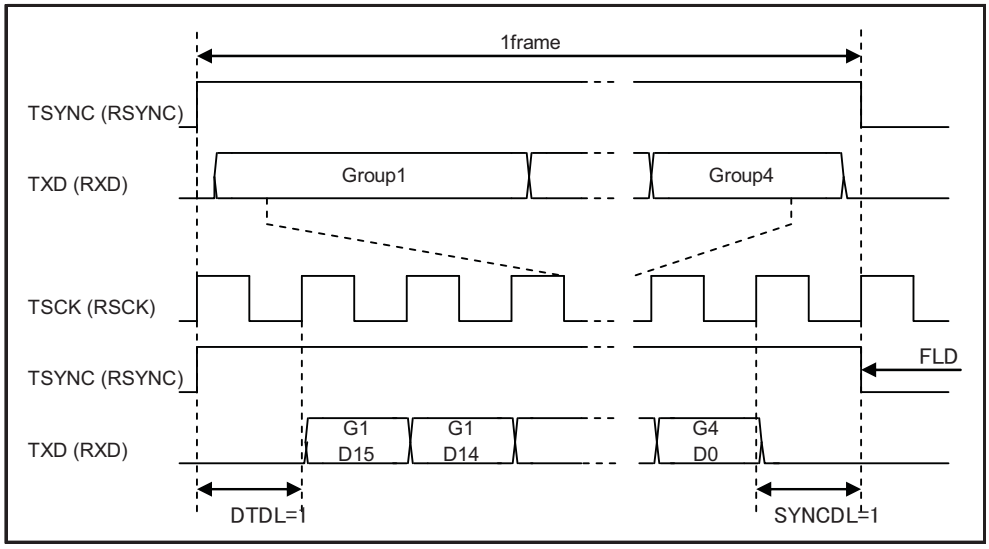

Figure 25.5 Synchronization Timing in Level Synchronization Mode

- L/R Synchronization

A high level in the synchronization signal indicates the first-half groups and a low level indicates the last-half groups.

The delay between the rising or falling edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits and the delay between the end of transmission or reception and the rising or falling edge of the synchronization signal can be specified with the SYNCDL bits (DTDL = 0 to 2 and SYNCDL = 0 to 3).

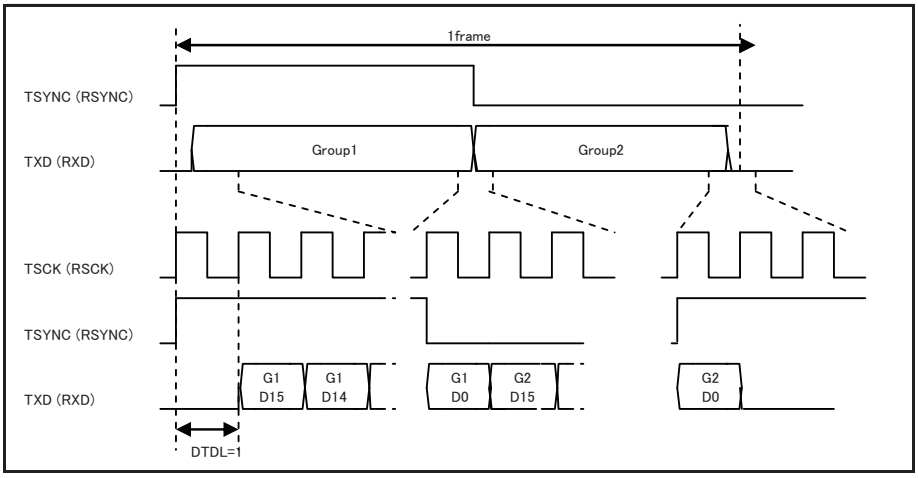

Figure 25.6 Synchronization Timing in L/R Synchronization Mode

(b) Transmit/Receive Timing

The BBIF2_TXD transmit timing and BBIF2_RXD receive timing relative to the BBIF2_TSCK and BBIF2_SCK can be specified as the sampling timing in the following two ways through the TEDG and REDG bits in SIMDR.

- Rising-edge sampling
- Falling-edge sampling

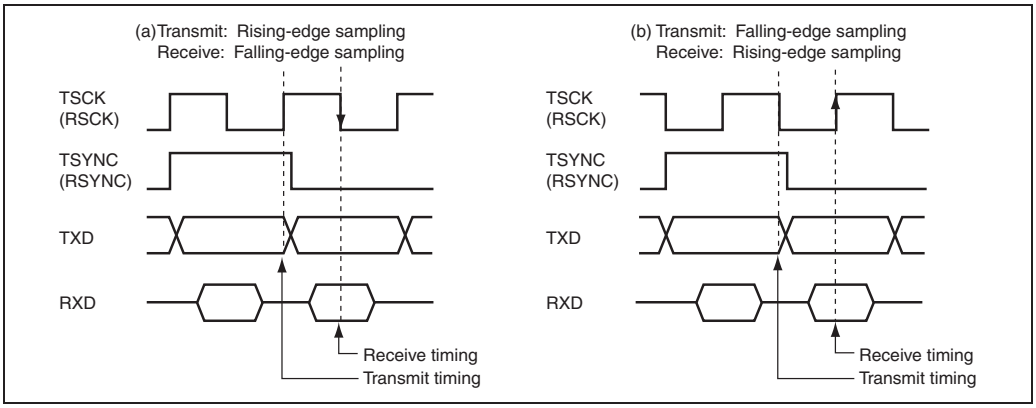

Figure 25.7 Transmit/Receive Timing

25.4.4 Control Data Interface

For the groups specified with the CRDE bits in SITMDR2 and SIRMDR2, data is not stored in the FIFOs but handled as control data to be stored in SITDR1/SITDR2 and SIRDR1/SIRDR2.

Control data is transferred in the following two ways, which can be selected through the CRDNUM bits in SITMDR2 and SIRMDR2, as shown in Figure 25.8.

- Only the first word in the group is transferred as valid data.
- All words in the group is transferred as valid data.

For the invalid data period during transmission, the value specified in the TXDIZ bit is output. The invalid receive data is not stored in SIRDR1 or SIRDR2.

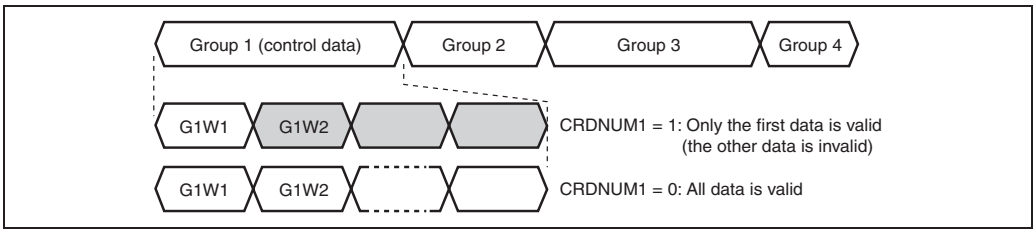

Figure 25.8 Control Data Allocation

25.4.5 Transfer Data Allocation to Registers

(1) Transmit/Receive Data

Transmit/receive data (FIFO data and control data) should be written to or read from the following registers.

- Writing of transmit FIFO data: SITFDR (32/16-bit access)
- Writing of control data: SITDR1 and SITDR2 (32/16-bit access)
- Reading of receive FIFO data: SIRFDR (32/16-bit access)
- Reading of control data: SIRDR1 and SIRDR2 (32/16-bit access)

When making a 16-bit access, only upper 16 bits of FIFO data is accessible. However, both upper 16 bits and lower 16 bits of control data are accessible.

When the word size is smaller than the transmit FIFO data access size, the upper bits are transmitted as valid data. For example, when writing data to the transmit FIFO by 32-bit access and transmitting a16-bit word, the upper 16 bits are transmitted and the lower 16 bits are discarded as invalid data.

In the same way, when the word size is larger than the receive FIFO data access size, the upper bits are received as valid data. For example, when 32-bit data is stored in the receive FIFO and the data is read by 16-bit access, the lower 16 bits are discarded as invalid data.

Figure 25.9 shows the bit alignment of these registers.

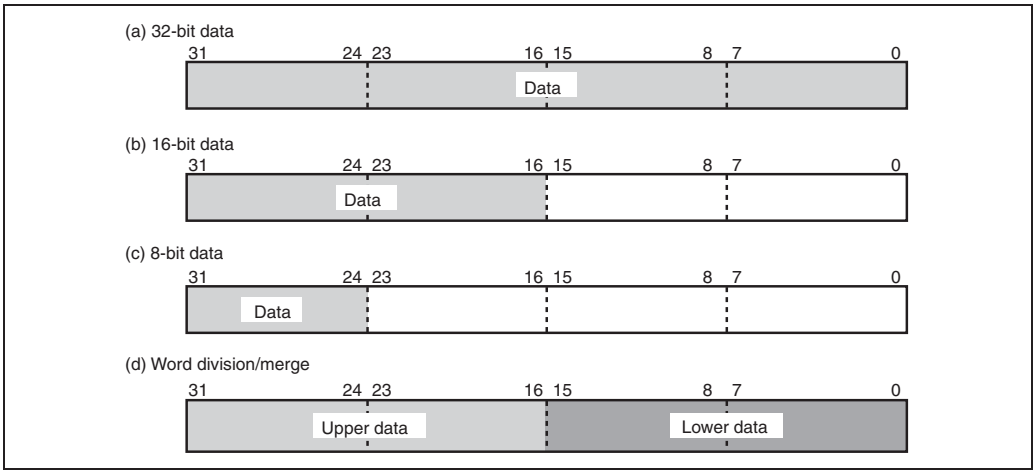

Figure 25.9 Transmit/Receive Data Bit Alignment

25.4.6 FIFO

(a) Overview

The transmit and receive FIFOs of the BBIF2 have the following features.

- 32 bits × 64 stages for transmission and 32 bits × 256 stages for reception
- The FIFO pointer is updated in one read or write cycle regardless of the access size of the CPU or DMAC. (One access cannot be divided into multiple accesses.)

(b) Transfer Request

A request for FIFO data transfer can be issued to the CPU or DMAC as the following interrupt sources.

- FIFO transmit request: TDREQ (interrupt source for transmission)
- FIFO receive request: RDREQ (interrupt source for reception)

The conditions for requesting FIFO data transfer can be specified separately for transmission and reception. The conditions for the transmit FIFO and receive FIFO are specified in the TFWM[2:0] bits and RFWM[2:0] bits in SIFCTR, respectively.

Table 25.5 Condition for Issuing Transmit Request

TFWM[2:0]	Number of Requested Stages	Condition for Transmit Request	Areas Used
000	1	64 stages of empty area	Smallest
001	32	32 or more stages of empty area	
010	40	24 or more stages of empty area	
011	48	16 or more stages of empty area	
100	52	12 or more stages of empty area	
101	56	8 or more stages of empty area	
110	60	4 or more stages of empty area	
111	64	1 or more stages of empty area	Largest

Table 25.6 Condition for Issuing Receive Request

RFWM[2:0]	Number of Requested Stages	Condition for Receive Request	Areas Used
000	1	1 or more stages of valid data	Smallest
001	4	4 or more stages of valid data	
010	8	8 or more stages of valid data	
011	16	16 or more stages of valid data	
100	32	32 or more stages of valid data	
101	64	64 or more stages of valid data	
110	128	128 or more stages of valid data	
111	256	256 stages of valid data	Largest

The maximum FIFO stages are always available even if the data area or empty area exceeds the size specified for the transfer condition. Accordingly, an overflow error or an underflow error occurs if the data area or empty area exceeds the maximum number of FIFO stages.

The FIFO transfer request is canceled when the specified condition is not satisfied even if the FIFO does not become empty or full.

(c) Number of FIFOs

The number of transmit and receive FIFO stages used are indicated by the following registers.

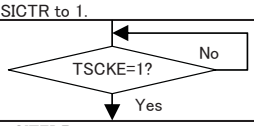
- Transmit FIFO: The number of empty FIFO stages is indicated by the TFUA[6:0] bits in SIFCTR.
- Receive FIFO: The number of valid data stages is indicated by the RFUA[8:0] bits in SIFCTR.

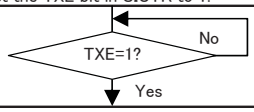
These registers show the number of data stages that can be transferred by the CPU or DMAC.

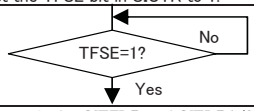
25.4.7 Transmit and Receive Procedures

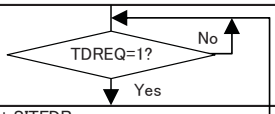
(a) Transmission in Master Mode

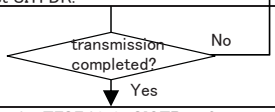
Figure 25.10 shows an example of settings and operation for transmission in master mode.

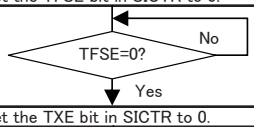


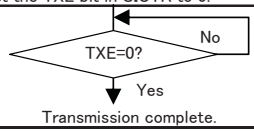










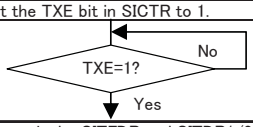


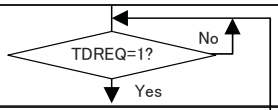
No.	Flow chart	Setting	operation
1	Set SITMDR1/2/3 SITSCR , SIFCTR , and SIIER.	Set the operating mode, serial clock , and FIFO threshold value, and enable interrupts.	
2	Set the TSCKE bit in SICTR to 1.	Set output sampling and start the baud rate generator.	Outputs the serial clock.
3		Read 1 from TSCKE bit in SICTR.	
4	Set SITFDR, SITDR1/2.	Set transmit data.	
5	Set the TXE bit in SICTR to 1.	Enable transmittion.	
6		Read 1 from TXE bit in SICTR.	
7	Set the TFSE bit in SICTR to 1.	Starting output frame of synchronization signal.	Outputs the frame syncronization signal.
8		Read 1 from TFSE bit in SICTR.	
9	Transmit the SITFDR and SITDR1/2 contents through TXD in synchronization with		Transmit data.
10			Assert transmit data transfer request according to the FIFO threshold valu
11	Set SITFDR.	Set transfer data.	
12		Read 1 from TFEMP bit in SICTR.	
13	Set the TFSE bit in SICTR to 0.	Disable output frame of synchronization signal.	
14		Read 0 from TFSE bit in SICTR.	
15	Set the TXE bit in SICTR to 0.	Disable transmit enable.	
16	 Transmission complete.	Read 0 from TXE bit in SICTR.	

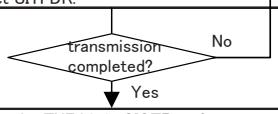
Figure 25.10 Example of Transmit Procedure in Master Mode

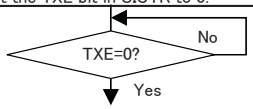
(b) Transmission in Slave Mode

Figure 25.11 shows an example of settings and operation for transmission in slave mode.







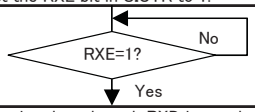


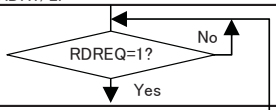
No.	Flow chart	Setting	operation
1	Setting master device polarity	Depend on master device.	Decide SYNC/SCK polarity
2	Set SITMDR1/2/3 SIFCTR and SIIER.	Set operating mode FIFO threshold value and enable interrupts.	
3	Set SITFDR, SITDR1/2.	Set transmit data.	
4	Set the TXE bit in SICTR to 1.	Enable transmittion.	
5		Read 1 from TXE bit in SICTR.	
6	Transmit the SITFDR and SITDR1/2 contents through TXD in synchronization with		Transmit data
7			Assert transmit data transfer request according to the FIFO threshold valu
8	Set SITFDR.	Set transfer data.	
9			
10	Set the TXE bit in SICTR to 0.	Disable transmit enable.	
11	 Transmission complete.	Read 0 from TXE bit in SICTR.	

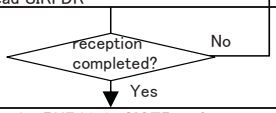
Figure 25.11 Example of Transmit Procedure in Slave Mode

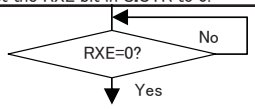
(c) Reception in Slave Mode

Figure 25.12 shows an example of settings and operation for reception in slave mode.









No.	Flow chart	Setting	operation
1	Setting master device polarity	Depend on master device.	Decide SYNC/SCK polarity
2	Set SIRMDR1/2/3 SIFCTR and SIIER.	Set operating mode FIFO threshold value and enable interrupts.	
3	Set the RXE bit in SICTR to 1.	Enable reception.	
4		Read 1 from RXE bit in SICTR.	
5	Receive data through RXD in synchronization with MSIOF_RSYNC and store it in SIRFDR and SIRDR1/2.		Receive data
6			Assert reception data transfer request according to the FIFO threshold valu
7	Read SIRFDR	Read reception data.	
8			
9	Set the RXE bit in SICTR to 0.	Disable reception enable	
10	 Reception complete.	Read 0 from RXE bit in SICTR.	

Figure 25.12 Example of Receive Procedure in Slave Mode

(d) Reset

After a power-on reset is applied, module stop state is canceled, or a reset signal is asserted through the TXRST or RXRST setting in SICTR, it takes about SUBϕ20 cycles to complete the internal reset of the module. During a period from the beginning of reset until the TXRST or RXRST value is read as 0, do not modify the control register or access the FIFOs.

The BBIF2 can separately reset the transmit and receive units by setting the following bits to 1.

- Transmit reset: TXRST bit in SICTR
- Receive reset: RXRST bit in SICTR

Table 25.7 Transmit and Receive Reset

Type	Objects Initialized
Transmit reset	SITDR1, SITDR2, and SITFDR
	Transmit FIFO write pointer
	TCRDY, TFEMP, and TDREQ bits in SISTR
	TXE bit in SICTR
Receive reset	SIRDR1, SIRDR2, and SIRFDR
	Receive FIFO read pointer
	RCRDY, RFFUL, and RDREQ bits in SISTR
	RXE bit in SICTR

(e) Initial Operating Mode

After a power-on reset, both the transmit and receive units are initialized to master mode (0 is output through CLK and SYNC). When using slave mode, keep the connected device outputting 0 until the operating mode setting is completed.

25.4.8 Interrupts

The BBIF2 has one type of interrupt.

(a) Interrupt Sources

Interrupts can be generated by several sources. Each source is shown as a BBIF2 status in SISTR. Table 25.8lists the BBIF2 interrupt sources.

Table 25.8 BBIF2 Interrupt Sources

No.	Classification	Bit Name	Function Name	Description
1	Transmission	TDREQ	Transmit FIFO transfer request	The transmit FIFO has empty space of specified size or more.
2		TFEMP	Transmit FIFO empty	The transmit FIFO is empty.
3		TEOF	Frame transmission end	Transmission of data with a length of one frame is completed.
4	Reception	RDREQ	Receive FIFO transfer request	The receive FIFO stores data of specified size or more.
5		RFFUL	Receive FIFO full	The receive FIFO is full.
6		REOF	Frame reception end	Reception of data with a length of one frame is completed.
7	Control	TCRDY	Transmit control data ready	The transmit control data register is ready to be written.
8		RCRDY	Receive control data ready	The receive control data register stores valid data.
9	Error	TFUDF	Transmit FIFO underflow	Serial data transmit timing has arrived while the transmit FIFO is empty.
10		TFOVF	Transmit FIFO overflow	The transmit FIFO is written to while it is full.
11		RFOVF	Receive FIFO overflow	Serial data is received while the receive FIFO is full.
12		RFUDF	Receive FIFO underflow	The receive FIFO is read while the receive FIFO is empty.
13		TFSERR	Transmit FS error	A transmit frame synchronization signal is input before the specified number of bits has been reached (in slave mode).
14		RFSERR	Receive FS error	A receive frame synchronization signal is input before the specified number of bits has been reached (in slave mode).

Whether an interrupt is issued from an interrupt source is determined by the SIIER settings. If an interrupt source bit is set to 1 and the corresponding bit in SIIER is set to 1, a BBIF2 interrupt is issued.

(b) TDREQ and RDREQ

The transmit FIFO transfer request (TDREQ) and receive FIFO transfer request (RDREQ) are signals indicating the state. If the state changes after TDREQ or RDREQ is set, it is automatically cleared by the BBIF2.

When the DMA transfer is used, a DMA transfer request signal is pulled low for one cycle at the end of DMA transfer.

(c) Processing when Errors Occur

- Transmit FIFO underflow (TFUDF)
  The value specified with TXDIZ in SICTR is output.
- Transmit FIFO overflow (TFOVF)
  The contents of the transmit FIFO are protected, and the write operation causing the overflow is ignored.
- Receive FIFO overflow (RFOVF)
  Data causing the overflow is discarded and lost.
- Receive FIFO underflow (RFUDF)
  An undefined value is output on the bus.
- Transmit FS error (TFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.
- Receive FS error (RFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.

25.4.9 Transmit and Receive Timing

Examples of the BBIF2 serial transmission and reception are shown in Figure 25.13 and 25.14.

(a) 16-Bit Synchronization Pulse

Synchronization pulse method, one group, one word, 16 bits in a word, no bit delay

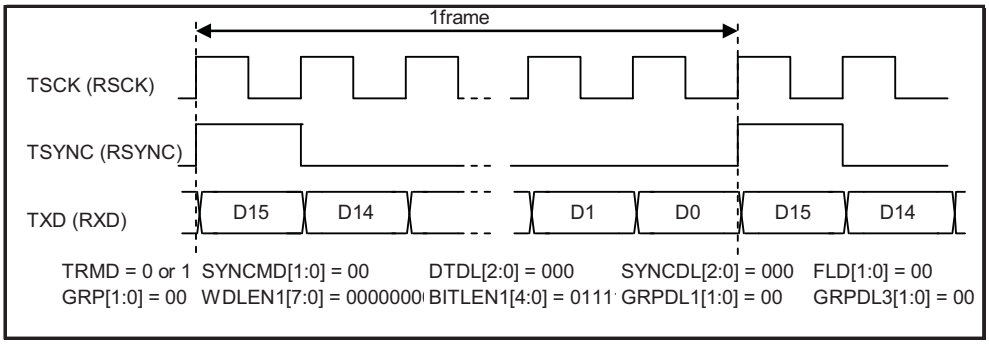


Figure 25.13 Transmit and Receive Timing (16 Bits)

(b) 32-Bit Synchronization Pulse

Synchronization pulse method, one group, 32 words, 32 bits in a word, 1-bit delay

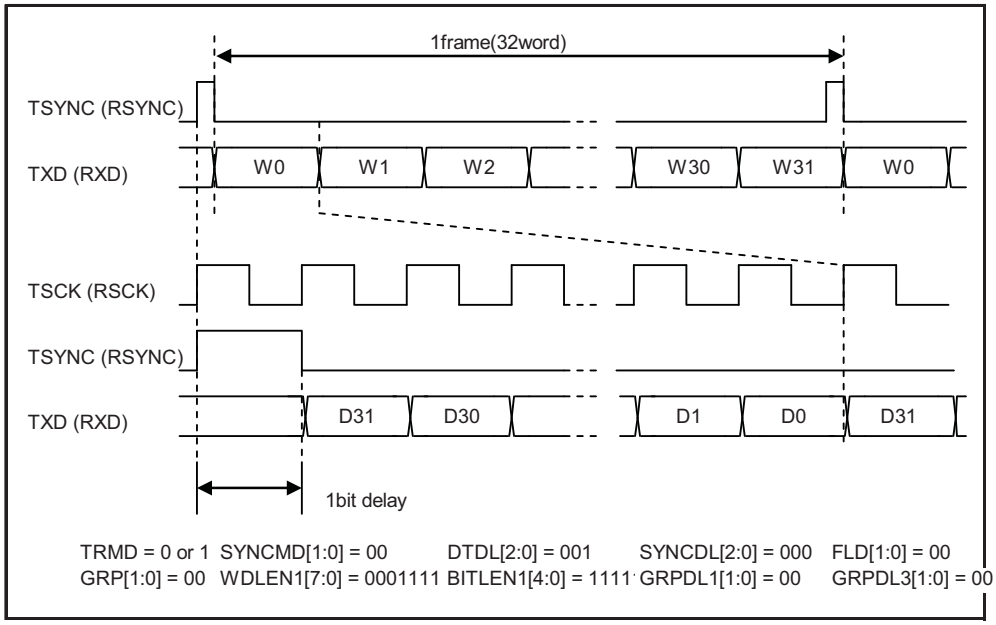

Figure 25.14 Transmit and Receive Timing (32 Bits)

(c) 24-Bit IIS Transmission

L/R mode, 2 groups, 1 word for each group, 24-bit word for each group, 1-bit delay.

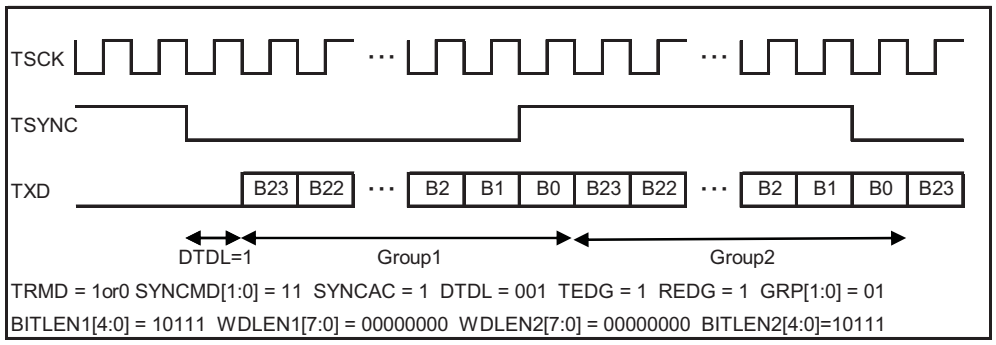

Figure 25.15 Transmit and Receive Timing (24-Bit IIS)

25.4.10 SPI

The BBIF can be used as an SPI device by setting the registers appropriately. Set the following: SITMDR1.PCON = 1'b1, SITMDR1.SYNCMD = 2'b10, and SICTR.TSCKIZ ≠ 2'b00 (for the receiver, SICTR.RSCKIZ ≠ 2'b00).

(a) Example of SPI Device Connection

Figure 25.16 shows an example of connection with an SPI device.

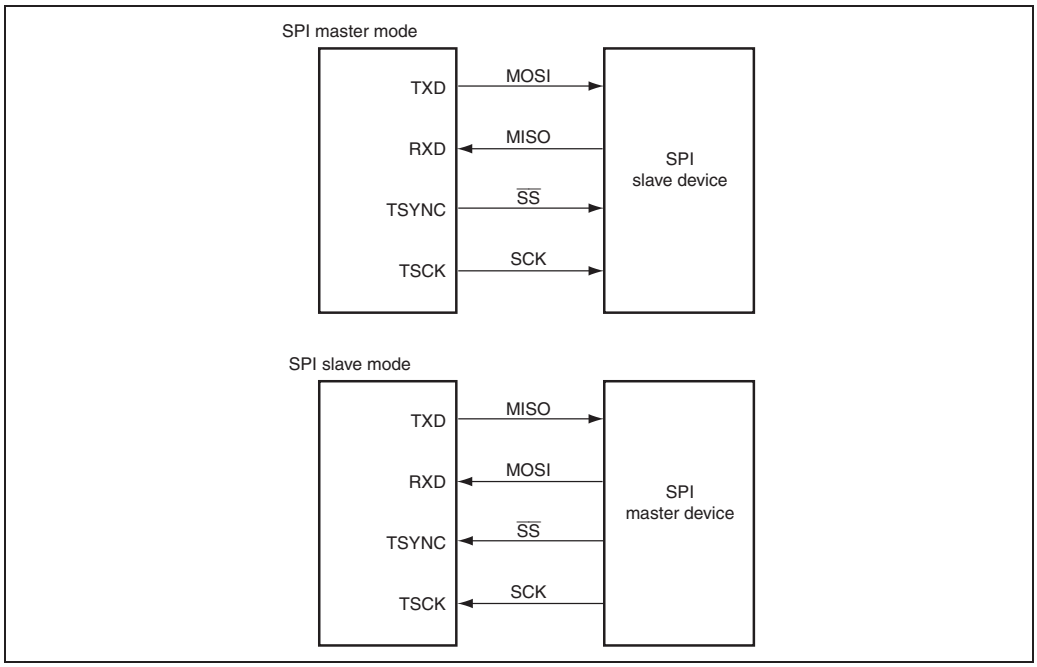

Figure 25.16 Example of SPI Device Connection

(b) SPI Serial Clock Timing

Figure 25.17and 25.18 show the data and clock timing in SPI mode. As shown in the figures, four types of serial transfer formats can be used.

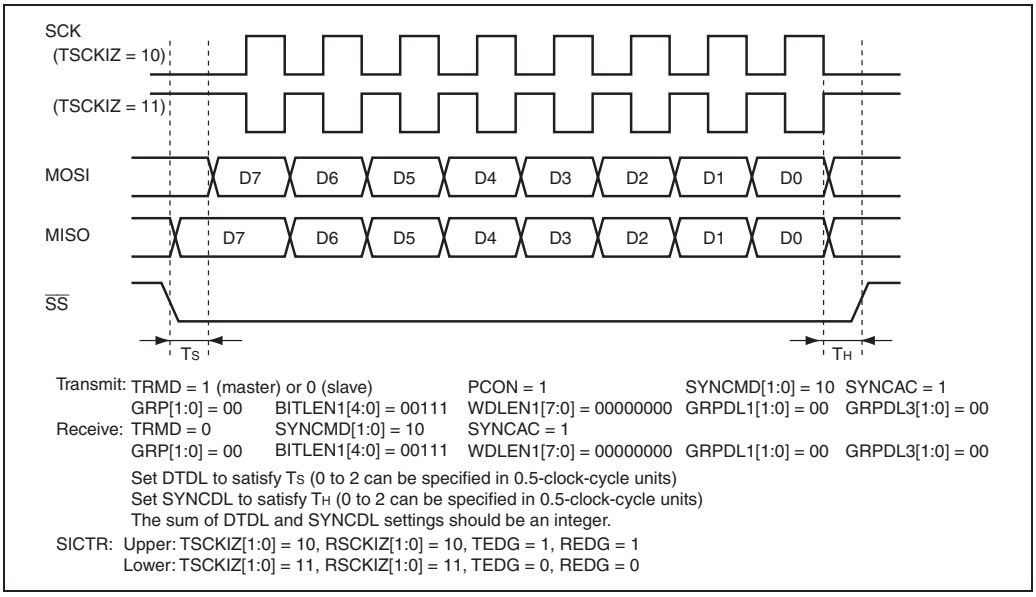

Figure 25.17 SPI Clock and Data Timing 1

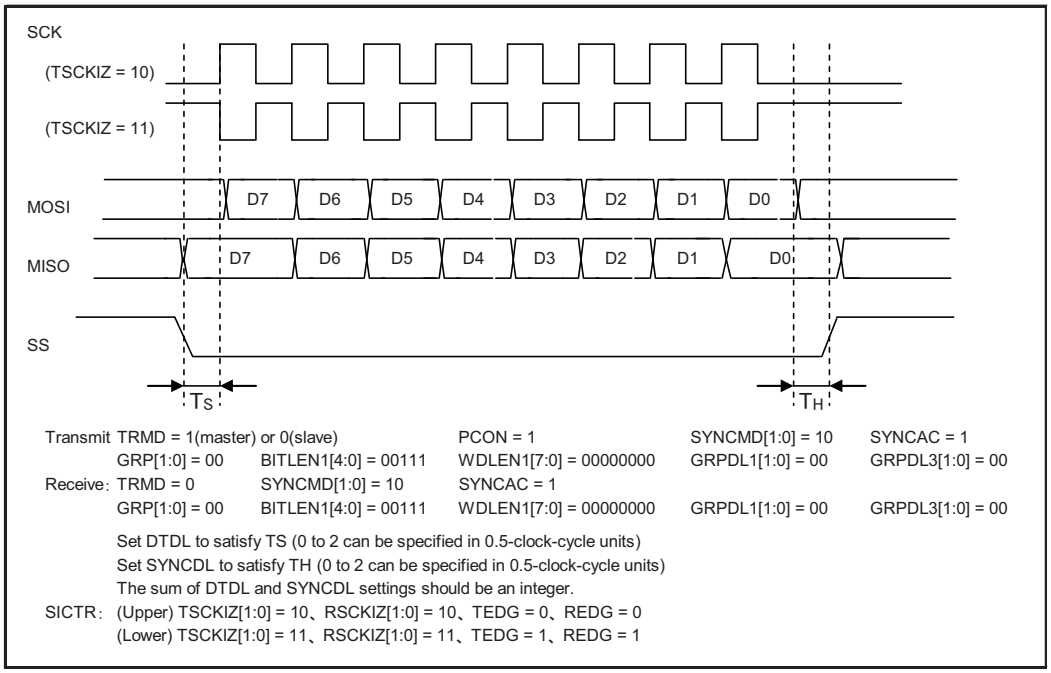

Figure 25.18 SPI Clock and Data Timing 2

25.4.11 Notes for Using SPI Mode

- When the module stop release or software reset is performed in SPI mode, set the control register (SICTR) again with each of the receive-setting bits (RSCKIZ/REDG) being 0.
- When using SPI master mode, set the FLD bits in SITMDR1 to ensure SUBCK4 cycles or more.
- When using SPI slave mode, set SUBCK4 cycles or more for the frame synchronization signal interval.
- For SPI slave mode operation, The setting for data delay should always set 0.
- For SPI slave mode operation, TXDIZ bits work on SS signal invalid state.

25.4.12 IIS

This module can support IIS format with following setting which is shown Figure 25.19 and Figure 25.20.BITLEN1/2 bit will change by usage.

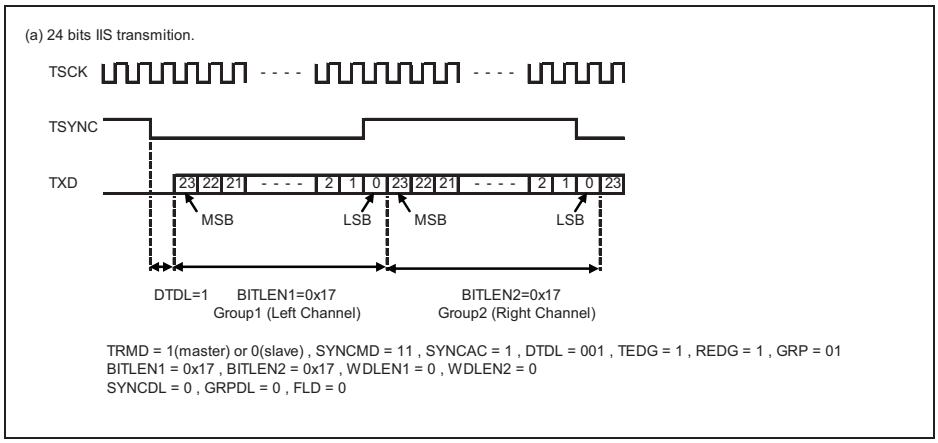

Figure 25.19 24 bits IIS transmition

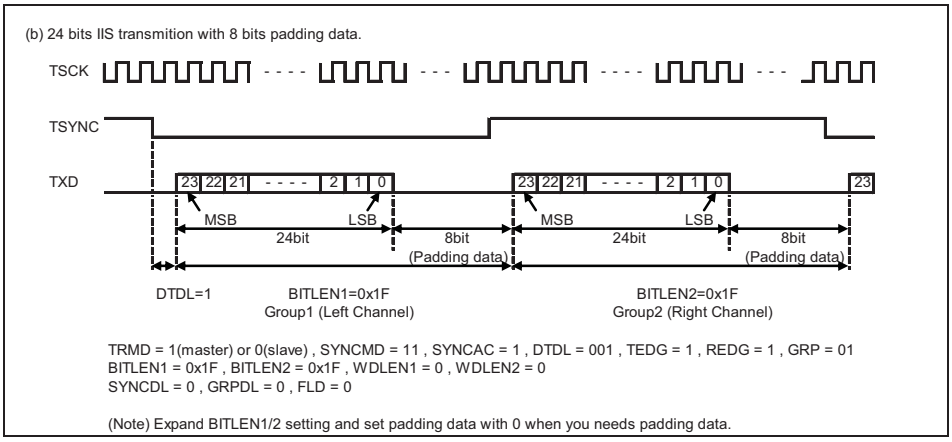

Figure 25.20 24 bits IIS transmition with 8 bits padding data

Section 26 MIPI-HSI

26.1 Features

This LSI circuit incorporates a MIPI-HSI (Mobile Industry Processor Interface–High-speed Sync. Serial Interface) that complies with Version 1.01.00 of the MIPI-HSI specification (30 September 2008).

Features of the HSI are listed below.

- Compliant with Version 1.01.00 of the MIPI-HSI specification (30 September 2008)
- Transmission FIFO with four 64-frame banks
- Reception FIFO with four 64-frame banks
- Automatic attachment of channel IDs to transmitted frames
- Automatic sorting of received frames into banks according to channel IDs
- Reception and transmission at up to 100 Mbps
- Generation of interrupts and DMA requests in response to amounts of data in the reception FIFO and transmission FIFO
- Automatic flow control in response to the reception of break transmission
- CAWAKE and ACWAKE pins
- Detection of tailing bits
- Support for 1.8V I/O interfaces

26.2 Block Diagram

Figure 26.1 is a block diagram of the HSI.

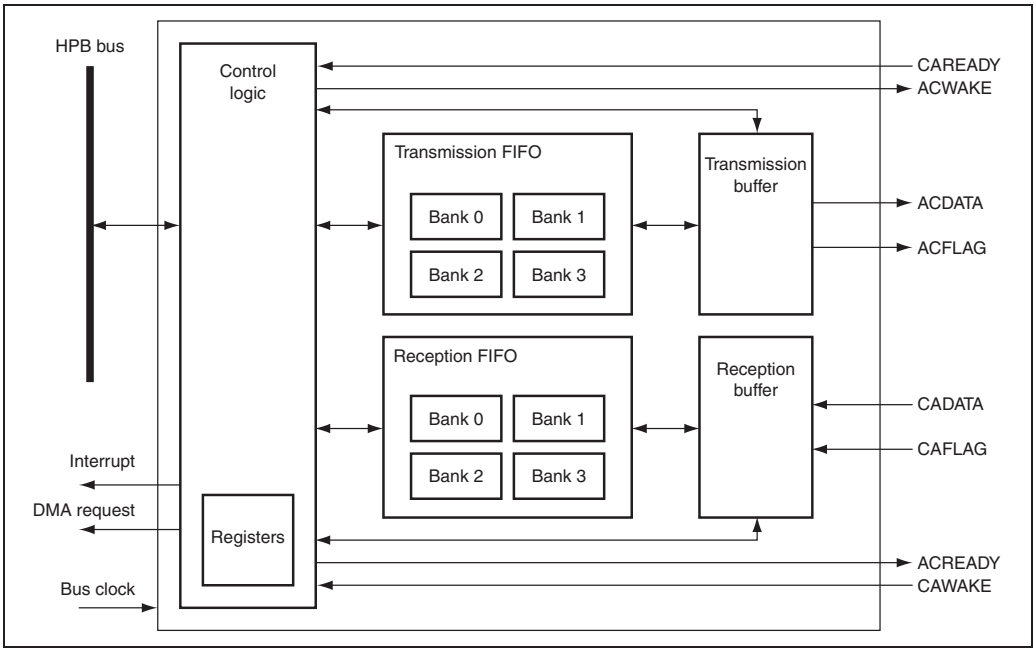

Figure 26.1 Block Diagram of the MIPI-HSI

26.3 Input/Output Pins

Table 26.1 shows the pin configuration of the HSI.

Table 26.1 Pin Configuration

Signal	MIPI Specification	I/O	Function
MP_RX_READY	ACREADY	Output	READY pin in the reception side
GP_RX_WAKE	CAWAKE	Input	WAKE pin in the reception side
GP_RX_FLAG	CAFLAG	Input	FLAG pin in the reception side
GP_RX_DATA	CADATA	Input	DATA pin in the reception side
GP_TX_READY	CAREADY	Input	READY pin in the transmission side
MP_TX_WAKE	ACWAKE	Output	WAKE pin in the transmission side
MP_TX_FLAG	ACFLAG	Output	FLAG pin in the transmission side
MP_TX_DATA	ACDATA	Output	DATA pin in the transmission side

26.4 Register Description

Table 26.2 shows the HSI register configuration.

Table 26.2 Register Configuration

Register Name	Abbreviation	R/W	Address	Initial Value	Access Size
TX control register	HSI_TXCR	R/W	H'E6A40000	H'00000000	32
TX ready negation control register	HSI_TXRNCR	R/W	H'E6A40004	H'00000000	32
TX timeout control register	HSI_TXTOCR	R/W	H'E6A40008	H'00000000	32
TX break control register	HSI_TXBRKCR	R/W	H'E6A4000C	H'00000000	32
TXFIFO status register	HSI_TXFSR	R	H'E6A40020	H'00000000	32
RX control register	HSI_RXCR	R/W	H'E6A40030	H'00000000	32
RX timeout detection time period control register	HSI_RXTOCR	R/W	H'E6A40034	H'00000000	32
RX tailing bit detection time period control register	HSI_RXTLCR	R/W	H'E6A40038	H'00000000	32
Receiver drain timeout detection time period control register	HSI_RXDTOCR	R/W	H'E6A4003C	H'00000000	32
RX burst count constraint register	HSI_RXBCCR	R/W	H'E6A40040	H'00000000	32
RX FIFO status register	HSI_RXFSR	R	H'E6A40050	H'00000000	32

26.4.1 TX Control Register (HSI_TXCR)

HSI_TXCR is a 32-bit readable/writable register that carries out setting of the transmitter.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXBRKLEN								TXRATE							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXRATEEN	TXCHLEN			—	—	—	TX MODE	—	—	—	TX RESET	—	TXBRK	—	TX START
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/W	R	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TXBRKLEN	All 0	R/W	Sets the length of a break transmission. A value equal to or greater than H'24 should be set to TXBRKLEN. During the break transmission, a break transmission is issued which is of a length that is TXBRKLEN + 1.
23 to 16	TXRATE	All 0	R/W	Transmission transfer rate is set. The allowed range is between H'00 and H'FE when TXRATEEN is enabled. (H'FF is not allowed)

Bit	Bit Name	Initial Value	R/W	Description
15	TXRATEEN	0	R/W	Transmission transfer rate that is set to TXRATE is enabled. 0: Transmitter transmits at 100 MHz. 1: Transmitter transmits at 100/(TXRATE + 2) MHz.
14 to 12	TXCHLEN	All 0	R/W	Number of bits of a channel descriptor is specified. This bit should be set at equal to or less than H'4.
11 to 9	—	All 0	R	Reserved The write value should be the same as the read value.
8	TXMODE	0	R/W	Sets transmission mode. 0: Stream mode 1: Frame mode
7 to 5	—	All 0	R	Reserved The write value should be the same as the read value.
4	TXRESET	0	R/W	When 1 is written to this bit, the transmitter is initialized. Transmission setting and data stored in transmission FIFO are cleared. To cancel initialization, 0 should be written to this bit. The registers to be initialized are as follows: HSI_TXCR (except TXRESET), HSI_TXRNCR, HSI_TXTOCR, HSI_TXBRKCR, HSI_TXFSR, HSI_DMATXCR, HSI_IRQCR.TXOVFEN, HSI_IRQCR.TXF0EN to TXF3EN, HSI_IRQCR.TXRNEN, HSI_IRQCR.TXTOEN, HSI_IRQCR.TXBRKEN, HSI_IRQCR.TXENDEN, HSI_IRQSR.TXOVF, HSI_IRQSR.TXF0 to TXF3, HSI_IRQSR.TXRN, HSI_IRQSR.TXTO, HSI_IRQSR.TXBRK, HSI_IOCR.ACWAKE, HSI_TX_CH0 to HSI_TX_CH3, HSI_TX_DATA0 to HSI_TX_DATA3, HSI_TX_CHSR, HSI_TX_CHDATA0 to HSI_TX_CHDATA3
3	—	0	R	Reserved The write value should be the same as the read value.
2	TXBRK	0	R/W	If 1 is written when TXBRK is 0, the transmitter carries out break transmission at the frame boundary that is being transmitted.
1	—	0	R	Reserved The write value should be the same as the read value.

Bit	Bit Name	Initial Value	R/W	Description
0	TXSTART	0	R/W	If 1 is written when TXSTART is 0, the transmitter takes in the transmission setting and starts transmission. Even if writing is carried out simultaneously to the other fields in HSI_TXCR, it is reflected in the transmission setting. If 0 is written to TXSTART, the transmission is terminated at the frame boundary that is being transmitted.

26.4.2 TX Ready Negation Control Register (HSI_TXRNCR)

HSI_TXRNCR is a 32-bit readable/writable register that carries out setting to measure the time period during which CAREADY is negated and to detect CAREADY negation timeout.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXRNSTP	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXRNC															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	TXRNSTP	0	R/W	Sets whether to temporarily terminate transmission at the time of CAREADY negation timeout detection. 0: Transmission is not terminated temporarily at the time of negation timeout detection. 1: Transmission is terminated temporarily at the time of negation timeout detection.
30 to 16	—	All 0	R	Reserved The write value should be the same as the read value.
15 to 0	TXRNC	All 0	R/W	Sets the number of cycles for detecting CAREADY negation timeout. This number of cycles is counted by HPϕ. If CAREADY is negated during the number of cycles that are set by TXRNC, CAREADY negation timeout is detected. To this bit, a value should be set that is equal to or greater than twice the number of cycles necessary for transmitting one frame (for example, if the frame length is 37 bits, the value should be 74 or more). When transmission transfer rate is set, a value should be set that is obtained by multiplying the normal value by the transmission transfer rate.

26.4.3 TX Timeout Control Register (HSI_TXTOCR)

HSI_TXTOCR is a 32-bit readable/writable register that carries out setting to measure the time period during which the frame transmission is terminated when CAREADY is in negated status and to detect transmission timeout.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXTOSTP	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXTOC															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	TXTOSTP	0	R/W	Sets operation of the transmitter at the time of transmission timeout detection. 0: Transmission is not terminated at the time of detection. 1: Transmission is terminated at the time of detection.
30 to 16	—	All 0	R	Reserved The write value should be the same as the read value.
15 to 0	TXTOC	All 0	R/W	Sets the number of cycles for detecting transmission timeout. This number of cycles is counted by HPϕ. During the number of cycles that are set by TXTOC, if the transmission is stopped due to CAREADY being negated, transmission timeout is detected. To this bit, a value should be set that is equal to or greater than twice the number of cycles necessary for transmitting one frame (for example, if the frame length is 37 bits, the value should be 74 or more). When the transmission transfer rate is set, a value should be set that is obtained by multiplying the normal value by the transmission transfer rate.

26.4.4 TX Break Control Register (HSI_TXBRKCR)

HSI_TXBRKCR is a 32-bit readable/writable register that carries out setting at the time of break transmission.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXBRKSTP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved The write value should be the same as the read value.
0	TXBRKSTP	0	R/W	Sets whether to temporarily terminate transmission of the next frame after break transmission. 0: Transmission is not terminated temporarily. 1: Transmission is terminated temporarily.

26.4.5 TXFIFO Status Register (HSI_TXFSR)

HSI_TXFSR is a 32-bit readable/writable register that indicates number of data stored in each bank of transmission FIFO.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	TXFCB3						—	TXFCB2							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	TXFCB1						—	TXFCB0							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved The write value should be the same as the read value.
30 to 24	TXFCB3	All 0	R	Number of data stored in transmission FIFO bank 3 can be read.
23	—	0	R	Reserved The write value should be the same as the read value.
22 to 16	TXFCB2	All 0	R	Number of data stored in transmission FIFO bank 2 can be read.
15	—	0	R	Reserved The write value should be the same as the read value.
14 to 8	TXFCB1	All 0	R	Number of data stored in transmission FIFO bank 1 can be read.
7	—	0	R	Reserved The write value should be the same as the read value.
6 to 0	TXFCB0	All 0	R	Number of data stored in transmission FIFO bank 0 can be read.

26.4.6 RX Control Register (HSI_RXCR)

HSI_RXCR is a 32-bit readable/writable register that carries out setting of the receiver.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXBRKLEN								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	RXCHLEN			RXAFC	RXFLOW		RX MODE	—	—	—	RX RESET	—	—	—	RX START
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RXBRKLEN	0	R/W	Sets the length of a 0 string, to be recognized as break transmission in frame mode. This bit should be set to equal to or greater than H'25. Set the transmitter of the opposite communication device so that it should transmit two more 0 bits than this set value as the break transmission (when RXBRKLEN = H'25, set the transmitter of the opposite communication device so that it transmits 39 or more bits of 0s as break transmission).
23 to 15	—	0	R	Reserved The write value should be the same as the read value.
14 to 12	RXCHLEN	All 0	R/W	Sets the number of bits of a channel descriptor. This bit should be set at equal to or less than H'4.
11	RXAFC	0	R/W	Enables or disables automatic flow control when receiving break transmission at the time of Receiver Realtime Data Flow in frame mode. 0: Automatic flow control is disabled. 1: Automatic flow control is enabled.
10, 9	RXFLOW	All 0	R/W	Read: Indicates current data flow. Write: Receiving data flow is set. 00: Synchronized Data Flow 01: Pipelined Data Flow 10: Receiver Realtime Data Flow However, transition is made to Synchronized Data Flow if break transmission is detected when RXAFC = 1. 11: Receiver Realtime Data Flow However, transition is made to Pipelined Data Flow if break transmission is detected when RXAFC = 1.
8	RXMODE	0	R/W	Sets receiving mode. 0: Stream mode 1: Frame mode
7 to 5	—	All 0	R	Reserved The write value should be the same as the read value.

Bit	Bit Name	Initial Value	R/W	Description
4	RXRESET	0	R/W	If 1 is written to this bit, the receiver, reception FIFO, and receiver setting registers are initialized. To cancel initialization, 0 should be written to this bit. The registers to be initialized are as follows: HSI_RXCR (except RXRESET), HSI_RXRNCR, HSI_RXTLCR, HSI_RXDTOCR, HSI_RXBCCR, HSI_DMARXCR, HSI_IRQCR.RXOVFEN, HSI_IRQCR.RXUDFEN, HSI_IRQCR.RXF0EN to RXF3EN, HSI_IRQCR.RXDTOEN, HSI_IRQCR.RXTLEN, HSI_IRQCR.RXTOEN, HSI_IRQCR.RXBRKEN, HSI_IRQCR.RXOVF, HSI_IRQSR.RXUDF, HSI_IRQSR.RXF0 to RXF3, HSI_IRQSR.RXDTO, HSI_IRQSR.RXTL, HSI_IRQSR.RXTO, HSI_IRQSR.RXBRK, HSI_IOCR.ACREADY, HSI_RX_CH0 to HSI_RX_CH3, HSI_RX_DATA0 to HSI_RX_DATA3, HSI_RX_CHSR, HSI_RX_CHDATA0 to HSI_RX_CHDATA3
3 to 1	—	All 0	R	Reserved The write value should be the same as the read value.
0	RXSTART	0	R/W	Reception starts when this bit is set to 1. This bit should not be set to 0 when the opposite communication device or the receiver of this HSI is carrying out the reception operation.

26.4.7 RX Timeout Detection Time Period Control Register (HSI_RXTOCR)

HSI_RXTOCR is a 32-bit readable/writable register that sets the number of cycles from the start of the frame reception until timeout. The value of this register can be changed even during the operation of the receiver.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXTOP															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should be the same as the read value.
15 to 0	RXTOP	All 0	R/W	Sets the number of timeout cycles of frame reception. This number of cycles is counted by HPϕ. A value should be set that is equal to or greater than the arrival completion time period of the frame to be received.

26.4.8 RX Tailing Bit Detection Time Period Control Register (HSI_RXTLCR)

HSI_RXTLCR is a 32-bit readable/writable register that sets the time period to detect the bit that is received before asserting ACREADY after completion of frame reception. The value of this register can be changed even during the operation of the receiver.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXTLP															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should be the same as the read value.
15 to 0	RXTLP	All 0	R/W	Sets the number of cycles, during which the tailing bit is detected. This number of cycles is counted by HPϕ. If the transmission frequency of the opposite communication device is lower, the number of cycles should be set such that the tailing bit detection time period is equal to or greater than the cycle of the transmission frequency.

