(If there is not a DMA request before it is accepted, then this request is not held and the DMA request bit (DREQ) is cleared. Thus, if the level sense mode is selected, hold a DMA request until it is accepted.

Note: If the selected request factor is not the software trigger, do not write 1 to the DMA request bit (DREQ) by software. If this is done, proper operation is not guaranteed.

<When an Option Other Than the Software Trigger Is Selected with the DMA Request Factor Select Bits (DCTG) and the Edge Sense Mode Is Selected>

- Setting Condition

The DREQ bit is set to 1 if the edge selected with the input sense mode select bit (STRG) is detected (i.e., if there is a DMA request).

After the DREQ bit is set to 1, it remains set regardless of the status of the subsequent DMA request signal until one of the actions for clearing it to 0 is taken.

- Clearing Condition

The DREQ bit is cleared to 0 if one of these actions is taken:

— Write 0 to this bit by software.
— Start an operand transfer associated with this bit.

Notes: 1. If the selected request factor is not the software trigger, do not write 1 to the DMA request bit (DREQ) by software. If this is done, proper operation is not guaranteed.
2. If the DMA request factor select bits (DCTG) and input sense mode select bit (STRG) of the DMA control register (F1DMAC0/1_DMCNTAn) are set, be sure to clear the DMA request bit (DREQ) for the selected channel to 0 and then enable a DMA transfer (with DMST = 1 and DEN = 1).

(3) ECLR (DMA Transfer Enable Clear) Bit

Use this bit to select whether to clear the DMA transfer enable bit (DEN) to 0 when the DMA transfer end condition is detected.

If this bit is cleared to 0, the DMA transfer enable bit (DEN) is not cleared to 0 when the DMA transfer end condition is detected.

If set to 1, the DMA transfer enable bit (DEN) is cleared to 0 when the DMA transfer end condition is detected.

Note: If a write to the DMA transfer enable clear bit occurs while the associated channel is being used for 1-operand transfer, proper operation is not guaranteed.

(4) DSCLR (DMAC Internal Status Clear) Bit

This bit is available to initialize the DMAC internal status by aborting a 1-DMA transfer (before the byte count reaches 0). Writing 1 to this bit clears only the transfer status of the DMA internal circuit and does not initialize each register. This bit is always read as 0.

Note: Write to this bit only when both these conditions are satisfied:

(1) The relevant channel is not involved in 1-operand transfer (DMA arbitration status register (F1DMAC0/1_DMASTS) DASTS = 0 for that channel).
(2) DMA transfer is prohibited (DMA start control register (F1DMAC0/1_DMSCNT) DMST = 0 or DMA control register B (F1DMAC0/1_DMCNTBn) DEN = 0).
If a write to this register occurs in any other case, proper operation is not guaranteed.

46.4.12 F1DMAC0/1 DMA Start Control Register (F1DMAC0/1_DMSCNT)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	DMST	B'0	R/W	DMAC module start 0: Stops the DMAC. 1: Starts the DMAC.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

(1) DMST (DMAC Module Start) Bit

Use this bit to start or stop the DMAC module.

If this bit is cleared to 0, the DMAC module becomes inactive.

If set to 1, the DMAC module becomes active (see section 46.4.35, DMA Startup, and section 46.4.36 (4), Suspending, Resuming and Aborting a DMA Transfer, for details).

46.4.13 F1DMAC0/1 DMA Interrupt Control Register (F1DMAC0/1_DMICNT)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DINTM[31:24]								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	DINTM[31:24]	All 0	R/W	DMA interrupt control 0: Disables interrupts. 1: Enables interrupts.
23 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: Bits 31 to 24 correspond to channels 0 to 7.

(1) DINTM (DMA Interrupt Control) Bit

Use this bit to control whether to generate DMA transfer end interrupts to the interrupt controller for each channel.

If this bit is cleared to 0, no interrupt request is generated to the interrupt controller.

If set to 1, an interrupt request can be generated to the interrupt controller when the DMA transfer end condition is detected (see section 46.4.36 (2), DMA Interrupt Requests, for details).

46.4.14 F1DMAC0/1 DMA Common-Interrupt Control Register (F1DMAC0/1_DMICNTA)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DINTA[31:24]								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	DINTA[31:24]	All 0	R/W	DMA common-interrupt request signal control 0: Does not share an interrupt request. 1: Shares an interrupt request.
23 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: Bits 31 to 24 correspond to channels 0 to 7.

(1) DINTA (DMA Common-Interrupt Request Signal Control) Bits

Use these bits to specify whether to share an interrupt request signal among channels.

If one of the bits is set to 1, the signal for the relevant channel is shared as the common interrupt request signal among the channels.

If set to 0, the signal for the relevant channel is not shared as the common interrupt request signal.