26.4.9 RX Drain Timeout Detection Time Period Control Register (HSI_RXDTOCR)

HSI_RXDTOCR is a 32-bit readable/writable register that sets the time period until the opposite communication device is considered as terminated while the receiver is in operation due to Receiver Realtime Data Flow. The value of this register can be changed even during the operation of the receiver.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXDTO															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should be the same as the read value.
15 to 0	RXDTO	All 0	R/W	Sets the number of cycles until the opposite communication device is considered as terminated. This number of cycles is counted by HPϕ. The number of cycles to be set here should be large enough for considering the transmitter of the opposite communication device as terminated.

26.4.10 RX Burst Count Constraint Register (HSI_RXBCCR)

HSI_RXBCCR is a 32-bit readable/writable register that sets the upper limit of the number of frames that can be received without negating ACREADY in Pipelined Data Flow. The value of this register can be changed even when the receiver is in operation.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	RXBCEN	—	—	—	—	RXBC							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved The write value should be the same as the read value.
12	RXBCEN	0	R/W	Sets the RX burst count constraint. 0: RX burst count constraint is disabled. 1: RX burst count constraint is enabled.
11 to 8	—	All 0	R	Reserved The write value should be the same as the read value.
7 to 0	RXBC	All 0	R/W	Sets the upper limit of RX burst count.

26.4.11 RXFIFO Status Register (HSI_RXFSR)

HSI_RXFSR is a 32-bit readable/writable register that indicates number of data stored in each bank of reception FIFO.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	RXFCB3							—	RXFCB2						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	RXFCB1							—	RXFCB0						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved The write value should be the same as the read value.
30 to 24	RXFCB3	All 0	R	Number of data stored in reception FIFO bank 3 can be read.
23	—	0	R	Reserved The write value should be the same as the read value.
22 to 16	RXFCB2	All 0	R	Number of data stored in reception FIFO bank 2 can be read.
15	—	0	R	Reserved The write value should be the same as the read value.
14 to 8	RXFCB1	All 0	R	Number of data stored in reception FIFO bank 1 can be read.
7	—	0	R	Reserved The write value should be the same as the read value.
6 to 0	RXFCB0	All 0	R	Number of data stored in reception FIFO bank 0 can be read.

26.4.12 TXDMA Control Register (HSI_DMATXCR)

HSI_DMATXCR is a 32-bit readable/writable register used to carry out DMA transfer setting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXD3CHID				TXD3ASNEN	—	TXD3EN		TXD2CHID				TXD2ASNEN	—	TXD2EN	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXD1CHID				TXD1ASNEN	—	TXD1EN		—	—	—	—	—	—	TXD0EN	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	TXD3CHID	All 0	R/W	The channel ID of the data to be stored in the transmission FIFO bank 3 should be set. The bit count should be the same as that of HSI_TXCR.TXCHLEN.
27	TXD3ASNEN	0	R/W	Enables the channel ID set in TXD3CHID. 0: The channel ID is not allocated to the transmission FIFO bank 3. 1: The channel ID set in TXD3CHID is allocated to the transmission FIFO bank 3. If this bit is set to 1, TXD3CHID is set as the channel ID when data is written to HSI_TXDATA3.
26	—	0	R	Reserved The write value should be the same as the read value.

Bit	Bit Name	Initial Value	R/W	Description
25, 24	TXD3EN	All 0	R/W	Issues a DMA request TX[3] according to the availability of space in the transmission FIFO bank 3. 00: DMA request is not issued (disabled). 01: DMA request is issued if space for one frame or more is available. 10: DMA request is issued if space for two or more frames is available. 11: DMA request is issued if space for eight or more frames is available. This bit should not be enabled when the transmission FIFO bank 3 interrupt is enabled.
23 to 20	TXD2CHID	All 0	R/W	The channel ID of the data to be stored in the transmission FIFO bank 2 should be set. The bit count should be the same as that of HSI_TXCR.TXCHLEN.
19	TXD2ASNEN	0	R/W	Enables the channel ID set in TXD2CHID. 0: The channel ID is not allocated to the transmission FIFO bank 2. 1: The channel ID set in TXD2CHID is allocated to the transmission FIFO bank 2. If this bit is set to 1, TXD2CHID is set as the channel ID when data is written to HSI_TXDATA2.
18	—	0	R	Reserved The write value should be the same as the read value.
17, 16	TXD2EN	All 0	R/W	Issues a DMA request TX[2] according to the availability of space in the transmission FIFO bank 2. 00: DMA request is not issued (disabled). 01: DMA request is issued if space for one frame or more is available. 10: DMA request is issued if space for two or more frames is available. 11: DMA request is issued if space for eight or more frames is available. This bit should not be enabled when the transmission FIFO bank 2 interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	TXD1CHID	All 0	R/W	The channel ID of the data to be stored in the transmission FIFO bank 1 should be set. The bit count should be the same as that of HSI_TXCR.TXCHLEN.
11	TXD1ASNEN	0	R/W	Enables the channel ID set in TXD1CHID. 0: The channel ID is not allocated to the transmission FIFO bank 1. 1: The channel ID set in TXD1CHID is allocated to the transmission FIFO bank 1. If this bit is set to 1, TXD1CHID is set as the channel ID when data is written to HSI_TXDATA1.
10	—	0	R	Reserved The write value should be the same as the read value.
9, 8	TXD1EN	All 0	R/W	Issues a DMA request TX[1] according to the availability of space in the transmission FIFO bank 1. 00: DMA request is not issued (disabled). 01: DMA request is issued if space for one frame or more is available. 10: DMA request is issued if space for two or more frames is available. 11: DMA request is issued if space for eight or more frames is available. This bit should not be enabled when the transmission FIFO bank 1 interrupt is enabled.
7 to 2	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	TXD0EN	All 0	R/W	Issues a DMA request TX[0] according to the availability of space in the transmission FIFO bank 0. 00: DMA request is not issued (disabled). 01: DMA request is issued if space for one frame or more is available. 10: DMA request is issued if space for two or more frames is available. 11: DMA request is issued if space for eight or more frames is available. This bit should not be enabled when the transmission FIFO bank 0 interrupt is enabled.

26.4.13 RXDMA Control Register (HSI_DMARXCR)

HSI_DMARXCR is a 32-bit readable/writable register used to perform DMA transfer setting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXD3CHID				RXD3 ASNEN	—	RXD3EN		RXD2CHID				RXD2 ASNEN	—	RXD2EN	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXD1CHID				RXD1 ASNEN	—	RXD1EN		—	—	—	—	—	—	RXD0EN	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	RXD3CHID	All 0	R/W	The channel ID of the data to be stored in the reception FIFO bank 3 should be set. The bit count should be the same as that of HSI_RXCR.RXCHLEN. The channel ID allocated to other banks should not be set to this bit.

Bit	Bit Name	Initial Value	R/W	Description
27	RXD3ASNEN	0	R/W	Enables the channel ID set in RXD3CHID. 0: The channel ID is not allocated to the reception FIFO bank 3. 1: The channel ID set in RXD3CHID is allocated to the reception FIFO bank 3. If this bit is set to 1, and if the channel ID of the received frame matches RXD3CHID, the frame is stored in the reception FIFO bank 3.
26	—	0	R	Reserved The write value should be the same as the read value.
25, 24	RXD3EN	All 0	R/W	Issues a DMA request RX[3] if the received data is stored in the reception FIFO bank 3. 00: DMA request is not issued (disabled). 01: DMA request is issued if data of one frame or more is stored. 10: DMA request is issued if data of two or more frames is stored. 11: DMA request is issued if data of eight or more frames is stored. This bit should not be enabled when the reception FIFO bank 3 interrupt is enabled.
23 to 20	RXD2CHID	All 0	R/W	The channel ID of the data to be stored in the reception FIFO bank 2 should be set. The bit count should be the same as that of HSI_RXCR.RXCHLEN. The channel ID allocated to other banks should not be set to this bit.
19	RXD2ASNEN	0	R/W	Enables the channel ID set in RXD2CHID. 0: The channel ID is not allocated to the reception FIFO bank 2. 1: The channel ID set in RXD2CHID is allocated to the reception FIFO bank 2. If this bit is set to 1, and if the channel ID of the received frame matches RXD2CHID, the frame is stored in the reception FIFO bank 2.

Bit	Bit Name	Initial Value	R/W	Description
18	—	0	R	Reserved The write value should be the same as the read value.
17, 16	RXD2EN	All 0	R/W	Issues a DMA request RX[2] if the received data is stored in the reception FIFO bank 2. 00: DMA request is not issued (disabled). 01: DMA request is issued if data of one frame or more is stored. 10: DMA request is issued if data of two or more frames is stored. 11: DMA request is issued if data of eight or more frames is stored. This bit should not be enabled when the reception FIFO bank 2 interrupt is enabled.
15 to 12	RXD1CHID	All 0	R/W	The channel ID of the data to be stored in the reception FIFO bank 1 should be set. The bit count should be the same as that of HSI_RXCR.RXCHLEN. The channel ID allocated to other banks should not be set to this bit.
11	RXD1ASNEN	0	R/W	Enables the channel ID set in RXD1CHID. 0: The channel ID is not allocated to the reception FIFO bank 1. 1: The channel ID set in RXD1CHID is allocated to the reception FIFO bank 1. If this bit is set to 1, and if the channel ID of the received frame matches RXD1CHID, the frame is stored in the reception FIFO bank 1.
10	—	0	R	Reserved The write value should be the same as the read value.

Bit	Bit Name	Initial Value	R/W	Description
9, 8	RXD1EN	All 0	R/W	Issues a DMA request RX[1] if the received data is stored in the reception FIFO bank 1. 00: DMA request is not issued (disabled). 01: DMA request is issued if data of one frame or more is stored. 10: DMA request is issued if data of two or more frames is stored. 11: DMA request is issued if data of eight or more frames is stored. This bit should not be enabled when the reception FIFO bank 1 interrupt is enabled.
7 to 2	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	RXD0EN	All 0	R/W	Issues a DMA request RX[0] if the received data is stored in the reception FIFO bank 0. 00: DMA request is not issued (disabled). 01: DMA request is issued if data of one frame or more is stored. 10: DMA request is issued if data of two or more frames is stored. 11: DMA request is issued if data of eight or more frames is stored. This bit should not be enabled when the reception FIFO bank 0 interrupt is enabled.

26.4.14 Interrupt Control Register (HSI_IRQCR)

HSI_IRQCR is a 32-bit readable/writable register that enables or disables interrupts and sets the interrupt conditions.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TX OVFEN	RX OVFEN	RX UDFEN	—	—	—	—	—	RXF3EN		RXF2EN		RXF1EN		RXF0EN	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXF3EN		TXF2EN		TXF1EN		TXF0EN		TX RNEN	TX TOEN	RX DTOEN	RX TLEN	RX TOEN	RX BRKEN	TX BRKEN	TX ENDEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	TXOVFEN	0	R/W	Transmission Overflow Interrupt Enable
30	RXOVFEN	0	R/W	Reception Overflow Interrupt Enable
29	RXUDFEN	0	R/W	Reception Underflow Interrupt Enable
28 to 24	—	All 0	R	Reserved The write value should be the same as the read value.
23, 22	RXF3EN	All 0	R/W	Enables the interrupt when received data is stored in the reception FIFO bank 3. 00: The interrupt is not issued (disabled). 01: The interrupt is issued if data of one frame or more is stored. 10: The interrupt is issued if data of 16 or more frames is stored. 11: The interrupt is issued if data of 32 or more frames is stored. This bit should not be enabled when the reception FIFO bank 3 DMA request is enabled.

Bit	Bit Name	Initial Value	R/W	Description
21, 20	RXF2EN	All 0	R/W	Enables the interrupt when received data is stored in the reception FIFO bank 2. 00: The interrupt is not issued (disabled). 01: The interrupt is issued if data of one frame or more is stored. 10: The interrupt is issued if data of 16 or more frames is stored. 11: The interrupt is issued if data of 32 or more frames is stored. This bit should not be enabled when the reception FIFO bank 2 DMA request is enabled.
19, 18	RXF1EN	All 0	R/W	Enables the interrupt when received data is stored in the reception FIFO bank 1. 00: The interrupt is not issued (disabled). 01: The interrupt is issued if data of one frame or more is stored. 10: The interrupt is issued if data of 16 or more frames is stored. 11: The interrupt is issued if data of 32 or more frames is stored. This bit should not be enabled when the reception FIFO bank 1 DMA request is enabled.
17, 16	RXF0EN	All 0	R/W	Enables the interrupt when received data is stored in the reception FIFO bank 0. 00: The interrupt is not issued (disabled). 01: The interrupt is issued if data of one frame or more is stored. 10: The interrupt is issued if data of 16 or more frames is stored. 11: The interrupt is issued if data of 32 or more frames is stored. This bit should not be enabled when the reception FIFO bank 0 DMA request is enabled.

Bit	Bit Name	Initial Value	R/W	Description
15, 14	TXF3EN	All 0	R/W	Enables the interrupt when space is available in the transmission FIFO bank 3. 00: The interrupt is not issued (disabled). 01: The interrupt is issued if space for one frame or more is available. 10: The interrupt is issued if space for 16 or more frames is available. 11: The interrupt is issued if space for 32 or more frames is available. This bit should not be enabled when the transmission FIFO bank 3 DMA request is enabled.
13, 12	TXF2EN	All 0	R/W	Enables the interrupt when space is available in the transmission FIFO bank 2. 00: The interrupt is not issued (disabled). 01: The interrupt is issued if space for one frame or more is available. 10: The interrupt is issued if space for 16 or more frames is available. 11: The interrupt is issued if space for 32 or more frames is available. This bit should not be enabled when the transmission FIFO bank 2 DMA request is enabled.
11, 10	TXF1EN	All 0	R/W	Enables the interrupt when space is available in the transmission FIFO bank 1. 00: The interrupt is not issued (disabled). 01: The interrupt is issued if space for one frame or more is available. 10: The interrupt is issued if space for 16 or more frames is available. 11: The interrupt is issued if space for 32 or more frames is available. This bit should not be enabled when the transmission FIFO bank 1 DMA request is enabled.

Bit	Bit Name	Initial Value	R/W	Description
9, 8	TXF0EN	All 0	R/W	Enables the interrupt when space is available in the transmission FIFO bank 0. 00: The interrupt is not issued (disabled). 01: The interrupt is issued if space for one frame or more is available. 10: The interrupt is issued if space for 16 or more frames is available. 11: The interrupt is issued if space for 32 or more frames is available. This bit should not be enabled when the transmission FIFO bank 0 DMA request is enabled.
7	TXRNEN	0	R/W	Enables the TX ready negation timeout interrupt.
6	TXTOEN	0	R/W	Enables the TX timeout interrupt.
5	RXDTOEN	0	R/W	Enables the RX drain timeout detection interrupt.
4	RXTLEN	0	R/W	Enables the RX tailing bit detection interrupt.
3	RXTOEN	0	R/W	Enables the RX reception timeout interrupt.
2	RXBRKEN	0	R/W	Enables the RX break-transmission reception interrupt. Even if this bit is set to 0, automatic flow control by HSI_RXCR.RXAFC is enabled.
1	TXBRKEN	0	R/W	Enables the TX break-transmission transmission end interrupt.
0	TXENDEN	0	R/W	Enables the TX frame-transmission end interrupt.

26.4.15 Interrupt Status Register (HSI_IRQSR)

HSI_IRQSR is a 32-bit readable/writable register that indicates the source of the generated interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXOVF	RXOVF	RXUDF	—	—	—	—	—	—	RXF3	—	RXF2	—	RXF1	—	RXF0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/WC0	R/WC0	R/WC0	R	R	R	R	R	R	R/WC0	R	R/WC0	R	R/WC0	R	R/WC0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	TXF3	—	TXF2	—	TXF1	—	TXF0	TXRN	TXTO	RXDTO	RXTL	RXTO	RXBRK	TXBRK	TXEND
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/WC0	R	R/WC0	R	R/WC0	R	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R/WC0	R

Bit	Bit Name	Initial Value	R/W	Description
31	TXOVF	0	R/WC0	Transmission FIFO overflow was detected. This bit can be cleared by writing 0 to the bit.
30	RXOVF	0	R/WC0	A frame was received when ACREADY was negated. This bit can be cleared by writing 0 to the bit.
29	RXUDF	0	R/WC0	Reception FIFO was read when there was no data. This bit can be cleared by writing 0 to the bit.
28 to 23	—	All 0	R	Reserved The write value should be the same as the read value.
22	RXF3	0	R/WC0	The reception FIFO bank 3 interrupt was generated. This bit can be cleared by writing 0 to the bit.
21	—	0	R	Reserved The write value should be the same as the read value.
20	RXF2	0	R/WC0	The reception FIFO bank 2 interrupt was generated. This bit can be cleared by writing 0 to the bit.
19	—	0	R	Reserved The write value should be the same as the read value.
18	RXF1	0	R/WC0	The reception FIFO bank 1 interrupt was generated. This bit can be cleared by writing 0 to the bit.
17	—	0	R	Reserved The write value should be the same as the read value.
16	RXF0	0	R/WC0	The reception FIFO bank 0 interrupt was generated. This bit can be cleared by writing 0 to the bit.

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved The write value should be the same as the read value.
14	TXF3	0	R/WC0	The transmission FIFO bank 3 interrupt was generated. This bit can be cleared by writing 0 to the bit.
13	—	0	R	Reserved The write value should be the same as the read value.
12	TXF2	0	R/WC0	The transmission FIFO bank 2 interrupt was generated. This bit can be cleared by writing 0 to the bit.
11	—	0	R	Reserved The write value should be the same as the read value.
10	TXF1	0	R/WC0	The transmission FIFO bank 1 interrupt was generated. This bit can be cleared by writing 0 to the bit.
9	—	0	R	Reserved The write value should be the same as the read value.
8	TXF0	0	R/WC0	The transmission FIFO bank 0 interrupt was generated. This bit can be cleared by writing 0 to the bit.
7	TXRN	0	R/WC0	CAREADY negation in the opposite communication device was detected during the set period. This bit can be cleared by writing 0 to the bit. If 1 is set in HSI_TXRNCR.TXRNSTP, transmission is temporarily suspended upon detection. Transmission is resumed when this bit is cleared.
6	TXTO	0	R/WC0	TXFIFO was detected to be nonempty and CAREADY negation in the opposite communication device was detected during the set period. This bit can be cleared by writing 0 to the bit. If 1 is set in HSI_TXTOCR.TXTOSTP, transmission is temporarily suspended upon detection. Transmission is resumed when this bit is cleared.
5	RXDTO	0	R/WC0	Activity suspension of the opposite communication device was detected during the set period. This bit can be cleared by writing 0 to the bit.
4	RXTL	0	R/WC0	The tailing bit was detected after frame reception. This bit can be cleared by writing 0 to the bit.
3	RXTO	0	R/WC0	Timeout occurred during frame reception. This bit can be cleared by writing 0 to the bit.

Bit	Bit Name	Initial Value	R/W	Description
2	RXBRK	0	R/WC0	Break transmission was received. This bit can be cleared by writing 0 to the bit. This bit is set regardless of the value of HSI_IRQCR.RXBRKEN.
1	TXBRK	0	R/WC0	Transmission of break transmission was completed. This bit can be cleared by writing 0 to the bit. This bit is set regardless of the value of HSI_IRQCR.TXBRKEN.
0	TXEND	1	R	Transmission of all the frames stored in TXFIFO and requested break transmission was completed. This bit is set regardless of the value of HSI_IRQCR.TXENDEN.

26.4.16 IO Port Control Register (HSI_IOCR)

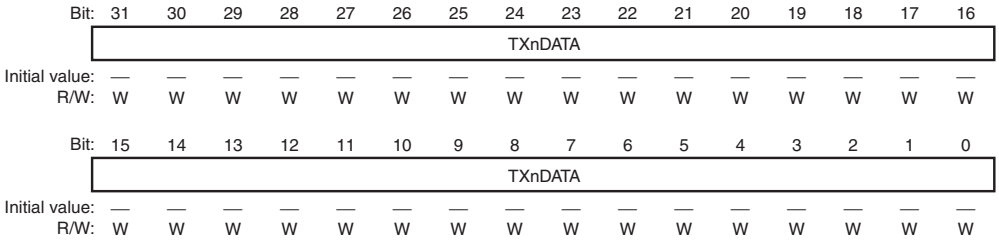
HSI_IOCR is a 32-bit readable/writable register that monitors and changes the state of the pins.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	CARDY	—	—	—	ACRDY	—	—	—	CA WAKE	—	—	—	AC WAKE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved The write value should be the same as the read value.
12	CARDY	0	R	Indicates the CAREADY status.
11 to 9	—	All 0	R	Reserved The write value should be the same as the read value.
8	ACRDY	0	R	Indicates the ACREADY status.

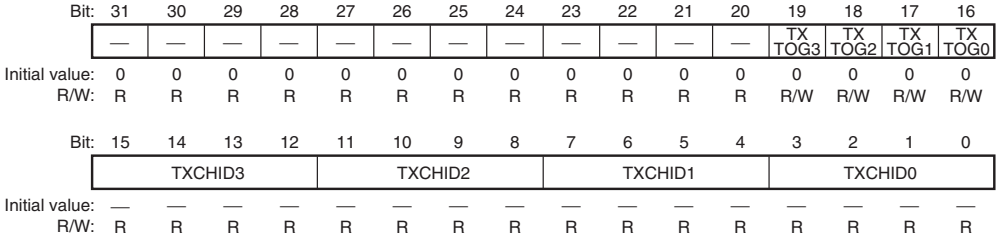
Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	All 0	R	Reserved The write value should be the same as the read value.
4	CAWAKE	0	R	Indicates the CAWAKE status.
3 to 1	—	All 0	R	Reserved The write value should be the same as the read value.
0	ACWAKE	0	R/W	Changes the ACWAKE status.



26.4.17 TXCH_ID Register (Banks 0 to 3) (HSI_TX_CH0 to HSI_TX_CH3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	TXnCHID			
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W



Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	Undefined	W	Reserved The write value should be the same as the read value.
3 to 0	TXnCHID	Undefined	W	The channel ID of the data to be stored in the transmission FIFO bank n should be set. The bit count should be the same as that of HSI_TXCR.TXCHLEN. Data is written to the transmission FIFO simultaneously when data is written to TXnDATA. Writing to TXnCHID does not allow data to be written to the transmission FIFO.

26.4.18 TX Data Window (Banks 0 to 3) (HSI_TX_DATA0 to HSI_TX_DATA3)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TXnDATA	Undefined	W	The data in the frame to be stored in the transmission FIFO bank n should be written. The current value of TXnDATA and the value previously set in TXnCHID are stored as a set in the transmission FIFO bank n. When HSI_DMATXCR.TXDnASNEN is enabled, the current value of TXnDATA and the value of HSI_DMATXCR.TXDnCHID are stored as a set in the transmission FIFO bank n.

26.4.19 TXCH_ID Status Register (HSI_TX_CHSR)

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved The write value should be the same as the read value.

Bit	Bit Name	Initial Value	R/W	Description
19	TXTOG3	0	R/W	Sets whether the channel ID or the data is to be written to HSI_TX_CHDATA3. Once HSI_TX_CHDATA3 has been written to, the setting automatically toggles between the channel ID and data. 0: Channel ID is written. 1: Data is written.
18	TXTOG2	0	R/W	Sets whether the channel ID or the data is to be written to HSI_TX_CHDATA2. Once HSI_TX_CHDATA2 has been written to, the setting automatically toggles between the channel ID and data. 0: Channel ID is written. 1: Data is written.
17	TXTOG1	0	R/W	Sets whether the channel ID or the data is to be written to HSI_TX_CHDATA1. Once HSI_TX_CHDATA1 has been written to, the setting automatically toggles between the channel ID and data. 0: Channel ID is written. 1: Data is written.
16	TXTOG0	0	R/W	Sets whether the channel ID or the data is to be written to HSI_TX_CHDATA0. Once HSI_TX_CHDATA0 has been written to, the setting automatically toggles between the channel ID and data. 0: Channel ID is written. 1: Data is written.
15 to 12	TXCHID3	Undefined	R	The value written in HSI_TX_CHID3 is set. When HSI_DMATXCR.TXD3ASNEN is enabled, the value of HSI_DMATXCR.TXD3CHID is set when HSI_TX_DATA3 is written to. When TXTOG3 is 0, the value of TXCHID3 is set to the value of the channel ID written to HSI_TX_CHDATA3.

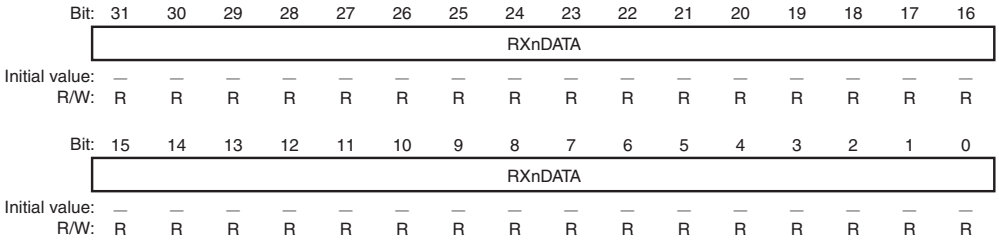
Bit	Bit Name	Initial Value	R/W	Description
11 to 8	TXCHID2	Undefined	R	The value written in HSI_TX_CHID2 is set. When HSI_DMATXCR.TXD2ASNEN is enabled, the value of HSI_DMATXCR.TXD2CHID is set when HSI_TX_DATA2 is written to. When TXTOG2 is 0, the value of TXCHID2 is set to the value of the channel ID written to HSI_TX_CHDATA2.
7 to 4	TXCHID1	Undefined	R	The value written in HSI_TX_CHID1 is set. When HSI_DMATXCR.TXD1ASNEN is enabled, the value of HSI_DMATXCR.TXD1CHID is set when HSI_TX_DATA1 is written to. When TXTOG1 is 0, the value of TXCHID1 is set to the value of the channel ID written to HSI_TX_CHDATA1.
3 to 0	TXCHID0	Undefined	R	The value written in HSI_TX_CHID0 is set. When TXTOG0 is 0, the value of TXCHID0 is set to the value of the channel ID written to HSI_TX_CHDATA0.

26.4.20 TXCH_ID/Data Window (Banks 0 to 3) (HSI_TX_CHDATA0 to HSI_TX_CHDATA3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXnCHDATA															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXnCHDATA															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

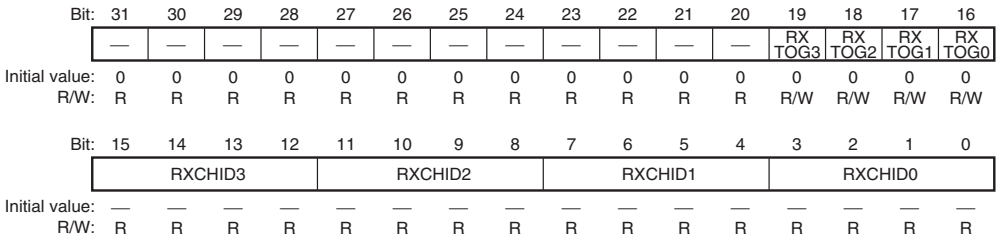
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TXnCHDATA	Undefined	W	When HSI_TX_CHSR.TXTOGn is 0, the channel ID of the data to be stored in the transmission FIFO bank n should be set. The bit count should be the same as that of HSI_TXCR.CHLEN. Writing to TXnCHDATA does not allow data to be written to the transmission FIFO. When HSI_TX_CHSR.TXTOGn is 1, the data of the frame to be stored in the transmission FIFO bank n should be written. The current value of TXnCHDATA and the previously set value of TXnCHID are stored as a set in the transmission FIFO bank n.



26.4.21 RXCH_ID Register (Banks 0 to 3) (HSI_RX_CH0 to HSI_RX_CH3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	RXnCHID			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R



Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved The write value should always be 0.
3 to 0	RXnCHID	Undefined	R	The channel ID stored in the reception FIFO bank n is read. Reading RXnCHID does not allow the channel ID of the next frame stored in the reception FIFO bank n to be retrieved.

26.4.22 RX Data Window (Banks 0 to 3) (HSI_RX_DATA0 to HSI_RX_DATA3)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RXnDATA	Undefined	R	The data of the frame stored in the reception FIFO bank n is read. When reading RXnDATA, the channel ID of the next frame in the reception FIFO bank n is retrieved to HSI_RX_CHn, and the data of the next frame is retrieved to HSI_RX_DATAn. When frame reception is completed and no frames are stored in the reception FIFO bank n, the channel IDs of the received frames are retrieved to HSI_RX_CHn and the data of the received frames are retrieved to HSI_RX_DATAn.

26.4.23 RXCH_ID Status Register (HSI_RX_CHSR)

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved The write value should be the same as the read value.
19	RXTOG3	0	R/W	Sets whether to read the value of HSI_RX_CHDATA3 as a channel ID or data. Once HSI_RX_CHDATA3 is read, the setting automatically toggles between the channel ID and data. 0: Reads channel ID. 1: Reads data.
18	RXTOG2	0	R/W	Sets whether to read the value of HSI_RX_CHDATA2 as a channel ID or data. Once HSI_RX_CHDATA2 is read, the setting automatically toggles between the channel ID and data. 0: Reads channel ID. 1: Reads data.
17	RXTOG1	0	R/W	Sets whether to read the value of HSI_RX_CHDATA1 as a channel ID or data. Once HSI_RX_CHDATA1 is read, the setting automatically toggles between the channel ID and data. 0: Reads channel ID. 1: Reads data.
16	RXTOG0	0	R/W	Sets whether to read the value of HSI_RX_CHDATA0 as a channel ID or data. Once HSI_RX_CHDATA0 is read, the setting automatically toggles between the channel ID and data. 0: Reads channel ID. 1: Reads data.
15 to 12	RXCHID3	Undefined	R	The value read is the same as the value of HSI_RX_CH3.RX3CHID.
11 to 8	RXCHID2	Undefined	R	The value read is the same as the value of HSI_RX_CH2.RX2CHID.
7 to 4	RXCHID1	Undefined	R	The value read is the same as the value of HSI_RX_CH1.RX1CHID.
3 to 0	RXCHID0	Undefined	R	The value read is the same as the value of HSI_RX_CH0.RX0CHID.

26.4.24 RXCH_ID/Data Window (Banks 0 to 3) (HSI_RX_CHDATA0 to HSI_RX_CHDATA3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RXnCHDATA															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXnCHDATA															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RXnCHDATA	Undefined	R	When HSI_RX_CHSR.RXTOGn is 0, the channel ID stored in the reception FIFO bank n is read. Reading this bit does not allow the channel ID of the next frame stored in the reception FIFO bank n to be retrieved. When HSI_RX_CHSR.RXTOGn is 1, data stored in the reception FIFO bank n is read. When this bit is read, the channel ID of the next frame stored in the reception FIFO bank n is retrieved in this register. When frame reception is completed and no frames are stored in the reception FIFO bank n, the channel IDs of the received frames are retrieved in this register.

26.5 Operation

26.5.1 Transmission Interface

Figure 26.2 is an overview of the transmission interface.

When the ACDATA signal is the same value for two continuous bits, the ACFLAG signal is toggled. Furthermore, the values of the ACDATA and ACFLAG signals last transmitted are maintained in inter-frame.

The CAREADY signal is used in the module after being synchronized with the bus clock.

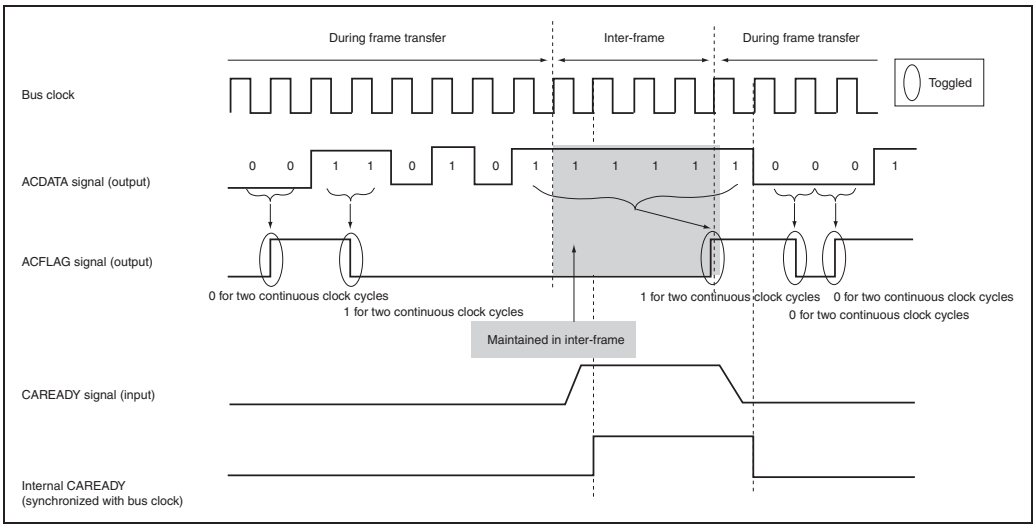


Figure 26.2 Overview of Transmission Interface

26.5.2 Reception Interface

Figure 26.3 is an overview of the reception interface.

Because the values of the CADATA and CAFLAG signals are maintained in inter-frame, the CADATA and CAFLAG signals of the inter-frame are ignored.

The ACREADY signal is output after being synchronized with the bus clock.

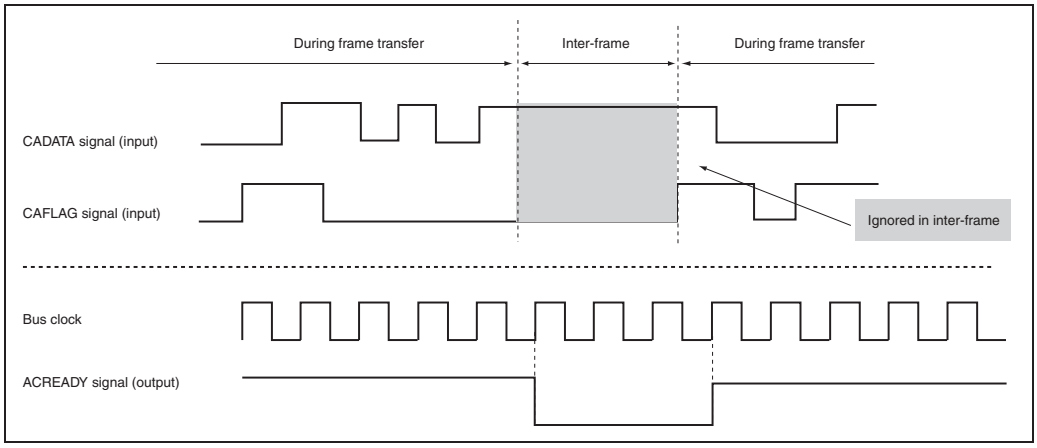

Figure 26.3 Overview of Reception Interface

26.5.3 Transmission FIFO

A transmission FIFO of four 64-frame (4-bit CH, 32-bit data) banks is included (figure 26.4).

An interrupt source or a DMA request can be set for each bank.

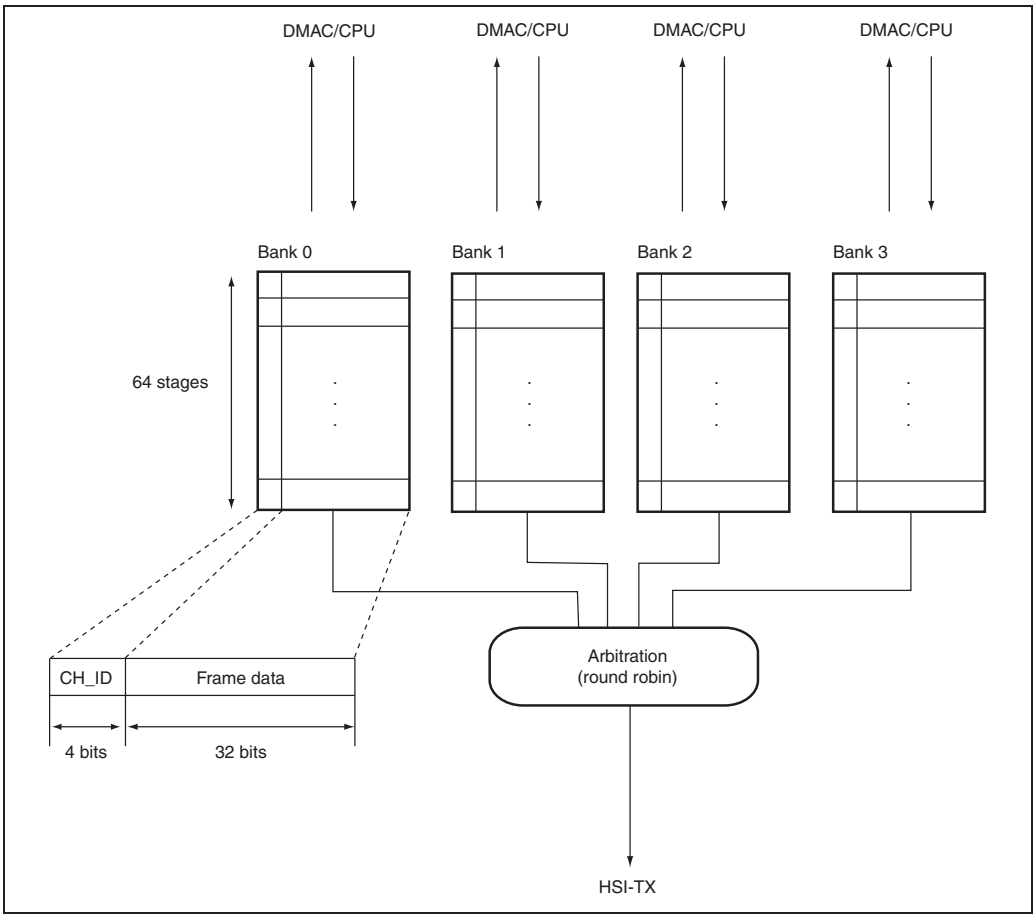

Figure 26.4 Transmission FIFO

26.5.4 Reception FIFO

A reception FIFO of four 64-frame (4-bit CH, 32-bit data) banks is included (figure 26.5).

An interrupt source or a DMA request can be set for each bank.

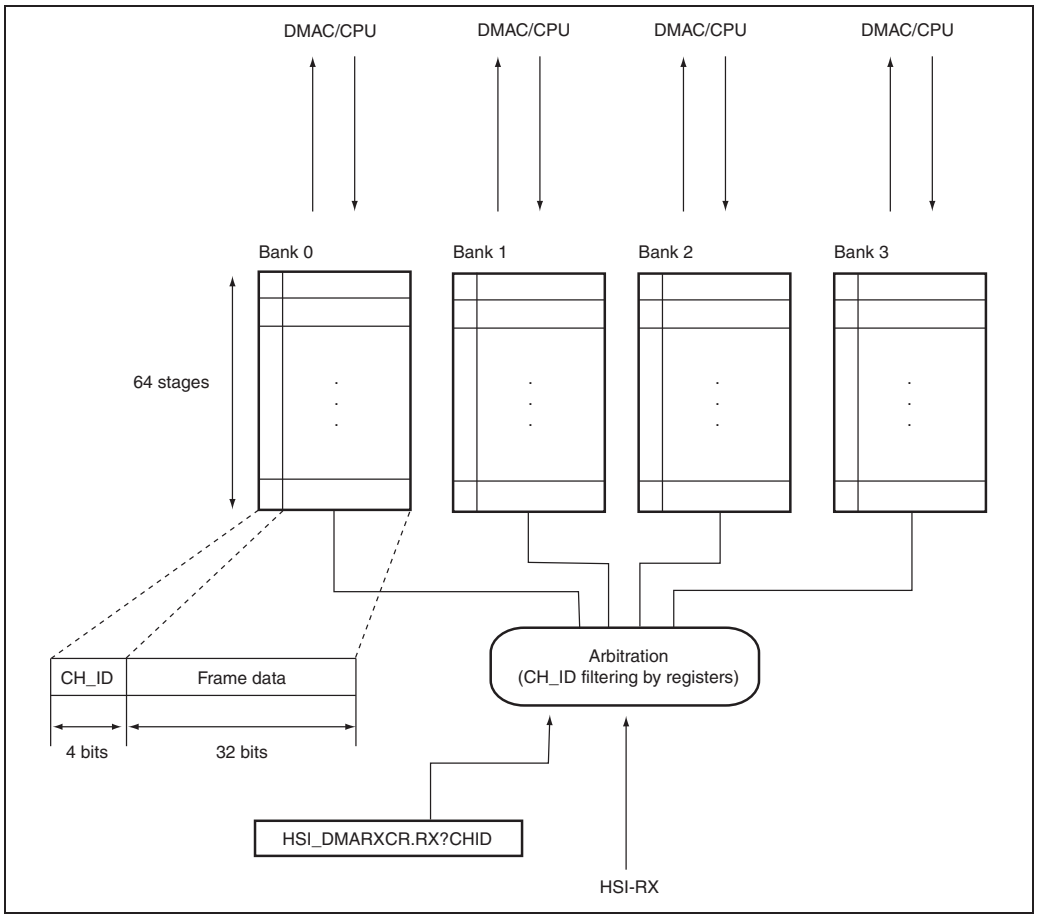

Figure 26.5 Reception FIFO

26.5.5 Transmission Procedure

(1) Transmission System

Transmission FIFO has four banks. Each bank can be operated in parallel and asynchronously.

When multiple banks are to be operated simultaneously, the round robin system is used in which the banks having transmission awaiting frames take turns with transmission each frame.

When transmission sequence is to be confirmed, transmit data using one bank at a time in a sequence.

(2) Preparation of Data to be Transmitted

Data to be transmitted to the memory can be prepared in the form of frame data only and in the form of CH_ID and frame data MIX (figure 26.6).

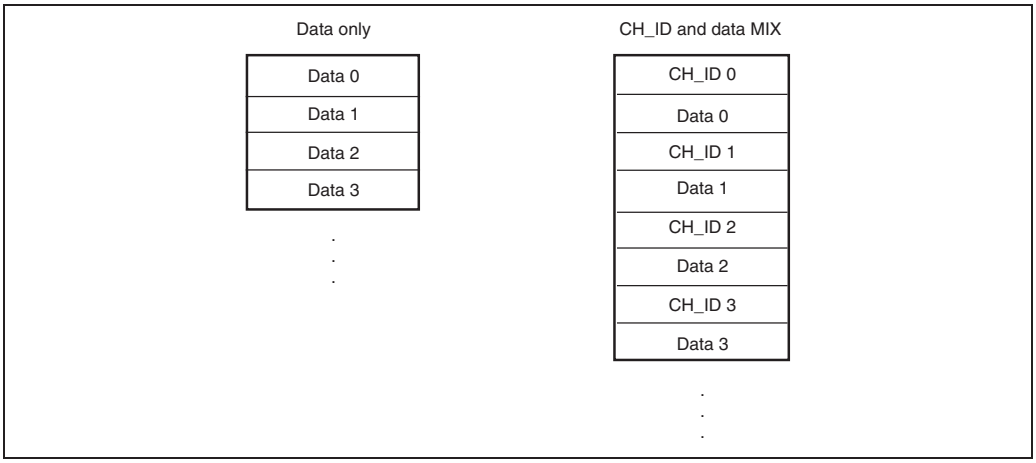

Figure 26.6 Memory Storage Form of Transmit Data

In the form of frame data only, the longword frame data is continuously arranged from the start address of the memory. In the form of CH_ID and frame data MIX, CH_ID that is arranged at the lower position of the longword and the corresponding longword frame data are arranged at alternate positions.

(3) Transmission Start Procedure

Change pin settings and select CAREADY, ACWAKE, ACFLAG, and ACDATA.

Set HSI_IOCR.ACWAKE to 1. Set HSI_TXRNCR, HSI_TXTOCR, HSI_TXBRKCR, and HSI_IRQCR and enable interrupts related to each error.

When carrying out data transfer using multiple banks, HSI_DMATXCR.TXDnASNEN and HSI_DMATXCR.TXDnCHID should also be set. When data is to be transferred through the CPU, HSI_IRQCR.TXFnEN should be set. When data is to be transferred through DMA, HSI_DMATXCR.TXDnEN should be set. For details, see sections 26.5.5 (4) and 26.5.5 (5). HSI_IRQCR.TXFnEN and HSI_DMATXCR.TXDnEN should not be used simultaneously.

When 1 is set to HSI_TXCR.TXSTART after carrying out the above settings, the transmission operation starts according to the settings simultaneously written to HSI_TXCR. Note that TXBRKLEN, TXRATE, TXRATEEN, TXCHLEN, and TXMODE set in HSI_TXCR should not be changed when the transmitter is being operated.

(4) Procedure for Transferring through CPU

(a) Frame Data Only (only banks 1 to 3)

When banks 1 to 3 are to be used, set HSI_DMATXCR.TXDnASNEN to 1 and set CH_ID that is to be assigned to HSI_DMATXCR.TXDnCHID. Check that there is enough space in the transmission FIFO by reading transmission FIFO interrupt or HSI_TXFSR and write frame data to HSI_TX_DATA1 to HSI_TX_DATA3. The transmission operation of HSI starts according to the transmission start procedure. Transmission can be started before or during writing the frame data.

When bank 0 is to be used, transmission in the form of frame data only cannot be carried out.

(b) CH_ID and Frame Data MIX

When bank n is to be used, check that there is enough space in the transmission FIFO by reading transmission FIFO interrupt or HSI_TXFSR, and alternately write the channel ID to HSI_TX_CHn and frame data to HSI_TX_DATAn. The transmission operation of HSI starts according to the transmission start procedure. Transmission can be started before or during writing the frame data.

(5) Procedure for Transferring through DMAC

(a) Frame Data Only

When banks 1 to 3 are to be used, set HSI_DMATXCR.TXDnASNEN to 1 and set CH_ID that is to be assigned to HSI_DMATXCR.TXDnCHID.

The transmission operation of HSI starts according to the transmission start procedure.

In the memory, data is stored in the form of frame data only.

Check that there is enough space in the transmission FIFO by reading transmission FIFO interrupt or HSI_TXFSR.

Specify HSI_TX_DATAn as a transfer destination of the DMAC and set and activate the DMAC.

Set HSI_DMATXCR.TXDnEN to the value other than 0. If the transmission FIFO has more space than specified, the DMA request is output according to the settings of HSI_DMATXCR.TXDnEN.

When transmission is carried out through the DMAC, the value set in HSI_TX_CHn is not used.

When bank 0 is to be used, transmission in the form of frame data only cannot be carried out.

(b) CH_ID and Frame Data MIX

The transmission operation of HSI starts according to the transmission start procedure.

In the memory, the data is stored in the form of CH_ID and frame data MIX.

Check that there is enough space in the transmission FIFO by reading transmission FIFO interrupt or HSI_TXFSR.

Check whether toggle bits of CH_ID and data of TX Ch_ID status register are 0. If any toggle bit is 1, set it to 0.

Specify HSI_TX_CHDATAn as the transfer destination of the DMAC and set and activate the DMAC.

Set HSI_DMATXCR.TXDnEN to the value other than 0. If the transmission FIFO has more space than specified, the DMA request is output according to the settings of HSI_DMATXCR.TXDnEN.

When the transmission is carried out through the DMAC, the value set in HSI_TX_CHn is not used.

(6) Executing Procedure for Break Transmission

If 1 is written to HSI_TXCR.TXBRK when data is being transmitted in the TX transmission start procedure, break transmission is executed at the boundary of the frame that is currently being transmitted. Once transmission is completed, 1 is set to HSI_IRQSR.TXBRK. After issuing the break transmission, 0 should be written to HSI_TXCR.TXBRK.

26.5.6 Reception Procedure

(1) Reception System

Reception FIFO has four banks. By specifying the specific CH_ID in banks 1 to 3, bank 0 and multiple banks can be operated simultaneously. Each bank can be operated in parallel and asynchronously.

When reception sequence is to be confirmed, receive data using one bank at a time.

(2) Memory Storage Method for Received Data

Received data can be stored in the memory in the form of frame data only and in the form of CH_ID and frame data MIX (figure 26.7).

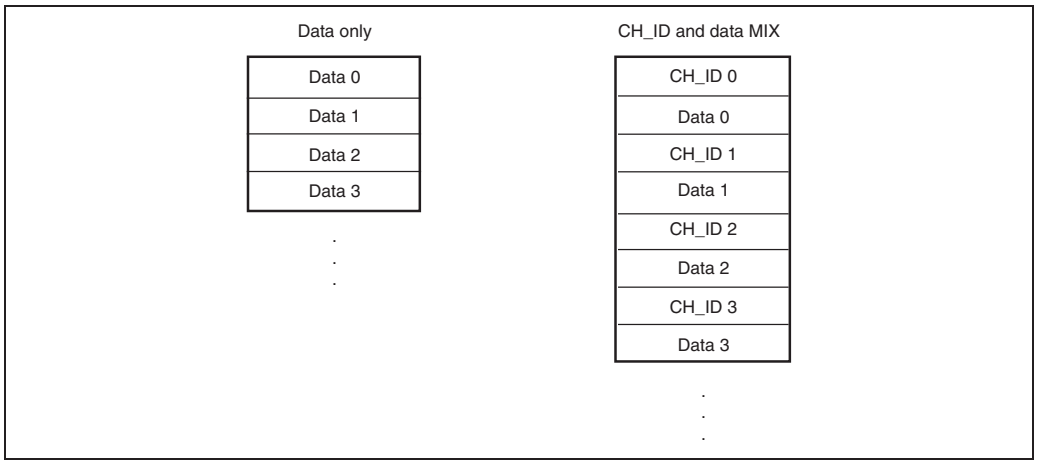

Figure 26.7 Memory Storage Form of Received Data

In the form of frame data only, the longword frame data is continuously arranged from the start address of the memory. In the form of CH_ID and frame data MIX, CH_ID that is arranged at the

lower position of the longword and the corresponding longword frame data are arranged at alternate positions.

(3) Reception Start Procedure

Change pin settings and select ACREADY, CAWAKE, CAFLAG, and CADATA.

Set HSI_RXTOCR, HSI_RXTLCR, HSI_RXDTOCR and HSI_IRQCR and enable interrupts related to each error.

When carrying out data transfer using multiple banks, HSI_DMARXCR.RXDnASNEN and HSI_DMARXCR.RXDnCHID should also be set. When data is to be transferred through the CPU, HSI_IRQCR.RXFnEN should be set. When data is to be transferred through DMA, HSI_DMARXCR.RXDnEN should be set. For details, see sections 26.5.6 (4) and 26.5.6 (5). HSI_IRQCR.RXFnEN and HSI_DMARXCR.RXDnEN should not be used simultaneously.

When 1 is set to HSI_RXCR.RXSTART after carrying out the above settings, the reception operation starts according to the settings simultaneously written to HSI_RXCR. Note that the value set in HSI_RXCR should not be changed when the receiver is being operated. When the transmitter of the opposite communication device is being operated, HSI_RXCR.RXSTART should not be set to 0.

(4) Procedure for Transferring through CPU

(a) Frame Data Only

When banks 1 to 3 are to be used, set HSI_DMARXCR.RXDnASNEN to 1 and set CH-ID that is to be assigned to HSI_DMARXCR.RXDnCHID.

The reception operation of this HSI starts according to the reception start procedure.

Check that the reception FIFO has received data by the reception FIFO frame reception interrupt or reading HSI_RXFSR.

When reading data that is received from bank 0, first, CH_ID is read from HSI_RX_CH0.

Next, the frame data is read from HSI_RX_DATA0.

When banks 1 to 3 are to be used, the CH_ID, which is set in HSI_DMARXCR.RXDnCHID, is used as the CH_ID. When the CH_ID is not necessary, the frame data is read from HSI_RX_DATAn. When the CH_ID is used, similarly as bank 0, the CH_ID is read from HSI_RX_CHn, and next, the frame data is read from HSI_RX_DATAn.

The next data is read from each bank of the reception FIFO by reading HSI_RX_DATAn, not by reading HSI_RX_CHn.

(b) CH_ID and Frame Data Mix

When banks 1 to 3 are to be used, set HSI_DMARXCR.RXDnASNEN to 1 and set CH_ID that is to be assigned to HSI_DMARXCR.RXDnCHID.

Check whether HSI_RX_CHSR.RXTOGn is 0, and if HSI_RX_CHSR.RXTOGn is 1, set it to 0.

The reception operation of this HSI starts according to the reception start procedure.

Check that the reception FIFO has received data by the reception FIFO frame reception interrupt or reading HSI_RXFSR. Data is read from HSI_RX_CHDATAn for each frame in the sequence of CH_ID and frame data.

(5) Procedure for Transferring through DMAC

(a) Frame Data Only

When banks 1 to 3 are to be used, set HSI_DMARXCR.RXDnASNEN to 1 and set CH_ID that is to be assigned to HSI_DMARXCR.RXDnCHID.

Specify HSI_RX_DATAn as the transfer source of the DMAC and set and activate the DMAC.

Set HSI_DMARXCR.RXDnEN to the value other than 0.

The reception operation of HSI starts according to the reception start procedure.

If reception FIFO receives data, the DMA request is output according to the settings of HSI_DMARXCR.RXDnEN.

DMA transfer with HSI_RX_DATA0 as the transfer source is possible even for bank 0. However, if the frames having different CH_ID have been received, the information of CH_ID is lost.

(b) CH_ID and Frame Data MIX

When banks 1 to 3 are to be used, set HSI_DMARXCR.RXDnASNEN to 1 and set CH_ID that is to be assigned to HSI_DMARXCR.RXDnCHID.

Check whether HSI_RX_CHSR.RXTOGn is 0, and if HSI_RX_CHSR.RXTOGn is 1, set it to 0.

Specify HSI_RX_CHDATAn as the transfer source of the DMAC and set and activate the DMAC.

Set HSI_DMARXCR.RXDnEN to the value other than 0. The reception operation of HSI starts according to the reception start procedure.

If reception FIFO receives data, the DMA request is output according to the settings of HSI_DMARXCR.RXDnEN.

26.5.7 Transmission Mode and Data Flow

The following shows the transmission modes and the types of data flow that can be selected. For details on each of the transmission modes and the data flow type, see MIPI-HSI Standards manual.

- Transmission modes: Stream mode, frame mode
- Data flow types: Synchronous data flow, pipelined data flow, receiver realtime data flow

26.5.8 Error and Status Notification

The HSI provides functions for error detection and status notification in both the transmitter and the receiver. This section describes each error source and status and the procedures for recovering from errors. The error detection function and status notification function in the transmitter and receiver work independently.

(1) Transmitter Errors

(a) Error Sources in Transmitter

The transmitter in the HSI can detect the following three types of error.

1. Transmission Overflow

   This error occurs when data is written to a transmission FIFO bank that has already become full. If this error occurs, the written data that caused the error is lost and HSI_IRQSR.TXOVF is set to 1. This error detection function is always enabled.

2. TX Ready Negation Timeout

   This error occurs when the opposite communication device continues negating CAREADY for a specified period. If this error occurs, HSI_IRQSR.TXRN is set. When HSI_TXRNCR.TXRNSTP is set to 1'b1, next frame transmission will not start and transmission will be temporarily suspended even if the opposite communication device asserts CAREADY after this error. In this case, clearing HSI_IRQSR.TXRN restarts transmission. This error detection function is enabled by setting HSI_IRQCR.TXRNEN. The timeout period before detection of this error should be specified in HSI_TXRNCR.TXRNC.

3. TX Timeout

   This error occurs when a valid frame stored in the transmission FIFO enters transmission wait state because the opposite communication device continues negating CAREADY for a specified period. If this error occurs, HSI_IRQSR.TXTO is set. When HSI_TXTOCR.TXTOSTP is set to 1'b1, frame transmission will not restart and temporary suspension of transmission will continue even if the opposite communication device asserts CAREADY after this error. In this case, clearing HSI_IRQSR.TXTO restarts transmission. This error detection function is enabled by setting HSI_IRQCR.TXTOEN to 1'b1. The timeout period before detection of this error should be specified in HSI_TXTOCR.TXTOC.

(b) Issuing Break Transmission

Writing 1'b1 to HSI_TXCR.TXBRK during operation in frame mode issues a break transmission at the frame boundary in the current transmission. The break transmission consists of a sequence of 0s whose length is one bit plus the number of bits specified in HSI_TXCR.TXBRKLEN. After a break transmission is completed, HSI_IRQSR.TXBRK is set to 1. Be sure to write 0 to HSI_TXCR.TXBRK after a break transmission. When HSI_TXBRKCR.TXBRKSTP is set to 1'b1, next frame transmission will not start and transmission will be temporarily suspended even if the opposite communication device asserts CAREADY. In this case, clearing HSI_TXCR.TXBRK restarts transmission.

(c) All Frame Transmission End Notification

When all data written to the transmission FIFO has been transmitted and there is no data waiting for transmission or being transmitted, HSI_IRQSR.TXEND is set to 1'b1; in other cases, it is cleared to 1'b0.

(d) Procedures for Recovering from Transmitter Errors

1. When Transmission Overflow has been Detected

   Some data that had been written by the CPU or DMAC has been lost. Clear HSI_IRQSR.TXOVF and then write the lost data again. HSI_IRQS.TXOVF is cleared by writing 0 when it is set to 1.

2. When TX Ready Negation Timeout or TX Timeout has been Detected

   A TX ready negation timeout or a TX timeout is detected when the opposite communication devices keeps CAREADY in non-asserted state for some reason. When the transmitter is in frame mode, issue a break transmission, and after the transmission, check that CAREADY is asserted. The CAREADY status can be checked through HSI_IOCR.CAREADY. When the opposite communication device keeps CAREADY in non-asserted state, the previous frame transmission might have been unsuccessful and the frame should be transmitted again. If CAREADY is not asserted even after a break transmission or if the transmitter is in stream mode, wait again for a certain period of time; if CAREADY is still in non-asserted state after that, restart the opposite communication device.

(2) Receiver Errors

(a) Error Sources in Receiver

The receiver in the HSI can detect the following five types of error.

1. Reception Overflow

   This error occurs when new frame reception is detected while the receiver negates ACREADY; that is, the receiver is not ready for new frame reception. If this error occurs, the receiver stops operation with ACREADY negated and sets HSI_IRQSR.RXOVF. The frame that caused the error and subsequent frames are not written to the reception FIFO. To restart frame reception, set HSI_RXCR.RXFLOW to 2'b10 or 2'b11 and then clear HSI_IRQSR.RXOVF. This error detection function is enabled by setting HSI_IRQCR.RXOVFEN to 1'b1.

2. Reception Underflow

   This error occurs when the reception FIFO is read when it has no valid frame. If this error occurs, the receiver does not stop operation but sets HSI_IRQSR.RXUDF. The frames received after this error will be written to the reception FIFO. This error detection function is enabled by setting HSI_IRQCR.RXUDFEN to 1'b1.

3. RX Drain Timeout

   This error occurs when the opposite communication device does not send any frame for a specified period while the receiver is in Receiver Realtime Data Flow. If this error occurs, the receiver does not stop operation but sets HSI_IRQSR.RXDTO. The receiver can detect suspension of the opposite communication device operation through this error. If this error is detected, clear HSI_RXCR.RXSTART to 1'b0 to stop the receiver. To restart reception after stopping the receiver, use the reception start procedure described before. This error detection function is enabled by setting HSI_IRQCR.RXDTOEN to 1'b1. The period before the receiver recognizes that the opposite communication device has stopped should be specified in HSI_RXDTOCR.

4. RX Tailing Bit Detection

   This error occurs when frame reception is detected before ACREADY is asserted after frame reception is completed while the receiver is in Synchronized Data Flow or Pipelined Data Flow. In Synchronized Data Flow, this error is detected every time a frame is received, and in Pipelined Data Flow, this error is detected in the state where ACREADY is negated. Note that this error is not detected for a sequence of 0s after reception of the last bit of a frame in frame mode. If this error occurs, the receiver stops operation with ACREADY negated and sets HSI_IRQSR.RXTL. The frame that caused the error and subsequent frames will not be written to the reception FIFO. To restart frame reception, set HSI_RXCR.RXFLOW to 2'b10 or 2'b11 and then clear HSI_IRQSR.RXTL. This error detection function is enabled by setting HSI_IRQCR.RXTLEN to 1'b1. The period before this error is detected (the period between completion of frame reception and reassertion of ACREADY) should be specified in HSI_RXTLCR. During this error detection period, ACREADY is not asserted, so the reception throughput is degraded when a long detection period is specified.

5. RX Reception Timeout

   This error occurs when frame reception is not completed within a specified period while the receiver is in Synchronized Data Flow or Pipelined Data Flow. If this error occurs, the receiver stops operation with ACREADY negated and sets HSI_IRQSR.RXTO. The frame that caused the error and subsequent frames will not be written to the reception FIFO. To restart frame reception, set HSI_RXCR.RXFLOW to 2'b10 or 2'b11 and then clear HSI_IRQSR.RXTO. This error detection function is enabled by setting HSI_IRQCR.RXTOEN to 1'b1. The period before this error is detected (the period between start and completion of frame reception) should be specified in HSI_RXTOCR.

(b) Receiving Break Transmission

The receiver detects a break transmission when receiving a sequence of 0s for the same number or a greater number of bits than specified in HSI_RXCR.RXBRKLEN while the receiver is in frame mode. The receiver detects a break transmission regardless of the HSI_IRQCR.RXBRKEN setting. If the receiver detects a break transmission in Synchronized Data Flow or Pipelined Data Flow, it continues working in Synchronized Data Flow or Pipelined Data Flow. If the receiver detects a break transmission while it is in Receiver Realtime Data Flow with HSI_RXCR.RXAFC set to 1'b1, it automatically enters Synchronized Data Flow when HSI_RXCR.RXFLOW is set to 2'b10 or Pipelined Data Flow when HSI_RXCR.RXFLOW is set to 2'b11. An interrupt can be generated when HSI_IRQCR.RXBRKEN is set to 1'b1. Note that even if the opposite communication device issues break transmissions twice or more in a row, the receiver detects them as a single break transmission. The length of the sequence of 0s sent as a break transmission from the opposite communication device should be two or more bits longer than the length of the sequence of 0s that can be recognized as a break transmission by the receiver in the HSI.

(c) Procedures for Recovering from Receiver Errors

1. When Reception Underflow has been Detected

   The read data includes invalid data. Discard the data and then clear HSI_IRQSR.RXUDF. HSI_IRQSR.RXUDF is cleared by writing 0 when it is set to 1.

2. When Reception Overflow, RX Tailing Bit, or RX Reception Timeout has been Detected (Including RX Drain Timeout Detection)

   Figure 26.8 shows the procedure for recovering from a reception overflow, RX tailing bit detection, or RX reception timeout detection error.

   When a reception overflow, RX tailing bit detection, or RX reception timeout error is detected while the receiver is in Synchronized Data Flow or Pipelined Data Flow, the receiver negates ACREADY, stops reception, and then sends an interrupt request to the CPU. Here, note that part of the data in the reception FIFO may be incorrect because synchronization has failed between the opposite communication device and the receiver. In this state, if a correct frame is received after recovering through the procedure described below, the reception FIFO will include a mixture of correct and incorrect data; to avoid this, read data from the reception FIFO before proceeding to the next step.

After reading data from the reception FIFO, modify HSI_RXCR.RXFLOW. If the receiver was in Synchronized Data Flow when the error was detected, modify HSI_RXCR.RXFLOW to 2'b10: if the receiver was in Pipelined Data Flow, modify HSI_RXCR.RXFLOW to 2'b11. When modifying HSI_RXCR, be careful not to modify any bits other than HSI_RXCR.RXFLOW. After that, clearing all of HSI_IRQSR.RXOVF, HSI_IRQSR.RXTL, and HSI_IRQSR.RXTO restarts reception in Receiver Realtime Data Flow. The HSI_IRQSR.RXOVF, HSI_IRQSR.RXTL, and HSI_IRQSR.RXTO error flags are cleared by writing 0 when they are set to 1. The data received here in Receiver Realtime Data Flow is invalid because it is received in the state where synchronization has failed between the opposite communication device and the receiver, and therefore this data is not written to the reception FIFO.

When data is received in Receiver Realtime Data Flow mode, if HSI_RXCR.RXMODE is 1 (frame mode) and HSI_RXCR.RXAFC is 1, the receiver is automatically recovered to Synchronized Data Flow or Pipelined Data Flow upon detection of a break transmission. In this case, the receiver enters Synchronized Data Flow when HSI_RXCR.RXFLOW is set to 2'b10 or Pipelined Data Flow when HSI_RXCR.RXFLOW is set to 2'b11. After completion of this transition to a new Flow, the frames received after a break transmission are written to the reception FIFO.

Likewise, when data is received in Receiver Realtime Data Flow, if HSI_IRQCR.RXDTOEN is 1, the RX drain timeout detection function is enabled. The RX drain timeout detection function detects the period where the opposite communication device transmits nothing. Through RX drain timeout detection and interrupt generation, suspension of the opposite communication device due to a hang-up or a wait for a handshake can be detected to restart the receiver of the HSI. To restart the receiver, clear HSI_RXCR.RXSTART to 0, make the necessary settings for reception again, and then set HSI_RXCR.RXSTART to 1. When specifying the period before detection of an RX drain timeout, be sure to specify a large enough value in HSI_RXDTOCR to prevent restart of the receiver during operation of the opposite communication device.

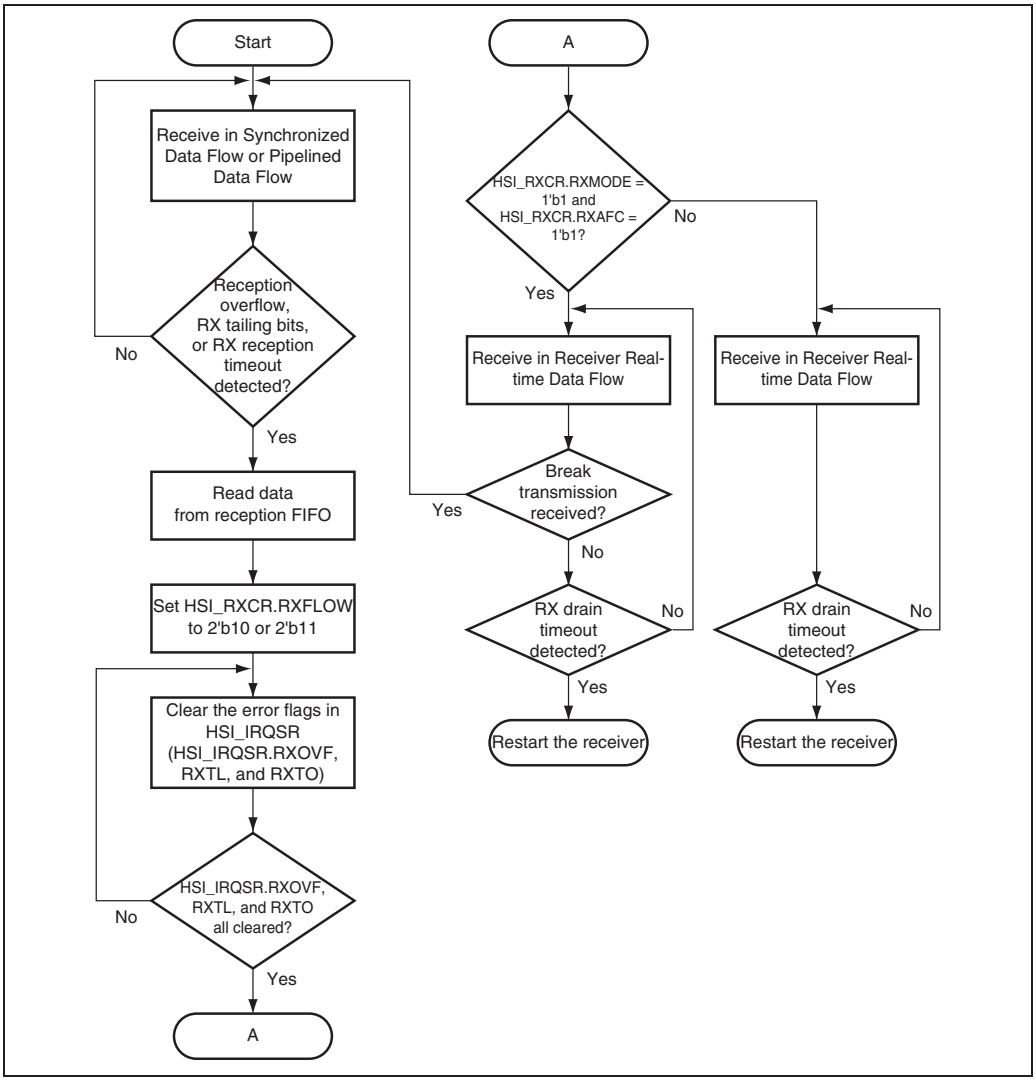

Figure 26.8 Procedure for Recovering from Reception Overflow, RX Tailing Bit Detection, or RX Reception Timeout Detection Error

26.5.9 Interrupts

The following table shows the interrupt sources in this module and the enable bits that enable or disable the interrupt sources. Some interrupt sources can activate the DMAC using the DMA request instead of enabling the interrupt.

Status Bit (HSI_IRQSR)	Enable Bit (HSI_IRQCR)	Content	DMAC Activation
TXOVF	TXOVFEN	Transmission overflow interrupt	Impossible
RXOVF	RXOVFEN	Reception overflow interrupt	Impossible
RXUDF	RXUDFEN	Reception underflow interrupt	Impossible
RXFn	RXFnEN	Reception FIFO bank n interrupt	Possible
TXFn	RXFnEN	Transmission FIFO bank n interrupt	Possible
TXRN	TXRNEN	TX ready negation timeout interrupt	Impossible
TXTO	TXTOEN	TX timeout interrupt	Impossible
RXDTO	RXDTOEN	RX drain timeout detection interrupt	Impossible
RXTL	RXTLEN	RX tailing bit detection interrupt	Impossible
RXTO	RXTOEN	RX reception timeout interrupt	Impossible
RXBRK	RXBRKEN	RX break-transmission reception interrupt	Impossible
TXBRKEND	TXBRKENDEN	TX break-transmission end interrupt	Impossible
TXEND	TXENDEN	TX frame transmission end interrupt	Impossible

Section 27 Multi Media Card Interface (MMCIF)

This module is a host interface supports JEDEC STANDARD JESD84-A43.This module allows connection with Multi Media Card (referred to as MMC hereafter), which is a flash memory card, or HDD that conforms to the Consumer Electronics AT Attachment (CE-ATA) standard, which is an applied version of MMC standard.

27.1 Features

- Supports 1/4/8-bit MMC
- Supports Boot Operation
- MMC clock frequency ≤ 1/2 × bus clock frequency (HPϕ).
- Supports change MMC clock frequency during Boot Operation
- Data buffer : 512 × 2
- Two types of interrupt requests: normal operation and error/timeout.
- DMA transfer requests: buffer write and buffer read
- Supports Command Completion Signal (CCS) and Command Completion Signal Disable (CCSD)

Figure 27.1 shows a block diagram of this module.

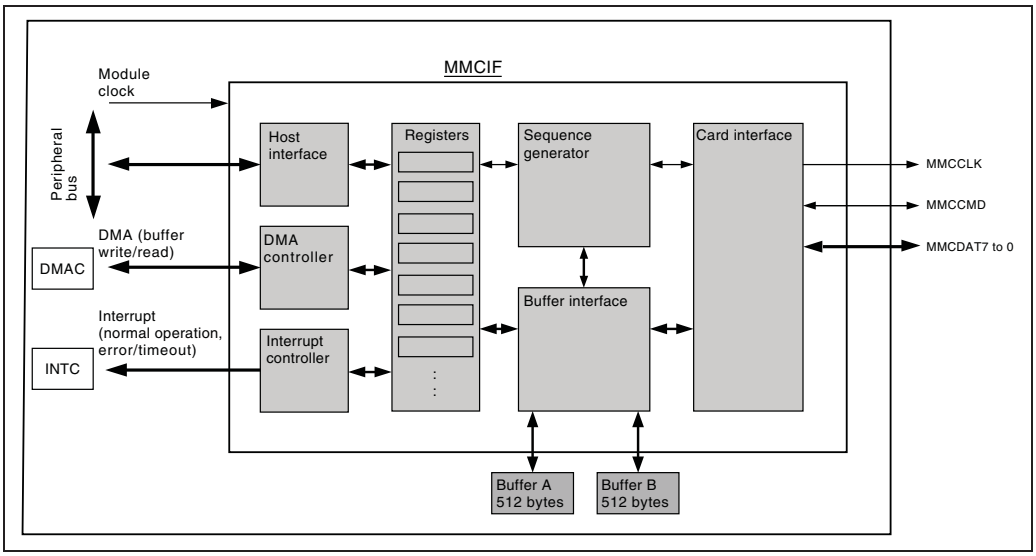

Figure 27.1 Block Diagram of MMCIF

27.2 Input/Output Pins

Table 27.1 shows the pin configuration of the MMCIF.

Table 27.1 Pin Configuration

Pin Name	I/O	Function
MMCCLK	Output	MMC clock
MMCCMD	Input/output	Command/response
MMCDAT[7:0]	Input/output	Transmit/receive data

27.3 Register Descriptions

Table 27.2 shows the register configuration of the MMCIF and Table 27.3 shows the register state in each processing mode.

Table 27.2 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size

27.3.1 Command Setting Register (CE_CMD_SET)

CE_CMD_SET sets a command sequence. The command sequence starts when a command index has been set along with other required settings. If this register is accessed in 16-bit units, the command sequence starts when the settings have been made in bits 31 to 16. Note that writing to CE_CMD_SET is disabled while a command sequence is proceeding (i.e., the value of CMDSEQ in CE_HOST_STS1 is 1). For the setting values of CE_CMD_SET, see section 27.7.17, Setting Values of CE_CMD_SET.

1, 0	DATW[1:0]	00	R/W	Data Bus Width Setting 00: 1 bit 01: 4 bits 10: 8 bits 11: Setting prohibited

27.3.2 Argument Register (CE_ARG)

CE_ARG sets the argument for the command to be transmitted. This register must be set before CMD[5:0] in CE_CMD_SET is set.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ARG[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	ARG[31:0]	H'00000000	R/W	Set bits 31 to 0 of the argument. Note: Set argument for the automatically-issued CMD12 in CE_ARG_CMD12

27.3.3 Argument Register for Automatically-Issued CMD12 (CE_ARG_CMD12)

CE_ARG_CMD12 is used to set the argument for the automatically-issued CMD12 in multi-block transfer. This register must be set before CMD[5:0] in CE_CMD_SET is set. For automatic issuance of CMD12, see section 27.6.4, Automatic CMD12 Issuance.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	CCSD	1'b0	R/W	CCSD Issuance Writing 1 to this bit while it is 0 issues a CCSD. After making sure that the CCSDE bit in CE_INT has become 1, write 0 to this bit to reset. Note: Before issuing a CCSD, make sure that the value of the CMDSEQ bit in CE_HOST_STS1 is 0.
0	BREAK	1'b0	R/W	Forcible Termination of Command Sequence Writing 1 to this bit while it is 0 and then writing 0 to it discontinues the current command sequence. Note: After this bit is set as described above, check if the value of the CMDSEQ bit in CE_HOST_STS1 has become 0, which indicates that the next processing can be performed.

27.3.5 Transfer Block Setting Register (CE_BLOCK_SET)

CE_BLOCK_SET specifies the size of the block and the number of blocks for the data to be transferred. This register must be set before CMD[5:0] in CE_CMD_SET is set.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BLKCNT[15:0]

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	BLKCNT [15:0]	H'0000	R/W	Number of Blocks for Transfer Note: This setting is valid for multi-block transfer.
15 to 0	BLKSIZ [15:0]	H'0200	R/W	Transfer Block Size Note: Transfer block size should be set as follows. • Single-block transfer: 1 to 512 bytes • Multi-block transfer: 512 bytes

27.3.6 Clock Control Register (CE_CLK_CTRL)

CE_CLK_CTRL controls the MMC clock and sets timeout values. Do not change the setting of this register while a command sequence is in progress.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	CLKEN	—	—	—	—	CLKDIV[3:0]

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	CLKEN	0	R/W	MMC Clock Output Control 0: Does not output the MMC clock (tied to low level) 1: Outputs the MMC clock
23 to 20	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	CLKDIV[3:0]	0000	R/W	MMC Clock Frequency Setting 0000: Bus clock/2 0001: Bus clock/2^2 : 0111: Bus clock/2^8 1000: Bus clock/2^9 1001 to 1111: Setting prohibited See section 27.6.5 MMC clock operation during Boot Operation and 27.3.11 Boot Operation register(CE_BOOT) about Boot Operation
15,14	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
13, 12	SRSPTO [1:0]	00	R/W	Response Timeout Setting Specifies the timeout period for the RSPTO bit of CE_INT. 00: 64 MMC clock cycles 01: 128 MMC clock cycles 10: 256 MMC clock cycles 11: Setting prohibited
11 to 8	SRBSYTO [3:0]	0000	R/W	Response Busy Timeout Setting Specifies the timeout period for the RBSYTO bit of CE_INT. 0000: 2^{14} MMC clock cycles 0001: 2^{15} MMC clock cycles : 1110: 2^{28} MMC clock cycles 1111: 2^{29} MMC clock cycles
7 to 4	SRWDTO [3:0]	0000	R/W	Write Data/Read Data Timeout Setting Specifies the timeout period for the WDATTO and RDATTO bits of CE_INT. 0000: 2^{14} MMC clock cycles 0001: 2^{15} MMC clock cycles : 1110: 2^{28} MMC clock cycles 1111: 2^{29} MMC clock cycles
3 to 0	SCCSTO [3:0]	0000	R/W	CCS Timeout Setting Specifies the timeout period for the CCSTO bit of CE_INT. 0000: 2^{14} MMC clock cycles 0001: 2^{15} MMC clock cycles : 1110: 2^{28} MMC clock cycles 1111: 2^{29} MMC clock cycles

27.3.7 Buffer Access Configuration Register (CE_BUF_ACC)

CE_BUF_ACC configures the method of accessing data registers and mode of DMA transfer. This register must be set before CMD[5:0] in CE_CMD_SET is set. For explanation of the buffers, see section 27.6.3, Buffer Structure and Access Buffer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

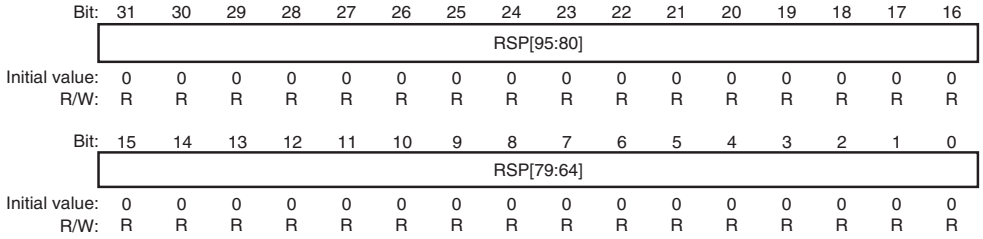
Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	DMAWEN	0	R/W	Buffer Write DMA Transfer Request Enable 0: Disables DMA transfer request for buffer writing 1: Enables DMA transfer request for buffer writing
24	DMAREN	0	R/W	Buffer Read DMA Transfer Request Enable 0: Disables DMA transfer request for buffer reading 1: Enables DMA transfer request for buffer reading
23 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17	BUSW	0	R/W	Data register access size selection 0: When access to CE_DATA in 32-bit. 1: When access to CE_DATA in 16-bit.
16	ATYP	0	R/W	Select access buffer 0: Without swapped byte-wise 1: With swapped byte-wise. Note: See section 27.6.3 Buffer Structure and Access Buffer

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

27.3.8 Response Registers 3 to 0 (CE_RESP3 to CE_RESP0)



CE_RESP3 to CE_RESP0 are the registers for storing the response that has been received. For the formats of response values, see section 27.6.1, Command/Response Formats.

- CE_RESP3

Bit	Bit Name	Initial Value	R/W	Description (CE_RESP3)
31 to 0	RSP[127:96]	H'00000000	R	R2 response [127:96]

- CE_RESP2

Bit	Bit Name	Initial Value	R/W	Description (CE_RESP2)
31 to 0	RSP[95:64]	H'00000000	R	R2 response [95:64]

- CE_RESP1

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RSP[63:48]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RSP[47:32]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description (CE_RESP1)
31 to 0	RSP[63:32]	H'00000000	R	R2 response [63:32]

- CE_RESP0

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RSP[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RSP[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description (CE_RESP0)
31 to 0	RSP[31:0]	H'00000000	R	Response [31:0] or R2 response [31:0]

27.3.9 Response Register for Automatically-Issued CMD12 (CE_RESP_CMD12)

CE_RESP_CMD12 is the register for storing the response to the automatically-issued CMD12.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RSP12[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RSP12[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RSP12[31:0]	H'00000000	R	CMD12 response [31:0]

27.3.10 Datta Register (CE_DATA)

CE_DATA is used to access the buffers of this module. In 16-bit access, only DATA[31:16] is accessible. For the write/read data formats, see section 27.6.2, Data Formats.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DATA[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATA[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DATA[31:0]	H'00000000	R/W	Buffer write/read data [31:0]

27.3.11 Boot Operation setting Register (CE_BOOT)

CE_BOOT is the register for setting MMC clock frequency and the timeout period for Boot Operation. Do not change the setting of this register while a command sequence is in progress.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BTCLKDIV[3:0]				SBTACKTO[3:0]				S1STBTDATTO[3:0]				SBTDATTO[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	BTCLKDIV [3:0]	0000	R/W	MMC Clock Frequency Setting for Boot Operation 0000: Bus clock/2 0001: Bus clock/2^2 : 0111: Bus clock/2^8 1000: Bus clock/2^9 1001 to 1111: Setting prohibited Set value less than CE_CLK_CTRL.CLKDIV to BTCLKDIV See section 27.6.5 MMC clock operation during Boot Operation
27 to 24	SBTACKTO [3:0]	0000	R/W	Boot Acknowledge Timeout Setting 0000: 2^{14} MMC clock cycles 0001: 2^{15} MMC clock cycles : 1110: 2^{28} MMC clock cycles 1111: 2^{29} MMC clock cycles

Bit	Bit Name	Initial Value	R/W	Description
23 to 20	S1STBTDATTO[3:0]	0000	R/W	1st Boot Timeout Setting 0000: 2^{14} MMC clock cycles 0001: 2^{15} MMC clock cycles : 1110: 2^{28} MMC clock cycles 1111: 2^{29} MMC clock cycles
19 to 16	SBTDATTO[3:0]	0000	R/W	Boot Interval Timeout Setting 0000: 2^{14} MMC clock cycles 0001: 2^{15} MMC clock cycles : 1110: 2^{28} MMC clock cycles 1111: 2^{29} MMC clock cycles
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

27.3.12 Interrupt Flag Register (CE_INT)

CE_INT indicates various statuses during execution of a command sequence. Each bit is set when its setting condition has been met. To clear flag(s), write 0 only to the bit(s) to be cleared and write 1 to the other bits.

For the operation in the case of an error or timeout, see section 27.6.6, Operation in the Case of Error/Timeout.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	00	R	Reserved These bets are always read as 0. The writing value should always be 0.
29	CCSDE	0	R/W*	CCSD Issuance Complete [Setting conditions] CCSD has been issued [Clearing condition] Writing a 0 to this bit
28, 27	—	00	R	Reserved These bets are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
26	CMD12DRE	0	R/W*	Automatic CMD12 Issuance & Buffer Read Complete [Setting conditions] Response busy for automatically-issued CMD12 and buffer reading have been completed. [Clearing condition] Writing a 0 to this bit Note: When CMD12DRE has been set, CMD12RBE, CMD12CRE, and BUFRE have also been set. So, these bits should be cleared as well.
25	CMD12RBE	0	R/W*	Automatic CMD12 Issuance Response Busy Complete [Setting conditions] Reception of the response and response busy for an automatically-issued CMD12 have been completed. [Clearing condition] Writing a 0 to this bit Note: When CMD12RBE has been set, CMD12CRE has also been set. So, this bit should be cleared as well.
24	CMD12CRE	0	R/W*	Automatic CMD12 Response Complete [Setting conditions] The response to an automatically-issued CMD12 has been received. [Clearing condition] Writing a 0 to this bit
23	DTRANE	0	R/W*	Data Transmission Complete [Setting conditions] Transmission of all blocks of data has been completed. • When configured to receive CRC status: Completion of busy (data busy) after reception of CRC status • When configured not to receive CRC status: Completion of data transmission [Clearing condition] Writing a 0 to this bit

Bit	Bit Name	Initial Value	R/W	Description
22	BUFRE	0	R/W*	Buffer Read Complete [Setting conditions] All blocks of data have been received and the data have been read from the buffer [Clearing condition] Writing a 0 to this bit
21	BUFWEN	0	R/W*	Buffer Write Ready [Setting conditions] The buffer has become empty and ready for writing. [Clearing condition] Writing a 0 to this bit Note: This bit is not set when DMA transfer request for buffer writing is enabled.
20	BUFREN	0	R/W*	Buffer Read Ready [Setting conditions] Transfer block size of data have been stored in the buffer and it has become ready for reading [Clearing condition] Writing a 0 to this bit Note: This bit is not set when DMA transfer request for buffer reading is enabled.
19	CCSRCV	0	R/W*	CCS Reception Complete [Setting conditions] CCS has been received. [Clearing condition] Writing a 0 to this bit
18	—	0	R	Reserved This bet is always read as 0.The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
17	RBSYE	0	R/W*	Response Busy Complete [Setting conditions] Reception of a response and response busy have been completed. [Clearing condition] Writing a 0 to this bit Note: When RBSYE has been set, CRSPE has also been set. So, this bit should be cleared as well. Completion of reception of the response and response busy for automatically-issued CMD12 is reflected in CMD12RBE.
16	CRSPE	0	R/W*	Command/Response Complete [Setting conditions] A command has been transmitted or a response has been received • When configured not to receive response: A command has been transmitted • When configured to receive 6- or 17-byte response: A response has been received [Clearing condition] Writing a 0 to this bit Note: Completion of reception of the response to automatically-issued CMD12 is reflected in CMD12CRE.

Bit	Bit Name	Initial Value	R/W	Description
15	CMDVIO	0	R/W*	Command Issuance Error [Setting conditions] Illegal setting has been made in CE_CMD_SET or CE_BLOCK_SET. • During execution of a command sequence: Writing to CMD[5:0] in CE_CMD_SET • At the start of command sequence: Writing to CMD[5:0] in CE_CMD_SET when the registers have been set for one of the following combinations of selection — No response + response busy — No response + with data — No response + acceptance of CCS enabled — No data + automatic CMD12 issuance — With data + single-block transfer + automatic CMD12 issuance — With data + automatic CMD12 issuance + acceptance of CCS enabled — With data + transfer block size = 0 — With data + transfer block size ≥ 513 — With data + multi-block transfer + number of blocks for transfer = 0 [Clearing condition] Writing a 0 to this bit Note: When CMDVIO has been set, the command sequence is not stopped automatically.

Bit	Bit Name	Initial Value	R/W	Description
14	BUFVIO	0	R/W*	Buffer Access Error [Setting conditions] Illegal buffer access has been attempted. • CE_ DATA has been accessed exceeding the block size set in BLKSIZ[15:0] in CE_BLOCK_SET • While data is being read from the card: CE_DATA has been accessed with BUFREN not set (when DMA is used, with no DMA transfer request asserted for buffer reading) • While data is being written to the card: CE_DATA has been accessed with BUFWEN not set (when DMA is used, with no DMA transfer request asserted for buffer writing) [Clearing condition] Writing a 0 to this bit Note: When BUFVIO has been set, the command sequence is not stopped automatically.
13, 12	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
11	WDATERR	0	R/W*	Write Data Error [Setting conditions] Error is found in the data that has been written. • Error is in the status of the CRC status • Error is in the end bits of the CRC status [Clearing condition] Writing a 0 to this bit Note: When WDATERR has been set, the command sequence is stopped automatically.

Bit	Bit Name	Initial Value	R/W	Description
10	RDATERR	0	R/W*	Read Data Error [Setting conditions] Error is found in the read data. • Error is in CRC16 of the read data • Error is in the end bits of the read data [Clearing condition] Writing a 0 to this bit Note: When RDATERR has been set, the command sequence is stopped automatically.
9	RIDXERR	0	R/W*	Response Index Error [Setting conditions] Error has been found in the index value of the response. • When RIDXC[1:0] in CE_CMD_SET is 2'b00: The index value in the received response does not match that of the transmitted command • When RIDXC[1:0] in CE_CMD_SET is 2'b01: The check bits are not all 1 [Clearing condition] Writing a 0 to this bit Note: When RIDXERR has been set, the command sequence is stopped automatically.

Bit	Bit Name	Initial Value	R/W	Description
8	RSPERR	0	R/W*	Response Error [Setting conditions] Error has been found in the response values of the response. • Transmission bit in the response is high • Error is in the end bits of the response • When RCRC7C[1:0] in CE_CMD_SET is 2'b00: Error is in CRC7 of the response • When RCRC7C [1:0] in CE_CMD_SET is 2'b01: The check bits are not all 0 • When RCRC7C[1:0] in CE_CMD_SET is 2'b10: Error is in internal CRC7 of the response [Clearing condition] Writing a 0 to this bit Note: When RSPERR has been set, the command sequence is stopped automatically.
7, 6	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
5	CCSTO	0	R/W*	CCS Timeout [Setting conditions] CCS could not be received [Clearing condition] Writing a 0 to this bit Note: The period for timeout detection is set in SCCSTO[3:0] of CE_CLK_CTRL. The command sequence is not stopped even if CCSTO is set.
4	CRCSTO	0	R/W*	CRC Status Timeout [Setting conditions] CRC status could not be received [Clearing condition] Writing a 0 to this bit Note: The command sequence is not stopped even if CRCSTO is set.

Bit	Bit Name	Initial Value	R/W	Description
3	WDATTO	0	R/W*	Write Data Timeout [Setting conditions] Data busy that follows CRC status does not end [Clearing condition] Writing a 0 to this bit Note: The period for timeout detection is set in SRWDTO[3:0] of CE_CLK_CTRL. The command sequence is not stopped even if WDATTO is set.
2	RDATTO	0	R/W*	Read Data Timeout [Setting conditions] Read data could not be received [Clearing condition] Writing a 0 to this bit Note: The period for timeout detection is set in SRWDTO[3:0] of CE_CLK_CTRL. The command sequence is not stopped even if RDATTO is set.
1	RBSYTO	0	R/W*	Response Busy Timeout [Setting conditions] Response busy does not end [Clearing condition] Writing a 0 to this bit Note: The period for timeout detection is set in SRBSYTO[3:0] of CE_CLK_CTRL. The command sequence is not stopped even if RBSYTO is set.
0	RSPTO	0	R/W*	Response Timeout [Setting conditions] Response could not be received [Clearing condition] Writing a 0 to this bit Note: The period for timeout detection is set in SRSPTO[1:0] of CE_CLK_CTRL. The command sequence is not stopped even if RSPTO is set.

Note: * A 0 is the only value that can be written to these bits. Writing a 1 is ignored.

27.3.13 Interrupt Mask Register (CE_INT_MASK)

CE_INT_MASK controls output of the CE_INT-related interrupt signals. If a flag in CE_INT is set to 1 while its corresponding bit in CE_INT_MASK is set to 1, an interrupt request is output. For details on interrupt requests, see section 27.4, Interrupt Requests.

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	CMDSEQ	0	R	Command Sequence in Progress 0: Command sequence is in the initial state 1: Command sequence is being executed
30	CMDSIG	Undefined	R	CMD Line Status Indicates the state on the command line.
29 to 24	RSPIDX [5:0]	H'00	R	Response Index Indicate the index of the response that has been received
23 to 16	DATSIG [7:0]	Undefined	R	DAT[7:0] Status Indicate the states on the DAT lines Note:When transfer error or timeout error occur, MMCDAT[0] may be with 1’b0.
15 to 0	RCVBLK [15:0]	H'0000	R	Number of Transferred Blocks Indicate the number blocks that have been transferred. When the DWEN bit in CE_CMD_SET is 0 Number of blocks read from the card When the DWEN bit in CE_CMD_SET is 1 Number of blocks written to the card

27.3.15 Status Register 2 (CE_HOST _STS2)

CE_HOST _STS2 indicates timeout and error statuses.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRC STE	CRC 16E	AC12 CRCE	RSP CRC7E	CRC STEBE	RDAT EBE	AC12R EBE	RSP EBE	AC12 IDXE	RSP IDXE	BTACK PATE	BTACK EBE	—	CRCST[2:0]

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	CRCSTE	0	R	CRC Status Error Set to 1 when an error is found in the CRC status value.
30	CRC16E	0	R	Read Data CRC16 Error Set to 1 when an error is found in CRC16 in the read data.
29	AC12CRCE	0	R	Automatic CMD12 Response CRC7 Error Set to 1 when an error is found in CRC7 of the response to the automatically-issued CMD12.
28	RSPCRC7E	0	R	Command Response CRC7 Error Set to 1 when an error is found in CRC7 of the response.
27	CRCSTEBE	0	R	CRC Status End Bit Error Set to 1 when an error is found in the end bits in CRC status.
26	RDATEBE	0	R	Read Data End Bit Error Set to 1 when an error is found in the end bits in the read data.
25	AC12REBE	0	R	Automatic CMD12 Response End Bit Error Set to 1 when an error is found in the end bits of the response to the automatically-issued CMD12.

Bit	Bit Name	Initial Value	R/W	Description
24	RSPEBE	0	R	Command Response End Bit Error Set to 1 when an error is found in the end bits of the response.
23	AC12IDX	0	R	Automatic CMD12 Response Index Error Set to 1 when an error is found in the index of the response to the automatically-issued CMD12.
22	RSPIDXE	0	R	Command Response Index Error Set to 1 when an error is found in the index of the response.
21	BTACKPATE	0	R	Boot Acknowledge Pattern Error Set to 1 when an error is found in the Pattern in Boot Acknowledge.
20	BTACKEBE	0	R	Boot Acknowledge End Bit Error Set to 1 when an error is found in the end bit in Boot Acknowledge.
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	CRCST [2:0]	000	R	CRC Status Indicate the value of the CRC status that has been received.
15	CCSTO	0	R	CCS Timeout Set to 1 if CCS is not received within the period set by the SCCSTO bits in CE_CLK_CTRL.
14	RDATTO	0	R	Read Data Timeout Set to 1 if read data is not received within the period set by the SRWDTO bits in CE_CLK_CTRL.
13	DATBSYTO	0	R	Data Busy Timeout Set to 1 if data busy continues exceeding the period set by the SRWDTO bits in CE_CLK_CTRL.
12	CRCSTTO	0	R	CRC Status Timeout Set to 1 if CRC status could not be received.
11	AC12BSYTO	0	R	Automatic CMD12 Response Busy Timeout Set to 1 if the response busy of the automatically-issued CMD12 continues exceeding the period set by the SRBSYTO bits in CE_CLK_CTRL.

Bit	Bit Name	Initial Value	R/W	Description
10	RSPBSYTO	0	R	Response Busy Timeout Set to 1 if the response busy continues exceeding the period set by the SRBSYTO bits in CE_CLK_CTRL.
9	AC12RSPTO	0	R	Automatic CMD12 Response Timeout Set to 1 if the response to the automatically-issued CMD12 is not received within the period set by the SRSPTO bits in CE_CLK_CTRL.
8	RSPTO	0	R	Response Timeout Set to 1 if the response is not received within the period set by the SRSPTO bits in CE_CLK_CTRL.
7	BTACKTO	0	R	Boot Acknowledge Timeout Set to 1 if the Boot Acknowledge is not received within the period set by the SBTACKTO bits in CE_BOOT when Boot Operation.
6	1STBTDATT	0	R	1st Boot data Timeout Set to 1 if 1st read data is not received within the period set by the S1STBTDATO bits in CE_BOOT when Boot Operation.
5	BTDATO	0	R	Boot Interval Timeout Set to 1 if read data is not received within the period set by the SBTDATTO bits in CE_BOOT after previous read data was received when Boot Operation.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

27.3.16 Version Register (CE_VERSION)

CE_VERSION indicates the version number and controls software reset of this module.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SW RST	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VERSION[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	SWRST	0	R/W	Software Reset 0: Software reset cleared (normal operation) 1: Executes software reset
30 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	VERSION [15:0]	H’0002	R	Version Information Indicates the version number of this module.

27.4 Interrupt Requests

This module generates these types of interrupt requests: normal operation and error/timeout. The interrupt flags are accommodated in the CE_INT. When a bit in the flag register is set to 1 and also the corresponding bit in the interrupt mask register is set to 1 (enabled), an interrupt request is generated.

Table 27.4 Specification of the Interrupt Requests

Flag Register	Bit	Mask Register	Bit	Interrupt Request
CE_INT	CCSDE	CE_INT_MASK	MCCSDE	Normal operation interrupt
	CMD12DRE		MCMD12DRE	
	CMD12RBE		MCMD12RBE	
	CMD12CRE		MCMD12CRE	
	DTRANE		MDTRANE	
	BUFRE		MBUFRE	
	BUFWEN		MBUFWEN	
	BUFREN		MBUFREN	
	CCSRCV		MCCSRCV	
	RBSYE		MRBSYE	
	CRSPE		MCRSPE	
	CMDVIO		MCMDVIO	Error/timeout interrupt
	BUFVIO		MBUFVIO	
	WDATERR		MWDATERR	
	RDATERR		MRDATERR	
	RIDXERR		MRIDXERR	
	RSPERR		MRSPERR	
	CCSTO		MCCSTO	
	CRCSTO		MCRCSTO	
	WDATTO		MWDATTO	
	RDATTO		MRDATTO	
	RBSYTO		MRBSYTO	
	RSPTO		MRSPTO	

27.5 DMA Specifications

27.5.1 DMA for Buffer Writing

The DMA transfer request is asserted for buffer writing when the buffer has become empty while the DMAWEN bit in CE_BUF_ACC is set to 1.

The DMA transfer request stays asserted for the amount of data specified by BLKSIZ (the block size set in CE_BLOCK_SET) × BLKCNT (the number of blocks for transfer set in CE_BLOCK_SET), and negated after the last block has been transferred. Note that the BUFWEN bit in CE_INT will not be asserted during DMA transfer.

If an error has occurred during DMA transfer or DMA transfer is forcibly terminated, the command sequence is stopped automatically, which causes the DMA transfer request to be negated.

27.5.2 DMA for Buffer Reading

The DMA transfer request is asserted for buffer reading when the buffer stores data of the block size specified in CE_BLOCK_SET while the DMAREN bit in CE_BUF_ACC is set to 1.

The DMA transfer request stays asserted for the amount of data specified by BLKSIZ (the block size set in CE_BLOCK_SET) × BLKCNT (the number of blocks for transfer set in CE_BLOCK_SET), and negated after the last block has been transferred. Note that the BUFREN bit in CE_INT will not be asserted during DMA transfer.

If an error has occurred during DMA transfer or DMA transfer is forcibly terminated, the command sequence is stopped automatically, which causes the DMA transfer request to be negated.

27.6 Operation

This section describes the formats of the command and response, timing of automatic CMD12 issuance, buffer structures, buffer access select function, and the operation when an error has occurred.

27.6.1 Command/Response Formats

Figure 27.2 shows the format of the command to be transferred. The command index that is set in CMD[5:0] of CE_CMD_SET and the argument set in ARG[31:0] of CE_ARG are reflected in the command.

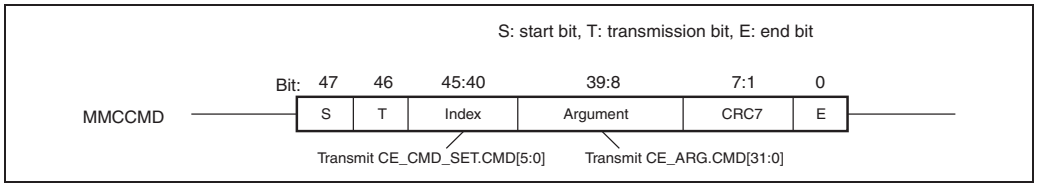

Figure 27.2 Command Format

Figures 27.3 and 27.4 show the formats when a 6-byte response and 17-byte response are received, respectively. The response index is stored in RSPIDX[5:0] of CE_HOST_STS1, and the status value of the response is stored to CE_RESP0 or CE_RESP3 to CE_RESP0.

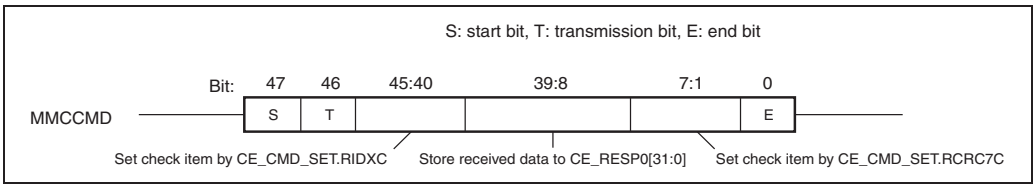

Figure 27.3 Format of 6-Byte Response

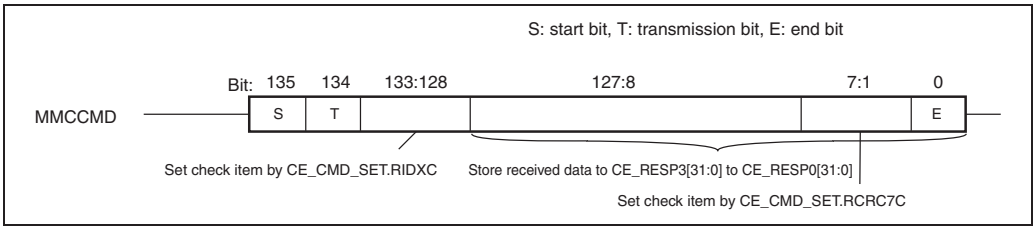

Figure 27.4 Format of 17-Byte Response (R2)

27.6.2 Data Formats

Figures 27.5 to 27.7 show the formats of data. In transmission, the value written to the buffer is reflected on the data lines, and in reception, the value of the received data is stored in the buffer.

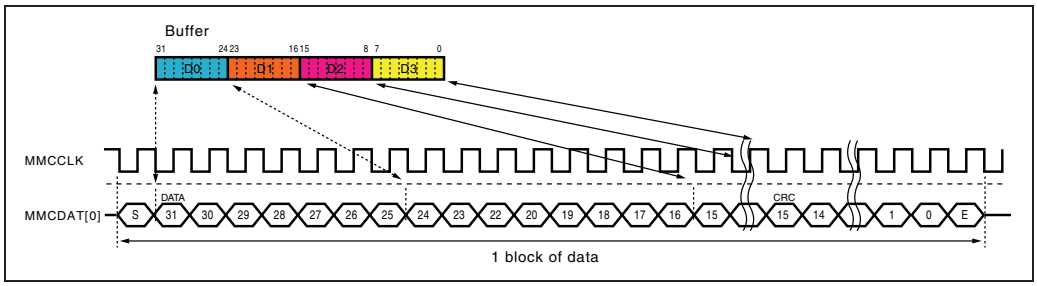

Figure 27.5 Data Format (1-Bit Mode)

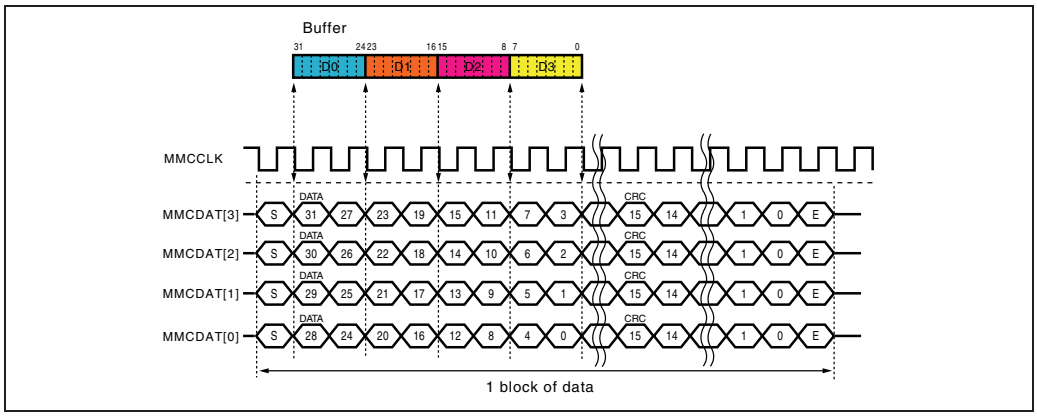

Figure 27.6 Data Format (4-Bit Mode)

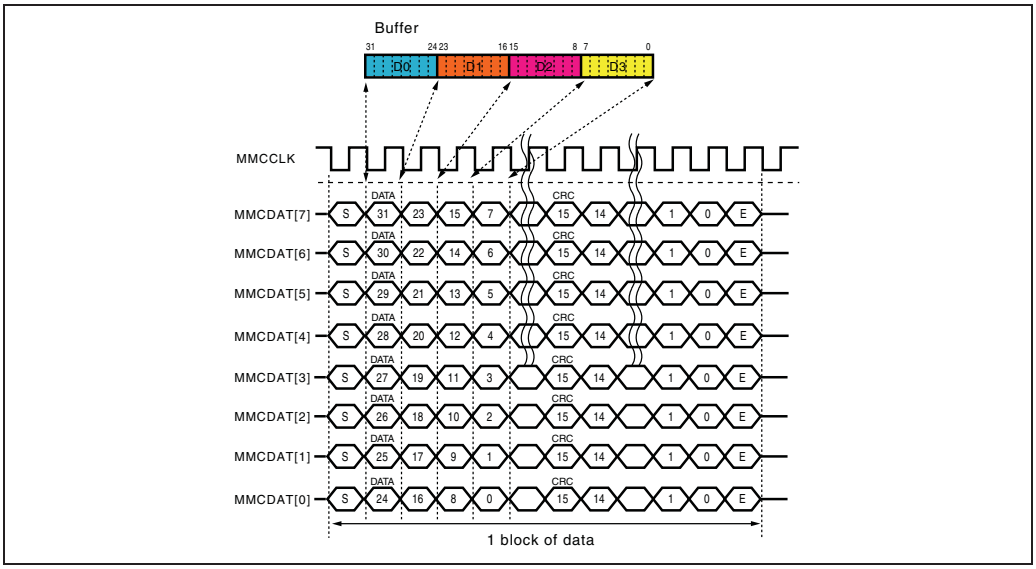

Figure 27.7 Data Format (8-Bit Mode)

27.6.3 Buffer Structure and Buffer Access

This module has two 512-byte RAM units which are used for double buffering. If the transfer block size is set to 4 × n + 1 or 4 × n + 3, access should be made for 4 × n + 2 bytes or 4 × (n + 1) bytes in 16-bit access, and for 4 × (n + 1) bytes in 32-bit access. (n = 0, 1, 2, …, 127)

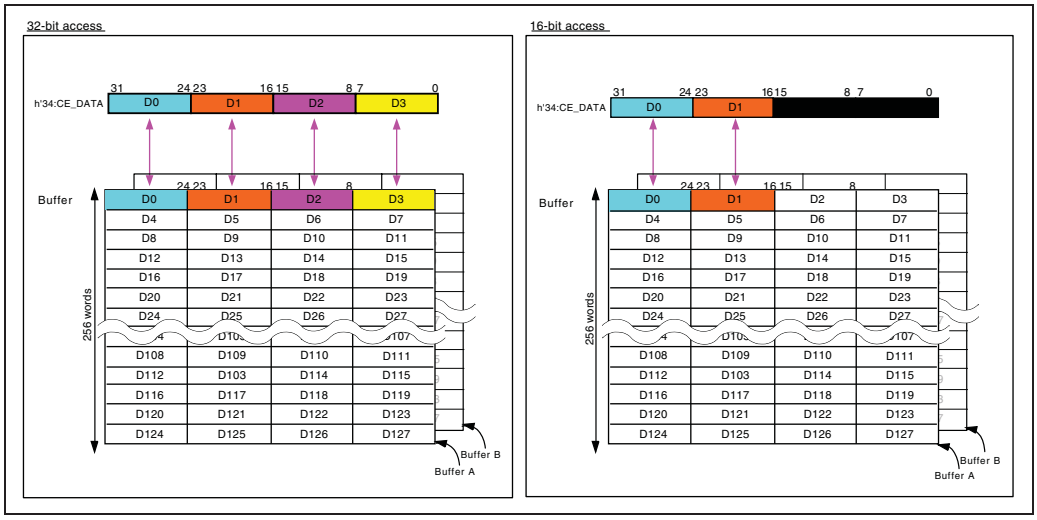

Figure 27.8 Double Buffer Structure

This module has the buffer access select function that allows byte-wise swapping of data when the buffer is accessed by writing to or reading from CE_DATA. This function is enabled by the setting of CE_BUFF_ACC. Figure 27.8 shows the specification of 32-bit and 16-bit accesses.

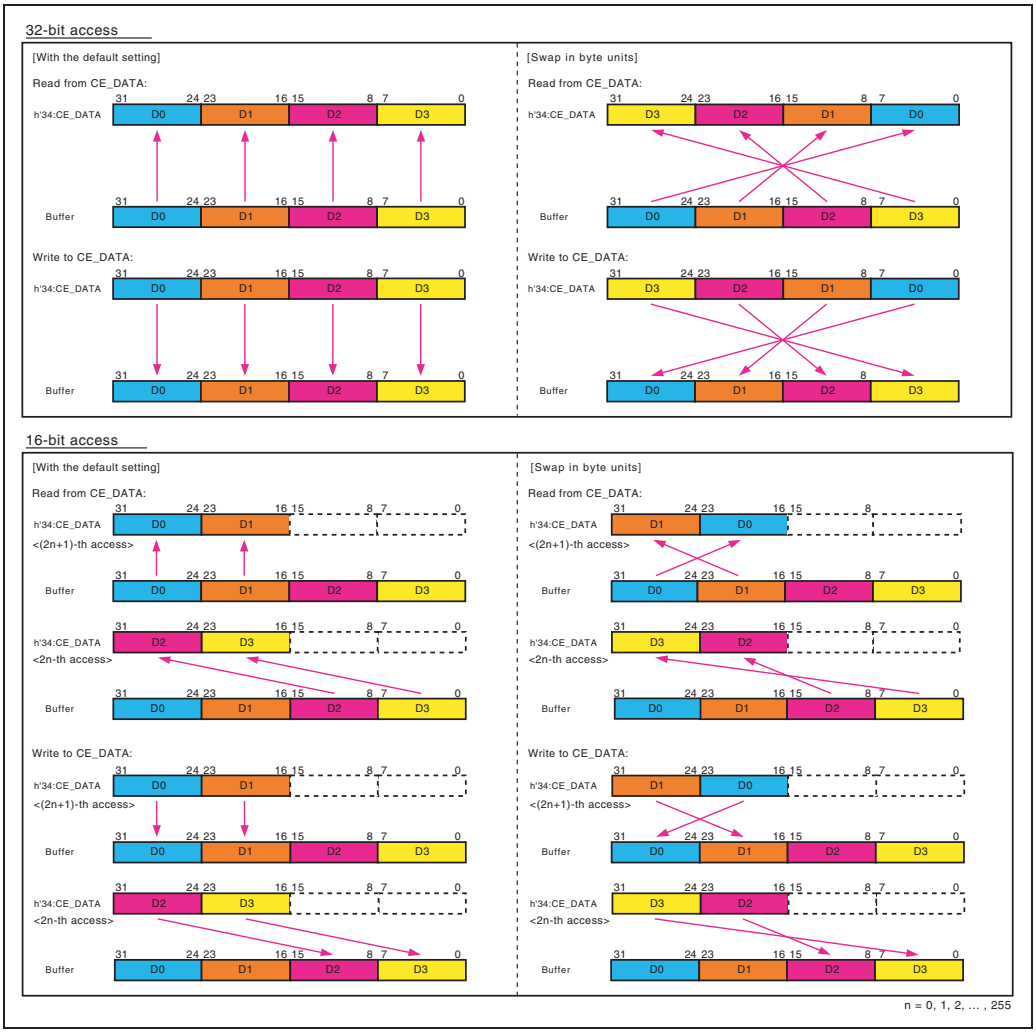

Figure 27.9 Specification of Byte-Swapping in 32/16-Bit Accesses

27.6.4 Automatic CMD12 Issuance

This module has the function that automatically issues CMD12 when multi-block transfer is performed with the CMD12EN in CE_CMD_SET set to 1. Timing of automatic CMD12 issuance is described for the case of multi-block reading and multi-block writing.

Figure 27.10 shows the timing of automatic CMD12 issuance in multi-block read. CMD12 is issued such that the end bit of the command is sent two bits before the end bit of the data during reception of the last block.

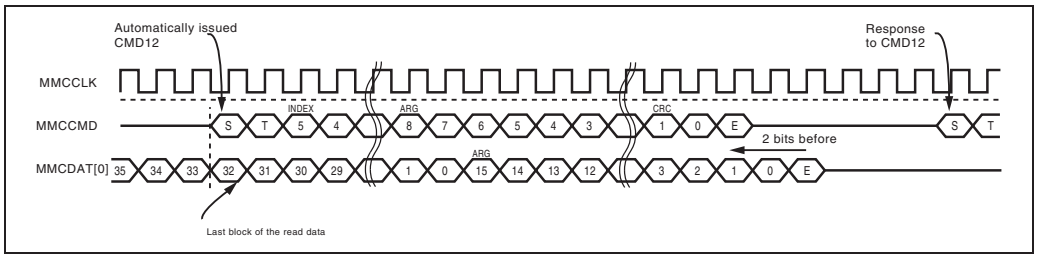

Figure 27.10 Timing of Automatically-Issued CMD12 in Multi-Block Read (1-Bit Mode)

Figure 27.11 shows the timing of automatic CMD12 issuance in multi-block write. CMD12 is issued after the data busy after transmission of the last block has ended.

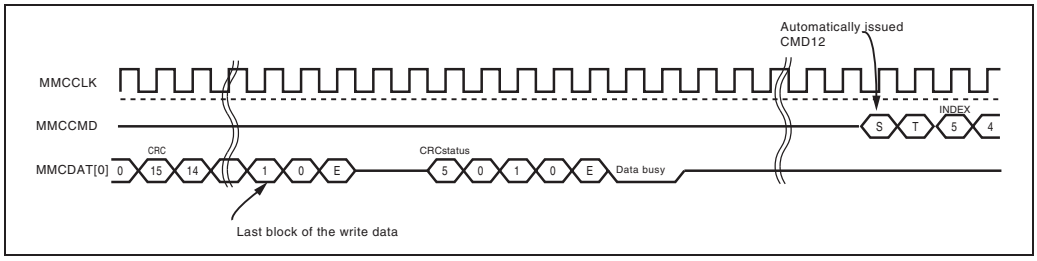

Figure 27.11 Timing of Automatically-Issued CMD12 in Multi-Block Write (1-Bit Mode)

27.6.5 MMC Clock frequency for Boot Operation

Figure 27.12 shows the operation which changes MMC Clock frequency for Boot Operation. After MMCCMD is changed from 1 into 0 and 74 cycles of MMC Clock, it changes into the MMC clock frequency corresponding to CE_BOOT.BTCLKDIV. After MMCCMD is changed from 0 into 1 and 48 cycles of MMC Clock, it changes into the MMC clock frequency corresponding to CE_CLK_CTRL.CLKDIV.

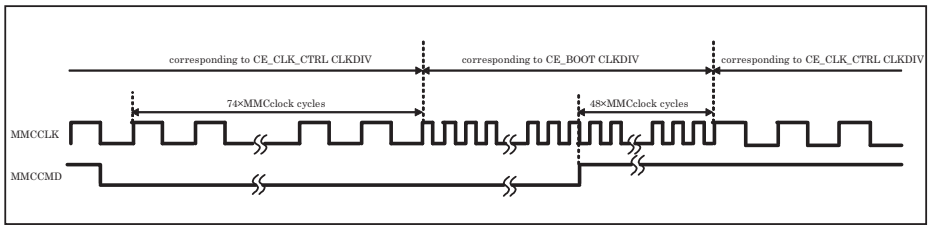

Figure 27.12 MMC Clock frequency for Boot Operation

27.6.6 Operation in the Case of Error/Timeout

This module might not stop when the error has occurred. Execute software reset after terminate the sequence forcibly if the command sequence is still in progress (Confirm it with CMDSEQ of CE_HOST_STS1) when the error has occurred. The data for transmission or received data that had been stored in the buffers at the time of error occurrence are not guaranteed.

This module is not stopped when a timeout has occurred. Issue the next command terminate the sequence forcibly when the next command is issued after a timeout has occurred.

27.6.7 For processing when terminate forcibly

The command sequence might not end in the MMC/CE-ATA host interface according to set timing of the BREAK bit of the CE_CMD_CTRL register when the command sequence terminate forcibly.

Therefore, process it by either of the following two methods when the command sequence terminate forcibly.

(1) When the command sequence terminate forcibly, execute software reset without using the BREAK bit of the CE_CMD_CTRL register.

(2) When the command sequence terminate forcibly in the following after the command of the R1b response is issued, execute software reset without using the BREAK bit of the CE_CMD_CTRL register.

- Busy timeout for response

- Abnormality of response value

27.7 Examples of Setting

This section shows the procedures for executing typical command sequences.

27.7.1 Legends

Figure 27.13 shows the legends for the symbols used in the figures in the following subsections.

Section 28 NAND Flash Memory Controller (FLCTL)

The NAND flash memory controller (FLCTL) provides a memory interface for an external NAND-type flash memory. To take measures for errors specific to flash memory, the FLCTL supports the ECC-code generation function and error detection function. It also supports ×16-bit configuration products. The FLCTL generates ECC code with up to 4 symbols, detects ECC code errors and has an error pattern generation circuit.

28.1 Features

28.1.1 NAND-Type Flash Memory Interface

- Interface directly connectable to NAND-type flash memory
- Read or write in sector units (512 + 16 bytes) and ECC processing executed
- In this manual, an access unit of 512 + 16 bytes, referred to as a sector, is always used. Note, however, that the size of a page is (515 + 16), (1024 + 32), or (2048 + 64) bytes depending on the type of flash memory being connected.
- Read or write in byte units
- Supports addresses of up to 5 bytes

Note: An access unit of 512 + 16bytes is referred to as a page in some datasheets for NAND-type flash memory. In this manual, this access unit of 512 + 16 bytes is always referred to as a sector. Each page of 2048 + 64 bytes is divided into four sectors, each consisting of 512 + 16 bytes. Although each page consists of 1024 + 32 words for 16-bit I/O products, a page is divided into four sectors even for 16-bit products.

28.1.2 Access Modes

The FLCTL can select one of the following two access modes.

- Command access mode: Performs an access by specifying a command to be issued from the FLCTL to flash memory, address, and data size to be input or output. Read, write, or erasure of data without ECC processing can be achieved.
- Sector access mode: Performs a read or write in sector units by specifying a sector address and controls ECC-code generation and check. By specifying the number of sectors, the continuous sectors can be read or written (specify addresses in sector addresses).
- High-speed sector access mode: The following commands are supported to access the flash memory at a high speed. Note that some flash memory products do not support these

commands:
- “Auto Page Program Operation with Data Cache”
- “Read Operation with Read Cache”

28.1.3 Sectors and Control Codes

- A sector is comprised of 512-byte data and 16-byte control code. The 16-byte control code includes 8-byte ECC.
- The control code includes 10-byte ECC when using a 4-symbol ECC circuit.
- The position of the ECC in the control code can be specified in 4-byte units.
- The user can write any data into bytes 0 to 5 in the control code area when using a 4-symbol ECC circuit.
- User information can be written to the control code other than the ECC.

28.1.4 3-symbol ECC

- 8-byte ECC code is generated and error check is performed for a sector (512-byte data + 16-byte control code). (Note that the ECC code generation in the 16-byte control code and the number of bytes to be checked differ depending on the specifications.)
- Error correction capability is up to three errors.
- In a write operation, an ECC code is generated for data and control code prior to the ECC. The control code following the ECC is not considered.
- In a read operation, an ECC error is checked for data and control code prior to the ECC. An ECC on the control code in the FIFO is replaced with the check result by the ECC circuit, not an ECC code read from flash memory.
- An error correction is not performed even when an ECC error occurs. Error corrections must be performed by software.

28.1.5 4-symbol ECC

- 80-bit (10-byte) ECC code is added to a sector (512-byte data + 6-byte control code).
- Error correction and detection capability covers up to four random errors (up to 40 bits).
- In a write operation, an ECC code is generated for data and control code prior to the ECC.
- In a read operation, an ECC error is checked for data and control code prior to the ECC. An ECC on the control code in the FIFO is replaced with the check result by the ECC circuit, not an ECC code read from flash memory.
- The 4-symbol ECC circuit in this FLCTL can generate error correction patterns using the hardware. The error correction pattern generation and checking are performed in sector units.

- The hardware-based error correction outputs addresses indicating the locations of errors and error patterns to correct errors.
- ECC correction algorithm in the 3-symbol ECC circuit and the 4-symbol ECC circuit use Reed-Solomon

28.1.6 Data Error

- When a program error or erase error occurs, the error is reflected on the error source flags. Interrupts for each source can be specified.
- When a read error occurs, an ECC in the control code is other than 0. This read error is reflected on the ECC error source flag.
- When an ECC error occurs, perform an error correction, specify another sector to be replaced, and copy the contents of the block to another sector as required.

28.1.7 Data Transfer FIFO and Data Register

- The 224-byte FLDTFIFO is incorporated for data transfer of flash memory.
- The 32-byte FLECFIFO is incorporated for data transfer of control code.
- The overrun/underrun detection flag is provided for the access from the CPU and DMA.

28.1.8 DMA Transfer

- By individually specifying the destinations of data and control code of flash memory to the DMA controller, data and control code can be sent to different areas.

28.1.9 Access Size

- Registers can be accessed in 32 bits or 8 bits. Registers must be accessed in the specified access size.
- The FIFO is accessed in 32-bit (4-byte) units. If the specified number of bytes for read and write accesses is not a multiple of 4, the fractional bytes are handled as padding bytes.
- The register contents are damaged if the access size is violated.

28.1.10 Access Time

- The operating frequency of the FLCTL pins can be specified by the FCKSEL bit and the QTSEL bit in the common control register (FLCMNCR), regardless of the operating frequency of the peripheral bus. To ensure the setup time, these operating frequencies must be specified within the maximum operating frequency of memory to be connected.

28.1.11 Connection of ×16-Bit Configuration Flash Memory on the External Bus

Before connecting the LSI with a ×16-bit configuration flash memory, observe the following notes.

- The maximum number of bytes that can be continuously written to in sector access mode is that of one page. To write data that exceeds the maximum number of bytes, the address must be specified again.

Figure 28.1 shows a block diagram of the FLCTL.

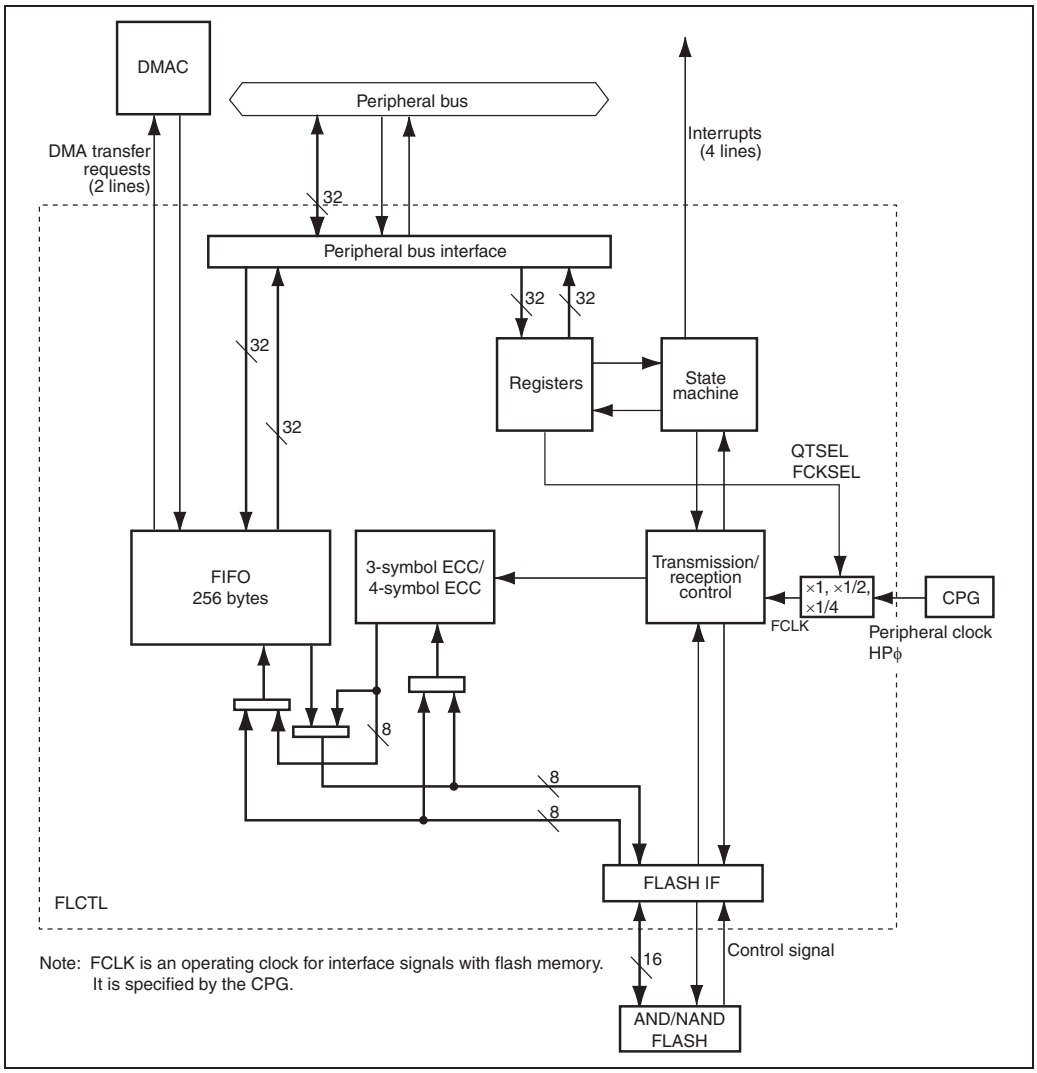

Figure 28.1 FLCTL Block Diagram

28.2 Input/Output Pins

The pin configuration of the FLCTL is listed in table 28.1.

Table 28.1 Pin Configuration

Pin Name	Function	I/O	Corresponding Flash Memory Pin	Description
$\overline{\text{FCE0}}$	Chip enable	Output	$\overline{\text{CE0}}$	Enables flash memory connected to this LSI.
$\overline{\text{FCE1}}$			$\overline{\text{CE1}}$	
NAF15 to NAF0	Data I/O pins	I/O	I/O15 to I/O0	I/O pins for command, address, and data.
FCDE	Command data enable	Output	CLE	Command Latch Enable (CLE) Asserted when a command is output. Command Data Enable ($\overline{\text{CDE}}$) Asserted when a command is output.
FOE	Output enable	Output	ALE	Address Latch Enable (ALE) Asserted when an address is output and negated when data is input or output. Output Enable ($\overline{\text{OE}}$) Asserted when data is input or when a status is read.
FSC	Serial clock	Output	$\overline{\text{RE}}$	Read Enable ($\overline{\text{RE}}$) Reads data at the falling edge of $\overline{\text{RE}}$. Serial Clock (SC) Inputs or outputs data synchronously with the SC.
$\overline{\text{FWE}}$	Write enable	Output	$\overline{\text{WE}}$	Write Enable Flash memory latches a command, address, and data at the rising edge of $\overline{\text{WE}}$.
FRB	Ready/busy	Input	R/$\overline{\text{B}}$	Ready/Busy Indicates ready state at high level; indicates busy state at low level.
—*	—	—	$\overline{\text{WP}}$	Write Protect/Reset When this pin goes low, erroneous erasure or programming at power on or off can be prevented.
—*	—	—	$\overline{\text{SE}}$	Spare Area Enable Used to access spare area. This pin must be fixed at low in sector access mode.

Note: * Not supported in this LSI.

28.3 Register Descriptions

Table 28.2 shows the FLCTL register configuration. Table 28.3 shows the register state in each processing mode.

Table 28.2 Register Configuration of FLCTL

Name	Abbreviation	R/W	Address	Access Size

28.3.1 Common Control Register (FLCMNCR)

FLCMNCR is a 32-bit readable/writable register that specifies the type (NAND) of flash memory, access mode, and $\overline{\text{FCE}}$ pin output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27	PULSE[3]	0	R/W	Use this bit to set the pulse width of each clock (WE and RE) used to access the flash memory. Refer to PULSE[2] for details.
26	FLMLC	0	R/W	Large Block Access Select Selects a data alignment used to access a large-block product. This bit is invalid when the SNAND bit is set to 0. 0: A large block is accessed in 512-byte + 16-byte units. 1: A large block is accessed in 2048-byte + 64-byte units. (A large block is accessed by changing the column address.) Note: When setting PULSE[3:0] to 4'b1000, setting this bit to 1 is prohibited.
25	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
24	4ECCCNTEN	0	R/W	4-Symbol ECC Error Count Outputs the total number of errors included in the read sector and the maximum number of errors in the read sector. 0: Counting is not executed. 1: The 4-symbol ECC circuit is used to output the total number of errors and the maximum number of errors included in the read sector. Note: When setting this bit to 1, set the 4ECCCORRECT bit to 0.
23	4ECCEN	0	R/W	4-Symbol ECC Circuit Enable When this bit is set to 1 in sector access mode, the 4-symbol ECC circuit is enabled. Flash memory can only be read and written. 0: The 3-symbol ECC circuit is enabled. 1: The 4-symbol ECC circuit is enabled.
22	4ECC CORRECT	0	R/W	4-Symbol ECC Correction Information Generation The 4-symbol ECC circuit is used to generate information required for correction for one sector. After finishing reading one sector, set the 4-symbol ECC control register to generate error patterns. For details, see section 28.4, 4-Symbol ECC. 0: Only outputs ECC code, not outputting correction patterns. 1: Stops reading when an ECC error occurs. Resume the operation after reading the error pattern.
21	BUSYON	0	R/W	Busy Select This bit is only enabled when the FLCTL pins are multiplexed with the external bus. Set this bit to select whether or not to release the external bus mastership during a busy period. Note that $\overline{CE}$ must not be negated during a busy period depending on the flash memory in use. 0: Holds bus mastership during a busy period. 1: Releases bus mastership during a busy period. Note: When FLCTL processing is completed, $\overline{CE}$ is negated regardless of the status of ready/busy. For details, see section 28.9, Usage Notes.

Bit	Bit Name	Initial Value	R/W	Description
20	SHBUSSEL	1	R/W	External Bus Connection Set this bit to 1 when the I/O section is multiplexed with the external bus through BSC. 0: When the I/O pins of the flash memory are for exclusive use by the I/O function 1: When the I/O pins of the flash memory are multiplexed with the external bus Note: Set this bit to 1 because the FLCTL pins are multiplexed with the external bus.
19	16BITSEL	0	R	16-Bit I/O Select Set this bit to 1 when flash memory with ×16-bit configuration is specified. 0: When flash memory with ×8-bit configuration is specified 1: When flash memory with ×16-bit configuration is specified
18	SNAND	0	R/W	Large-Capacity NAND Flash Memory Select Set this bit to 1 when using 1-Gbit or larger NAND-type flash memory, in which one page is equal to 2048 + 64 bytes, or 1-Gbit or larger AG-AND-type flash memory. 0: When using flash memory in which one page is equal to 512 + 16 bytes or AND-type flash memory 1: When using NAND-type flash memory, in which one page is equal to 2048 + 64 bytes, or 1-Gbit or larger AG-AND-type flash memory

Bit	Bit Name	Initial Value	R/W	Description
17	PULSE[2]	0	R/W	Flash Clock Select Use this bit to set the pulse width of each clock (WE and RE) used to access the flash memory. • When connecting an 8-bit IO product 000: Low: 1 HPϕ cycle, High: 1 HPϕ cycle 001: Low: 2 HPϕ cycles, High: 2 HPϕ cycles 010: Low: 0.5 HPϕ cycle, High: 0.5 HPϕ cycle 011: Low: 1 HPϕ cycle, High: 1 HPϕ cycle 100: Low: 2 HPϕ cycles, High: 2 HPϕ cycles 101: Low: 4 HPϕ cycles, High: 4 HPϕ cycles 110: Low: 1.5 HPϕ cycle, High: 1.5 HPϕ cycle 111: Low: 3 HPϕ cycles, High: 3 HPϕ cycles • When connecting an 16-bit IO product — RE pulse width ***0: Setting prohibited 0001: Low: 6 HPϕ cycles, High: 2 HPϕ cycles 0011: Setting prohibited 0101: Low: 12 HPϕ cycles, High: 4 HPϕ cycles 0111: Low: 9 HPϕ cycles, High: 3 HPϕ cycles 1000: Low : 6 HPϕ cycles, High: 2 HPϕ cycles Note: When ; page read and setting this bits to 1000,this bits is replaced to 0001 — WE pulse width ***0: Setting prohibited 0001: Low: 2 HPϕ cycles, High: 6 HPϕ cycles 0011: Setting prohibited 0101: Low: 4 HPϕ cycles, High: 12 HPϕ cycles 0111: Low: 3 HPϕ cycles, High: 9 HPϕ cycles

Bit	Bit Name	Initial Value	R/W	Description
16	ENDIAN	0	R/W	FIFO Data Endian Specification 0: Big endian When writing to flash memory the data in FLDTFIFO and FLECFIFO in the FLCTL is output in the order of bits 31 to 24, 23 to 16, 15 to 8, 7 to 0, and then again 31 to 24, and so on. When reading from flash memory, output data from the flash memory is stored in FIFO in the order of: the first data to bits 31 to 24, the second data to 23 to 16, the third data to 15 to 8, the fourth data to 7 to 0, the fifth data to 31 to 22, and so on, in FLDTFIFO and FLECFIFO. 1: Little endian When writing to flash memory the data in FLDTFIFO and FLECFIFO in the FLCTL is output in the order of bits 7 to 0, 15 to 8, 23 to 16, 31 to 24, and then again 7 to 0, and so on. When reading from flash memory, output data from the flash memory is stored in FIFO in the order of: the first data to bits 7 to 0, the second data to 15 to 8, the third data to 23 to 16, the fourth data to 31 to 24, the fifth data to 7 to 0, and so on, in FLDTFIFO and FLECFIFO.
15	PULSE[1]	0	R/W	Flash Clock Select Use this bit to set the pulse width of each clock (WE and RE) used to access the flash memory. For details, see the description for the PULSE[2] bit.
14	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11, 10	ACM[1:0]	00	R/W	Access Mode Specification Specifies access mode. 00: Command access mode 01: Sector access mode 10: High-speed sector access mode 11: Setting prohibited. Note: Set the FLMLC bit to 0 in high-speed sector access mode.
9	PULSE[0]	0	R/W	Flash Clock Select Use this bit to set the pulse width of each clock (WE and RE) used to access the flash memory. For details, see the description for the PULSE[2] bit.
8 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	CE1	0	R/W	Chip Enable 1 0: Disable (Outputs a high-level signal to the $\overline{\text{FCE1}}$ pin) 1: Enable (Outputs a low-level signal to the $\overline{\text{FCE1}}$ pin)
3	CE0	0	R/W	Chip Enable 0 0: Disable (Outputs a high-level signal to the $\overline{\text{FCE0}}$ pin) 1: Enable (Outputs a low-level signal to the $\overline{\text{FCE0}}$ pin)
2, 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TYPESEL	0	R/W	Memory Interface Select When this module is used, Write 1 to this bit.

Note: Both the CE0 and CE1 bits should not be enabled at the same time.

28.3.2 Command Control Register (FLCMDCR)

FLCMDCR is a 32-bit readable/writable register that issues a command in command access mode, specifies address issue, and specifies source or destination of data transfer. In sector access mode, FLCMDCR specifies the number of sector transfers.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADR CNT2	SCTCNT[19:16]				ADR MD	CDS RC	DOSR	—	—	SEL RW	DOA DR	ADRCNT[1:0]		DOC MD2	DOC MD1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SCTCNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	ADRCNT2	0	R	Address Issue Byte Count Specification Specifies the number of bytes for the address data to be issued in address stage. This bit is used together with ADRCNT[1:0]. 0: Issue the address of byte count, specified by ADRCNT[1:0]. 1: Issue 5-byte address. Set the ADRCNT1 and ADRCNT0 bits to B'00.
30 to 27	SCTCNT [19:16]	All 0	R/W	Sector Transfer Count Specification [19:16] These bits are extended bits of the sector transfer count specification [15:0], SCTCNT[15:0]. SCTCNT[19:16] and SCTCNT[15:0] are used together to operate as SCTCNT[19:0], the 20-bit counter.
26	ADRMD	0	R/W	Sector Access Address Specification This bit is invalid in command access mode. This bit is valid only in sector access mode. 0: The value of the address register is handled as a physical sector number. Use this value usually in sector access. 1: The value of the address register is output as the address of flash memory. Note: Clear this bit to 0 in continuous sector access.

Bit	Bit Name	Initial Value	R/W	Description
25	CDSRC	0	R/W	Data Buffer Specification Specifies the data buffer to be read from or written to in the data stage in command access mode. 0: Specifies FLDATAR as the data buffer. 1: Specifies FLDTFIFO as the data buffer.
24	DOSR	0	R/W	Status Read Check Specifies whether or not the status read is performed after the second command has been issued. 0: Performs no status read 1: Performs status read
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	SELRW	0	R/W	Data Read/Write Specification Specifies the direction of read or write in data stage. 0: Read 1: Write
20	DOADR	0	R/W	Address Stage Execution Specification Specifies whether or not the address stage is executed in command access mode. 0: Performs no address stage 1: Performs address stage
19, 18	ADRCNT [1:0]	00	R/W	Address Issue Byte Count Specification Specify the number of bytes for the address data to be issued in address stage. 00: Issue 1-byte address 01: Issue 2-byte address 10: Issue 3-byte address 11: Issue 4-byte address
17	DOCMD2	0	R/W	Second Command Stage Execution Specification Specifies whether or not the second command stage is executed in command access mode. 0: Does not execute the second command stage 1: Executes the second command stage

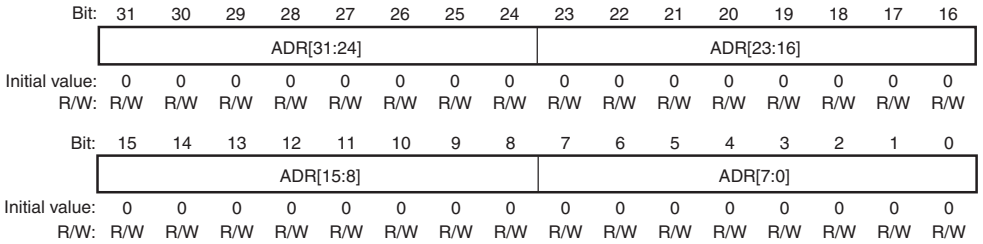
Bit	Bit Name	Initial Value	R/W	Description
16	DOCMD1	0	R/W	First Command Stage Execution Specification Specifies whether or not the first command stage is executed in command access mode. 0: Does not execute the first command stage 1: Executes the first command stage
15 to 0	SCTCNT [15:0]	H'0000	R/W	Sector Transfer Count Specification [15:0] Specify the number of sectors to be read continuously in sector access mode. These bits are counted down for each sector transfer end and stop when they reach 0. These bits are used together with SCTCNT[19:16]. In command access mode, these bits are H'0 0001.

28.3.3 Command Code Register (FLCMCDR)

FLCMCDR is a 32-bit readable/writable register that specifies a command to be issued in command access or sector access.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMD[15:8]								CMD[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	CMD[15:8]	H'00	R/W	Specify a command code to be issued in the second command stage.
7 to 0	CMD[7:0]	H'00	R/W	Specify a command code to be issued in the first command stage.

28.3.4 Address Register (FLADR)

FLADR is a 32-bit readable/writable register that specifies an address to be output in command access mode. In sector access mode, a physical sector number specified in the physical sector address bits is converted into an address to be output by setting the ADRMD bit in FLCMDCR to 0.

Specify the start sector address in continuous sector access mode.

(a) ADRMD = 1

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	ADR[31:24]	H'00	R/W	Fourth Address Data Specify 4th data to be output to flash memory as an address in command access mode.
23 to 16	ADR[23:16]	H'00	R/W	Third Address Data Specify 3rd data to be output to flash memory as an address in command access mode.
15 to 8	ADR[15:8]	H'00	R/W	Second Address Data Specify 2nd data to be output to flash memory as an address in command access mode.
7 to 0	ADR[7:0]	H'00	R/W	First Address Data Specify 1st data to be output to flash memory as an address in command access mode.

(b) ADRMD = 0

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	ADR[25:16]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25 to 0	ADR[25:0]	H'000 0000	R/W	Physical Sector Address Specify a physical sector number to be accessed in sector access mode. For a large-block or 16-bit I/O product, a page address can be specified in the ADR25 to ADR2 bits or ADR17 to ADR2 bits, and a sector-based column address can be specified in the ADR1 and ADR0 bits. For a small-block product, only page addresses can be specified. When the ADRCNT2 bit is set to 1, the ADR25 to ADR0 bits are enabled. When the ADRCNT2 bit is set to 0, the ADR17 to ADR0 bits are enabled. • 8-bit I/O product (large-block) ADR[1:0]: B'00 → 0th byte (0 sectors) ADR[1:0]: B'01 → 512+16th byte (1 sector) ADR[1:0]: B'10 → 1024+32nd byte (2 sectors) ADR[1:0]: B'11 → 1536+48th byte (3 sectors) • 16-bit I/O product ADR[1:0]: B'00 → 0th word (0 sectors) ADR[1:0]: B'01 → 512+16th word (2 sectors) For details, see figure 28.3.

28.3.5 Address Register 2 (FLADR2)

FLADR2 is a 32-bit readable/writable register, and is valid when the ADRCNT2 bit in FLCMDCR is set to 1. FLADR2 specifies an address to be output in command access mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ADR[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	ADR[7:0]	H'00	R/W	Fifth Address Data Specify 5th data to be output to flash memory as an address in command access mode.

28.3.6 Data Counter Register (FLDTCNTR)

FLDTCNTR is a 32-bit readable/writable register that specifies the number of bytes to be read or written in command access mode.

Note: This register is unavailable for reading or writing continuous data of five bytes or more.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECFLW[7:0]								DTFLW[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	ECFLW[7:0]	H'00	R	FLECFIFO Access Count Specify the number of longwords in FLECFIFO to be read or written. These bit values are used when the CPU reads from or writes to FLECFIFO. In FLECFIFO read, these bits specify the number of longwords of the data that can be read from FLECFIFO. In FLECFIFO write, these bits specify the number of longwords of unoccupied area that can be written in FLECFIFO.
23 to 16	DTFLW[7:0]	H'00	R	FLDTFIFO Access Count Specify the number of longwords in FLDTFIFO to be read or written. These bit values are used when the CPU reads from or writes to FLDTFIFO. In FLDTFIFO read, these bits specify the number of longwords of the data that can be read from FLDTFIFO. In FLDTFIFO write, these bits specify the number of longwords of unoccupied area that can be written in FLDTFIFO.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 0	DTCNT[11:0]	H'000	R/W	Data Count Specification Specify the number of bytes of data to be read or written in command access mode. (Up to 2048 + 64 bytes can be specified.)

28.3.7 Data Register (FLDATAR)

FLDATAR is a 32-bit readable/writable register. It stores input/output data used when 0 is written to the CDSRC bit in FLCMDCR in command access mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DT[31:24]								DT[23:16]

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DT[15:8]								DT[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	DT[31:24]	H'00	R/W	Fourth Data Specify the 4th data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data
23 to 16	DT[23:16]	H'00	R/W	Third Data Specify the 3rd data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data
15 to 8	DT[15:8]	H'00	R/W	Second Data Specify the 2nd data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data
7 to 0	DT[7:0]	H'00	R/W	First Data Specify the 1st data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data

28.3.8 Interrupt DMA Control Register (FLINTDMACR)

FLINTDMACR is a 32-bit readable/writable register that enables or disables DMA transfer requests or interrupts. A transfer request from the FLCTL to the DMAC is issued after each access mode has been started.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	ECER INTE	—	DMA MULTI	FIFOTRG [1:0]		AC1 CLR	AC0 CLR	DREQ1 EN	DREQ0 EN

R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	ECERINTE	0	R/W	ECC Error Interrupt Enable 0: Disables an interrupt when an ECC error occurs 1: Enables an interrupt when an ECC error occurs
23	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
22	DMAMULTI	0	R/W	DMA 16-byte Transfer Select 0: When DMA transfer is not used or in DMA longword transfer mode 1: In DMA 16-byte transfer mode

Bit	Bit Name	Initial Value	R/W	Description
21, 20	FIFOTRG [1:0]	00	R/W	FIFO Trigger Setting* Change the condition for the FIFO transfer request. In flash-memory read: 00: Issue an interrupt or a DMA transfer request to the CPU when FLDTFIFO stores 4 bytes of data. 01: Issue an interrupt or a DMA transfer request to the CPU when FLDTFIFO stores 16 bytes of data. 10: Issue an interrupt or a DMA transfer request to the CPU when FLDTFIFO stores 128 bytes of data. 11: Issue an interrupt to the CPU when FLDTFIFO stores 128 bytes of data, or issue a DMA transfer request to the CPU when FLDTFIFO stores 16 bytes of data. In flash-memory programming: 00: Issue an interrupt to the CPU when FLDTFIFO has empty area of 4 bytes or more (do not set DMA transfer). 01: Issue an interrupt or a DMA transfer request to the CPU when FLDTFIFO has empty area of 16 bytes or more. 10: Issue an interrupt to the CPU when FLDTFIFO has empty area of 128 bytes or more (do not set DMA transfer). 11: Issue an interrupt to the CPU when FLDTFIFO has empty area of 128 bytes or more, or issue a DMA transfer request to the CPU when FLDTFIFO has empty area of 16 bytes or more.
19	AC1CLR	0	R/W	FLECFIFO Clear Clears FLECFIFO. 0: Retains the FLECFIFO value. In flash-memory access, this bit should be cleared to 0. 1: Clears FLECFIFO. After FLECFIFO has been cleared, this bit should be cleared to 0.

Bit	Bit Name	Initial Value	R/W	Description
18	AC0CLR	0	R/W	FLDTFIFO Clear Clears FLDTFIFO. 0: Retains the FLDTFIFO value. In flash-memory access, this bit should be cleared to 0. 1: Clears FLDTFIFO. After FLDTFIFO has been cleared, this bit should be cleared to 0.
17	DREQ1EN	0	R/W	FLECFIFODMA Request Enable Enables or disables the DMA transfer request issued from FLECFIFO. 0: Disables the DMA transfer request issued from FLECFIFO 1: Enables the DMA transfer request issued from FLECFIFO
16	DREQ0EN	0	R/W	FLDTFIFODMA Request Enable Enables or disables the DMA transfer request issued from FLDTFIFO. 0: Disables the DMA transfer request issued from the FLDTFIFO 1: Enables the DMA transfer request issued from the FLDTFIFO
15	DTOERB	0	R/W	Data-area FIFO0 Buffer Overrun Detects and indicates an overrun of the FIFO0 address counter. No interrupt occurs even if this bit is set to 1. 1 cannot be written into this flag bit. Only 0 can be written to clear the flag. 0: No overrun has occurred in FLDTFIFO. 1: An overrun has occurred in FLDTFIFO.
14	DTUERB	0	R/W	Data-area FIFO0 Buffer Underrun Detects and indicates an underrun of the FIFO0 address counter. No interrupt occurs even if this bit is set to 1. 1 cannot be written into this flag bit. Only 0 can be written to clear the flag. 0: No underrun has occurred in FLDTFIFO. 1: An underrun has occurred in FLDTFIFO.

Bit	Bit Name	Initial Value	R/W	Description
13	ECOERB	0	R/W	Control code-area FIFO1 Buffer Overrun Detects and indicates an overrun of the FIFO1 address counter. No interrupt occurs even if this bit is set to 1. 1 cannot be written into this flag bit. Only 0 can be written to clear the flag. 0: No overrun has occurred in FLECFIFO. 1: An overrun has occurred in FLECFIFO.
12	ECUERB	0	R/W	Control code-area FIFO1 Buffer Underrun Detects and indicates an underrun of the FIFO1 address counter. No interrupt occurs even if this bit is set to 1. 1 cannot be written into this flag bit. Only 0 can be written to clear the flag. 0: No underrun has occurred in FLECFIFO. 1: An underrun has occurred in FLECFIFO.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	ECERB	0	R/W	ECC Error Indicates the result of ECC error detection. This bit is set to 1 if an ECC error occurs while flash memory is read in sector access mode. No interrupt occurs even if this bit is set to 1. This bit is a flag. 1 cannot be written to this bit. Only 0 can be written to clear the flag. 0: Indicates that no ECC error occurs (Latched ECC is all 0.) 1: Indicates that an ECC error occurs

Bit	Bit Name	Initial Value	R/W	Description
8	STERB	0	R/W	Status Error Indicates the result of status read. This bit is set to 1 if the specific bit in the bits STAT[7:0] in FLBSYCNT is set to 1 in status read. This bit is a flag. 1 cannot be written to this bit. Only 0 can be written to clear the flag. 0: Indicates that no status error occurs (the specific bit in the bits STAT[7:0] in FLBSYCNT is 0.) 1: Indicates that a status error occurs For details on the specific bit in STAT7 to STAT0 bits, see section 28.4.7, Status Read.
7	BTOERB	0	R/W	Timeout Error This bit is set to 1 if a timeout error occurs (the bits RBTIMCNT[19:0] in FLBSYCNT are decremented to 0). This bit is a flag. 1 cannot be written to this bit. Only 0 can be written to clear the flag. 0: Indicates that no timeout error occurs 1: Indicates that a timeout error occurs
6	TRREQF1	0	R/W	FLECFIFO Transfer Request Flag Indicates that a transfer request is issued from FLECFIFO. This bit is a flag. 1 cannot be written to this bit. Only 0 can be written to clear the flag. 0: Indicates that no transfer request is issued from FLECFIFO 1: Indicates that a transfer request is issued from FLECFIFO
5	TRREQF0	0	R/W	FLDTFIFO Transfer Request Flag Indicates that a transfer request is issued from FLDTFIFO. This bit is a flag. 1 cannot be written to this bit. Only 0 can be written to clear the flag. 0: Indicates that no transfer request is issued from FLDTFIFO 1: Indicates that a transfer request is issued from FLDTFIFO

Bit	Bit Name	Initial Value	R/W	Description
4	STERINTE	0	R/W	Interrupt Enable at Status Error Enables or disables an interrupt request to the CPU when a status error has occurred. 0: Disables the interrupt request to the CPU by a status error 1: Enables the interrupt request to the CPU by a status error
3	RBERINTE	0	RW	Interrupt Enable at Timeout Error Enables or disables an interrupt request to the CPU when a timeout error has occurred. 0: Disables the interrupt request to the CPU by a timeout error 1: Enables the interrupt request to the CPU by a timeout error
2	TEINTE	0	R/W	Transfer End Interrupt Enable Enables or disables an interrupt request to the CPU when a transfer has been ended (TREND bit in FLTRCR). 0: Disables the transfer end interrupt request to the CPU 1: Enables the transfer end interrupt request to the CPU
1	TRINTE1	0	R/W	FLECFIFO Transfer Request Enable to CPU Enables or disables an interrupt request to the CPU by a transfer request issued from FLECFIFO. When the DMA transfer is enabled, this bit should be cleared to 0. 0: Disables an interrupt request to the CPU by a transfer request from FLECFIFO. 1: Enables an interrupt request to the CPU by a transfer request from FLECFIFO.

Bit	Bit Name	Initial Value	R/W	Description
0	TRINTE0	0	R/W	FLDTFIFO Transfer Request Enable to CPU Enables or disables an interrupt request to the CPU by a transfer request issued from FLDTFIFO. When the DMA transfer is enabled, this bit should be cleared to 0. 0: Disables an interrupt request to the CPU by a transfer request from FLDTFIFO 1: Enables an interrupt request to the CPU by a transfer request from FLDTFIFO

28.3.9 Ready Busy Timeout Setting Register (FLBSYTMR)

FLBSYTMR is a 32-bit readable/writable register that specifies the timeout time when the FRB pin is busy.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	RBTMOUT[23:0]	H'00000	R/W	Ready Busy Timeout Specify timeout time (the number of HPϕ clocks) in busy state. When these bits are set to 0, timeout is not generated.

28.3.10 Ready Busy Timeout Counter (FLBSYCNT)

FLBSYCNT is a 32-bit read-only register.

The status of flash memory obtained by the status read is stored in the bits STAT[7:0].

The timeout time set in the bits RBTMOUT[19:0] in FLBSYTMR is copied to the bits RBTIMCNT[19:0] and counting down is started when the FRB pin is placed in a busy state. When values in the RBTIMCNT[19:0] become 0, 1 is set to the BTOERB bit in FLINTDMACR, thus notifying that a timeout error has occurred. In this case, an FLSTE interrupt request can be issued if an interrupt is enabled by the RBERINTE bit in FLINTDMACR.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	STAT[7:0]								RBTIMCNT[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RBTIMCNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	STAT[7:0]	H'00	R	Indicate the flash memory status obtained by the status read.
23 to 0	RBTIMCNT [23:0]	H'00 0000	R	Ready Busy Timeout Counter When the FRB pin is placed in a busy state, the values of the bits RBTMOUT[19:0] in FLBSYTMR are copied to these bits. These bits are counted down while the FRB pin is busy. A timeout error occurs when these bits are decremented to 0.

28.3.11 Data FIFO Register (FLDTFIFO)

FLDTFIFO is used to read or write the data FIFO area.

In DMA transfer, data in this register must be specified as the destination (source).

Note that the direction of read or write specified by the SELRW bit in FLCMDCR must match that specified in this register.

When transferring 16-byte DMA, access FLDTFIFO from the address (H'E6A3 0050) on the 16-byte address boundary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	DTFO[31:24]	H'00	R/W	First Data Specify 1st data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data Note: The fourth data is input or output if the ENDIAN bit of FLCMNCR is set to 1.
23 to 16	DTFO[23:16]	H'00	R/W	Second Data Specify 2nd data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data Note: The third data is input or output if the ENDIAN bit of FLCMNCR is set to 1.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	DTFO[15:8]	H'00	R/W	Third Data Specify 3rd data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data Note: The second data is input or output if the ENDIAN bit of FLCMNCR is set to 1.
7 to 0	DTFO[7:0]	H'00	R/W	Fourth Data Specify 4th data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data Note: The first data is input or output if the ENDIAN bit of FLCMNCR is set to 1.

28.3.12 Control Code FIFO Register (FLECFIFO)

FLECFIFO is used to read or write the control code FIFO area.

In DMA transfer, data in this register must be specified as the destination (source).

Note that the direction of read or write specified by the SELRW bit in FLCMDCR must match that specified in this register.

When transferring 16-byte DMA, access FLECFIFO from the address (H'E6A3 0060) on the 16-byte address boundary.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	ECFO[31:24]	H'00	R/W	First Data Specify 1st data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data Note: The fourth data is input or output if the ENDIAN bit of FLCMNCR is set to 1.
23 to 16	ECFO[23:16]	H'00	R/W	Second Data Specify 2nd data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data Note: The third data is input or output if the ENDIAN bit of FLCMNCR is set to 1.
15 to 8	ECFO[15:8]	H'00	R/W	Third Data Specify 3rd data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data Note: The second data is input or output if the ENDIAN bit of FLCMNCR is set to 1.
7 to 0	ECFO[7:0]	H'00	R/W	Fourth Data Specify 4th data to be input or output via the NAF7 to NAF0 pins. In write: Specify write data In read: Store read data Note: The first data is input or output if the ENDIAN bit of FLCMNCR is set to 1.

28.3.13 Transfer Control Register (FLTRCR)

Setting the TRSTRT bit to 1 initiates access to flash memory. Access completion can be checked by the TREND bit. During the transfer (from when the TRSTRT bit is set to 1 until the TREND bit is set to 1), the processing should not be forcibly ended (by setting the TRSTRT bit to 0).

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	TRANSTATUS	TREND	TRSTRT
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	TRANSTATUS	0	R	Transfer State Indicates if the bus mastership of the external bus is acquired and the transfer is being performed. When the I/O pins are for exclusive use by the I/O function and not multiplexed with the external bus, the TRSTRT bit is set to 1. This bit, TRANSTATUS, is also set to 1. 0: Transfer is not started 1: Transfer is being performed or completed
1	TREND	0	R/W	Processing End Flag Bit Indicates that the processing performed in the specified access mode has been completed. The write value should always be 0.
0	TRSTRT	0	R/W	Transfer Start By setting this bit from 0 to 1 when the TREND bit is 0, processing in the access mode specified by the access mode specification bits ACM[1:0] is initiated. 0: Stops transfer 1: Starts transfer

28.3.14 Bus Occupancy Period Setting Register (FLHOLDCR)

FLHOLDCR is used to set the release frequency for the external bus of the FLCTL when another module (including the CPU) accesses the memory in the BSC while writing or reading a page to or from NAND-type flash memory. When the HOLDEN bit in this register is set to 0, the FLCTL occupies the external memory during data exchange with flash memory. Note that a deadlock may occur depending on where the program code is stored or how it is used.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	BUSREQ[1:0]		HOLDEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2, 1	BUSREQ	All 0	R/W	Bus Occupancy Period Setting Sets the bus occupancy period of the FLCTL. 00: Releases the bus when the FLCTL's FIFO becomes empty or full. 01: Releases the bus if another module accesses the memory in the BSC when the FLCTL is using the external bus exclusively. 10: FLCTL accesses are given priority in the following cases even when another module accesses the memory in the BSC when the FLCTL is using the external bus exclusively. • When writing to flash memory If 128 bytes or more data is stored in the FLCTL's FIFO • When reading from flash memory If 128 bytes or less data is stored in the FLCTL's FIFO 11: Setting prohibited However, note that the bus is not released during the transfer period regardless of the setting of this bet if the HOLDEN bit is set to 0.
0	HOLDEN	0	R/W	Bus Occupancy Enable Releases the external bus when writing or reading a page to or from flash memory. 0: The bus is not released ruing the transfer period. 1: The bus is released when the FIFO becomes empty or full.

28.3.15 4-Symbol ECCRESULT1 (FL4ECCRESULT1)

This register is valid only when the 4ECCEN bit and 4ECCCORRECT bits in FLCMNCR are set to 1 and correction patterns are generated based on 4ECCCR. The error correction pattern for the first error location that the 4-symbol ECC circuit outputs and the error position's address for the first error location are set in this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

28.3.19 4-Symbol ECC Control Register (FL4ECCCR)

This register is valid only when the 4-symbol ECC circuit is enabled and the 4ECCCORRECT bit in FLCMNCR is set to 1. When the 4ECCEXST bit in this register is set to 1, the 4-symbol ECC circuit calculates an error correction pattern and the address of the error location for the read data for one sector. When the 4ECCEND bit is set to 1, this indicates that processing is completed. When the 4ECCFA bit is set to 1, this indicates that there are five or more errors or the errors are uncorrectable error patterns. Only 0 can be written to this register. Writing 0 to this register after the 4ECCEND is set to 1, the read operation to flash memory resumes.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	4ECCFA	4ECCEND	4ECCEXST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	4ECCFA	0	R/W	4-Symbol ECC Uncorrectable Only 0 can be written to this bit. Five or more errors detected are handled as uncorrectable and this bit is set to 1. 0: Correctable errors 1: Uncorrectable errors
1	4ECCEND	0	R/W	4-Symbol ECC Correction Pattern Generation Completion Only 0 can be written to this bit. When this bit is set to 1, this indicates that processing up to correction pattern generation is completed. When the 4ECCFA bit is set to 1 and this bit is set to 1, processing was aborted without generating a correction pattern since more than five errors have been detected.

Bit	Bit Name	Initial Value	R/W	Description
0	4ECCEXST	0	R/W	4ECC Correction Execution Only 0 can be written to this bit. When 4ECCCORRECT is 1 when an error is detected, error correction patterns are generated for one sector. 0: Error pattern generation stop 1: Correction patterns being generated When setting this bit to 1, do not write 0 to this register until the 4ECCEND bit is set to 1.

28.3.20 Error Address Indication Register (FLERRADR)

FLCTL stops its operation after reading the error sector if a status error or ECC error occurs while a write to or read from flash memory is in process in “Auto Page Program Operation with Data Cache” or “Read Operation with Read Cache” in high-speed sector access mode. This register indicates the address where read operation has stopped with a physical address.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	ECCADR_COL[1:0]		ERRADR_PAGE[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERRADR_PAGE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
25, 24	ECCADR_ COL [1:0]	00	R/W	When a status error or ECC error occurred, a column address where the read or write operation has stopped is set. Only 0 can be written. 00: First sector 01: Second sector 10: Third sector 11: Fourth sector Note: These bits are always set to 00 for a small-block product.
23 to 0	ERRADR_ PAGE [23:0]	H'00 0000	R/W	When a status error or ECC error occurred, a page address where the read or write operation has stopped is set. Only 0 can be written.

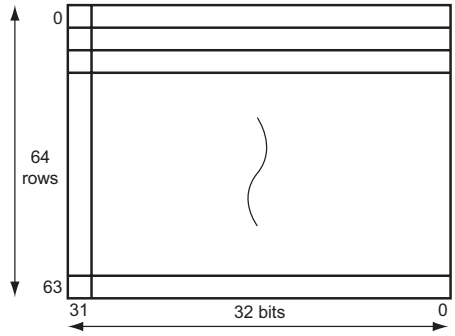
28.3.21 ECC Error Count Register (FL4ECCCNT)

This register is valid only when the 4ECCCNTEN bit in FLCMNCR is set to 1. FLCTL counts the number of ECC errors included in all the sectors that are read from flash memory. If more than five ECC errors are included in one sector, +5 is always set. This register also indicates the maximum number of errors included in one sector in all the sectors that have been read.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	ERRCNT1[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ERRMAX[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 16	ERRCNT [10:0]	H'000	R/W	Error Count Only 0 can be written to these bits. Indicate the total number of errors included in the sectors that have been read continuously (up to one block: 64 pages × 4 sectors). Even if a sector contains more than five errors, the number of errors is counted as 5.
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	ERRMAX [2:0]	000	R/W	Maximum Error Count Only 0 can be written to these bits. Indicates the maximum number of errors contained in a sector after comparing the number of errors contained in all the sectors that have been read. 000: The maximum number of errors was 0. 001: The maximum number of errors was 1. 010: The maximum number of errors was 2. 011: The maximum number of errors was 3. 100: The maximum number of errors was 4. 101: The maximum number of errors was 5 or more. 110: Not set. 111: Not set.



28.3.22 "Auto Page Program Operation with Data Cache" Command Address Specification Memory

This is a memory area to specify an address for the "Auto Page Program Operation with Data Cache" command. Write the page addresses to write from address 0 in the order of pages to be written. If the data written in this area matches H'8*** ****, the "Auto Page Program Operation with Data Cache" command is terminated.

If the ACM1 and ACM0 bits in the common control register (FLCMNCR) are set to B'10, the addresses set in the address register and address register 2 become invalid, and the address specified in this register becomes valid.

Only longword access can be made from the CPU to this memory area. Set the page address in bits 30 to 0 starting from the LSB. Set any unused upper bit to 0.

The address area is H'E6A3 1000 to H'E6A3 1100.

28.4 4-Symbol ECC

28.4.1 Overview of the 4-Symbol ECC Circuit

The former FLCTL used to have information that enables error correction for up to three symbols and the ECC code generation function that makes corrections using software. This FLCTL has information that enables error correction for up to four symbols and the ECC code generation function that can generate error correction patterns using hardware to support multi-level cell (MLC) flash memory. Generation of error correction patterns means generation of information required for error correction, not executing error correction.

Although the 4-symbol ECC circuit included in this FLCTL can correct errors of up to 10 bits per symbol (up to 40 bits in four symbols), it corrects errors of up to 32 bits because 8 bits are counted as one symbol in the data area of flash memory.

The 4-symbol ECC circuit consists of three stages:

1. ECC code generation circuit
2. Error location detection circuit
3. Error correction pattern generation circuit

ECC code can be generated consecutively. An error is determined and an error correction pattern is generated on a per-sector basis.

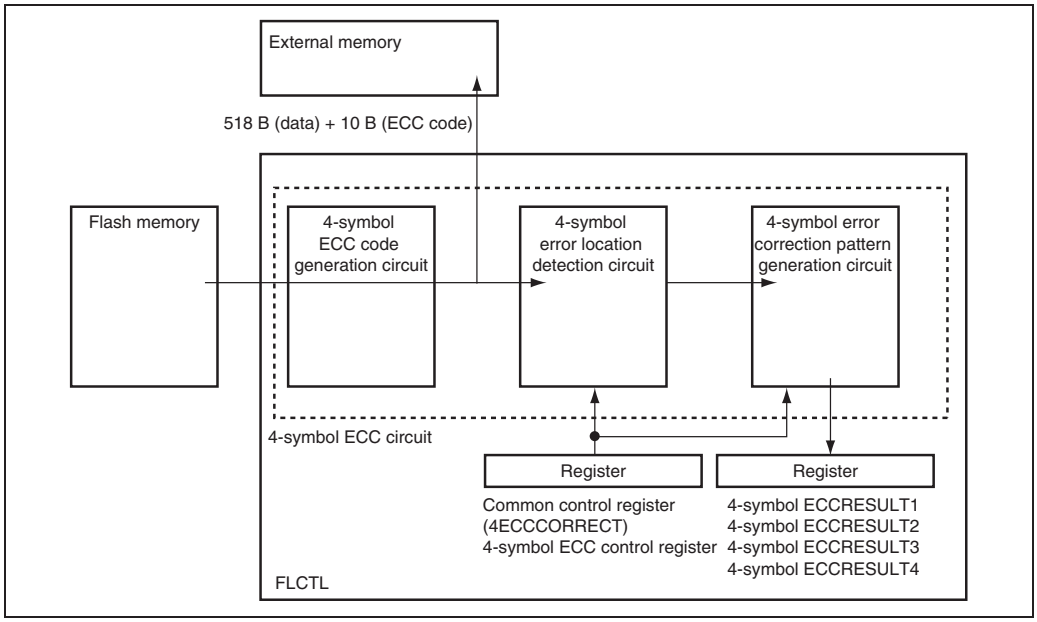


Figure 28.2 4-Symbol ECC Circuit Block Diagram

28.4.2 4-Symbol ECC Operation

Figure 28.3 shows the operation flow when the 4-symbol ECC circuit is used. When the 4ECCEN bit in FLCMNCR is set to 1, the 4-symbol ECC circuit is enabled. Information required for generating correction patterns is stored in the 4-symbol ECC circuit when the 4ECCCORRECT bit in the FLCMNCR is set to 1.

To execute ECC error determination and error correction, set the 4ECCCR register after reading one sector. No error can be corrected if there are five or more errors in one sector. If all of the 4-symbol ECCRESULT1, 4-symbol ECCRESULT2, 4-symbol ECCRESULT3 and 4-symbol ECCRESULT4 are set to the initial values after correction processing, this indicates that there has been no ECC error.

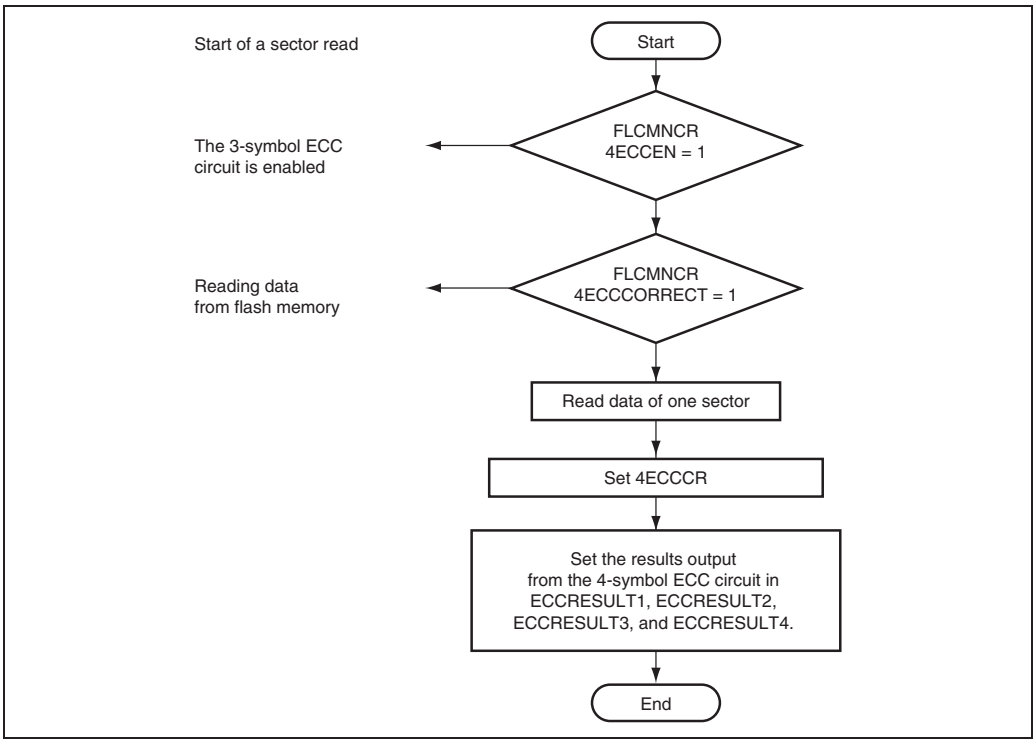

Figure 28.3 4-Symbol ECC Operation Flow

28.4.3 Error Correction Pattern Generation

The 4-symbol ECC circuit contained in this FLCTL can generate error correction patterns using hardware. Correction patterns allow data to be restored to the original correct values. Hardware can only generate error correction patterns. The data should be restored using software.

Error correction patterns are output in the following formats. Since the error bit is set to 1, the restoration data is EOR of the error data and error correction pattern.

Example 1
Original data: B'00000000
Error data: B'11111111
Correction pattern: B'0011111111 (The upper two bits are unnecessary)
Restoration data: B'00000000
(The error pattern and correction pattern are EORed.)

Example 2
Original data: B'10101010
Error data: B'01010101
Correction pattern: B'0011111111 (The upper two bits are unnecessary)
Restoration data: B'10101010
(The error pattern and correction pattern are EORed.)

Example 3
Original data: B'11110000
Error data: B'00000000
Correction pattern: B'0011110000 (The upper two bits are unnecessary)
Restoration data: B'11110000
(The error pattern and correction pattern are EORed.)

28.4.4 Flow when an ECC Error Occurs

figure 28.4 and figure 28.5 shows the flow when an ECC error occurs (when using 4-symbol ECC).

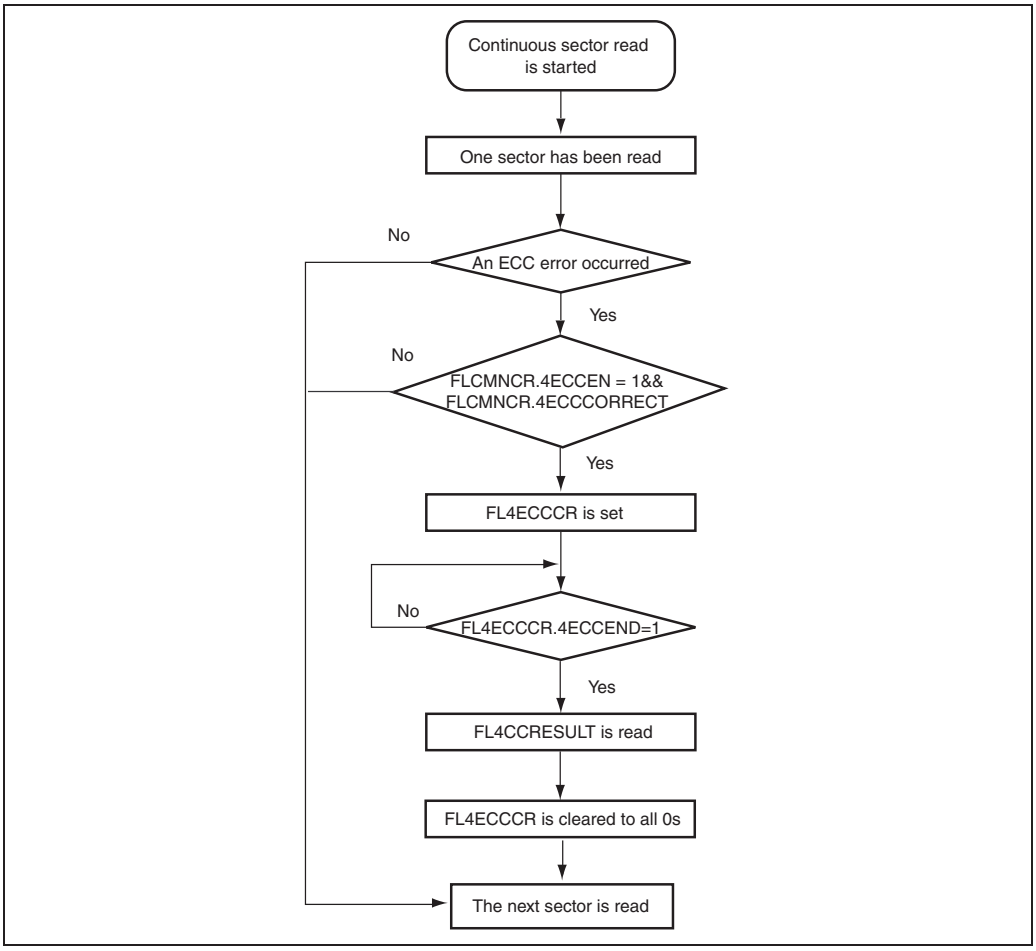

Figure 28.4 Flow when an ECC Error Occurs

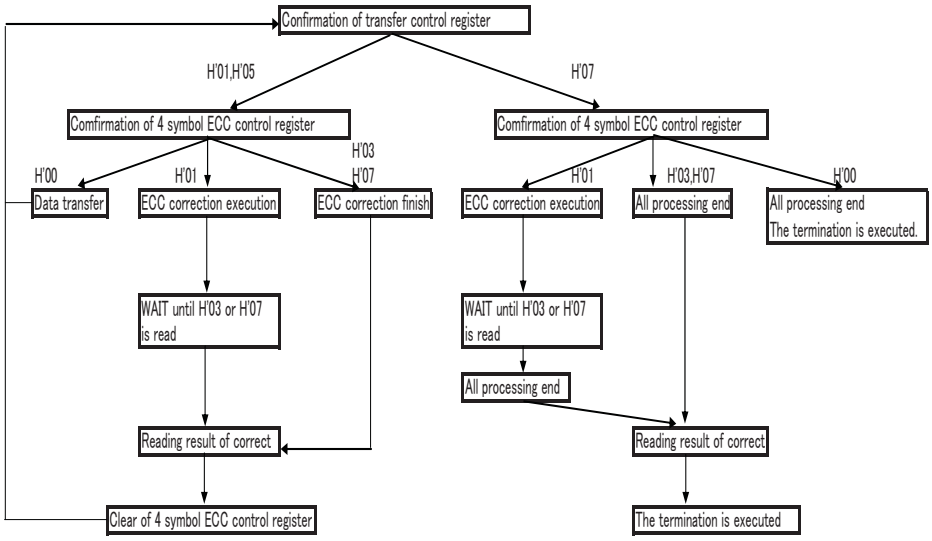

Figure 28.5 process end flow When ECC Error Occurs

28.5 Connection with 16-bit I/O Products

16-bit I/O flash memory can be connected by setting the 16BITSEL bit in FLCMNCR to 1. Set the NANDWF bit in FLCMNCR to 1 when connecting to a 16-bit I/O product.

The basic internal operation of FLCTL is the same as when connecting an 8-bit I/O product. The interface section of FLCTL performs 8- to 16-bit conversion and 16- to 8-bit conversion, and is connected to flash memory as shown in figure 28.6. Figure 28.7 shows an example when using FLDTFIFO with the ENDIAN bit in FLCMNCR set to 0.

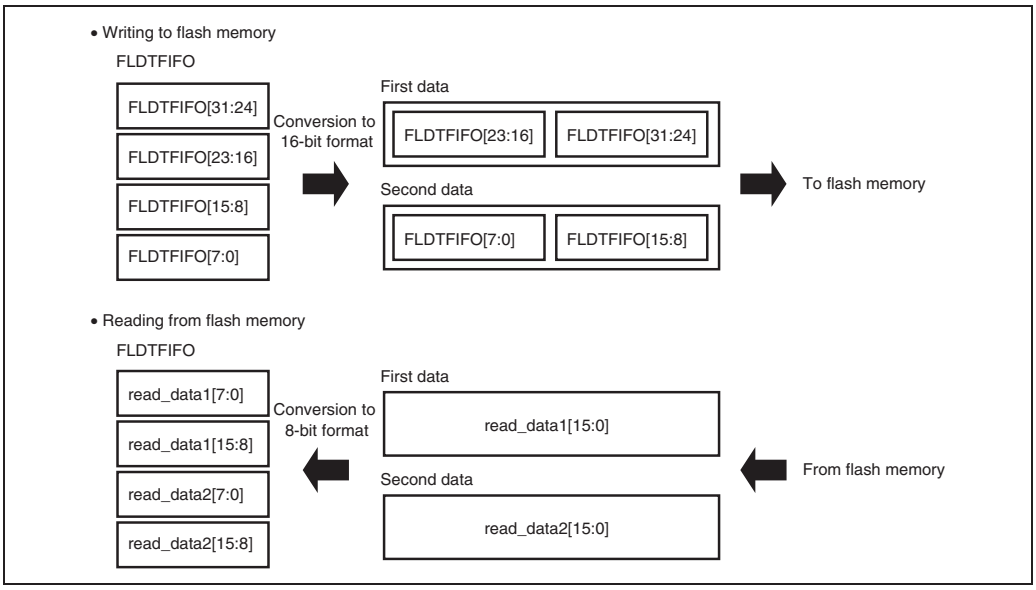

Figure 28.6 Connection with 16-bit I/O Flash Memory

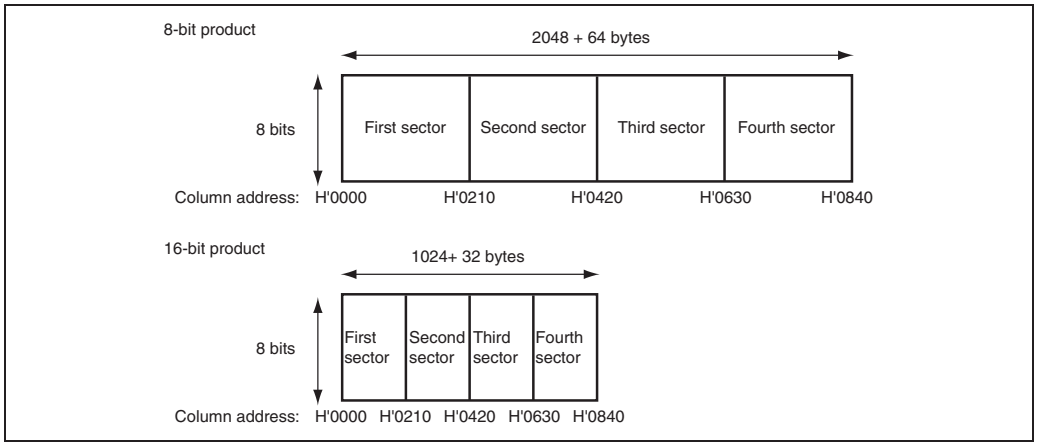

Figure 28.7 Data Allocation

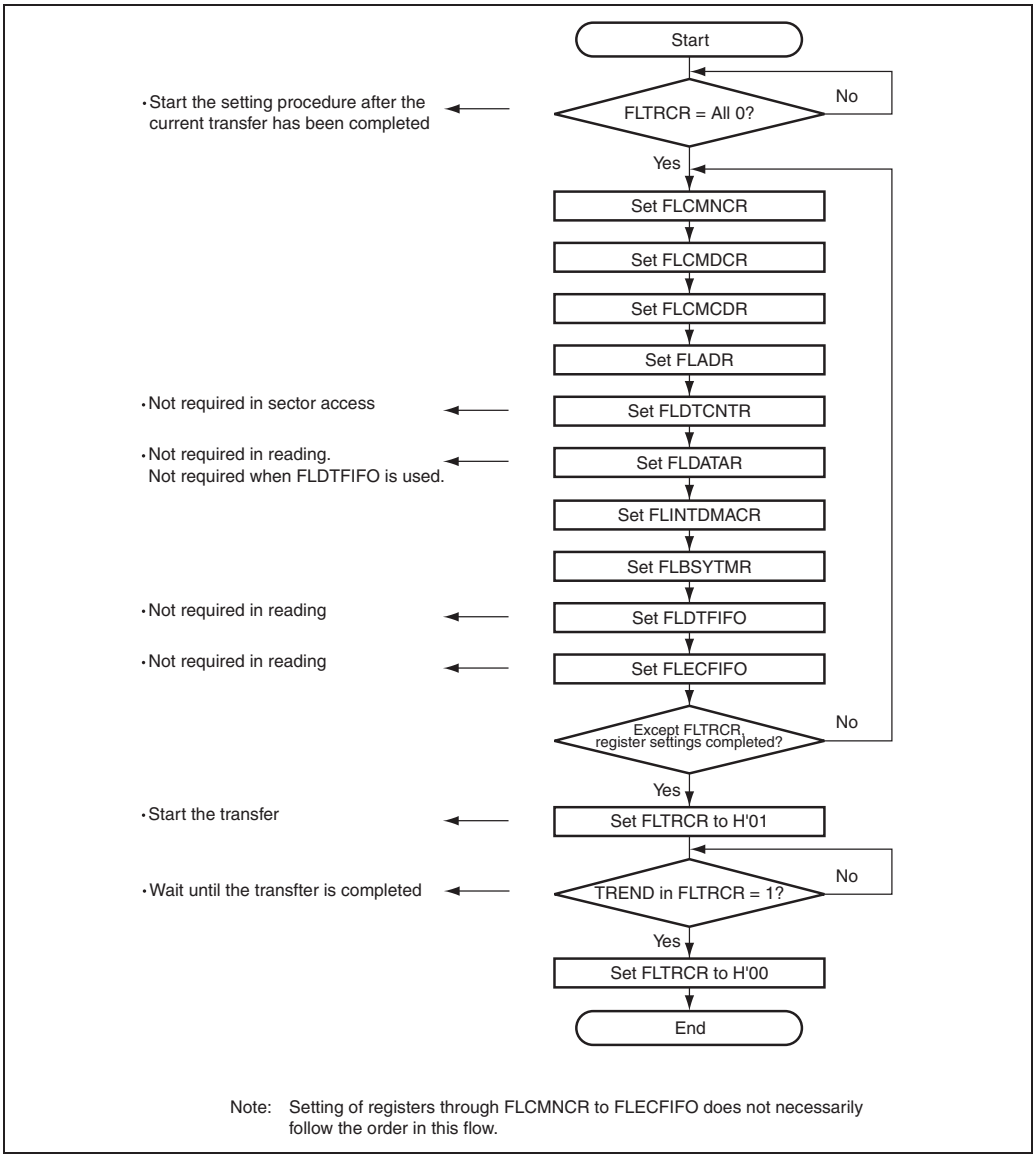
28.6 Operation

28.6.1 Operating Modes



Two operating modes are supported.

- Command access mode
- Sector access mode

The ECC generation and error check are performed in sector access mode.

28.6.2 Register Setting Procedure

Figure 28.8 shows the register setting flow required for accessing to the flash memory.

Note: Setting of registers through FLCMNCR to FLECFIFO does not necessarily follow the order in this flow.

Figure 28.8 Register Setting Flow

28.6.3 Command Access Mode

Command access mode accesses flash memory by specifying a command to be issued to flash memory, address, data, read or write direction, and number of times to the registers. In this mode, I/O data can be transferred by the DMA via FLDTFIFO.

(1) NAND-Type Flash Memory Access

Figure 28.9 shows an example of read operation for NAND-type flash memory. In this example, the first command is specified as H'00, address data length is specified as 3 bytes, and the number of read bytes is specified as 8 bytes in the data counter.

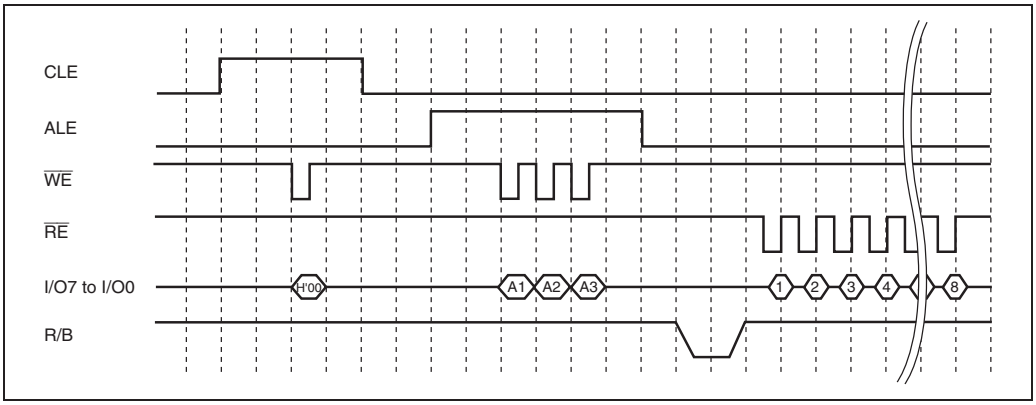


Figure 28.9 Read Operation Timing for NAND-Type Flash Memory (1)

Figures 28.9 and 28.10 show examples of programming operation for NAND-type flash memory.

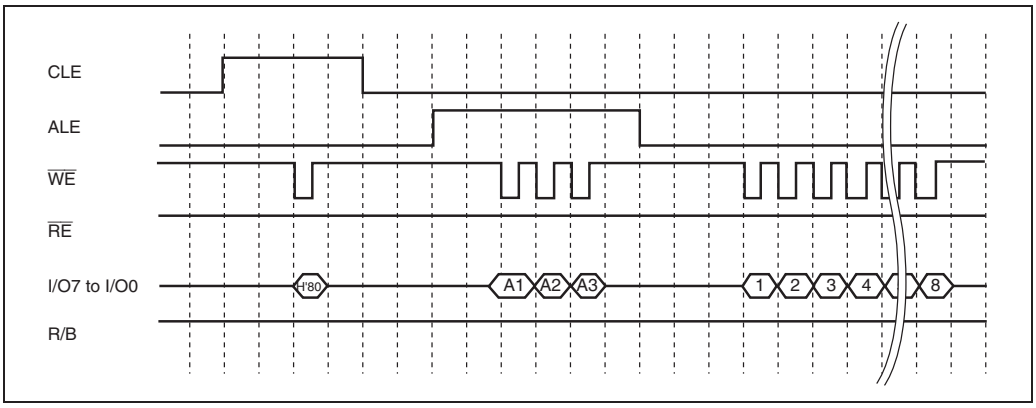

Figure 28.10 Programming Operation Timing for NAND-Type Flash Memory (1)

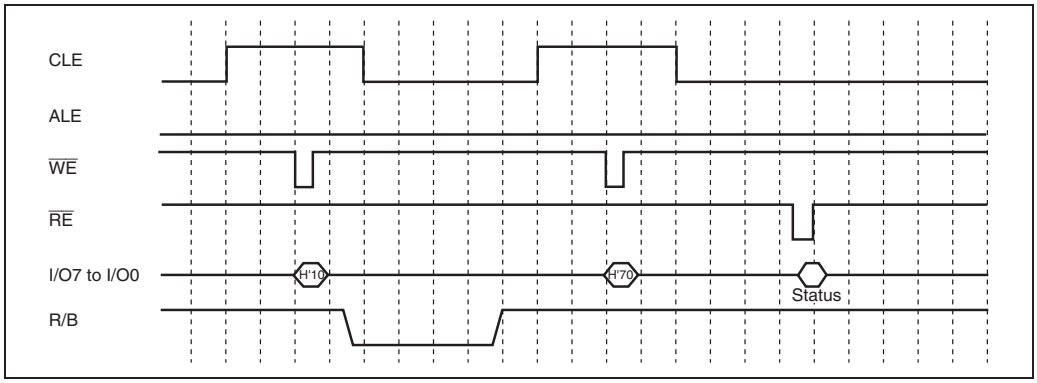

Figure 28.11 Programming Operation Timing for NAND-Type Flash Memory (2)

(2) NAND-Type Flash Memory (2048 + 64 Bytes) Access

Figure 28.12 shows an example of read operation for NAND-type flash memory (2048 + 64 bytes). In this example, the first command is specified as H'00, the second command is specified as H'30, and address data length is specified as 4 bytes. The number of read bytes is specified as 4 bytes in the data counter.

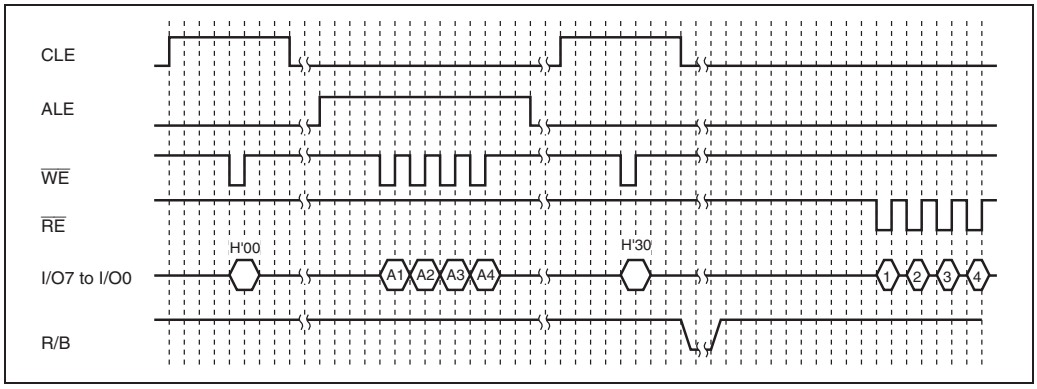

Figure 28.12 Read Operation Timing for NAND-Type Flash Memory

Figures 28.13 and 28.14 show examples of programming operation for NAND-type flash memory (2048 + 64 bytes).

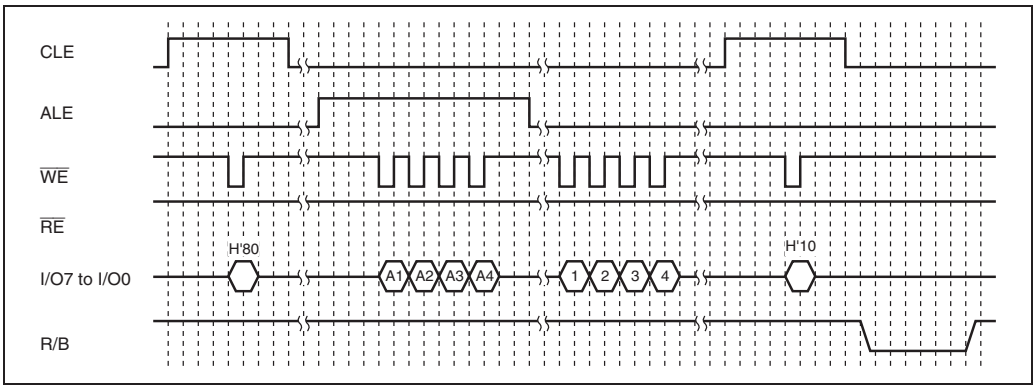

Figure 28.13 Programming Operation Timing for NAND-Type Flash Memory (1)

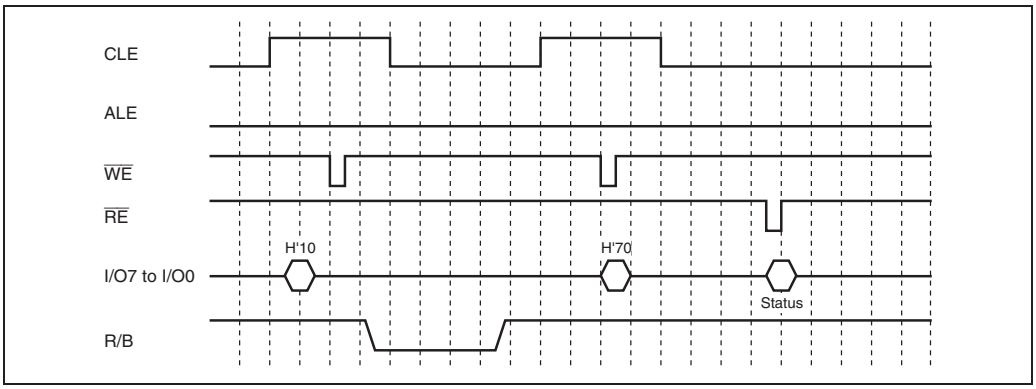

Figure 28.14 Programming Operation Timing for NAND-Type Flash Memory (2)

28.6.4 Sector Access Mode

In sector access mode, flash memory can be read or programmed in sector units by specifying the number of physical sectors to be accessed. In programming, an ECC is added. In read, an ECC error check (detection) is performed.

Since 512-byte data is stored in FLDTFIFO and 16-byte control code is stored in FLECFIFO, the DREQ1EN and DREQ0EN bits in FLINTDMACR can be set to transfer by the DMA.

Figure 28.15 and 28.16 shows the relationship of DMA transfer between sectors in flash memory (data and control code) and memory on the address space.

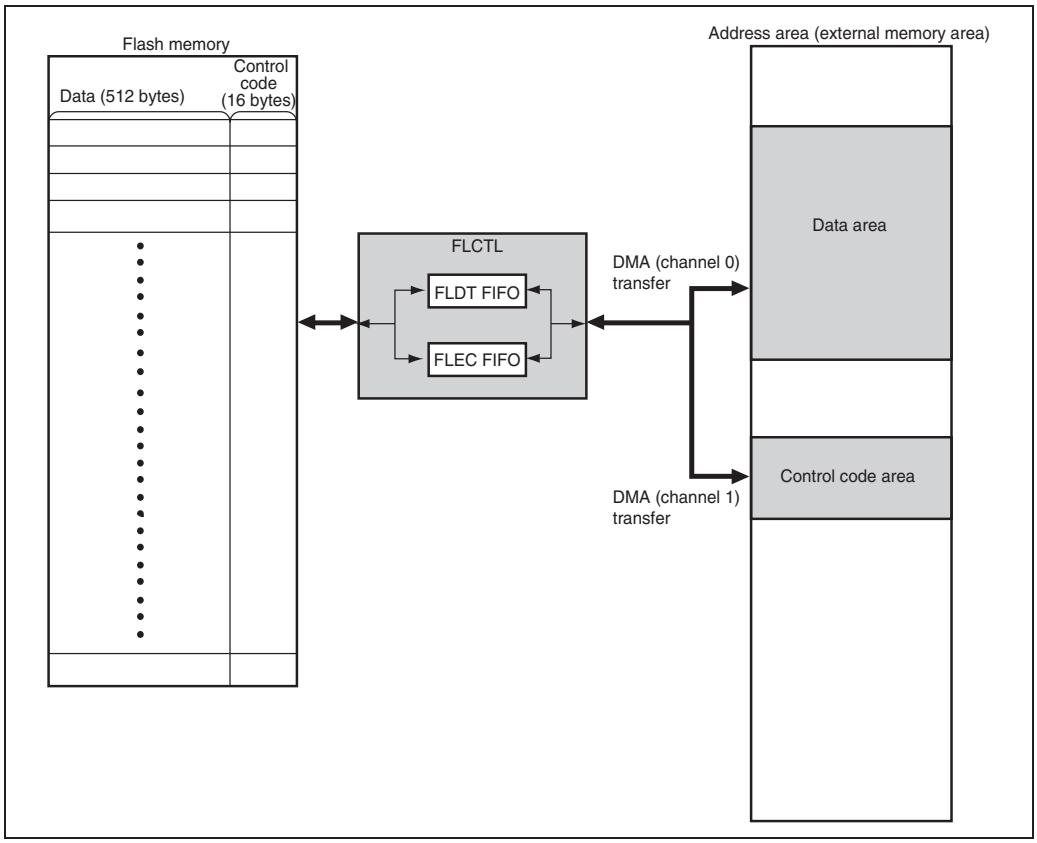

Figure 28.15 Relationship between DMA Transfer and Sector (Data and Control Code), and Memory and DMA Transfer

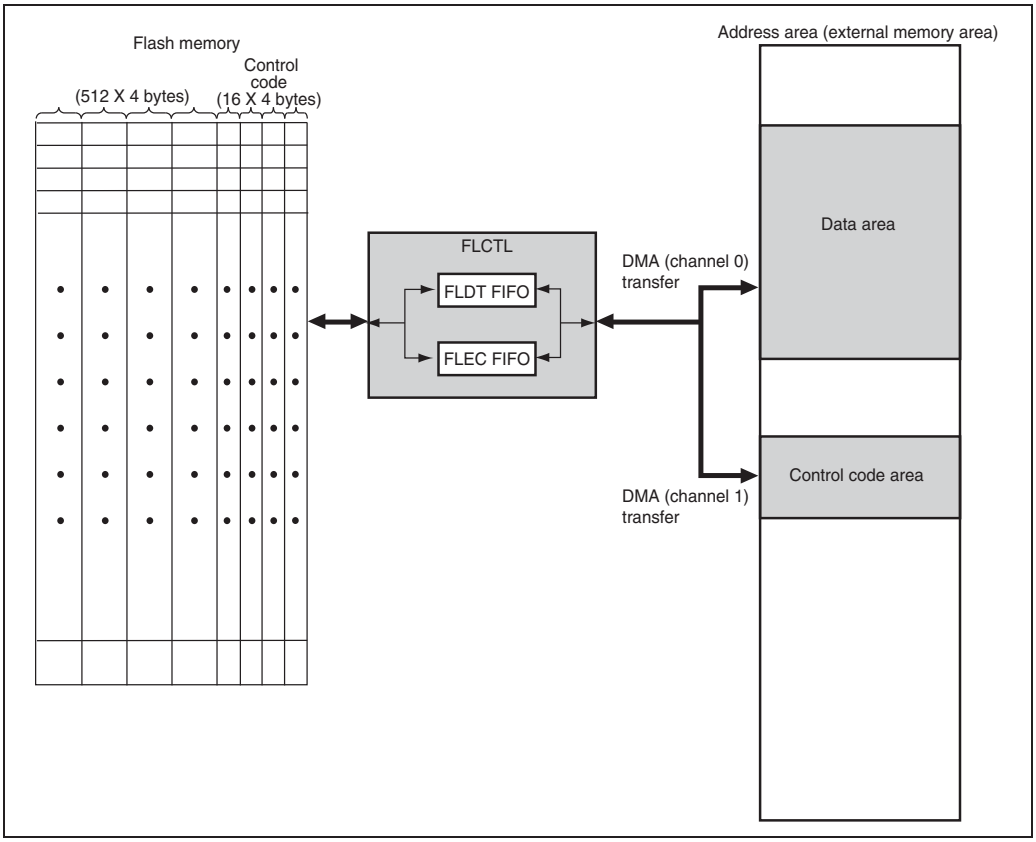

Figure 28.16 Relationship between DMA Transfer and Sector (Data and Control Code), and Memory and DMA Transfer

(1) Physical Sector

Figure 28.17 shows the relationship between the physical sector address of NAND-type flash memory and the address of flash memory.

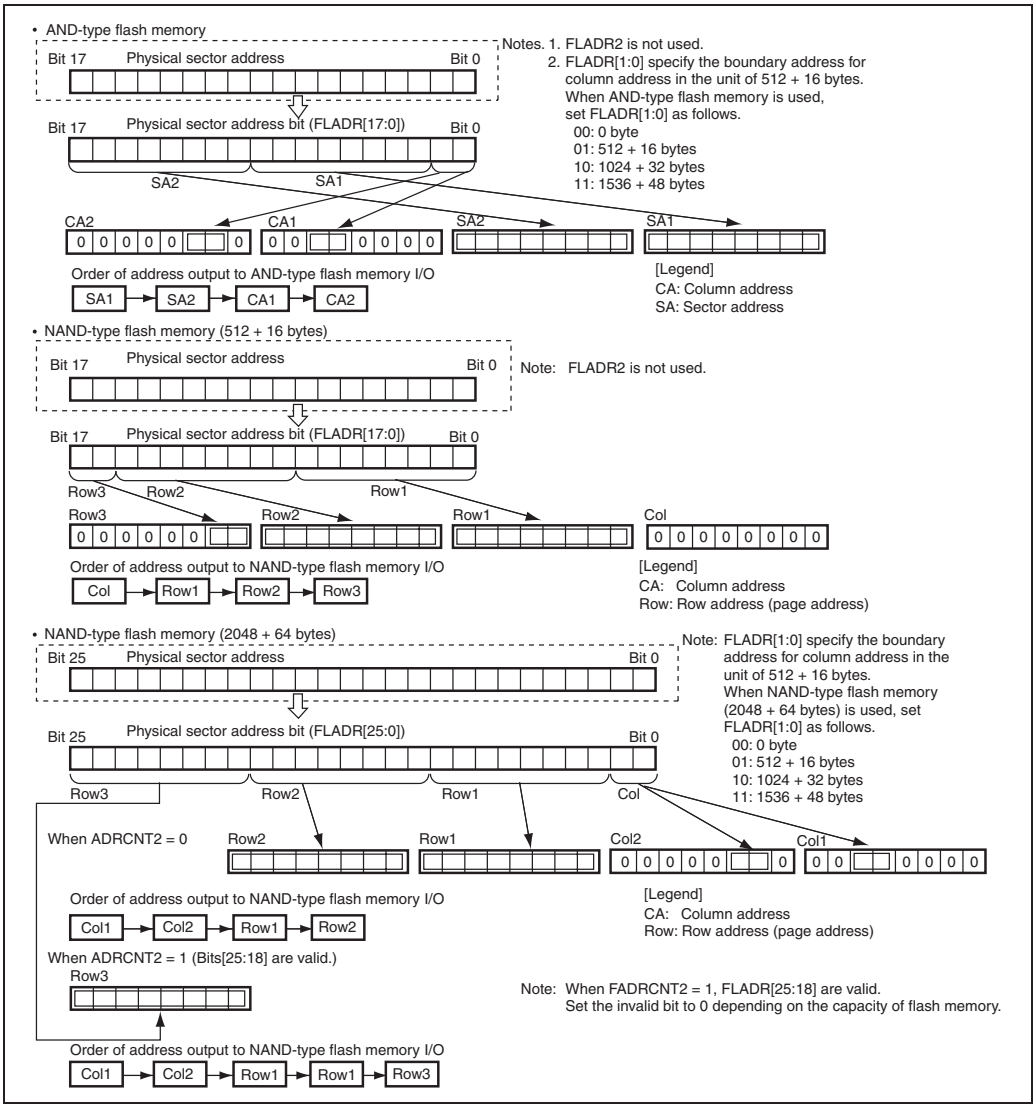

Figure 28.17 Relationship between Sector Number and Address Expansion of NAND-Type Flash Memory (1)

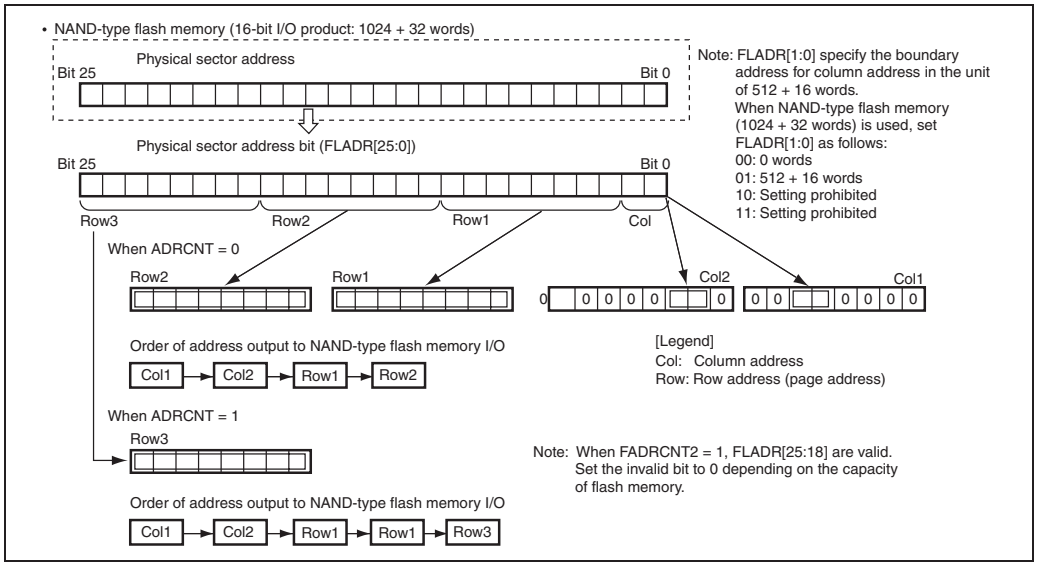

Figure 28.18 Relationship between Sector Number and Address Expansion of NAND-Type Flash Memory (2)

(2) Continuous Sector Access

Continuous physical sectors can be read or written by specifying the start physical sector of NAND-type flash memory and the number of sectors to be transferred. Figure 28.19 shows an example of physical sector specification register and transfer count specification register settings when transferring logical sectors 0 to 40, which are not contiguous because of an unusable sector in NAND-type flash memory.

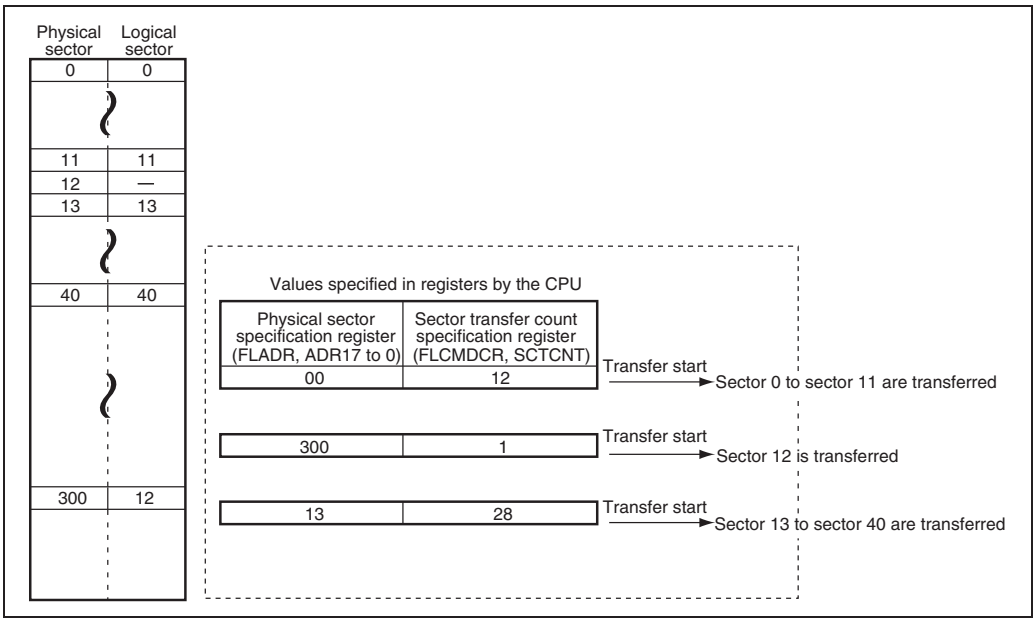

Figure 28.19 Sector Access when Unusable Sector Exists in Continuous Sectors

(3) Flash Memory Access In Sector Access Mode

Figures 28.20 and 28.21 show the waveforms when performing a programming and read operation to NAND-type flash memory in sector access mode.

Figure 28.20 shows the waveform when programming a large-block product whose IO size is 8 bits and memory size is 1 Gbits. A value is programmed into the flash memory in the waveform shown in figure 28.20 for each page (2048 + 64 bytes).

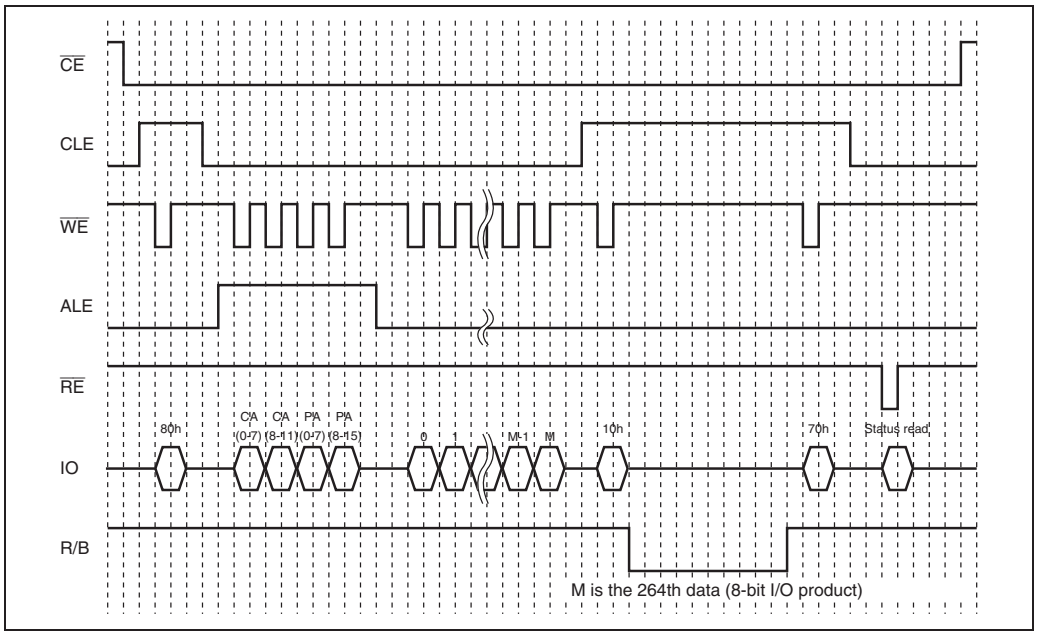

Figure28.20 Programming Operation Timing for NAND-Type Flash Memory (Sector Access Mode)

Figure 28.21 shows the waveform when programming a large-block product whose IO size is 8 bits and memory size is 1 Gbits. A value is programmed into the flash memory in the waveform shown in figure 28.21 for each page (2048 + 64 bytes).

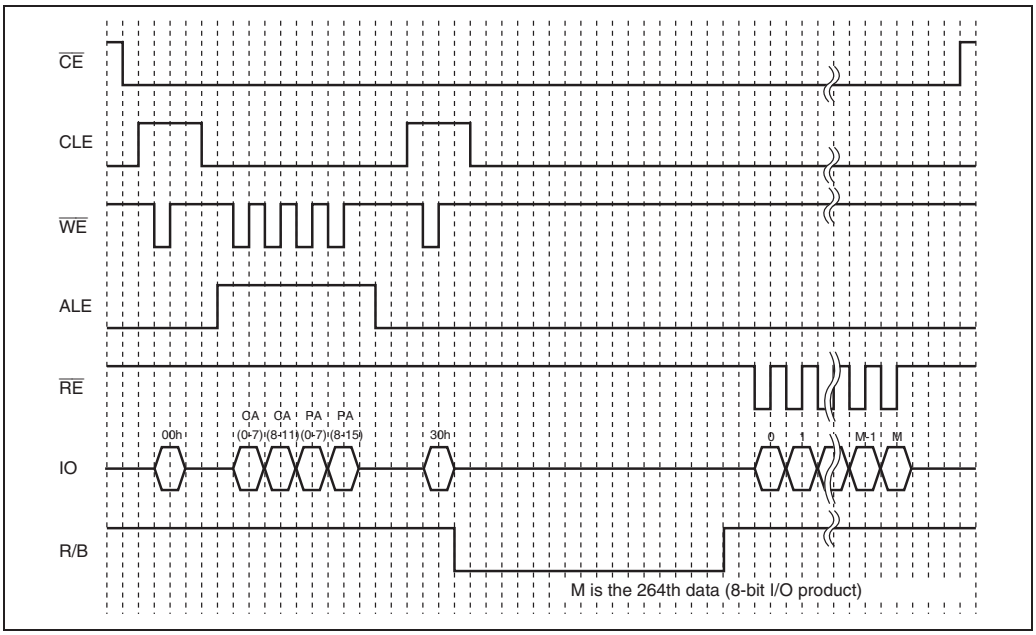

Figure 28.21 Read Operation Timing for NAND-Type Flash Memory (Sector Access Mode)

(4) Flash Memory Access in High-Speed Sector Access Mode

Figures 28.22 to 28.25 show the waveforms when performing a programming and read operation to NAND-type flash memory in high-speed sector access mode. Note that some products do not support high-speed access mode depending on the connected flash memory.

Figures 28.22 and 28.23 show the waveforms when programming in high-speed access mode a large-block product whose IO size is 8 bits and memory size is 1 Gbits. High-speed access mode shortens the busy period.

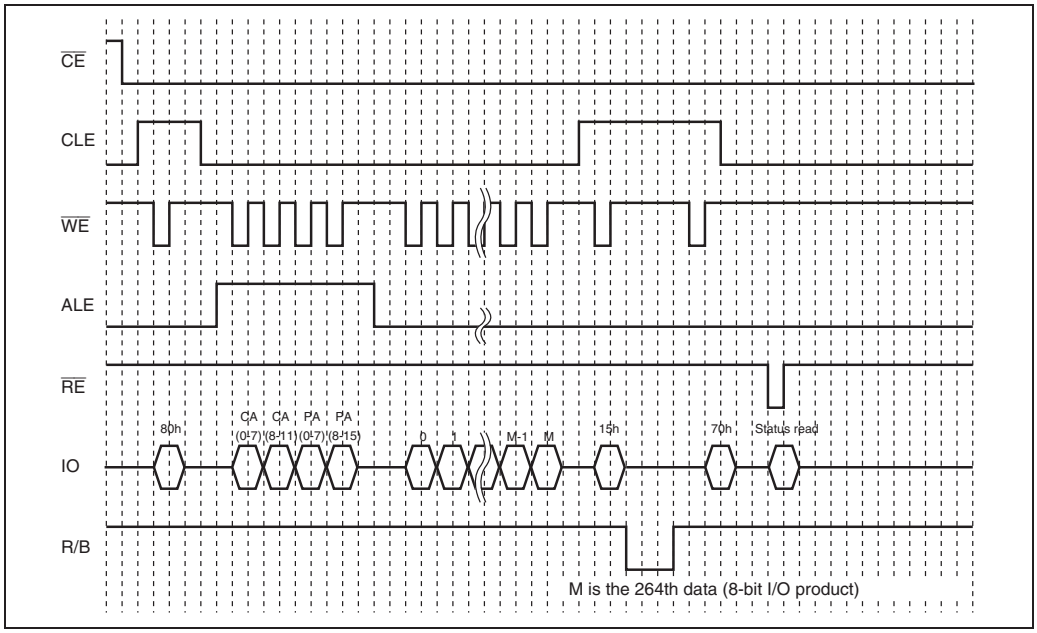

Figure28.22 Programming Operation Timing for NAND-Type Flash Memory (1) (High-speed Sector Access Mode)

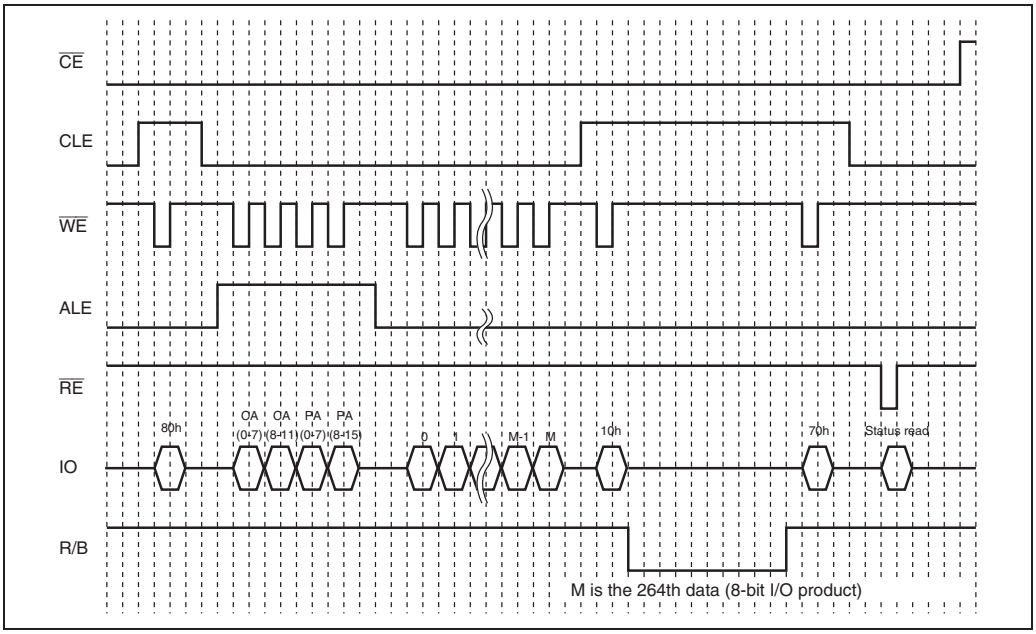

Figure28.23 Programming Operation Timing for NAND-Type Flash Memory (2) (High-speed Sector Access Mode)

Figures 28.24 and 28.25 show the waveforms when reading in high-speed access mode a large-block product whose IO size is 8 bits and memory size is 1 Gbits. High-speed access mode shortens the busy period.

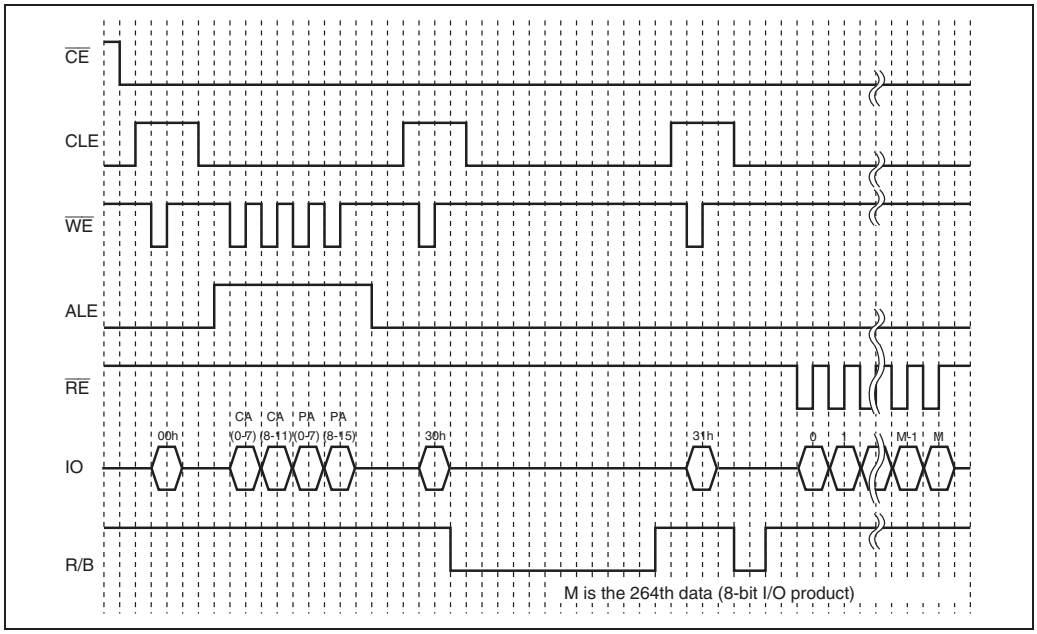

Figure 28.24 Read Operation Timing for NAND-Type Flash Memory (1) (High-speed Sector Access Mode)

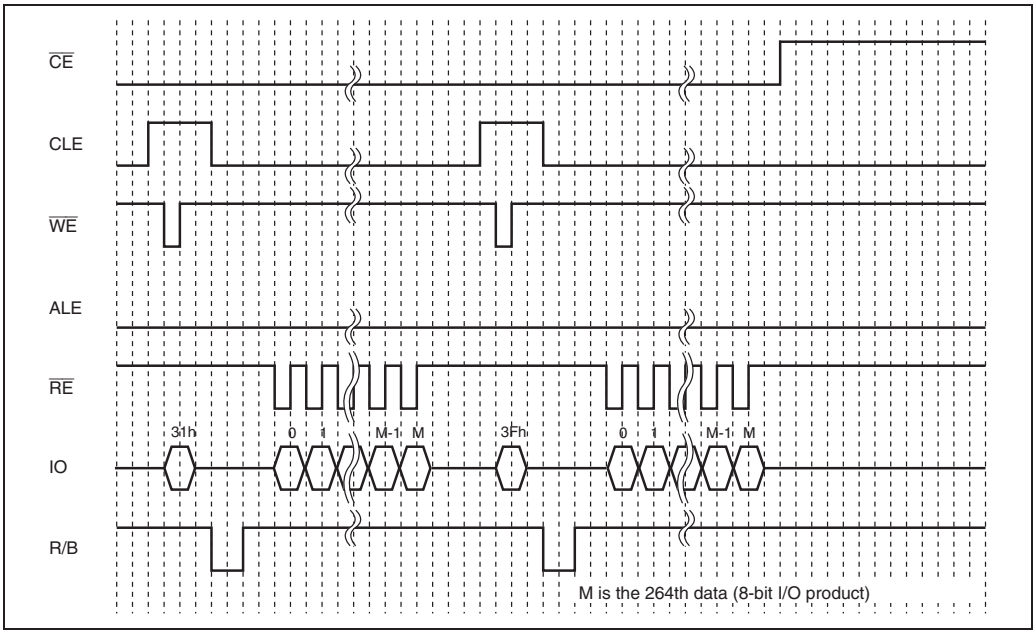

Figure28.25 Read Operation Timing for NAND-Type Flash Memory (2) (High-speed Sector Access Mode)

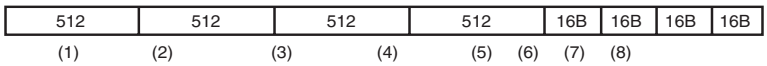
(5) Large-block Memory Access



FLCTL accesses large-block memory (2048 + 64 bytes per page) in two ways.

The FLMLC bit (bit 26) in the common control register can be used to switch the access method. The figures below show the data array in flash memory at each access.

a) When FLMLC=0

b) When FLMLC=1

When FLMLC=1, memory is accessed in the following sequence by changing the column address:

1. Access the first sector (sector (1) in the figure above)
2. Change the column address (change the address to control code area (5) in the figure above)
3. Access the control code area (area (5) in the figure above)
4. Change the column address (change the address to second sector (2) in the figure above)
5. Access the second sector (sector (2) in the figure above)
6. Change the column address (change the address to control code area (6) in the figure above)
7. Access the control code area (area (6) in the figure above)
8. Change the column address (change the address to third sector (3) in the figure above)
9. Access the third sector (sector (3) in the figure above)
10. Change the column address (change the address to control code area (7) in the figure above)
11. Access the control code area (area (7) in the figure above)
12. Change the column address (change the address to fourth sector (4) in the figure above)
13. Access the fourth sector (sector (4) in the figure above)

14. Change the column address (change the address to control code area (8) in the figure above)

15. Access the control code area (area (8) in the figure above)

28.6.5 ECC Error Correction

When using the 3-symbol ECC circuit, the FLCTL generates and adds an ECC code during write operation in sector access mode and performs ECC error check during read operation in sector access mode. The FLCTL, however, does not perform error correction. Note that errors must be corrected by software.

When using the 4-symbol ECC circuit, the FLCTL generates and adds an ECC code during write operation in sector access mode, and performs ECC error check during read operation in sector access mode and outputs error correction patterns. The FLCTL, however, does not replace error data. Note that error data must be replaced by software.

28.6.6 Status Read

The FLCTL can read the status register of an NAND-type flash memory. The data in the status register of an NAND-type flash memory is input through the I/O7 to I/O0 pins and stored in the STAT7 to STAT70 bits in FLBSYCNT. The STAT7 to STAT70 bits in FLBSYCNT can be read by the CPU. If a program error or erase error is detected when the status register value is stored in the STAT7 to STAT70 bits in FLBSYCNT, the STERB bit in FLINTDMACR is set to 1 and generates an interrupt to the CPU if the STERINTE bit in FLINTDMACR is enabled.

(1) Status Read of NAND-Type Flash Memory

The status register of NAND-type flash memory can be read by inputting command H'70 to NAND-type flash memory. If programming is executed in command access mode or sector access mode while the DOSR bit in FLCMDCR is set to 1, the FLCTL automatically inputs command H'70 to NAND-type flash memory and reads the status register of NAND-type flash memory. When the status register of NAND-type flash memory is read, the I/O7 to I/O0 pins indicate the following information as described in table 28.4.

Table 28.4 Status Read of NAND-Type Flash Memory

I/O	Status (definition)	Description
I/O7	Program protection	0: Cannot be programmed 1: Can be programmed
I/O6	Ready/busy	0: Busy state 1: Ready state
I/O5 to I/O1	Reserved	—
I/O0	Program/erase	0: Pass 1: Fail

28.7 Interrupt Sources

The FLCTL has six interrupt sources: Status error, ready/busy timeout error, ECC error, transfer end, FIFO0 transfer request, and FIFO1 transfer request. Each of the interrupt sources has its corresponding interrupt flag and the interrupt can be requested independently to the CPU if the interrupt is enabled by the interrupt enable bit. Note that the status error, ready/busy timeout error, and ECC error use the common FLSTE interrupt to the CPU.

Table 28.6 FLCTL Interrupt Requests

Interrupt Source	Interrupt Flag	Enable Bit	Description	Priority
FLSTE interrupt	STERB	STERINTE	Status error	Highest
	BTOERB	RBERINTE	Ready/busy timeout error	
	ECERB	ECERINTE	ECC error	
FLTEND interrupt	TREND	TEINTE	Transfer end	
FLTRQ0 interrupt	TRREQF0	TRINTE0	FIFO0 transfer request	
FLTRQ1 interrupt	TRREQF1	TRINTE1	FIFO1 transfer request	Lowest

Note: Flags for the FIFO0 overrun error/underrun error and FIFO1 overrun error/underrun error also exist. However, no interrupt is requested to the CPU.

28.8 DMA Transfer Specifications

The FLCTL can request DMA transfers separately to the data area FLDTFIFO and control code area FLECFIFO. Table 28.7 summarizes DMA transfer enable or disable states in each access mode.

Table 28.7 DMA Transfer Specifications

	Sector Access Mode	Command Access Mode
FLDTFIFO	DMA transfer enabled	DMA transfer enabled
FLECFIFO	DMA transfer enabled	DMA transfer disabled

In little endian form, these bits should not be used because a 16-byte DMA transfer causes a data replacement in longword units.

Usage Notes

(1) Usage Notes on the BUSYON Bit

The FLCTL negates $\overline{CE}$ when finishing a sequence of operations whether it is busy or ready. Note that $\overline{CE}$ is negated and the bus mastership is released at the same time as FLCTL processing is completed even during a busy period when bit 21 (BUSYON) in the common control register (FLCMNCR) is set to 0. When BUSYON = 0, the bus mastership can be obtained even during the busy period by setting bit 24 (DOSR) in the command control register (FLCMDCR) to 1 and executing a status read.

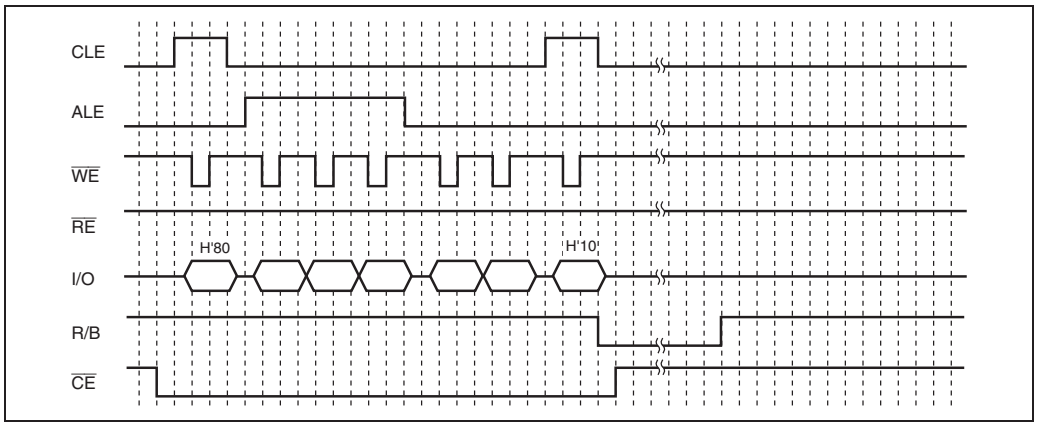


Figure28.26 BUSYON = 0 and DOSR = 0 (Programming to Flash Memory)

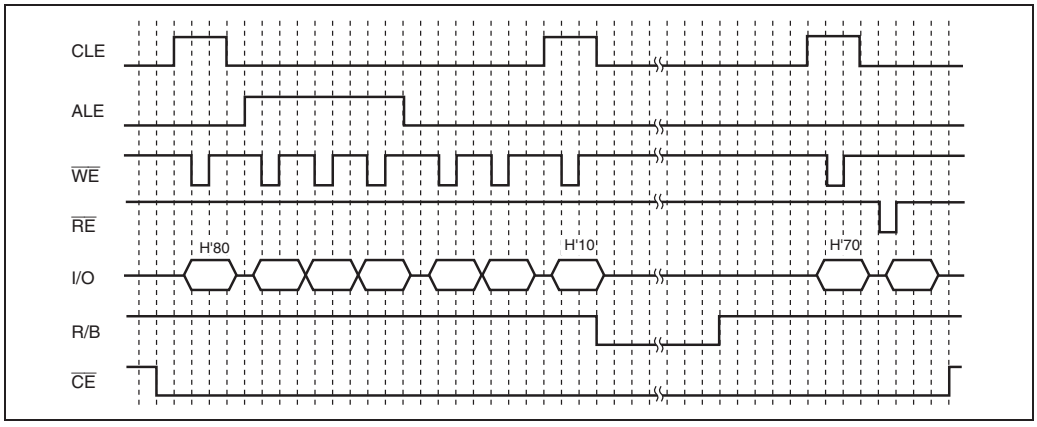

Figure28.27 BUSYON = 0 and DOSR = 1 (Programming to Flash Memory)

(2) Usage Notes on the SNAND Bit

When the SNAND bit of the common control register (FLCMNCR) is set to 1, only the first and second commands are supported regardless of the settings of DOCMD1 and DOCMD2 of the command control register (FLCMDCR).

Set the SNAND bit to 0 when no command is issued or only the first command is issued.

Section 29 Multifunctional Interface (MFI)

The multifunctional interface (MFI) incorporated in this LSI consists of the MFIM, which has an interface of the on-chip ROM, and the MFIS, which has an interface between the SYS domain and the realtime domain (RT domain).

The MFIM allows reading from the on-chip ROM space (MMFROM) for the MFIM, in 32-bit units. The MMFROM is accessible from the SYS domain.

From the SYS domain, the MFIS allows reading from and writing to the on-chip RAM space (SMFRAM) for the MFIS in 32-bit units. The SMFRAM is accessible from both the SYS domain and the RT domain. The MFIS also supports the issuing of interrupts by the SYS domain for the RT domain and interrupts by the RT domain for the SYS domain. The SMFRAM along with these interrupt functions allows software-like data transfer between the SYS domain and the RT domain.

29.1 Features of the MFIM

- The MMFROM space can be read from in 32-bit units.

Figure 29.1 shows a block diagram of the MFIM.

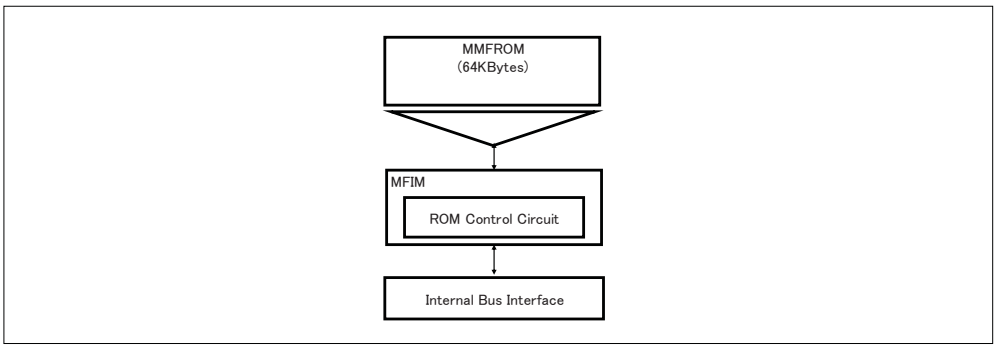

Figure 29.1 MFIM Block Diagram

29.2 Register Descriptions

Table 29.1 shows the MFIM register configuration.

Table 29.1 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
MMFROM	MMFROM	R	H'E6B0 0000 to H'E6B0 FFFF	32, 16, 8

29.3 Features of the MFIS

- Provides for reading from and writing to the SMFRAM in 32-bit units.
- Automatic address incrementation and selectable endian.
- By writing to specific bits of the internal registers of the MFIS from the SYS domain, interrupts can be sent to the RT domain. Conversely, interrupts can also be sent from the RT domain to the SYS domain.
- Two seven-bit interrupt sources are provided, one for the BB domain and the other for the SYS domain. As a result, 128 different interrupts can be controlled by software, enabling high-speed data transfer using interrupts.

Figure 29.7 shows a block diagram of the MFIS.

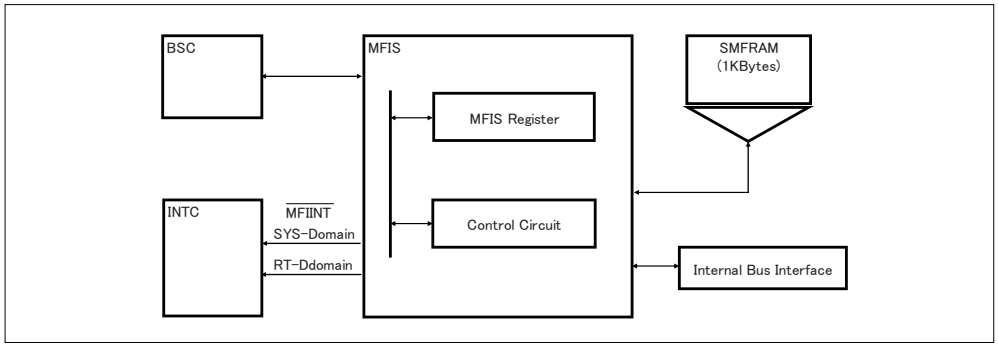

Figure 29.7 MFIS Block Diagram

29.4 Register Descriptions of MFIS

Table 29.5 shows the MFI register configuration. Table 29.6 shows the register states in each operating mode.

29.4.1 MFIS Index Register (MFISIDX)

MFISIDX is a 32-bit register used to specify the register for reading from and writing to the MFI with the second bit (A2) in the address of the bus state controller (BSC) held 0. From the MFI, this register can only be written while the A2 is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	REG[5:0]						BYTE[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 2	REG[5:0]	000000	R/W*	MFIS Internal Register Select 000000: MFISGSR 000001: MFISSCR 000010: MFISMCR 000011: MFISIICR 000100: MFISEICR 000101: MFISADR 000110: MFISDATA 100000: MFISSM4 Settings other than above are prohibited.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	BYTE[1:0]	00	R/W*	Internal Register Byte Specification These bits specify which 16 bits of the 32-bit register are to be accessed. • MFISSCR.BO = 0 00: Register bits 31 to 16 01: Setting prohibited 10: Register bits 15 to 0 11: Setting prohibited • MFISSCR.BO = 1 00: Register bits 15 to 0 01: Setting prohibited 10: Register bits 31 to 16 11: Setting prohibited However, when MFISDATA is selected using bits REG5 to REG0, each time reading or writing of MFISDATA occurs, bits BYTE1 and BYTE0 change according to the following rules. 16-bit bus: 00 → 10 → 00 → 10... repeated

Note: * These bits can only be written via the MFIS, while the A2 pin is held 1. They cannot be written from the peripheral bus of the RT domain.

29.4.2 MFIS General Status Register (MFISGSR)

MFISGSR is a 32-bit register that can be freely used to indicate the mutual states between the SYS domain and the RT domain. This register is read-only from the MFIS when the A2 pin is held 1. When writing to MFISGSR via the MFIS, writing should be performed with MFISGSR specified in bits REG5 to REG0 in MFISIDX, and with the A2 pin held 0. In this state, MFISGSR can also be read.

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
5 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	EDN	0	R/W	Endian (for MFRAM access) Specifies the byte positions when accessing the MFRAM from the on-chip CPU. 0: Big endian 1: Little endian
0	BO	0	R/W	Byte Order Specifies the byte position of the MFIS internal registers along with bits MFISIDX1 and MFISIDX0. 0: Big endian (MSB first) 1: Little endian (LSB first)

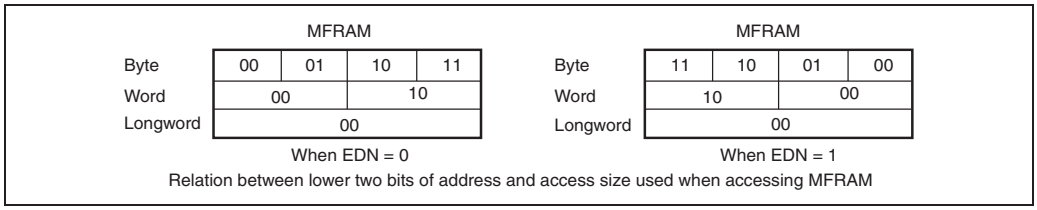

Figure 29.8 Differences in EDN Bit Specifications

29.4.4 MFIS Memory Control Register (MFISMCR)

MFISMCR is a 32-bit register used to control the SMFRAM via the MFIS.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	LOCK	—	WT	—	RD	—	—	AI/AD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W*1	R	R/W*1	R	R/W*1	R	R	R/W*1

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	LOCK	0	R/W*1	Lock This bit is used to lock read/write operations during continuous access. When 1 is written to the LOCK bit, the values of the RD and WT bits set at that time are held until the LOCK bit is next cleared to 0. By using the LOCK, RD, and WT bits, modes are as follows: LOCK RD WT 1 1 0 : Continuous read mode 1 0 1 : Continuous write mode The RD and WT bits should not both simultaneously be set to 1.

Bit	Bit Name	Initial Value	R/W	Description
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	WT	0	R/W*[1]	Write When this bit is set to 1, the MFIDATA value is written to the SMFRAM position corresponding to MFISADR.*[2]*[3] If the WT bit and LOCK bit are set to 1 simultaneously, a state of continuous writing to the MFIS is entered, and high-speed data transfer becomes possible. This state is maintained until the WT bit is next cleared to 0, or until the LOCK bit is cleared to 0. If the LOCK bit is not simultaneously set to 1, writing to SMFRAM is performed only once. The value of the WT bit is automatically cleared to 0.
4	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
3	RD	0	R/W*[1]	Read When this bit is set to 1, the SMFRAM data corresponding to MFISADR is read in MFISDATA.*[2]*[3] If the RD bit and LOCK bit are set to 1 simultaneously, a state of continuous reading of the MFIS is entered, and high-speed data transfer becomes possible. This state is maintained until the RD bit is next cleared to 0, or until the LOCK bit is cleared to 0. If the LOCK bit is not simultaneously set to 1, reading of SMFRAM is performed only once. The value of the RD bit is automatically cleared to 0.
2, 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	AI/AD	0	R/W*[1]	Address Auto-Increment/Decrement This bit is valid only when the LOCK bit is 1. The value of the MFIADR is automatically incremented by 4 or decremented by 4 according to the setting of this bit each time reading or writing of SMFRAM is performed. 0: Auto-increment mode (+4) 1: Auto-decrement mode (–4)

Notes: 1. This bit can only be written via the MFI. It cannot be written from the peripheral bus of the RT domain.
2. If access of SMFRAM via the BSC and access of SMFRAM from the peripheral bus of the RT domain occur simultaneously, the access via the BSC is executed first.
3. If a single reading or single writing is necessary after continuous reading or continuous writing, it should be performed after the WT bit and RD bit are cleared to 0.

29.4.5 MFIS Internal Interrupt Control Register (MFISIICR)

MFISIICR is used to issue interrupts from the SYS domain to the RT domain.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	IIC[6:0]							IIR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	IIC[6:0]	0000000	R/W	Internal Interrupt Source Bits used to specify the source for interrupts generated by the IIR. These bits can be written from both the BSC and peripheral bus of the RT domain. By using these bits, fast execution of an interrupt handler is possible. These bits are completely under software control, and their values have no effect on the operation of the RT domain.
0	IIR	0	R/W	Internal Interrupt Request While this bit is 1, an interrupt request is issued to the RT domain.

29.4.6 MFIS External Interrupt Control Register (MFISEICR)

MFISEICR is a 32-bit register used to issue interrupts from the RT domain to the SYS domain.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial Value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	RST END	EIC[6:0]							EIR
Initial Value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	RSTEND	1	R/W	Reset Period End Flag Flag indicating that the reset period has finished. 0: Clears the flag. 1: Retains the previous value.

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	EIC[6:0]	0000000	R/W	External Interrupt Source Bits used to specify the source for interrupts generated by the EIR. These bits can be written from both the BSC and RT domain peripheral bus. By using these bits, fast execution of an interrupt handler is possible. These bits are completely under software control, and their values have no effect on the operation of the RT domain.
0	EIR	0	R/W	External Interrupt Request While this bit is 1, an interrupt request is issued to the SYS domain.

29.4.7 MFIS Address Register (MFISADR)

MFISADR is a 32-bit register that indicates the address in the SMFRAM to be accessed via the BSC.

When using the setting of the LOCK bit in MFISMCR to specify continuous access of the SMFRAM, auto-increment (+4) or auto-decrement (-4) of the address, according to the AI/AD bit setting in MFISMCR, is performed automatically, and the MFISADR is updated. Wrap-around operation is performed if auto-increment or auto-decrement causes an excess of the following valid bits. MFISRCR is writable via the BSC. However, it is read-only and cannot be written from the peripheral bus of the RT domain.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	A[9:2]								—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 2	A[9:2]	H'00	R/W	Address These bits specify the 1-Kbyte memory space of SMFRAM to be accessed via the BSC, with 32-bit boundary.
1, 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

29.4.8 MFIS Data Register (MFISDATA)

MFISDATA is a 32-bit register used to store data for writing to the SMFRAM and data read from the SMFRAM. If MFISDATA is not used when accessing the SMFRAM, it can be used for software data transfer between the SYS domain and the RT domain.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	D[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	D[31:0]	H'0000 0000	R/W	32-Bit Data

29.4.9 MFIS Semaphore Register (MFISSM4)

MFISSM4 is a dedicated register allowing read modify write to be performed from the SYS domain and from the RT domain. Using MFISSM4 as a semaphore can improve the data transfer efficiency.

In a state where neither the SYS domain nor the RT domain makes a request, MFISSM4 indicates that the bits SM7 and SM6 = B'00. If a request (for read operation to the MFISSM4) from the SYS domain occurs in this state, bits SM7 and SM6 = B'00 is read. Viewing B'00, software can learn the successful acquisition. After this, MFISSM4 changes to the bits SM7 and SM6 = B'01.

Note that any request/access from the SYS domain means an access via the BSC. Any access from the AP-SYS to H’E6A60080 is handled as an access from the RT domain.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	SM[7:6]		INF[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	SM[7:6]	00	R/W	Bits for Semaphore If these bits are 00, reading to this register reads B'01 (read from the SYS domain) or B'10 (read from the RT domain). The read value means a value before the change. The change is made only when B'00 is read. 00: Only reading from both the SYS domain and the RT domain is possible. 01: Reading/writing from the SYS domain is possible, and only reading is possible from the RT domain. 10: Only reading is possible from the SYS domain, reading/writing from the RT domain is possible. 11: Setting prohibited.
5 to 0	INF[5:0]	000000	R/W	Reading/writing is allowed according to the semaphore conditions of bits SM7 and SM6. These bits are usually used as information.

Note: If reading from the SYS domain and the RT domain simultaneously occurs for MFISSM4 with the bits SM7 and SM6, = B'00, MFISSM4 returns data of the bits SM7 and SM6 = B'01 to the AP domain, while returns B'00 to the SYS domain.

29.5 Access to MFIS Registers

The MFIS register can be accessed from the SYS domain by accessing the MFIS register space from the SYS domain. Table 29.7 shows the correspondence between the access from the SYS domain and MFIS operations.

Table 29.7 MFIS Operations

A2	Access from SYS domain	Operation
0	Read	Reading of registers specified by the index register (MFISIDX7 to MFISIDX0)
0	Write	Writing of registers specified by the index register (MFISIDX7 to MFISIDX0)
1	Read	Reading of the status register (MFISGSR7 to MFISGSR0)
1	Write	Writing of the index register (MFISIDX7 to MFISIDX0)

29.5.1 Control Signal for Register Access and Access Restrictions

Table 29.8 lists restrictions by control signals and access sources to access to the MFIS register. For details on access restrictions, see the register descriptions.

Table 29.8 Register Access Restrictions

	Access Restriction	
Register Name	**RT domain**	**SYS domain**
MFISIDX	R only	W only
MFISGSR	R/W	R/W
MFISSCR	R/W	R/W
MFISMCR	R only	R/W
MFISIICR	R/W	R/W
MFISEICR	R/W	R/W
MFISADR	R only	R/W
MFISDATA	R/W	R/W
MFISSM4	R/W	R/W

[Legend]
R: Read
W: Write

29.6 Interface

Here the details of the MFIS interface between the SYS domain and the RT domain are described.

The access timing from the SYS domain must be adjusted by the BSC settings. The minimum write signal assert width for the MFIS space is 3 cycles of HPϕ, and the minimum read signal assert width is 4 cycles of HPϕ.

29.6.1 MFISIDX Write/MFISGSR Read

Writing of MFISIDX and reading of MFISGSR are shown in figure 29.9. $\overline{\text{MFIREGCS}}$ is a chip-select signal asserted by the BSC for the MFI when an MFI register is to be accessed.

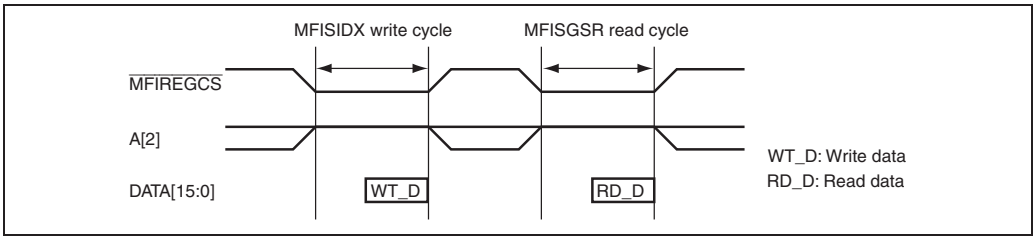

Figure 29.9 MFISIDX Write and MFISGSR Read

29.6.2 MFIS Register Read/Write

As shown in figure 29.10, in reading and writing of MFIS internal registers, first the A2 pin is held 1 and MFISIDX is written in order to select the register and byte position to be accessed. Then set the A2 pin to 0, and access the register selected by MFISIDX.

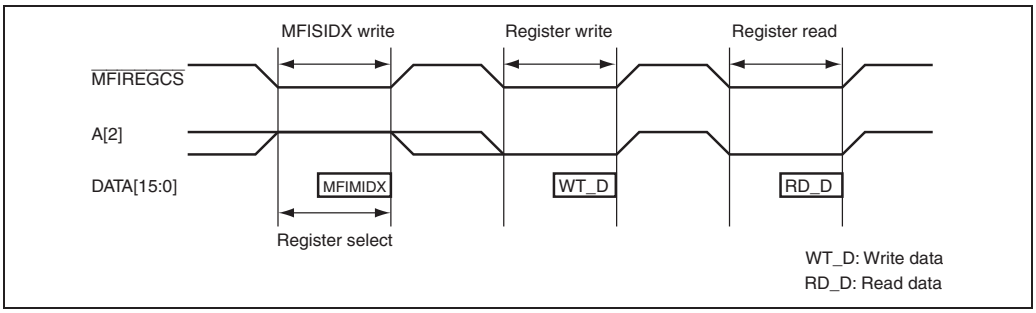

Figure 29.10 MFIS Register Settings

29.6.3 Continuous Data Writing from MFIS to SMFRAM

Figure 29.11 shows the timing chart for continuous data transfer from the MFIS to SMFRAM. As shown in this timing chart, by setting the start address and the data to be written first, continuous data transfer can subsequently be performed. As a result, effective data transfer to the SMFRAM can be performed using DMA transfer or similar methods.

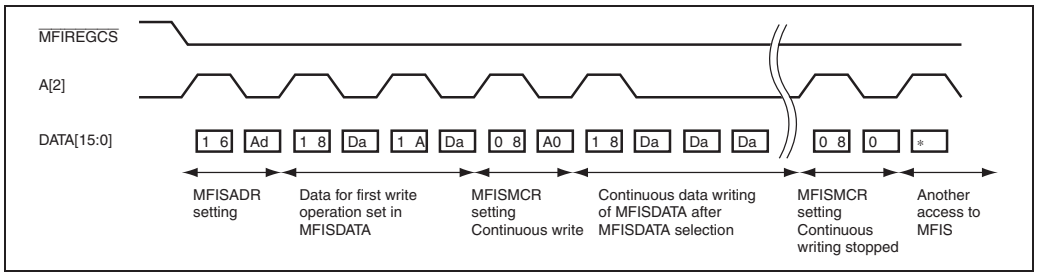

Figure 29.11 Continuous Data Writing to SMFRAM

29.6.4 Continuous Data Reading from SMFRAM through MFIS

Figure 29.12 shows the timing chart for continuous data reading from SMFRAM through the MFIS. As this timing chart indicates, by setting the start address, data can subsequently be read continuously. As a result, effective data transfer to the SMFRAM can be performed using DMA transfer or similar methods.

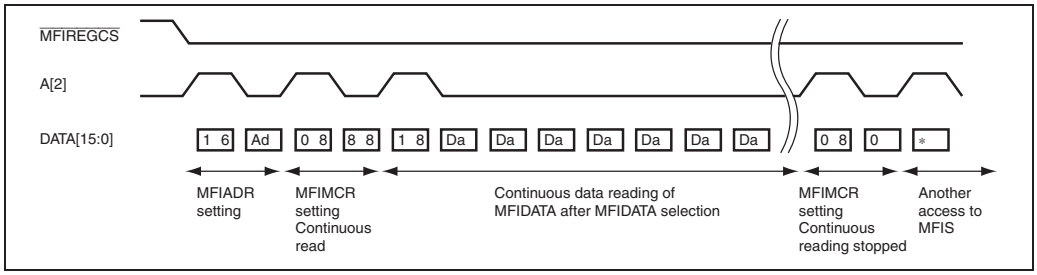

Figure 29.12 Continuous Data Reading from SMFRAM

Section 30 AC Parallel Interface 1 (ACMFI1)

This LSI has a non address-data multiplex type multifunctional interface (AC-MFI1 : AC-Multi Functional Interface 1 Non Address-Data multiplex) for use in high-speed transfer of data to external device, which cannot utilize the system bus.

The ACMFI1 allows external device to read from and write to 64 Kbytes of the on-chip ACMFRAM. This ACMFRAM can be accessed by both the ACMFI1 and on-chip CPU. Interrupts issued to this LSI by the external device, and interrupts sent from this LSI to the external device, are also supported. By using the ACMFRAM and these interrupt function, software-based data transfer between external device and on-chip CPU becomes possible, and connection to external device not releasing bus mastership is enabled.

30.1 Features

- The 64-Kbytes on-chip ACMFRAM can be read from and written to in 32-bit units.
- A 16-bit non address-data multiplex asynchronous interface is supported.
- Endian settings can be done.
- By writing specific bits in the ACMFI1 internal registers from the external device, interrupts can be issued. Conversely, interrupts can be sent from the on-chip CPU to the external device.
- Seven interrupt source bits each for internal interrupts and for external interrupts. As a result, software control of 128 different interrupts is possible, enabling high-speed data transfer using interrupts.
- Internal registers of this LSI (e.g. DMAC registers) can be accessed by using the ACMFI1 internal registers (bus master function).
- Data can be continuously read or written between the external device connected to the ACMFI1 and this LSI via ACMFRAM according to the register settings.

Figure 30.1 shows a block diagram of the ACMFI1.

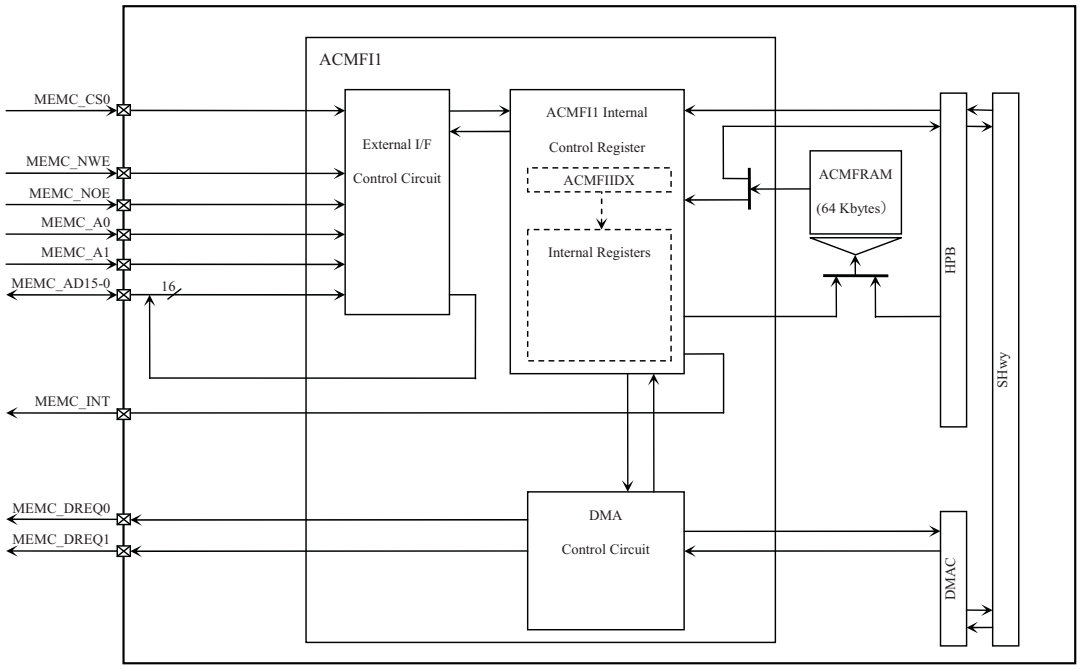

Figure 30.1 ACMFI1 Block Diagram

30.2 Input/Output Pins

The ACMFI1 pin configuration is listed in table 30.1.

Table 30.1 Pin Configuration

Name	Function	I/O	Description
MEMC_AD15 to MEMC_AD0	ACMFI1 data pins	I/O	Input/output to the ACMFI1
MEMC_CS0	ACMFI1chip select	Input	Chip select input to the ACMFI1
MEMC_A0	ACMFI1 register select 0	Input	Switching between ACMFI1 access types 0 L : Access to the register selected by ACMFIIDX H : Access to Index/status register
MEMC_A1	ACMFI1 register select 1	Input	Switching between ACMFI1 access types 1 L : Access in accordance with MEMC_A0 H : Access to ACMFIDATAW or ACMFIDATAR
MEMC_NWE	ACMFI1 write	Input	Write strobe signal; data is written while at low level
MEMC_NOE	ACMFI1 read	Input	Read strobe signal; data is read while at low level
MEMC_INT	ACMFI1 interrupt	Output	Interrupt request to the external device from the ACMFI1
MEMC_DREQ0	External DMA transfer request 0	Output	Output the DMA transfer request from the ACMFI1 to the external device
MEMC_DREQ1	External DMA transfer request 1	Output	Output the DMA transfer request from the ACMFI1 to the external device

30.3 Register Descriptions

Table 30.2 shows the ACMFI1 register configuration. Table 30.3 shows the register states in each operating mode.

Table 30.2 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
ACMFI index register	ACMFIIDX	R/W	H'E6B7 0000	32

30.3.1 ACMFI Index Register (ACMFIIDX)

ACMFIIDX is used to specify the register for reading and writing from the ACMFI1 with MEMC_A0 pin held low. From the ACMFI1, this register can only be written while MEMC_A0 pin is set high.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 2	REG[5:0]	000000	R/W*	ACMFI1 Internal Register Select 5 to 0 000000 : ACMFIGSR 000001 : ACMFISCR 000010 : ACMFIMCR 000011 : ACMFIIICR 000100 : ACMFIEICR 000101 : ACMFIADR 000110 : ACMFIDATA 000111 : ACMFIRCR 010000 : ACMFIADRW 010001 : ACMFIADRR 010010 : ACMFIDATAW 010011 : ACMFIDATAR 010100 : ACMFIMCRW 010101 : ACMFIMCRR 010110 : ACMFIDNRW 010111 : ACMFIDNRR 011000 : ACMFISIZEW 011001 : ACMFISIZER 100000 : ACMFISM4 Others : Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
1, 0	BYTE[1:0]	00	R/W*	Internal Register Byte Specification These bits specify of which 16 bits of the 32-bit register are to be accessed. Case of ACMFISCR.BO = 0 00 : Register bits [31:16] 01 : Setting prohibited 10 : Register bits [15:0] 11 : Setting prohibited Case of ACMFISCR.BO = 1 00 : Register bits [15:0] 01 : Setting prohibited 10 : Register bits [31:16] 11 : Setting prohibited However, when ACMFIDATA is selected using bits REG[5:0], each time reading or writing of ACMFIDATA occurs, bits BYTE[1:0] change according to the following rules. 16-bit bus : 00 → 10 → 00 → 10… repeated

[Note] * These bits can only be written via the ACMFI1, while MEMC_A0 pin is set high. They cannot be written by on-chip CPU.

30.3.2 ACMFI General Status Register (ACMFIGSR)

ACMFIGSR can be freely used for mutual display of states between the external device connected to ACMFI1 and the on-chip CPU. When MEMC_A0 pin is set high, this register is read-only from ACMFI1. When writing to the ACMFIGSR via ACMFI1, writing should be performed with ACMFIGSR specified in bits REG[5:0] in ACMFIIDX, and with MEMC_A0 pin set low. In this state, ACMFIGSR can also be read.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	STATUS[7:0]							
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	STATUS[7:0]	H'00	R/W	General Status These bits can be read and written by the software of the external device connected to the ACMFI1, and by the on-chip CPU. Except upon a reset, they are never overwritten by hardware.

30.3.3 ACMFI Status/Control Register (ACMFISCR)

ACMFISCR is used to control the ACMFI1 mode and state.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	MDREN	MDRN[2]	MDWN[2]	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W :	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MDRN[1:0]		MDWN[1:0]		MDWEN	-	MDCS	-	-	-	-	-	-	-	EDN	BO
Initial :	0	0	0	0	0	0	0	0	0	1	0	0	0	0	1	1
R/W :	R/W	R/W	R/W	R/W	R/W	R	R/W	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	MDREN	0	R/W*	Specifies whether MEMC_DREQ1 is output. 0 : MEMC_DREQ1 is not output 1 : MEMC_DREQ1 is output
19	MDRN[2]	0	R/W*	When using ACMFIADRR with MDRN[1:0], specifies the negate timing of MEMC_DREQ1. This negate timing is decided by increment count of ACMFIADRR. 000 : 1 time(for 4byte)、 001 : setting prohibited 010 : 1 time(for 16byte)、 011 : 4 times(for 16byte) 100 : 1 time(for 32byte)、 101 : 8 times(for 32byte) 110 : 1 time(for 64byte)、 111 : 16 times(for 64byte)
18	MDWN[2]	0	R/W*	When using ACMFIADRW with MDWN[1:0], specifies the negate timing of MEMC_DREQ0. This negate timing is decided by increment count of ACMFIADRW. 000 : 1 time(for 4byte)、 001 : setting prohibited 010 : 1 time(for 16byte)、 011 : 4 times(for 16byte) 100 : 1 time(for 32byte)、 101 : 8 times(for 32byte) 110 : 1 time(for 64byte)、 111 : 16 times(for 64byte)
17 to 16	-	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
15 to 14	MDRN[1:0]	00	R/W*	Refer to MDRN[2] bit.
13 to 12	MDWN[1:0]	00	R/W*	Refer to MDWN[2] bit.
11	MDWEN	0	R/W*	Specifies whether MEMC_DREQ0/MEMC_DREQ1 signal is used. 0 : MEMC_DREQ0/MEMC_DREQ1 signal is not used. 1 : MEMC_DREQ0/MEMC_DREQ1 signal is used.
10	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
9	MDCS	0	R/W*	MEMC_DREQ Signal Selection Specifies the MEMC_DREQ signal to be used. 0 : Only MEMC_DREQ1 (With this setting, one-side channel is only operable.) 1 : MEMC_DREQ0/MEMC_DREQ1
8 to 7	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	-	1	R	Reserved This bit is always read as 1. The write value should always be 1.

5 to 2	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	EDN	1	R/W	Endian (for ACMFRAM access) Specifies the byte positions when accessing the ACMFRAM from the on-chip CPU. 0 : Big endian 1 : Little endian
0	BO	1	R/W	Byte Order Specifies the byte position of the ACMFIDATA[31:0] bits corresponding to bits BYTE[1:0] in ACMFIIDX. 0 : Big endian (MSB first) 1 : Little endian (LSB first)

[Note] * This bit can only be written via ACMFI1. It cannot be written by the on-chip CPU.

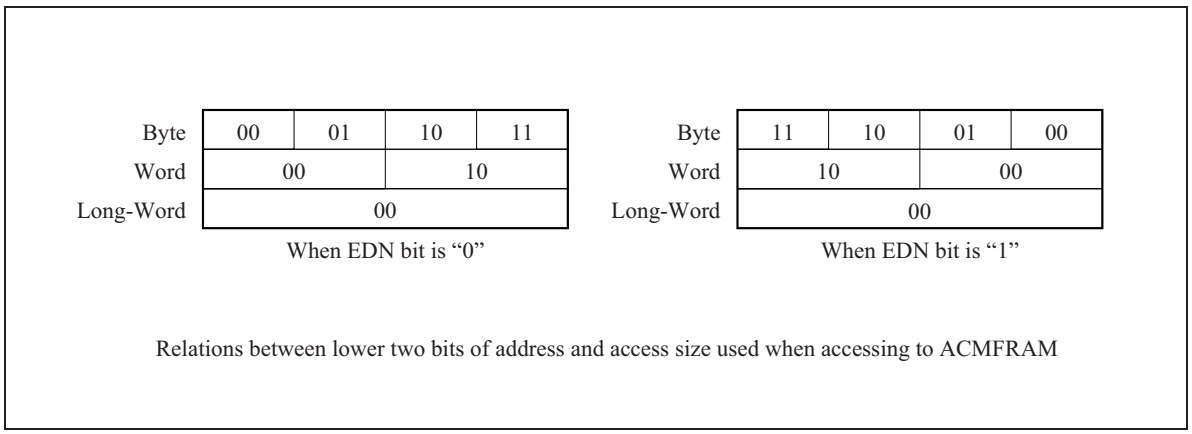

Figure 30.2 Difference in EDN Bit Specifications

30.3.4 ACMFI Memory Control Register (ACMFIMCR)

ACMFIMCR is used to control the ACMFRAM via ACMFI1.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	LOCK	-	WT	-	RD	-	-	AI/AD
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	LOCK	0	R/W*1	Lock This bit is used to lock read/write operations during continuous access. When “1” is written to the LOCK bit, the values of the RD and WT bits set at that time are held until the LOCK bit is next cleared to “0”. By using the LOCK, RD, and WT bits, modes are as follows : LOCK RD WT 1 1 0 : Continuous read mode 1 0 1 : Continuous write mode The RD and WT bits should be set to “1” simultaneously.
6	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	WT	0	R/W*1	Write When this bit is set to “1”, the ACMFIDATA value is written to ACMFRAM position corresponding to ACMFIADR.*2*3 • If the WT bit and LOCK bit are set to “1” simultaneously, a state of continuous writing to ACMFI1 is entered, and high-speed data transfer becomes possible. This state is maintained until the WT bit is next cleared to “0”, or until the LOCK bit is cleared to “0”. • If the LOCK bit is not simultaneously set to “1”, writing to ACMFRAM is performed only once. The value of the WT bit is automatically cleared to “0”.
4	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3	RD	0	R/W*1	Read When this bit is set to “1”, the ACMFRAM data corresponding to ACMFIADR is read in ACMFIDATA.*2*3*4 • If the RD bit and LOCK bit are set to “1” simultaneously, a state of continuous reading of the ACMFI1 is entered, and high-speed data transfer becomes possible. This state is maintained until the RD bit is next cleared to “0”, or until The LOCK bit is cleared to “0”. • If the LOCK bit is not simultaneously set to “1”, reading of ACMFRAM is performed only once. The value of the RD bit is automatically cleared to “0”.
2 to 1	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	AI/AD	0	R/W*1	Address Auto-Increment/Decrement This bit is valid only when the LOCK bit is “1”. The value of ACMFIADR is automatically incremented by 4 or decremented by 4 according to the setting of this bit each time reading or writing of ACMFRAM is performed. 0 : Auto-increment mode (+4) 1 : Auto-decrement mode (-4)

[Note] 1. This bit can only be written via ACMFI1. It cannot be written by the on-chip CPU.

2. If access of ACMFRAM from the on-chip CPU and access of ACMFRAM via ACMFI1 occur simultaneously, the access via ACMFI1 is executed first.

3. If a single reading or single writing is necessary after continuous reading or continuous writing, it should be performed after the WT bit and RD bit is cleared to “0”.

4. When continuous read with DMA transfer function is executed and this bit is set to “1”, dummy read from this register is executed before previous setting and ACMFI1 Bus Access, Dummy Read and set RD bit to “1” must continue.

30.3.5 ACMFI Internal Interrupt Control Register (ACMFIIICR)

ACMFIIICR is used to issue interrupts from the external device connected to ACMFI1 to the on-chip CPU.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	IIC[6:0]							IIR
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 1	IIC[6:0]	All 0	R/W	Internal Interrupt Source These bits used to specify the source for interrupts generated by the IIR. These bits can be written from both external device via ACMFI1 and on-chip CPU. By using these bits, fast execution of an interrupt handler is possible. These bits are completely under software control, and their values have no effect on the operation of the LSI.
0	IIR	0	R/W	Internal Interrupt Request While this bit is “1”, an interrupt request is issued to the on-chip CPU.

30.3.6 ACMFI External Interrupt Control Register (ACMFIEICR)

ACMFIEICR is used to issue interrupts to the external device connected to ACMFI1 from the on-chip CPU.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	WEFE	REFE	-	-	WDFE	-	RDFE	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R/W	R/W	R	R	R/W	R	R/W	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WEFF	REFF	-	-	WDF	RDF	-	RSTEND	EIC[6:0]							EIR
Initial :	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R	R	R/W	RW	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	WEFE	0	R/W	Register Write End Notification Sets whether to notify, through MEMC_INT pin, when register write operation finishes. 0 : Does not notify the end of register write operation through MEMC_INT pin 1 : Notifies the end of register write operation through MEMC_INT pin.
23	REFE	0	R/W	Register Read End Notification Sets whether to notify, through MEMC_INT pin, when register read operation finishes. 0 : Does not notify the end of register read operation through MEMC_INT pin. 1 : Notifies the end of register read operation through MEMC_INT pin.
22 to 21	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	WDFE	0	R/W	ACMFRAM Overflow Notification Sets whether to notify, through MEMC_INT pin, when ACMFRAM overflows during DMA transfer. 0 : Does not notify an overflow through MEMC_INT pin 1 : Notifies an overflow through MEMC_INT pin
19	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18	RDFE	0	R/W	ACMFRAM Read Data Empty Notification Sets whether to notify, through MEM_INT pin, when ACMFRAM becomes empty of read data during DMA transfer. 0 : Does not notify read data empty through MEMC_INT pin 1 : Notifies read data empty through MEMC_INT pin
17 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

15	WEFF	0	R/W	Register Write End Flag Flag indicating that register write operation has finished. 0 : Clears the flag 1 : Retains the previous value
14	REFF	0	R/W	Register Read End Flag Flag indicating that register read operation has finished. 0 : Clears the flag 1 : Retains the previous value
13 to 12	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	WDF	0	R/W	ACMFRAM Overflow Flag Flag indicating that ACMFRAM has lost free space during DMA transfer. 0 : Clears the flag 1 : Retains the previous value
10	RDF	0	R/W	ACMFRAM Read Data Empty Flag Flag indicating that no data to be read through ACMFI1 bus exists in ACMFRAM bus during DMA transfer. 0 : Clears the flag 1 : Retains the previous value
9	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
8	RSTEND	1	R/W	Reset Period End Flag Flag indicating that the reset period has finished. 0 : Clears the flag 1 : Retains the previous value
7 to 1	EIC[6:0]	All 0	R/W	External Interrupt Source These bits used to specify the source for interrupts generated by the EIR. These bits can be written from both external device and on-chip CPU. By using these bits, fast execution of an interrupt handler is possible. These bits are completely under software control, and their values have no effect on the operation of this LSI.
0	EIR	0	R/W	External Interrupt Request While this bit is “1”, the MEMC_INT pin is asserted and an interrupt request is issued to the external device from the LSI.

30.3.7 ACMFI Address Register (ACMFIADR)

ACMFIADR indicates the address in the ACMFRAM to be accessed via ACMFI1.

When using the setting of the LOCK bit in ACMFIMCR to specify continuous access of the ACMFRAM, auto-increment (+4) or auto-decrement (-4) of the address, according to the AI/AD bit setting in ACMFIMCR, is performed automatically, and the ACMFIADR is updated. Wrap-around operation is performed if auto-increment or auto-decrement causes an excess of the following valid bits.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	A[31:16]															
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	A[15:2]														-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	A[31:2]	All 0	R/W*	Address These bits specify the 64-Kbyte memory space of ACMFRAM to be accessed via ACMFI1, with 32-bit boundary. They also specify the address of an internal register of this LSI to be accessed via ACMFI1. These A[15:2] bits are valid when ACMFRAM is accessed, whereas A[31:10] bits are valid when an internal register of this LSI is accessed.
1 to 0	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

[Note] * These bits can only be written by the external device via ACMFI1. They cannot be written by the on-chip CPU.

30.3.8 ACMFI Data Register (ACMFIDATA)

ACMFIDATA is used to hold data for writing to the ACMFRAM and data read from the ACMFRAM. ACMFIDATA is also used to hold data read from and written to registers which are accessed via ACMFI1. If ACMFIDATA is not used when accessing ACMFRAM, it can be used for LSI software data transfer with the external device connected to the ACMFI1.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
15	AER	0	R/W	Address Error If the value set in the ADR bits is not consistent with the register access size, this bit is set to “1”. Read/write operation is canceled when an address error occurs. 0 : Clears the flag 1 : Retains the previous value
14	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
13	RWT	0	R/W	Register Write Write “1” to this bit when writing to a register. When writing to the register is completed, this bit is cleared to “0”.
12	RRD	0	R/W	Register Read Write “1” to this bit when reading from a register. When reading from the register is completed, this bit is cleared to “0”.
11 to 10	SZ[1:0]	00	R/W	Register Access Size These bits specify the access size for reading from/writing to a register. 00 : Byte 01 : Word 10 : Long-Word 11 : Setting prohibited
9 to 0	ADR[9:0]	All 0	R/W	Register Low-Order Address The address of the register to be accessed is specified in conjunction with ACMFIADR. Address = {ACMFIADR[31:10], ACMFIRCR[9:0]}

[Note] This register can be read and written by the external device via ACMFI1. It cannot be read or written by the on-chip CPU.

30.3.10 ACMFI address Register (for DMA Write) (ACMFIADRW)

ACMFIADRW is a register that indicates low-order address in the ACMFRAM for the write access via the ACMFI1 during DMA transfer. Auto-increment (+4) of the address is performed automatically each time 4 bytes of data are written and then ACMFIADRW is updated. The address is automatically updated to the one specified by ACMFIADRW if auto-increment causes an excess of the DMA transfer range set by ACMFISIZEW.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	A[15:2]														-	-
Initial :	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 2	A[15:2]	H'3800	R/W*	Address These bits specify the lower 16 bits of 64-Kbyte memory space in the ACMFRAM that is for the write access via ACMFI1 during DMA transfer. Address can set only “H’3800”.
1 to 0	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

[Note] * This register can be read and written by the external device via ACMFI1. It cannot be read or written by the on-chip CPU.

30.3.11 ACMFI Address Register (for DMA Read) (ACMFIADRR)

ACMFIADRR is a register that indicates low-order address in the ACMFRAM for the read access via the ACMFI1 during DMA transfer. Auto-increment (+4) of the address is performed automatically each time 4 bytes of data are written and then ACMFIADRR is updated. The address is automatically updated to the one specified by ACMFIADRR if auto-increment causes an excess of the DMA transfer range set by ACMFISIZER.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 2	A[15:2]	H'3C00	R/W*	Address These bits specify the lower 16 bits of 64-Kbyte memory space in the ACMFRAM that is for the read access via ACMFI1 during DMA transfer. Address can set only “H’3C00”.
1 to 0	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

[Note] * This register can be read and written by the external device via ACMFI1. It cannot be read or written by the on-chip CPU.

30.3.12 ACMFI Data Register (for DMA Write) (ACMFIDATAW)

ACMFIDATAW is used to hold data for writing to the ACMFRAM during DMA transfer.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D[31:16]

R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	D[31:0]	All 0	R/W	32-Bit Data

30.3.13 ACMFI Data Register (for DMA Read) (ACMFIDATAR)

ACMFIDATAR is used to hold data for reading from the ACMFRAM during DMA transfer.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D[31:16]															
Initial :	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	D[15:0]															
Initial :	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
R/W :	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	D[31:0]	Undefined	R/W	32-Bit Data

[Note] These bits cannot be written from the on-chip CPU when the MEMC_A1 pin is in high level.

30.3.14 ACMFI Memory Control Register (for DMA Write) (ACMFIMCRW)

ACMFIMCRW is a register that controls the write access to the ACMFRAM via the ACMFI1 during DMA transfer.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	DREQW	DRSW[1:0]		DRW	LOCKW	DWTW	WT	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0
R/W :	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	DREQW	0	R/W*[1]	Specifies whether the MEMC_DREQ0 signal is used for writing to the ACMFRAM. 0 : The MEMC_DREQ0 signal is not used 1 : The MEMC_DREQ0 signal is used
10 to 9	DRSW[1:0]	00	R/W*[1]	When the MEMC_DREQ0 signal is used for writing, if there is free space larger than the one specified by these bits, MEMC_DREQ0 signal is output. 00 : 4Byte 01 : 16Byte 10 : 32Byte 11 : 64Byte
8	DRW	0	R	Write Data Ready This bit is set to "1" when the number of long-word data (transfer pointer) written to the ACMFRAM is 1 or greater.
7	LOCKW	0	R/W*[1]	This bit locks the writing operation for the successive access. When this bit is set to "1", the DWTW bit should also set to "1".
6	DWTW	0	R/W*[1]	Specifies whether the DMA transfer is performed from the ACMFRAM. 0 : DMA transfer is not performed 1 : DMA transfer is performed
5	WT	0	R/W*[1]	When "1" is written to this bit, the value of ACMFIDATAW is written to the area in the ACMFRAM that corresponds to ACMFIADRW.
4 to 3	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 1	-	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.

0	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.

[Note] 1. This register can be read and written by the external device via ACMFI1. It cannot be read or written by the on-chip CPU.

2. When the ACMFRAM access from the on-chip CPU and the ACMFRAM access from the external device via the ACMFI1 occur simultaneously, the access from the external device takes the priority.

3. The writing should be performed after the WT bit is cleared to “0”.

30.3.15 ACMFI Memory Control Register (for DMA Read) (ACMFIMCRR)

ACMFIMCRR is a register that controls the read access from the ACMFRAM via the ACMFI1 during DMA transfer.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	DREQR	DRSR[1:0]		DRR	LOCKR	DWTR	RD	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0
R/W :	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	DREQR	0	R/W*1	Specifies whether the MEMC_DREQ1*2 signal is used for reading from the ACMFRAM. 0 : The MEMC_DREQ1*2 signal is not used 1 : The MEMC_DREQ1*2 signal is used
10 to 9	DRSR[1:0]	00	R/W*1	When the MEMC_DREQ1*2 signal is used for reading, if there is free space lager than the one specified by these bits, the MEMC_DREQ1*2 signal is output. 00 : 4Byte 01 : 16Byte 10 : 32Byte 11 : 64Byte
8	DRR	0	R	Read Data Ready This bit is set to “1” when the number of long-word data (transfer pointer) written to the ACMFRAM is 1 or greater.
7	LOCKR	0	R/W*1	This bit locks the reading operation for the successive access. When this bit is set to “1”, the DWTR bit should also set to “1”.

6	DWTR	0	R/W*[1]	Specifies whether the DMA transfer is performed from the ACMFRAM. 0 : DMA transfer is not performed 1 : DMA transfer is performed
5	RD	0	R/W*[1]	When "1" is written to this bit, the value of ACMFIDATAR is written to the area in the ACMFRAM that corresponds to ACMFIADRR.
4 to 3	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 1	-	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
0	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.

[Note] 1. This register can be read and written by the external device via ACMFI1. It cannot be read or written by the on-chip CPU.

2. When the MDCS bit in ACMFISCR is cleared to "0", the signal is output from the MEMC_DREQ0 pin.

3. The reading should be performed after the RD bit is cleared to "0".

30.3.16 ACMFI Transfer Number register (for DMA Write) (ACMFIDNRW)

ACMFIDNRW is a register that indicates the valid number of written data (in long-word units) stored in the ACRAM during DMA transfer.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	VDN[9:0]									
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	VDN[9:0]	All 0	R	Valid Number of ACMFRAM Data These bits indicate the valid number of data (in long-word units) stored in the ACMFRAM.

[Note] This register is a read-only register and cannot be written to from both the on-chip CPU and the external device via the ACMFI1.

30.3.17 ACMFI Transfer Number Register (DMA Read) (ACMFIDNRR)

ACMFIDNRR is a register that indicates the valid number of read data (in long-word units) stored in the ACMFRAM during DMA transfer.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	VDN[9:0]									
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	VDN[9:0]	All 0	R	Valid Number of ACMFRAM Data These bits indicate the valid number of data (in long-word units) stored in the ACMFRAM.

[Note] This register is a read-only register and cannot be written to from both the on-chip CPU and the external device via the ACMFI1.

30.3.18 ACMFI Transfer Size Register (for DMA Write) (ACMFISIZEW)

ACMFISIZEW is a register that specifies the number of transfer size for writing in long-word units during DMA transfer.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	SIZEW[10:0]										
Initial :	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	SIZEW[10:0]	H'100	R/W	Number of DMA Transfer Size for Writing These bits specify the number of DMA transfer size for writing in long-word units. Transfer size can set only “H’100”.

[Note] Rewriting to this register during DMA transfer is prohibited. If rewritten, the operation is not guaranteed.

30.3.19 ACMFI Transfer Size Register (for DMA Read) (ACMFISIZER)

ACMFISIZER is a register that specifies the number of transfer size for reading in long-word units during DMA transfer.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	SIZER[10:0]										
Initial :	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	SIZER[10:0]	H'100	R/W	Number of DMA Transfer Size for Reading These bits specify the number of DMA Transfer size for reading in long-word units. Transfer size can set only “H’100”.

[Note] Rewriting to this register during DMA transfer is prohibited. If rewritten, the operation is not guaranteed.

30.3.20 ACMFI Semaphore Register (ACMFISM4)

ACMFISM4 is dedicated register allowing read modify write to be performed from the external device via the ACMFI1 and from the on-chip CPU. Using ACMFISM4 as a semaphore can improve the data transfer efficiency.

In a state where neither the external device nor the on-chip CPU makes a request, ACMFISM4 indicates that the SM[7:6] = “00”. If a request (for read operation to the ACMFISM4) from the external device occurs in this state, the SM[7:6] = “00” is read. Viewing the SM[7:6] = “00”, software can learn the successful acquisition. After this, ACMFISM4 changes to the SM[7:6] = “01”.

Bit :	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit :	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	SM[7:6]		INF[5:0]					
Initial :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W :	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 6	SM[7:6]	00	R/W	Bits for Semaphore If these bits are “00”, reading to this register reads “01” (read from the external device via the ACMFI1) or “10” (read from the on-chip CPU). The read value means a value before the change. The change is made only when “00” is read. 00 : Only reading from both the external device via the ACMFI1 and the on-chip CPU is possible. 01 : Reading/writing from the external device via the ACMFI1 is possible, and only reading is possible from the on-chip CPU. 10 : Only reading from the external device via the ACMFI1 is possible, reading/writing from the on-chip CPU is possible. 11 : Setting prohibited.
5 to 0	INF[5:0]	All 0	R/W	Reading/writing is allowed according to the semaphore conditions of SM[7:6] bits. These bits are usually used as information.

[Note] 1. If reading from the external device via the ACMFI1 and the on-chip CPU simultaneously occurs for ACMFISM4 with the SM[7:6] = “00”, ACMFISM4 returns data of the SM[7:6] = “01” to the on-chip CPU, while returns “00” to the external device.

2. Access from the external device via the ACMFI1 to bits 31 to 16 is prohibited.

30.4 Operation

30.4.1 Access to ACMFI1 Registers

The ACMFI1 can be accessed by combining the MEMC_CS0, MEMC_A0, MEMC_NWE and MEMC_NOE signals. Table 30.4 shows the correspondence between combinations of these signals and ACMFI1 operations.

Table 30.4 ACMFI1 Operations

MEMC_CS0	MEMC_A0	MEMC_A1	MEMC_NWE	MEMC_NOE	Operation
H	X	X	X	X	No operation (NOP)
L	L	L	H	L	Read of register specified by ACMFIIDX[7:0]
L	L	L	L	H	Write of register specified by ACMFIIDX[7:0]
L	H	L	H	L	Read of ACMFIGSR
L	H	L	L	H	Write of ACMFIIDX
L	X	H	H	L	Read of ACMFIDATAR
L	X	H	L	H	Write of ACMFIDATAW
L	X	X	H	H	No operation (NOP)
L	X	X	L	L	Setting prohibited

[Legend]

X : Don't care

L : Low level

H : High level

30.4.2 Control Signal for Register Access and Access Restrictions

Table 30.5 lists restrictions to access to the ACMFI1 register. For details on access restrictions, see the register descriptions.

Table 30.5 Register Access Restrictions

Register Name		Access Restriction	
		On-Chip CPU	ACMFI1 Interface (External Device)
ACMFI1 Register	ACMFIIDX	R only	W only
	ACMFIGSR	R/W	R/W
	ACMFISCR	R/W	R/W
	ACMFIMCR	R only	R/W
	ACMFIIICR	R/W	R/W
	ACMFIEICR	R/W	R/W
	ACMFIADR	R only	R/W
	ACMFIDATA	R/W	R/W
	ACMFIRCR	R only	R/W
	ACMFIADRW	R only	R/W
	ACMFIADRR	R only	R/W

30.4.3 Memory Map

Table 30.6 shows the memory space in the on-chip ACMFRAM.

Table 30.6 Memory Map

	Start Address	End Address	Memory Size	Classification
Via ACMFI1	H'0000	H'FFFF	64 Kbytes	On-chip ACMFRAM area
Via on-chip CPU	H'E6B9 0000	H'E6B9 FFFF	64 Kbytes	

30.4.4 Connection

When connecting the ACMFI1 to an external device, a method like that shown in figure 30.3 should be used.

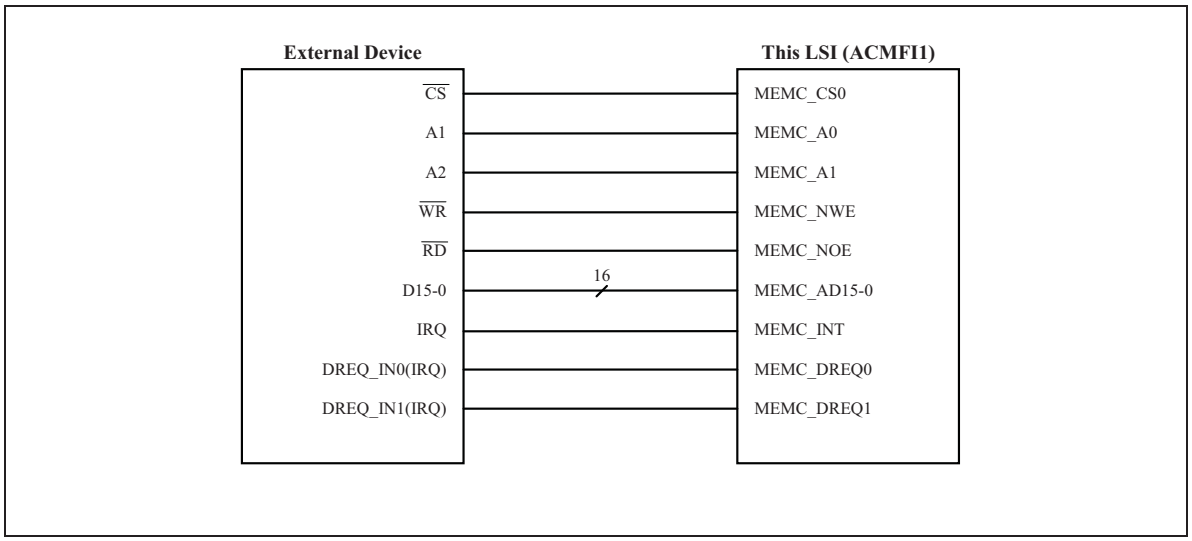

Figure 30.3 Example of ACMFI1 Connection

30.4.5 Access to LSI Internal Registers via the ACMFI1

By using function, on-chip peripheral module registers can be directly accessed from the external device via the ACMFI1. Write to and read from registers with the following procedures.

(1) Register Write Operation

1. Set the address of the register to be written to ACMFIADR and ACMFIRCR, and the data to be written to ACMFIDATA.
2. Setting the RWT bit in ACMFIRCR to “1” writes the data in ACMFIDATA to the address specified by ACMFIADR and ACMFIRCR.
3. When the write operation is completed, the RWT bit is automatically cleared to “0”.

(2) Register Read Operation

1. Set the address of the register to be read to ACMFIADR and ACMFIRCR.
2. Set the RRD bit in ACMFIRCR to “1”.
3. When the read operation is completed, the RRD bit is automatically cleared to “0” (read data is stored in ACMFIDATA）.

The register write operation flow and register read operation flow are shown in figure 30.4.

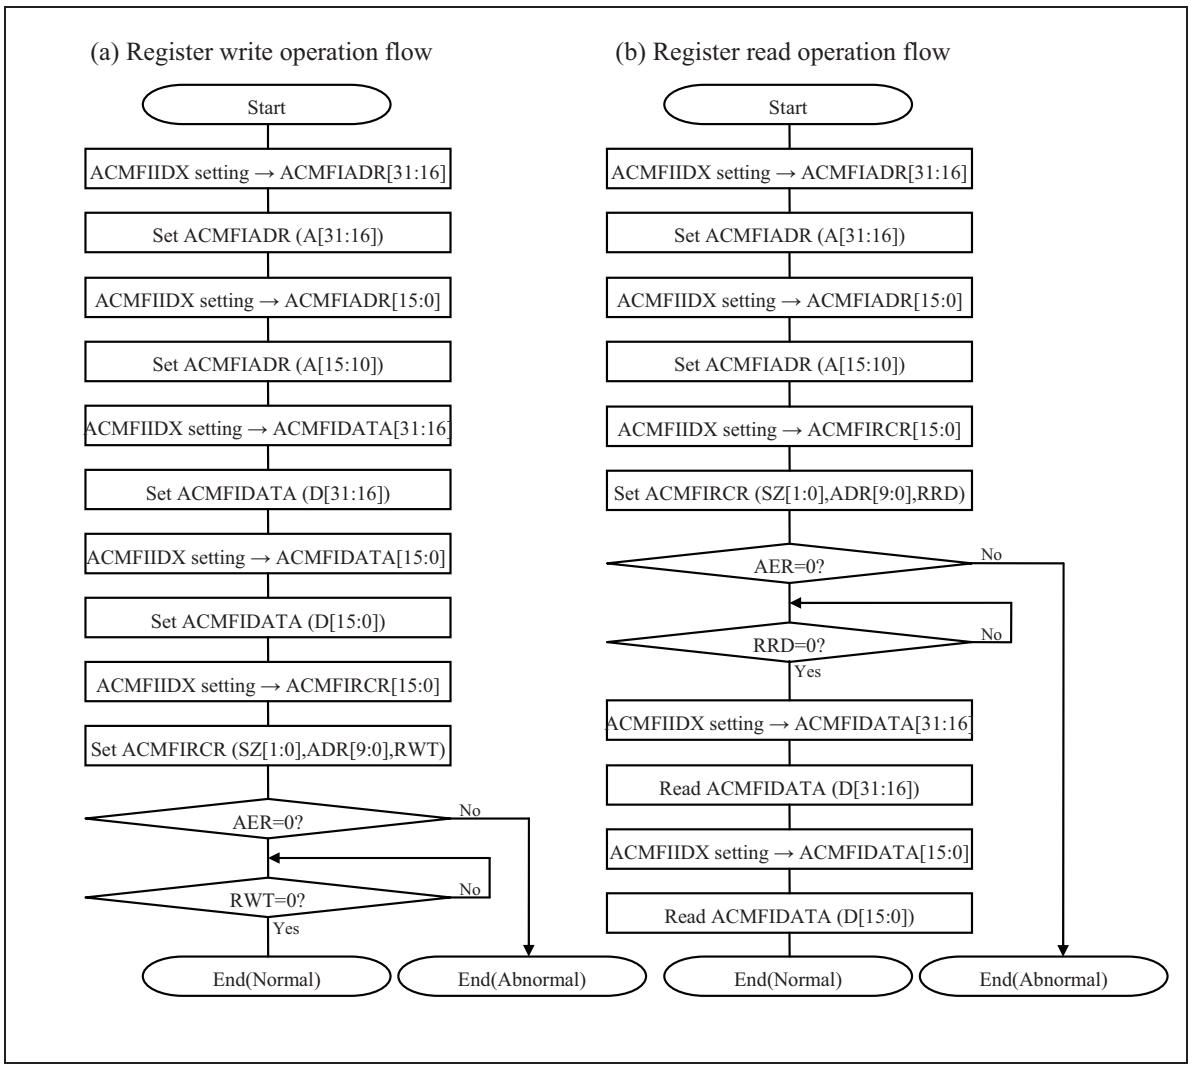

Figure 30.4 Register Write and Read Operation flows

30.4.6 DMA Transfer Request Output

By using this function, successive data read/write via the ACMFRAM is enabled with the reload mode of the DMAC.

First, the following shows the successive reading flow of the data written from the ACMFI1 bus.

1. Set the DMAC register with the reload mode enabled and start it up. At this time, DMA transfer size is 16bytes.
2. Set ACMFIADRW to “H’E000” and set ACMFISIZEW to “H’0100”.
3. Set the MDWN bit in ACMFISCR any value. This transfer unit must be corresponding to the transfer units of DRSW bit in ACMFIMCRW.
4. Set the LOCKW, DWTW and WT bits in ACMFIMCRW to “1”, respectively.
5. Drive the MEMC_A1 pin to high level and write data from the ACMFI1 bus.
6. The DMA transfers the valid data on the ACMFRAM.
7. When data write from the ACMFI1 bus is completed and number of transfers reaches the one specified in the DMAC, a DMA transfer end interrupt occurs.
8. After the interrupt source is handled in the interrupt handling routine, clear the LOCKW, DWTW and WT bits in ACMFIMCRW to “0”, respectively.

Then, the following shows the reading flow of the data that is successively written to the ACMFRAM by the DMAC from the ACMFI1 bus.

1. Set the DMAC register with the reload mode enabled and start it up. At this time, DMA transfer size is 16bytes.
2. Set ACMFIADRR to “H’F000” and set ACMFISIZER “H’0100”.
3. Set the MDRN bit in ACMFISCR any value. This transfer unit must be corresponding to the transfer units of DRSR bit in ACMFIMCRR.
4. Set the LOCKR and DWDR bits in ACMFIMCRR to “1”, respectively.
5. Wait until ACMFIDNRR is larger than transfer unit set by the above-mentioned “3.” or MEMC_DREQ* is asserted.
6. Set the RD bit in ACMFIMCRR to “1”.
7. Read ACMFIMCRR until the RD bit in ACMFIMCRR is “1”.
8. Drive the MEMC_A1 pin to high level and read data from the ACMFI1 bus.
9. When the DMA transfer is completed, a DMA transfer end interrupt occurs.
10. After the interrupt source is handled in the interrupt handling routine, clear the LOCKR, DWDR and RD bits in ACMFIMCRR to “0”, respectively.

Though successive read/write is enabled after the processing described above, caution should be paid to the following.

- The number of writing data from ACMFI1 bus is multiples of 16bytes when successive write is executed.
- The number of data transferred by DMAC is multiples of transfer unit of DRSR bits in ACMFIMCRR when successive read is executed.
- Set it again from the above flow “1.” when successive transfer is executed again.
- Please consider the response time of MEMC_INT pin when MEMC_INT pin is used and controlled during data transfer.
- Use any channels of DMAC as needed.

30.5 Interface (Basic)

The parallel interface using the ACMFI1 is described below. Access via the ACMFI1 is completed within a fixed time.

Figure 30.5 shows the basic read/write sequence.

Read operations are specified in the overlap period during which both the MEMC_NOE and MEMC_CS0 signals go low. Write operations are specified in the overlap period during which both the MEMC_NWE and MEMC_CS0 signals go low.

When the MEMC_A0 is low, the type is normal access, and when high, index/status registers access.

For details on the timing, refer to section **.*, AC characteristics.

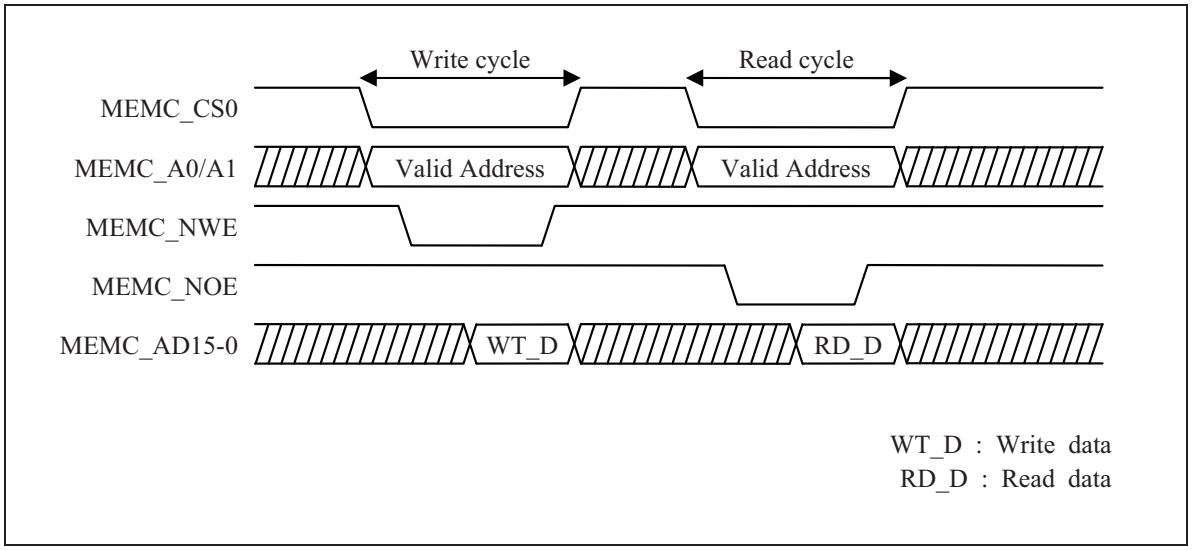

Figure 30.5 Basic Timing for ACMFI1 Interface

30.6 Interface (Details)

Here the details of the interface are described.

30.6.1 ACMFIIDX Write/ACMFIGSR Read

Writing of ACMFIIDX and reading of ACMFIGSR is shown in figure 30.6.

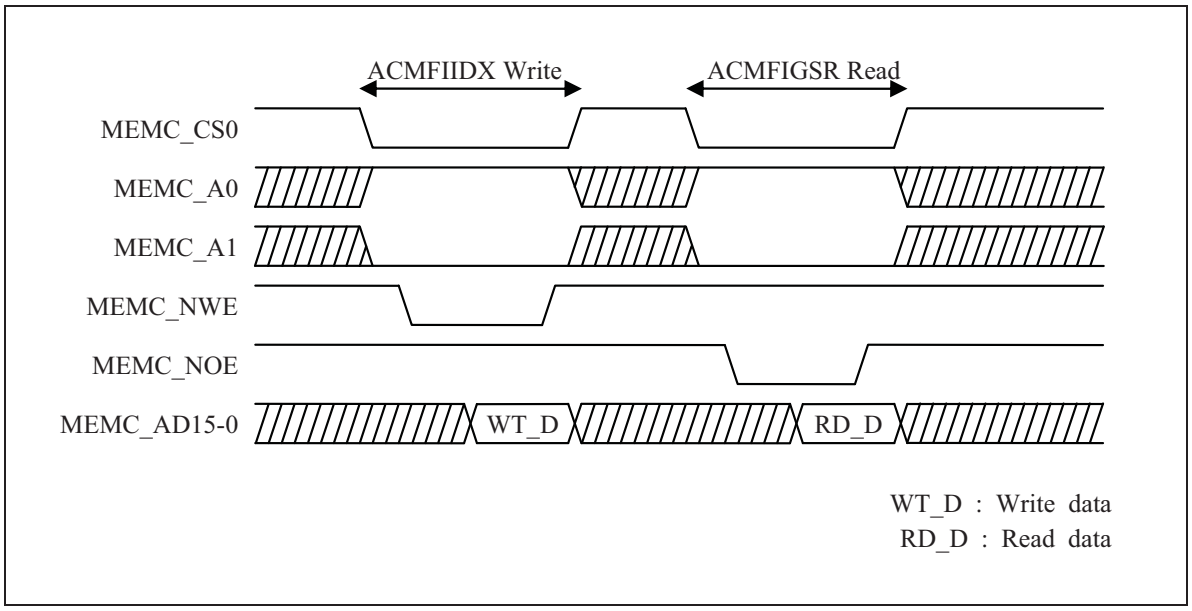

Figure 30.6 ACMFIIDX Write and ACMFIGSR Read

30.6.2 ACMFI1 Register Read/Write

As shown in figure 30.7, in reading and writing of ACMFI1 internal registers, first the MEMC_A0 signal is held high level and ACMFIIDX is written in order to select the register and byte position to be accessed. Then the MEMC_A0 signal is held low level and reading or writing of the register selected using ACMFIIDX is performed.

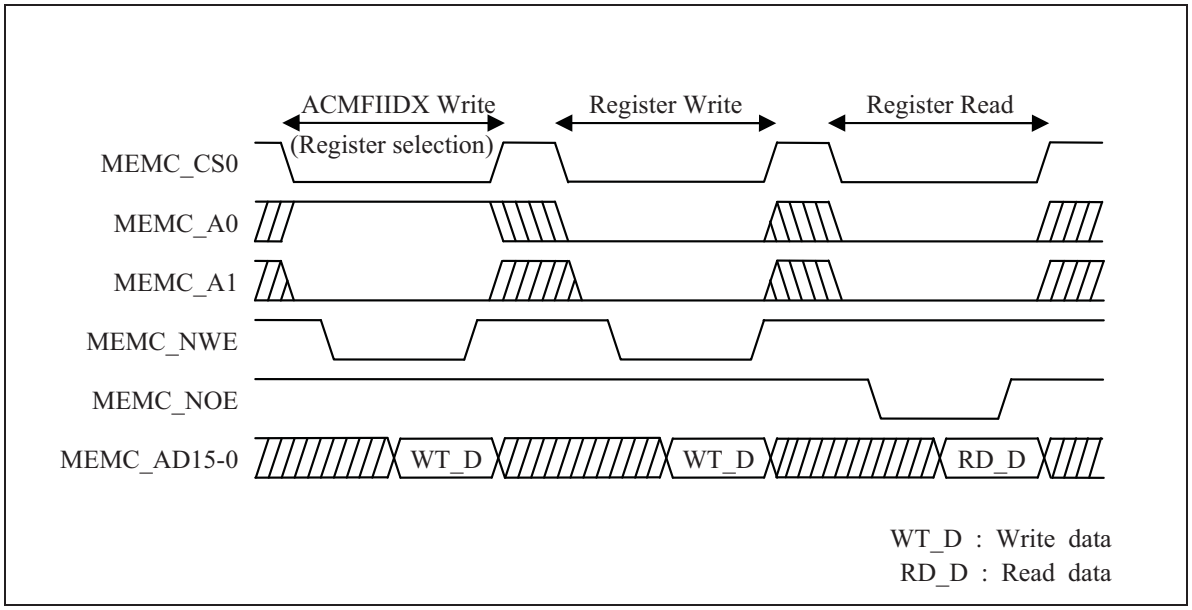

Figure 30.7 ACMFI1 Register Settings

Figure 30.8 shows the data drive timing at ACMFI1 bus read. MEMC_AD drive is controlled by the falling or rising edges of the MEMC_NOE signal.

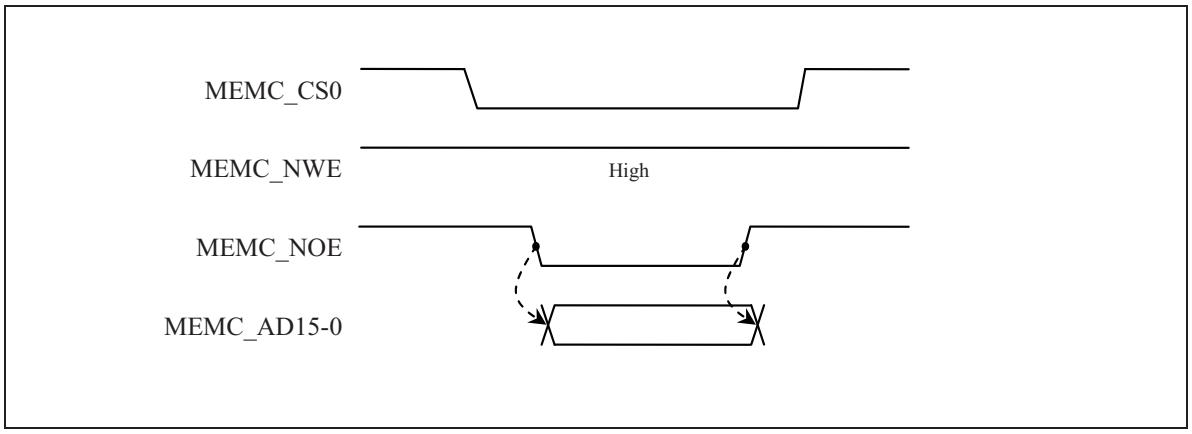

Figure 30.8 Data Drive Timing at ACMFI1 Bus Read

30.6.3 Continuous Data Writing from ACMFI1 to ACMFRAM

Figure 30.9 shows the timing chart for continuous data transfer from the ACMFI1 to ACMFRAM. As shown in this timing chart, by setting the start address and the data to be written first, continuous data transfer can subsequently be performed. As a result, effective data transfer to this LSI can be performed using DMA transfer or similar methods.

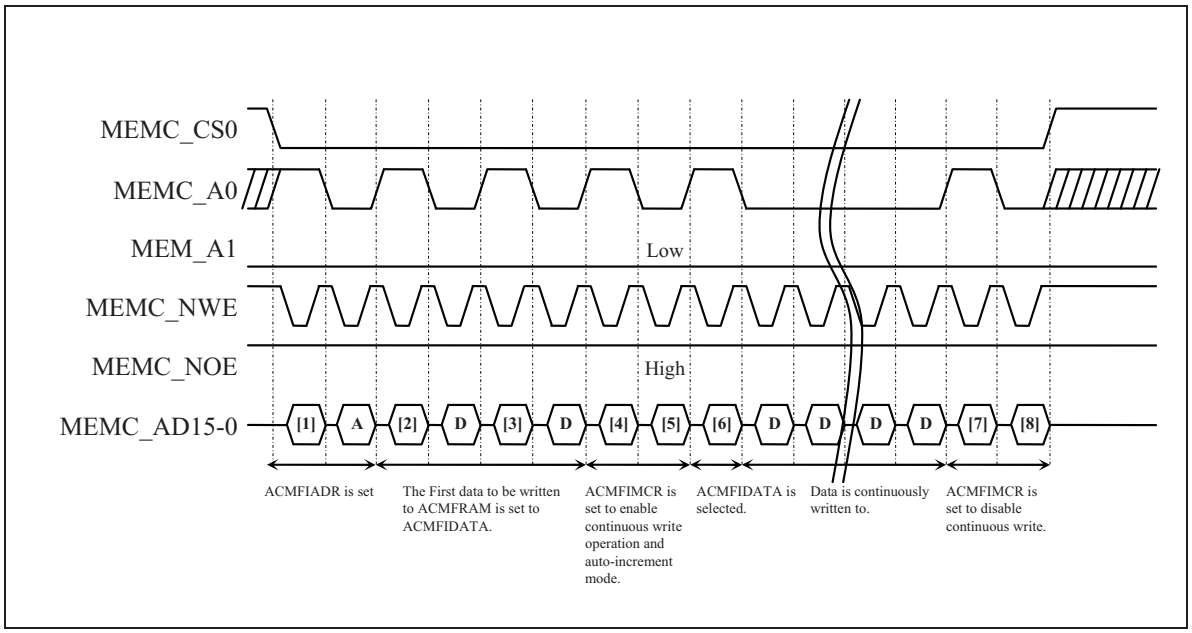

Figure 30.9 Continuous Data Writing to ACMFRAM

[Note] Details of symbols in figure are shown below.

A : The start address value of continuous write

D : The data value to be written to ACMFRAM

[1] : Index value in which ACMFIADR is selected (H'0014 or H'0016)

[2] : Index value in which ACMFIDATA is selected (H'0018 or H'001A)

[3] : Index value in which ACMFIDATA is selected (H'001A or H'0018)

[4] : Index value in which ACMFIMCR is selected (H'0008 or H'000A)

[5] : Set value of continuous write and auto-increment (H'00A0)

[6] : Index value in which ACMFIDATA is selected (H'0018 or H'001A)

[7] : Index value in which ACMFIMCR is selected (H'0008 or H'000A)

[8] : The value in which the continuous write and auto-increment are released (H'0000)

30.6.4 Continuous Data Reading from ACMFRAM

Figure 30.10 shows the timing chart for continuous data reading from ACMFRAM through the ACMFI1. As shown in this timing chart, by setting the start address, data can subsequently be read continuously. As a result, effective data transfer to this LSI can be performed using DMA transfer or similar methods.

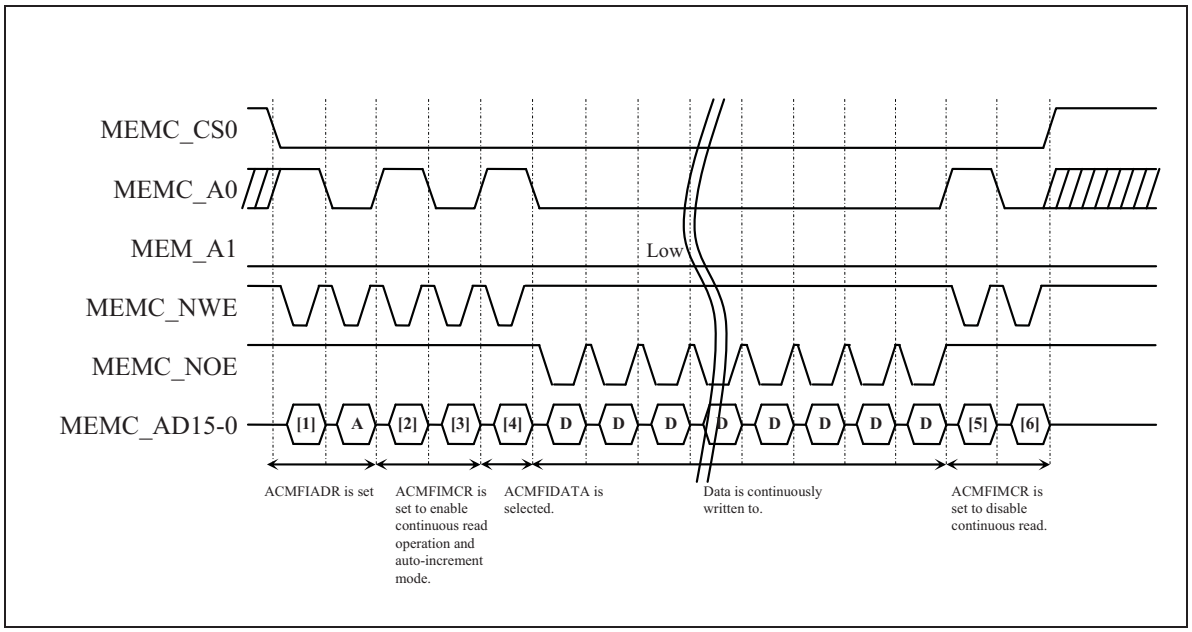

Figure 30.10 Continuous Data Reading from ACMFRAM

[Note] Details of symbols in figure are shown below.

A : The start address value of continuous read

D : The data value to be read by continuous read

[1] : Index value in which ACMFIADR is selected (H'0014 or H'0016)

[2] : Index value in which ACMFIMCR is selected (H'0008 or H'000A)

[3] : Set value of continuous read and auto-increment (H'0088)

[4] : Index value in which ACMFIDATA is selected (H'0018 or H'001A)

[5] : Index value in which ACMFIMCR is selected (H'0008 or H'000A)

[6] : The value in which the continuous read and auto-increment are released (H'0000)

Section 31 AC Parallel Interface 2 (ACMFI2)

This LSI has an address-data multiplex type multifunctional interface (AC-MFI2 : AC-Multi Functional Interface 2 Address-Data Multiplex) which realizes direct access from external device by 16bit parallel interface to the resource in this LSI. ACMFI2 has an asynchronous interface (MEMC_CS0) and a synchronous interface (MEMC_CS1), and high-speed access is possible to SDRAM connected to this LSI from external device.

31.1 Features

- This LSI has asynchronous interface chip select (MEMC_CS0) and synchronous interface chip select (MEMC_CS1).
- Both a synchronous interface and an asynchronous interface are an address-data multiplex.
- For an asynchronous interface, 16bit-read/write is possible for 64 K bytes of on-chip RAM, and ACMFI2 registers.
- High-speed burst access is possible to SDRAM connected to this LSI by the synchronous interface.
- The burst access size in a synchronous interface is unrestricted. (within target capacity)
- The input clock for a synchronous interface supports a maximum of 50MHz.
  (Conditions : Input clock frequency < internal clock frequency)
- It is possible to apply interrupt from external device to on-chip CPU or from on-chip CPU to external device.
- This LSI has an address complement register and it is possible to complement a certain specific address bit.
- This LSI has an address protective register and it is possible to restrict access for each address space.
- This LSI has an address auto increment function and high-speed continuous burst access is possible to SDRAM.
- This LSI has semaphore register and the communication can be assisted between external device and on-chip CPU.

The block diagram of ACMFI2 is shown in Fig.31.1.

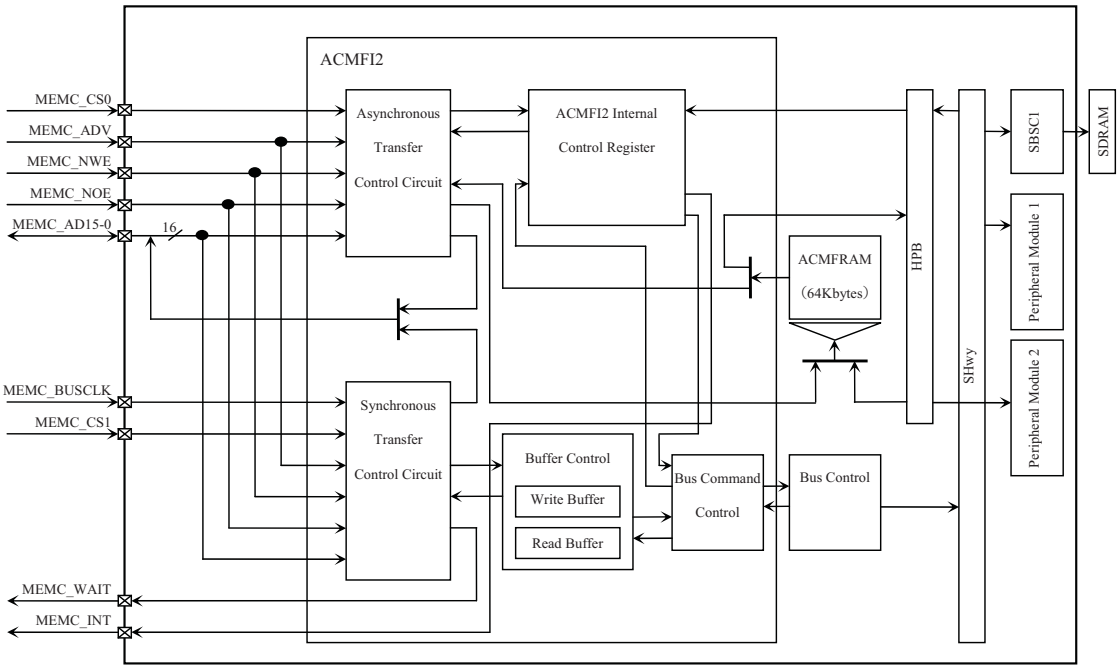

Figure 31.1 ACMFI2 block diagram

31.2 Input/Output Pins

The ACMFI2 pin configuration is listed in Table 31.1.

Table 31.1 Pin Configuration

Name	Function	I/O	Description
MEMC_CS0	Asynchronous interface chip select	Input	Chip select input to the ACMFI2 in asynchronous transfer.
MEMC_CS1	Synchronous interface chip select	Input	Chip select input to the ACMFI2 in synchronous transfer.
MEMC_BUSCLK	Synchronous interface input clock	Input	Clock input to the ACMFI2 in synchronous transfer.
MEMC_ADV	Address valid	Input	Address-valid input to the ACMFI2 in both synchronous and asynchronous transfer.
MEMC_NWE	Write strobe	Input	Write strobe input to the ACMFI2 in both synchronous and asynchronous transfer.
MEMC_NOE	Read strobe	Input	Read strobe input to the ACMFI2 in both synchronous and asynchronous transfer.
MEMC_AD15-AD0	Address/Data	I/O	Address/Data multiplex input-output in both synchronous and asynchronous transfer.
MEMC_WAIT	Access wait	Output	The Access wait output for a synchronous interface.
MEMC_INT	Interrupt	Output	Interrupt request to external device from the ACMFI2. (Low Active signal)

31.3 Register Descriptions

Table 31.2 shows the ACMFI2 register configuration of access from on-chip CPU. Table 31.3 shows the ACMFI2 register configuration of access from external device. Moreover, Table 31.4 shows the state of register in each operating mode.

Table 31.2 Register Configuration of access from on-chip CPU

Register Name	Abbreviation	R/W	Address	Access Size
ACMFI general status register	ACMFIGSR	R/W	H'E6B80000	32

31.3.1 ACMFI General Status Register (ACMFIGSR)

ACMFIGSR can be freely used for mutual display of status between external device connected to the ACMFI2 and on-chip CPU.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	STATUS[15:0]															
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	STATUS[15:0]	All 0	R/W	General Status These bits can be read and written by the software of external device connected to the ACMFI2, and by on-chip CPU. Except upon a reset, they are never overwritten by hardware.

31.3.2 ACMFI Semaphore Register (ACMFISM4)

ACMFISM4 is a dedicated register allowing read modify write to be performed from external device connected to the ACMFI2 and from on-chip CPU. Using ACMFISM4 as a semaphore can improve the data transfer efficiency.

When the bits SM[1:0] = 00 is read, software can learn the successful acquisition.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	SM[1:0]		INF[7:0]							
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 8	SM[1:0]	00	R/W	Bits for Semaphore If these bits are “00”, reading to this register reads “01” (read from external device connected to ACMFI2) or “10” (read from on-chip CPU). The read value means a value before the change. The change is made only when “00” is read. As for these bits, only writing “00” is possible. When values other than “00” are written, the value does not change. It is possible to write this register by the following condition. 00 : Only reading from both external device and on-chip CPU is possible. 01 : Reading/writing from the external device is possible, and only reading is possible from on-chip CPU. 10 : Only reading is possible from the external device, reading/writing from on-chip CPU is possible. 11 : Setting prohibited.
7 to 0	INF[7:0]	All 0	R/W	Bits for Information Reading/writing is allowed according to the semaphore conditions of bits SM[1:0]. These bits are usually used as information.

[Note] If reading from external device and on-chip CPU simultaneously occurs for ACMFISM4 with the bits SM[1:0] = “00”, ACMFISM4 returns data of the bits SM[1:0] = “01” to on-chip CPU, while returns “00” to external device.

31.3.3 ACMFI Internal Interrupt Control Register (ACMFIIICR)

ACMFIIICR is used to issue interrupts from external device connected to the ACMFI2 to on-chip CPU.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	IIC[6:0]							IIR
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 1	IIC[6:0]	All 0	R/W	Internal Interrupt Source Bits used to specify the source for interrupts generated by the IIR. These bits can be written from both external device and on-chip CPU. By using these bits, fast execution of an interrupt handler is possible. These bits are completely under software control, and their values have no effect on the operation of the LSI.
0	IIR	0	R/W	Internal Interrupt Request While this bit is “1”, an interrupt request is issued to on-chip CPU.

31.3.4 ACMFI External Interrupt Control Register 0（ACMFIEICR0）

ACMFIEICR0 is used to issue interrupts from on-chip CPU to external device connected to the ACMFI2.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERR3	ERR2	ERR1	ERR0	-	-	-	-	EIC[6:0]							EIR
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	ERR3	0	R	Internal Bus Error Interrupt Notification This bit is set to “1” when an error occurs in this LSI internal bus during access to this LSI via ACMFI2. This bit is cleared by setting SRST of ACMFISYNCS to “1”. This bit cannot be cleared by on-chip CPU.
14	ERR2	0	R	Synchronous Transfer Write Error Interrupt Notification This bit is set to “1” when a synchronous transfer write is issued in the unexpected access size. This bit is cleared by setting SRST of ACMFISYNCS to “1”. This bit cannot be cleared by on-chip CPU.
13	ERR1	0	R	ACMFRAM Access Error Interrupt Notification This bit is set to “1” when access to the access protection area in ACRAMPTCR occurs. This bit is cleared by setting ERST of ACRAMPTCR to “1”. This bit cannot be cleared by on-chip CPU.
12	ERR0	0	R	Access Error Interrupt Notification This bit is set to “1” when access to the access protection area in ACMFIPTCR occurs. This bit is cleared by setting ERST of ACMFIPTCR to “1”. This bit cannot be cleared by on-chip CPU.
11 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 1	EIC[6:0]	All 0	R/W	External Interrupt Source These bits are used to specify the source for interrupts generated by the EIR. These bits can be written from both external device and on-chip CPU. By using these bits, fast execution of interrupt handler is possible. These bits are completely under software control, and their values have no effect on the operation of the LSI.
0	EIR	0	R/W	External Interrupt Request While this bit is “1”, the MEMC_INT pin is asserted and an interrupt request is issued to the external device from this LSI.

31.3.5 ACMFI Indirect Access Control Register (ACMFIIDACR)

ACMFIIDACR is used when access to the internal registers of this LSI by using this register, ACMFIDAA and ACMFIDAD.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AERR	-	-	-	-	-	-	RWT	-	-	-	RRD	-	-	SZ[1:0]	
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R/W	R	R	R	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	AERR	0	R/W	Address Error This bit is set to “1” when the value set in the ADR bits is not consistent with the register access size. Read/write operation is canceled when an address error occurs. <Read> 0 : With No Error 1 : Error Occurred <Write> 0 : Clears the Error 1 : Retains the previous value
14 to 9	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	RWT	0	R/W	Register Write Write “1” to this bit when writing to the register. When writing to the register is completed, this bit is cleared to “0”.
7 to 5	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	RRD	0	R/W	Register Read Write “1” to this bit when reading from the register. When reading from the register is completed, this bit is cleared to “0”.
3 to 2	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial	R/W	Description
1 to 0	SZ[1:0]	All 0	R/W	Register Access Size These bits specify the access size for reading from/writing to the register. 00 : Byte 01 : Word 10 : Long-Word 11 : Setting prohibited

[Note] This register can be read and written by external device via ACMFI2. It cannot be written though can be read by the on-chip CPU.

31.3.6 ACMFI Indirect Access Address Register (ACMFIIDAA)

ACMFIIDAA is used to store an accessed address, when accessing to the register in this LSI via the register of ACMFI2.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADR[31:16]															
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADR[15:0]															
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Vale	R/W	Description
31 to 0	ADR[31:0]	All 0	R/W	Address The accessed address in accessing registers of this LSI via the register of ACMFI2 is specified.

[Note] This register can be read and written by external device via ACMFI2. It cannot be written though can be read by the on-chip CPU.

31.3.7 ACMFI Indirect Access Data Register (ACMFIIDAD)

ACMFIIDAD is used when access to the internal registers of this LSI. ACMFIDAD is used to hold data read from and written to register which are accessed by external device.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DATA[31:16]															
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATA[15:0]															
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Vale	R/W	Description
31 to 0	DATA[31:0]	All 0	R/W	Data In case of accessing to the register in this LSI via ACMFI2 registers, the write data is stored in this register in writing, and the read data is stored in reading.

[Note] This register can be read and written by external device via ACMFI2. It cannot be written though can be read by the on-chip CPU.

31.3.8 ACMFI Synchronous Transfer Control Register (ACMFISYNC)

ACMFISYNC is used to specify the function setting associated with the synchronous transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	RDW	-	-	WTW[1:0]	
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	INCS[1:0]		-	-	-	-	RDO[1:0]		-	-	WDO[1:0]		-	WBV
Initial:	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	RDW	0	R/W	Read Data Wait (Refer to 31.4.4(6) for details) 0 : Read data output no delay (Default) 1 : Read data output 1cycle delay mode
19 to 18	-	00	R	Reserved These bits are always read as 0. The write value should always be 0.
17 to 16	WTW[1:0]	00	R/W	Write Data Wait (Refer to 31.4.4(6) for details) 00 : Write Data input no delay (Default) 01 : Write Data input 1cycle delay mode 10 : Write Data input 2cycle delay mode 11 : Write Data input 3cycle delay mode
15 to 14	-	00	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 12	INCS[1:0]	00	R/W	Address Auto Increment Mode (Refer to 31.4.4(4) for details) 00:Address auto increment mode OFF 01:16Byte address auto increment mode ON 10:32Byte address auto increment mode ON 11 : Setting prohibited
11 to 10	-	00	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 8	-	11	R	Reserved These bits are always read as 1. The write value should always be 1.

Bit	Bit Name	Initial Value	R/W	Description
7 to 6	RDO[1:0]	00	R/W	Read Data Swapping 00 : No swapping 01 : Byte-wise swapping 10 : Word-wise swapping 11 : Both byte-wise and word-wise swapping
5 to 4	-	00	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 2	WDO[1:0]	00	R/W	Write Data Swapping 00 : No swapping 01 : Byte-wise swapping 10 : Word-wise swapping 11 : Both byte-wise and word-wise swapping
1	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	WBV	0	R	Indicates whether or not data remains in the write buffer. 0 : No data remains in the write buffer (the write operation complete). 1 : Data remains in the write buffer (the write operation is in progress).

[Note] Rewriting the value of this register during synchronous transfer is prohibited. Operation is not guaranteed if the value is rewritten.

Before rewriting the bits of ACMFISYNC, check to ensure that the WBV bit is “0”.

31.3.9 ACMFI Synchronous Transfer Address Register (ACMFISYNCA)

ACMFISYNCA is a register which can complement the access address in synchronous transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SYNCA[14:0]															-
Initial:	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	SYNCA[14:0]	H'2000	R/W	Offset Address Set the higher-order address bits [31:17] for use in synchronous transfer, i.e. specify the area for access. The initial value is SDRAM space.
16 to 0	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

[Note] Rewriting the value of this register during synchronous transfer is prohibited. Operation is not guaranteed if the value is rewritten.

Before rewriting the bits of ACMFISYNC, check to ensure that the WBV bit is "0".

31.3.10 ACMFI Synchronous Transfer Status Register (ACMFISYNCS)

ACMFISYNCS is a register which stores the status in using synchronous interface. (Indirect access in asynchronous interface is included)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SRST
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	INCRERR	INCWERR	-	-	-	BERR	-	-	WERR1	WERR0
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	SRST	0	W	Status Reset 0 : Invalid setting 1 : Status reset (ACMFISYNCS[15:0] are all cleared and ACMFIEICR0[15:14] are cleared.)
15 to 10	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	INCRERR	0	R	Address Increment Read Error This bit is set to “1” when an illegal synchronous read is issued when value of INCS[1:0](ACMFISYNC) is “01” or “10”.
8	INCWERR	0	R	Address Increment Write Error This bit is set to “1” when an illegal synchronous write is issued when value of INCS[1:0](ACMFISYNC) is “01” or “10”.
7 to 5	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	BERR	0	R	Internal Bus Error This bit is set to “1” when an internal bus error occurs.
3 to 2	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	WERR1	0	R	Write Access Size Over Error This bit is set to “1” when larger access than 2-burst access size (4byte) occurs in a synchronous write.

Bit	Bit Name	Initial Value	R/W	Description
0	WERR0	0	R	Write Access Size Under Error This bit is set to "1" when smaller access than 2-burst access size (4byte) occurs in a synchronous write.

31.3.11 ACMFI Synchronous Transfer Status Mask Register (ACMFISYNCMASK)

ACMFISYNCMASK is a register which external interrupt by error bit of ACMFISYNCS masked is possible. (Except BERR bit of ACMFISYNCS)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	MSK3	MSK2	-	-	-	-	-	-	MSK1	MSK0
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	MSK3	0	R/W	Address Increment Read Error Mask When this bit is set to "1", external interrupt by INCRERR bit of ACMFISYNCS is masked.
8	MSK2	0	R/W	Address Increment Write Error Mask When this bit is set to "1", external interrupt by INCWERR bit of ACMFISYNCS is masked.
7 to 2	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	MSK1	0	R/W	Write Access Size Over Error Mask When this bit is set to "1", external interrupt by WERR1 bit of ACMFISYNCS is masked.
0	MSK0	0	R/W	Write Access Size Under Error Mask When this bit is set to "1", external interrupt by WERR0 bit of ACMFISYNCS is masked.

31.3.12 ACMFI Address Protection Register (ACMFIPTCR)

ACMFIPTCR is a register which restrict access area in access from external device to inside of this LSI. In case of access to restricted area, the access becomes invalid.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PTCERR	-	ERST	ETC	-	-	PT4	-	-	-	-	-	-	-	PT1	PT0
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	W	R/W	R	R	R/W	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	PTCERR	0	R	Protection Error 0 : No error 1 : Error (Access to protection area)
14	-	0	R	Reserved This bit is always read as 0. The write value should always be 0.
13	ERST	0	W	Error Log Reset (Refer to 31.4.4(5) for details) 0 : Invalid setting 1 : Clears the error log
12	ETC	0	R/W	Other Area Protection All access restrictions are performed except area of PT0, PT1 and PT4 in this register. 0 : No access permitted 1 : Access permitted
11 to 10	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	PT4	0	R/W	CPG and SYSC Area Protection 0 : No access permitted 1 : Access permitted
8 to 2	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	PT1	0	R/W	BSC Area Protection 0 : No access permitted 1 : Access permitted

Bit	Bit Name	Initial Value	R/W	Description
0	PT0	0	R/W	SDRAM Area Protection 0 : No access permitted 1 : Access permitted

[Note] This register can be read and written by on-chip CUP. It cannot be written though can be read by external device via ACMFI2. Exceptionally, only ERST bit can be written by external device via ACMFI2.

31.3.13 ACMFI Protection Error Address Register (ACMFIPTCERA)

ACMFIPTCERA is a register to store the invalid accessed address when accessing to restricted area.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ERRADR[31:16]															
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERRADR[15:0]															
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	ERRADR[31:0]	All 0	R	Error Address Log Error address is stored in this register when accessing to protection area.

31.3.14 ACMFRAM Protection Register (ACRAMPTCR)

ACRAMPTCR is a register to restrict access by every 8KB for ACMFRAM area when accessing from external device to ACMFRAM. In case of access to the restrict area, this access becomes invalid.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RAMERRADR[15:0]															
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERR	-	-	ERST	-	-	-	-	AR7	AR6	AR5	AR4	AR3	AR2	AR1	AR0
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	RAMERRADR [15:0]	All 0	R	ACMFRAM Error Address Log Error Address is stored in these bits when accessing to protection area of ACMFRAM.
15	ERR	0	R	ACMFRAM Protection Error 0 : No error 1 : Error (access to protection area of ACMFRAM)
14 to 13	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	ERST	0	W	Error Log Reset (Refer to 31.4.4(5) for details) 0 : Invalid setting 1 : Clears the error log
11 to 8	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	AR7	0	R/W	ACMFRAM Protection Area 7 (address : H'E000 to H'FFFF) 0 : No access permitted 1 : Access permitted
6	AR6	0	R/W	ACMFRAM Protection Area 6 (address : H'C000 to H'DFFF) 0 : No access permitted 1 : Access permitted
5	AR5	0	R/W	ACMFRAM Protection Area 5 (address : H'A000 to H'BFFF) 0 : No access permitted 1 : Access permitted

Bit	Bit Name	Initial Value	R/W	Description
4	AR4	0	R/W	ACMFRAM Protection Area 4 (address : H'8000 to H'9FFF) 0 : No access permitted 1 : Access permitted
3	AR3	0	R/W	ACMFRAM Protection Area 3 (address : H'6000 to H'8FFF) 0 : No access permitted 1 : Access permitted
2	AR2	0	R/W	ACMFRAM Protection Area 2 (address : H'4000 to H'5FFF) 0 : No access permitted 1 : Access permitted
1	AR1	0	R/W	ACMFRAM Protection Area 1 (address : H'2000 to H'3FFF) 0 : No access permitted 1 : Access permitted
0	AR0	0	R/W	ACMFRAM Protection Area 0 (address : H'0000 to H'1FFF) 0 : No access permitted 1 : Access permitted

[Note] This register can be read and written by on-chip CUP. It cannot be written though can be read by external device via ACMFI2. Exceptionally, only ERST bit can be written by external device via ACMFI2.

31.3.15 ACMFI External Interrupt Control Register 1 (ACMFIEICR1)

ACMFIEICR1 is a register which interrupt notified external device can be notified also to on-chip CUP. And this register can prevent external interrupt by hardware source.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EMSK3	EMSK2	EMSK1	EMSK0	-	-	-	-	-	-	-	-	-	-	-	CINT
Initial:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
15	EMSK3	0	R/W	External Interrupt Mask by ERR3 bit of ACMFIEICR0 0 : No masked 1 : Masks
14	EMSK2	0	R/W	External Interrupt Mask by ERR2 bit of ACMFIEICR0 0 : No masked 1 : Masks
13	EMSK1	0	R/W	External Interrupt Mask by ERR1 bit of ACMFIEICR0 0 : No masked 1 : Masks
12	EMSK0	0	R/W	External Interrupt Mask by ERR0 bit of ACMFIEICR0 0 : No masked 1 : Masks
11 to 1	-	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CINT	0	R/W	External Interrupt Control When this bit is set to “1”, external interrupt transferred to MEMC_INT pin is also informed to on-chip CPU.

31.4 Operation

31.4.1 Access to ACMFI2 Registers

External access method which can access to ACMFI2 registers is an access only via asynchronous interface with MEMC_CS0. Please note that access to ACMFI2 registers via synchronous interface with MEMC_CS1 is invalid.

31.4.2 Memory Map

The memory space of on-chip ACMFRAM is shown in Table 31.5.

Table 31.5 ACMFI2 memory map

	Start address	End address	Memory size	Classification
Via ACMFI2 (external device)	H'10000	H'1FFFF	64K bytes	On-chip ACMFRAM area
Via on-chip CPU (this LSI)	H'E6B90000	H'E6B9FFFF	64K bytes	

31.4.3 Access to Internal Registers of this LSI via ACMFI2

By using this function, on-chip peripheral module registers can be directly accessed via asynchronous interface with MEMC_CS0. Write to and read from registers with the following procedures.

(1) Register Write Operation

1. Set the address of the register to be written to ACMFIIDAA.
2. Set the data of the register to be written to ACMFIIDAD.
3. Write access to the address set to ACMFIIDAA with the data set to ACMFIIDAD is executed by setting these SZ bits in ACMFIIDACR to access size and by setting the RWT bit in ACMFIIDACR to “1”. (Check the AERR bit in ACMFIIDACR is not set to “1”)
4. When the write operation is completed, the RWT bit is automatically cleared to “0”.

(2) Register Read Operation

1. Set the address of the register to be read to ACMFIIDAA.
2. Read access from the address set to ACMFIDAA is executed by setting these SZ bits in ACMFIIDACR to access size and by setting the RRD bit in ACMFIIDACR to “1”. (Check the AERR bit in ACMFIIDACR is not set to “1”)
3. When the read operation is completed, the RRD bit is automatically cleared to “0” and read data is stored in ACMFIIDAD.

When you access this LSI via ACMFI2 registers as mentioned above, please start these operations after checking that the WBV bit in ACMFISYNC is “0”.

31.4.4 Synchronous Transfer Mode

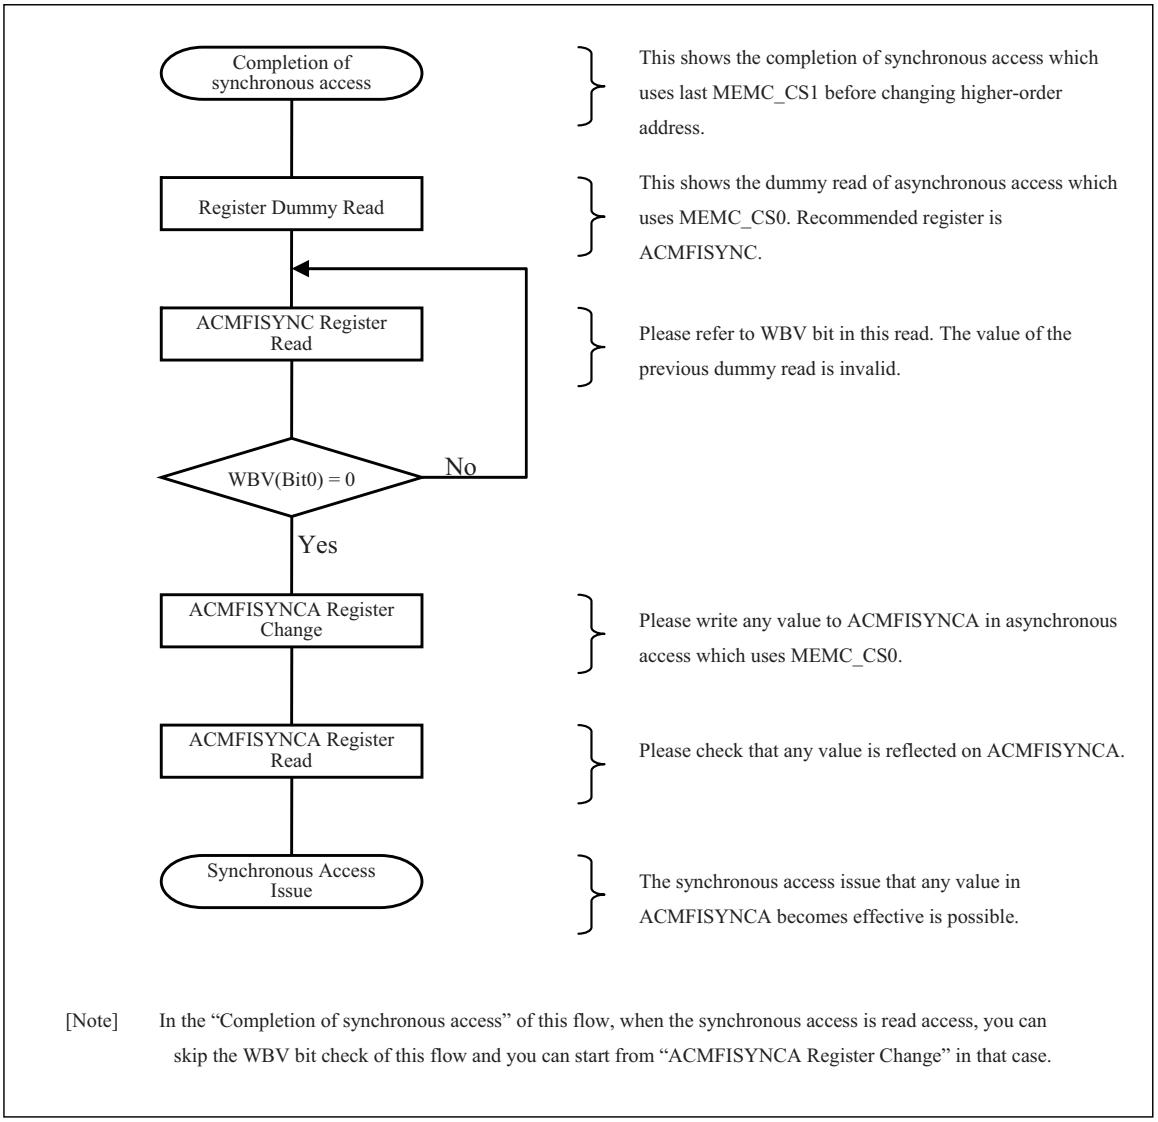
This function makes direct addressing and high-speed access to the memory device connected to this LSI via ACMFI2 by the synchronous interface.

(1) SDRAM Access

SDRAM connected to this LSI can be accessed in a direct address with the synchronous interface. Details are shown below.

- No limitation applies to the burst length. Write/read is executed until CS is negated.
- We recommended the 32-byte boundaries for burst access.
- Write/read buffers are incorporated in ACMFI2 and high-speed burst access is possible.

The higher-order address bits [31:17] for use in SDRAM access are provided by ACMFISYNCA. Please check the WBV bit in ACMFISYNC is “0” when you change the complemented address. (Refer to (3) Higher-order address change flow for details)



(2) Peripheral Module Access

Access to peripheral modules in this LSI is possible by using the synchronous interface. When you access to peripheral modules, please make sure of 4byte (2-burst) access. When access size is not 4Byte, operation is not guaranteed.

As SDRAM Access, the higher-order address bits [31:17] for use in SDRAM access are provided by ACMFISYNCA. Please check the WBV bit in ACMFISYNC is “0” when you change the complemented address. (Refer to (3) Higher-order address change flow for details)

(3) Higher-order Address Change Flow

ACMFI2 provides the function which complements higher-order address with ACMFISYNCA in the synchronous access. This function is available by the following flow.

[Note] In the “Completion of synchronous access” of this flow, when the synchronous access is read access, you can skip the WBV bit check of this flow and you can start from “ACMFISYNCA Register Change” in that case.

Figure 31.2 Higher-order address change flow

(4) Address Auto Increment Mode

Details of INCS[1:0] bits in ACMFISYNC are shown below.

[1] Automatic increment object area

Basically, only SDRAM area is an automatic increment object area.

[2] 16-byte/32-byte boundary increment setting

Please issue the 8-burst access (16byte) in the synchronous interface when INCS[1:0] bits are “01”. And only 16-byte boundary address must issue, and the access must issue continuous. When unexpected access is issued, MEMC_INT is asserted by internal error. The operation is not guaranteed at this time.

Also, please issue the 16-burst access (32byte) in the synchronous interface when INCS[1:0] bits are “10”. And only 32-byte boundary address must issue, and the access must issue continuous.

[3] Automatic address increment setting flow

Please set it according to the same procedure as “Higher-order Address Change Flow”. The mark of “ACMFISYNCA Register” in Fig.31.2 is replaced with “ACMFISYNC Register” and please refers.

[4] Notes

When the address increment setting is valid, SYNC[14:0] bits in ACMFISYNCA is changed for auto increment value. If you issue the access to other target in synchronous interface, please set ACMFISYNCA to higher-order address of the target after completion of auto increment access

(5) Error Reset Function

Details of ERST bit in ACMFIPTCR and ERST bit in ACRAMPTCR are shown below.

[1] About object of clear bits when ERST bit in ACMFIPTCR is set to “1”

Register Name. Bit Name	When the on-chip CPU writes "1" to ERST		When the external device writes "1" to ERST	
	Read from on-chip CPU	Read from external device	Read from on-chip CPU	Read from external device
ACMFIEICR0. ERR0	X	X	O	O
ACMFIPTCR. PTCERR	O	O	X	O
ACMFIPTCERA. ERRADR	X	X	O	O

[Note] “O” in above-mentioned table shows that it is cleared and “X” in above-mentioned table shows that it is not cleared.

[2] About object of clear bits when ERST bit in ACRAMPTCR is set to “1”

Register Name. Bit Name	When the on-chip CPU writes "1" to ERST		When the external device writes "1" to ERST	
	Read from on-chip CPU	Read from external device	Read from on-chip CPU	Read from external device
ACMFIEICR0. ERR1	X	X	O	O
ACRAMPTCR. ERR	O	X	X	O
ACRAMPTCR. RAMERRADR	X	X	O	O

[Note] “O” in above-mentioned table shows that it is cleared and “X” in above-mentioned table shows that it is not cleared.

(6) Variable Timing of Input/Output Data in Synchronous Interface

Details of RDW bit and WTD[1:0] bits in ACMFISYNC are shown below.

[1] About WTD[1:0] bits setting

The cycle time from MEMC_WAIT negate output timing to input write data can be changed by changing these bits.

Details of timing are shown below for every setting.

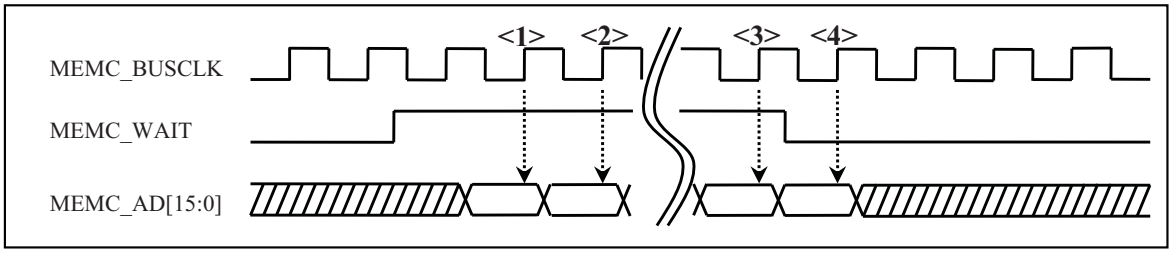


Figure 31.3 Valid timing of write data when WTD[1:0] bits in ACMFISYNC is “00”

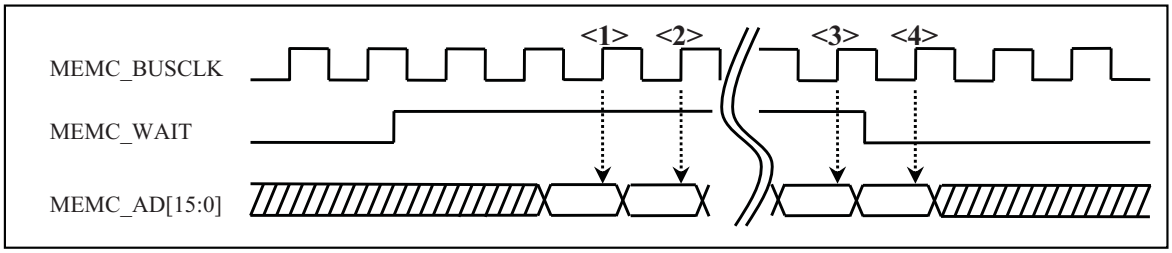

Figure 31.4 Valid timing of write data when WTD[1:0] bits in ACMFISYNC is “01”

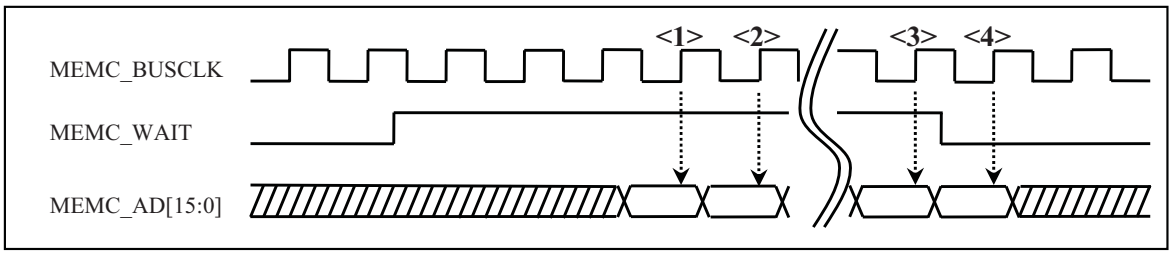

Figure 31.5 Valid timing of write data when WTD[1:0] bits in ACMFISYNC is “10”

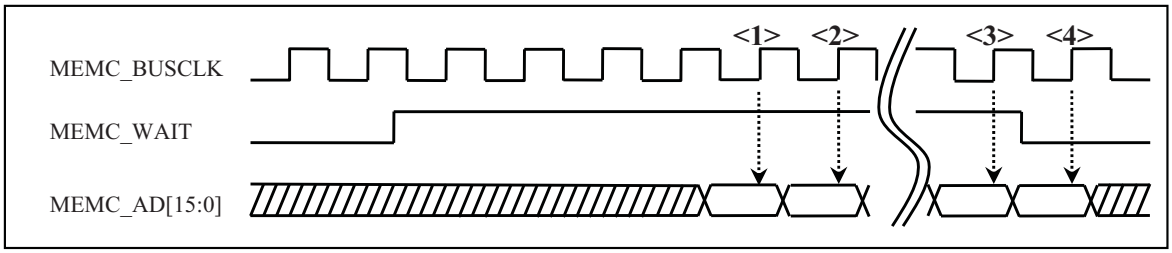

Figure 31.6 Valid timing of write data when WTD[1:0] bits in ACMFISYNC is “11”

• ”<1>” in the above figure is shown clock edge which retrieves the first write data after MEMC_WAIT negated, and “<2>” is shown the next write data. “<3>” and “<4>” is clock edge which retrieves the write data at MEMC_WAIT

asserted, and this timing is basically invariable at MEMC_WAIT asserted.

[2] About RDW bit setting

The cycle time from MEMC_WAIT negate output timing to output read data can be changed by setting "1" to this bit. Details of timing are shown below for every setting.

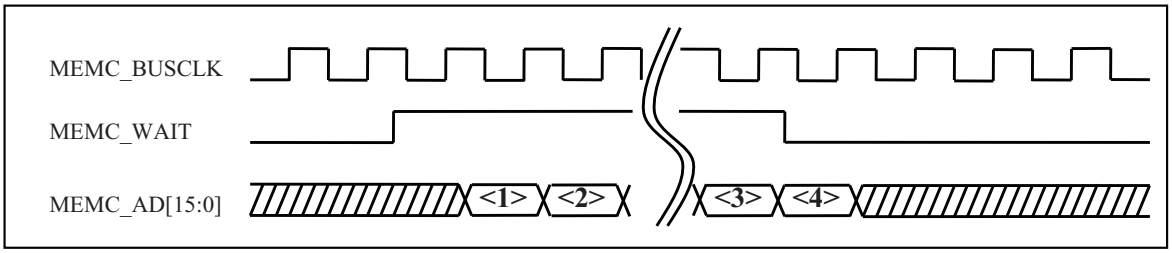

Figure 31.7 Valid timing of read data when RDW bit in ACMFISYNC is "0"

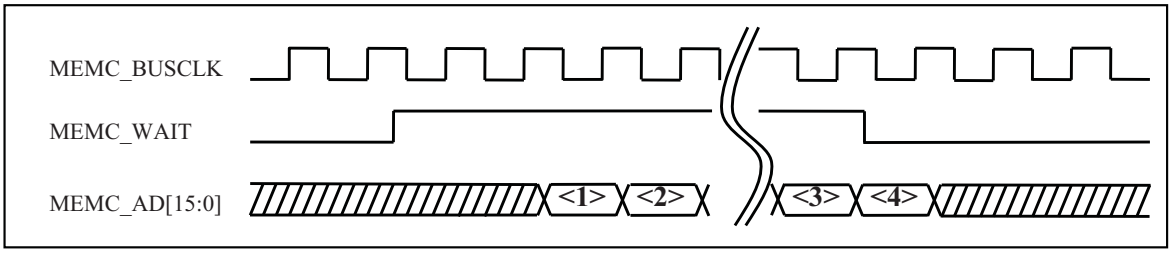

Figure 31.8 Valid timing of read data when RDW bit in ACMFISYNC is "1"

- "<1>" in the above figure is shown the first valid read data after MEMC_WAIT negated, and "<2>" is the next valid read data. "<3>" and "<4>" are the valid data output at MEMC_WIAT asserted, and this output timing is invariable at MEMC_WAIT asserted.

[3] Input/output data timing setting flow

Please set it according to the same procedure as "Higher-order Address Change Flow". The mark of "ACMFISYNCA Register" in Fig.31.2 is replaced with "ACMFISYNC Register" and please refers.

31.5 Interface

The parallel interface with ACMFI2 is described. ACMFI2 interface supports asynchronous interface and synchronous interface with MEMC_BUSCLK.

31.5.1 Asynchronous Interface

The basic write sequence of the asynchronous interface is shown in Fig.31.9 and the basic read sequence of the asynchronous interface shown in Fig.31.10. The Address/data multiplex is applied and the external address is 2-byte boundary.

Please refer to [***AC Characteristic] for detailed timing.

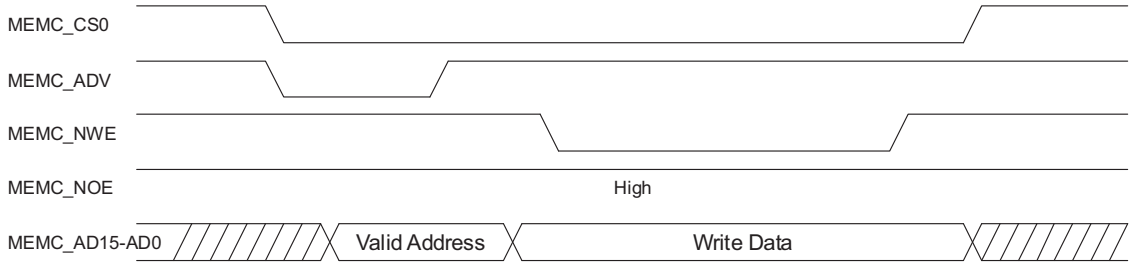

Figure 31.9 Write basic timing of asynchronous interface

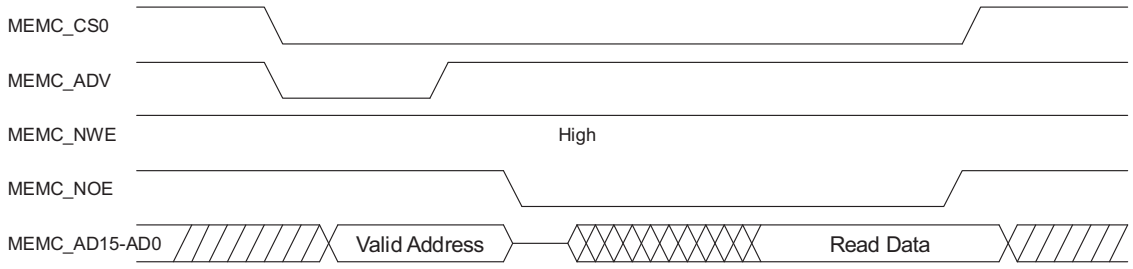

Figure 31.10 Read basic timing of asynchronous interface

31.5.2 Synchronous Interface

The basic write sequence of the synchronous interface is shown in Fig.31.11 and the basic read sequence of the synchronous interface shown in Fig.31.12. The Address/data multiplex is applied and the external address is 2-byte boundary.

Please refer to [***AC Characteristic] for detailed timing.

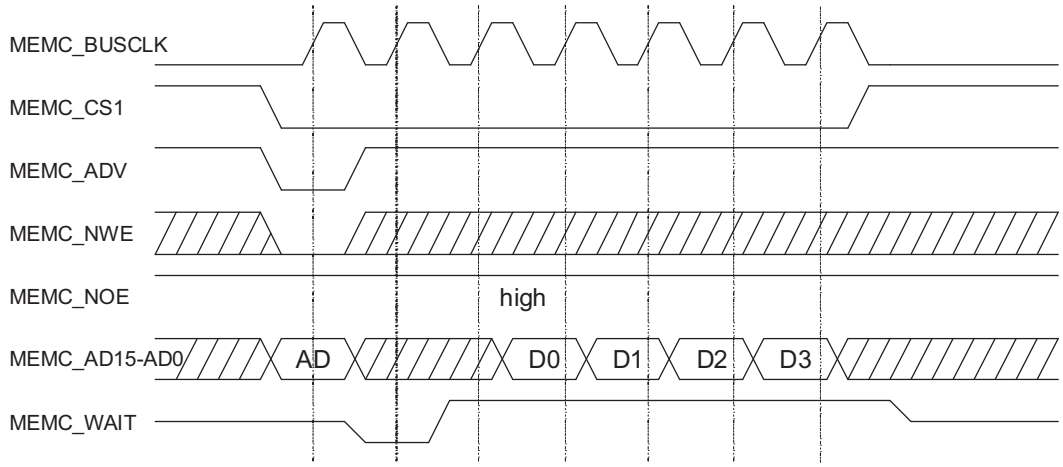

Figure 31.11 Write basic timing of synchronous interface

[Note] The asserting period of MEMC_WAIT is not constant and figure above is example.

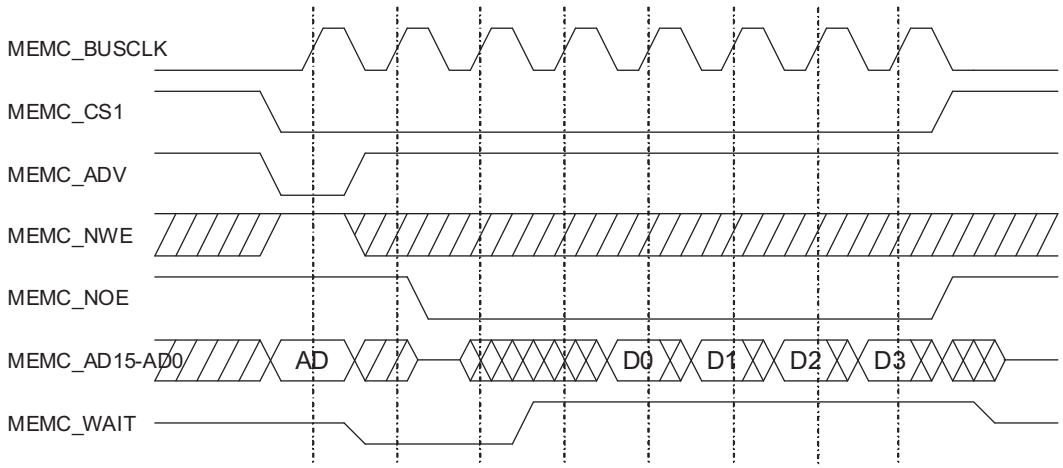

Figure 31.12 Read basic timing of synchronous interface

[Note] The asserting period of MEMC_WAIT is not constant and figure above is example.

The long burst (64bytes) write sequence is shown in Fig.31.13 and the long burst (64bytes) read sequence is shown in Fig.31.14. Continuous access is applied in long burst access, and address is incremented automatically, and access is continued while MEMC_CS1 is asserted. In the following figure, address of the burst access is issued by 32-byte boundary.

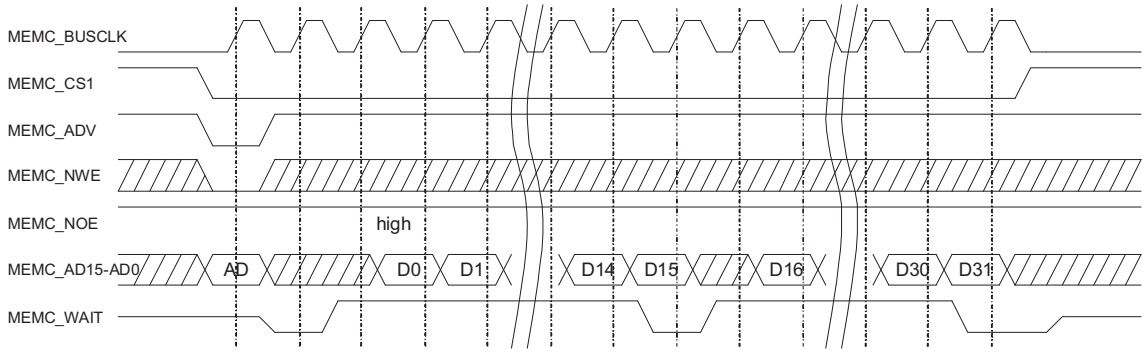

Figure 31.13 64byte-burst write timing of synchronous interface

[Note] The asserting period of MEMC_WAIT is not constant. One or more cycles of MEMC_WAIT is asserted by every 32byte write.

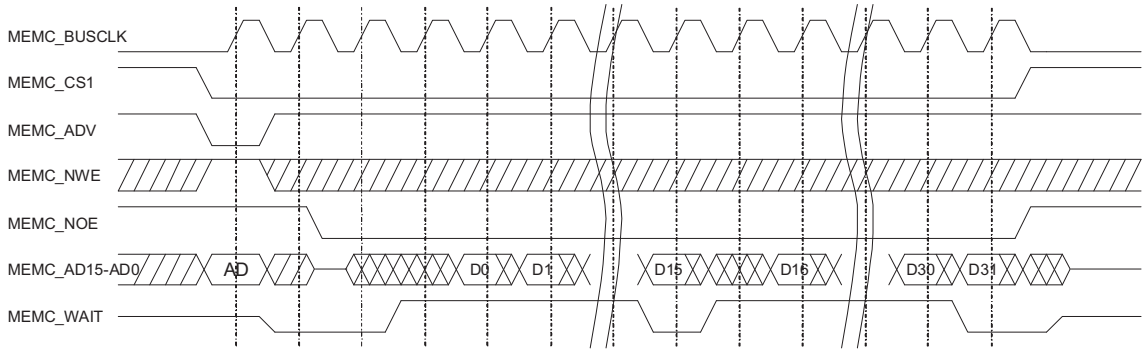

Figure 31.14 64byte-burst read timing of synchronous interface

[Note] The asserting period of MEMC_WAIT is not constant. One or more cycles of MEMC_WAIT is asserted by every 32byte write.

Section 32 USB High-Speed 0 Module (USBHS0)

This module is a USB controller provided with the USB host controller function and the function controller function. When the host controller function is selected, high-speed transfer, full-speed transfer, and low-speed transfer conforming to the USB (universal serial bus) Specification 2.0 are available. When the function controller function is selected, high-speed transfer and full-speed transfer are available. Provided with an on-chip USB transceiver, this module also supports all transfer types defined by the USB Specification.

This module can use up to ten pipes with an on-chip 16-Kbyte buffer memory for data transfer. Furthermore, for pipes 1 to 9, arbitrary endpoint numbers can be allocated according to peripheral devices to be communicated and user systems.

32.1 Features

(1) Incorporates a host controller and a function controller conforming to USB High Speed.

- On-chip USB host controller and function controller
- The USB host controller function and the function controller function are selectable by register setting.
- On-chip USB transceiver

(2) Achieves space-saving mount with less external elements.

- Direct connection of the VBUS0_0 and VBUS1_0 signal to the input pin of this module
- On-chip D+ pull-up resistor (function operation mode)
- On-chip D+/D- pull-down resistors (host operation mode)
- On-chip D+/D- terminating resistors (high-speed operation mode)
- On-chip D+/D- output resistors (full-speed operation mode)

(3) Supports all data transfer types for USB communication.

- Control transfer
- Bulk transfer
- Interrupt transfer (except for high bandwidth)
- Isochronous transfer (except for high bandwidth)

(4) Dedicated DMA interface

- On-chip 2-channel DMA interface

(5) Pipe configuration

- On-chip 16-Kbyte buffer memory for USB communication
- Up to ten pipes are selectable (including the default control pipe)
- Programmable pipe configuration
- Arbitrary endpoint numbers can be allocated to pipes 1 to 9.
- Settable transfer conditions for each pipe are as follows:

  Pipe 0: A pipe only for control transfer with a 64-byte (fixed) single buffer

  Pipes 1 and 2: Pipes that can select bulk transfer or isochronous transfer (Continuous transfer mode and buffer size are programmable.) (Double buffer can be specified with up to 2 Kbytes.)

  Pipes 3 to 5: Pipes only for bulk transfer (Continuous transfer mode and buffer size are programmable.) (Double buffer can be specified with up to 2 Kbytes.)

  Pipes 6 to 9: Pipes only for interrupt transfer with a 64-byte (fixed) single buffer

(6) Features with host controller function

- Supports high-speed transfer (480 Mbps), full-speed transfer (12 Mbps), and low-speed transfer (1.5 Mbps).
- Allows communication with multiple peripheral devices through a hub.
- Reset handshake auto-response
- Automated SOF/packet transmission schedule
- Isochronous transfer/interrupt transfer interval setting function

(7) Features with function controller function

- Supports high-speed transfer (480 Mbps) and full-speed transfer (12 Mbps).
- High-speed or full-speed automatic recognition of operation using the reset handshake auto-response function
- Control transfer stage management function
- Device state management function
- Auto-response to the SET_ADDRESS request
- NAK response interrupt function (NRDY)
- SOF interpolation function

(8) Other functions

- Transfer terminating function using transaction count
- SOF pulse output function
- BRDY interrupt event notification timing change function (BFRE)
- Buffer memory auto-clear function (DCLRM) after reading data of the pipe specified by the DnFIFO (n = 0, 1) port
- NAK setting function (SHTNAK) for the response PID due to the transfer end
- Supports data line pulsing as an OTG function.
- Supports the MAX3355E (OTG external device) interface.

32.2 Input/Output Pins

Table 32.1 lists the input and output pins of the USB.

Table 32.1 Pin Configuration of USB

Classification	Pin Name	Name	I/O	Description
USB bus interface	DP_0	USB D+ data	I/O	D+ Input/output of the On-chip Transceiver Connect this pin to the D+ pin of the USB bus.
	DM_0	USB D- data	I/O	D- Input/output of the On-chip Transceiver Connect this pin to the D- pin of the USB bus.
VBUS monitoring input	VBUS0_0	VBUS input 0	Input	USB Cable Connection Monitoring Pin For link. Connect this pin directly to VBUS of the USB bus. This pin is used to detect VBUS connection or disconnection. When not connecting to VBUS of the USB 0 bus, fix this pin to +5V. Also supply +5V to this pin when the host controller function is selected. However, VBUS cannot be supplied to devices to be connected.
	VBUS1_0	VBUS input 1	Input	USB Cable Connection Monitoring Pin for PHY. Connect this pin directly to VBUS of the USB bus. This pin is used to detect VBUS connection or disconnection. When not connecting to VBUS of the USB 0 bus, fix this pin to +5V. Also supply +5V to this pin when the host controller function is selected. However, VBUS cannot be supplied to devices to be connected.
Reference resistance	REFRIN_0	Reference input	Input	Reference Resistance Connecting Pin Connect this pin to the ground through a 5.6 kΩ ±1% resistor.

Classification	Pin Name	Name	I/O	Description
OTG external device interface	PWEN_0	Power enable	Output	VBUS0_0 and VBUS1_0 Supply ON/OFF Control Pin When using MAX3355E as an OTG external device, connect this pin directly to the OFFVBUS0_0 and VBUS1_0 pin of the MAX3355E.