If one of these bits is set to 1 for a channel, the DMA interrupt status register (F1DMAC0/1_DMISTS) shows only the status of that channel when the common interrupt request signal is generated (see section 46.4.36 (2), DMA Interrupt Requests, for details).

46.4.15 F1DMAC0/1 DMA Interrupt Status Register (F1DMAC0/1_DMISTS)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DISTS[31:24]								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	DISTS[31:24]	All 0	R	DMA interrupt request status 0: Interrupt request absent 1: Interrupt request present
23 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Notes: 1. This is a read-only register.
2. Bits 31 to 24 correspond to channels 0 to 7.

(1) DISTS (DMA Interrupt Request Status) Bits

Use these bits to check for the common interrupt request to the interrupt controller.

- Setting Condition

If one of the DMA common interrupt request signal control bits (DINTA) is 1, the channel-associated DISTS bit is set to 1 when the DMA transfer end condition is detected.

These bits are not affected by the DMA interrupt control bit (DINTM) settings.

- Clearing Condition

One of the DMA transfer end condition detect bits (DEDET) of the DMA transfer end detect register (F1DMAC0/1_DMEDET) is associated with the channel where an interrupt occurs. If this DEDET bit is cleared, then the DISTS bit is also cleared to 0 (see section 46.4.36 (2), DMA Interrupt Requests, for details).

46.4.16 F1DMAC0/1 DMA Transfer End Detect Register (F1DMAC0/1_DMEDET)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DEDET[31:24]								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	DEDET[31:24]	All 0	R/*	DMA transfer end condition detect for reads 0: DMA transfer end condition not detected 1: DMA transfer end condition detected DMA transfer end condition detect and DMA interrupt request status clear for writes 0: Invalid 1: DMA transfer end condition detected and DMA interrupt request status cleared
23 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Notes: Bits 31 to 24 correspond to channels 0 to 7.
* Indicates that writing 0 has no effect and that a value of 1 is not held after it is written.

(1) DEDET (DMA Transfer End Condition Detect) Bits

These bits are available to determine whether the DMA transfer end condition is detected for each channel. This register is not cleared automatically by reading from it. If its bits are set to 1, they always hold the value unless they are cleared by software.

- Setting Condition

If the DMA transfer end condition is detected, the bit is set to 1.

- Clearing Condition

If 1 is written to the bit to be cleared, it is cleared to 0.

Write 0 to the bit which should not be cleared. A write by software does not affect the bit which is 0. It holds the same value before and after that write.

To use a DMA transfer end interrupt, write 1 to the DMA transfer end condition detect bit (DEDET) with the interrupt handler. This bit should be associated with the channel where the interrupt request is generated.

The DMA transfer end condition bit (DEDET) is cleared to 0. Also, the DMA interrupt request status bit (DISTS) is cleared.

46.4.17 F1DMAC0/1 DMA Arbitration Status Register (F1DMAC0/1_DMASTS)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DASTS[31:24]								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	DASTS[31:24]	All 0	R	DMA arbitration status for reads 0: Operand transfer not underway 1: Operand transfer underway DMA arbitration status clear for writes
23 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: Bits 31 to 24 correspond to channels 0 to 7.

(1) DASTS (DMA Arbitration Status) Bits

These bits are available to determine whether the channels are involved in DMA transfer.

- **Setting Condition**
  At the start of 1-operand transfer or non-stop transfer on a channel, the bit associated with the channel is set to 1.

- **Clearing Condition**
  At the end of 1-operand transfer or non-stop transfer over a channel, the bit associated with the channel is cleared to 0.

<Current 2D Addressing Registers>

46.4.18 F1DMAC0/1 DMA 2D Column Setup Register n (F1DMAC0/1_DM2DCLMn)

(1) DRNBOST (DMA 2D Next-Block Offset Byte Count) Bits

Use these bits to specify the offset byte count which will be reloaded into the DMA 2D next-block offset register. The specified byte count should be a two's complement number.

46.4.29 F1DMAC0/1 DMA Reload 2D Line Offset Register n (F1DMAC0/1_DMR2DNLOSTn)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DRNLOST[31:0]	All ?	R/W	DMA reload 2D next-line offset data count Number of DMA reload 2D next-line offset bytes

(1) DRNLOST (DMA Reload 2D Next-Line Offset Byte Count) Bits

Use these bits to specify the offset byte count which will be reloaded into the DMA 2D next-line offset register. The specified byte count should be a two's complement number.

46.4.30 F1DMAC0/1 Error Flag Register (F1DMAC0/1_DMBERR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ERST	ERLD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	—	R	Reserved These bits are always read as 0. The write value should always be 0.
1	ERST	0	R	ST access error detect 0: No error 1: ST command error
0	ERLD	0	R	LD access error detect 0: No error 1: LD command error

(1) ERST (ST Access Error Detect) Bit

If an ST access error is detected on the SHwy bus, this bit is set to 1. It can be cleared to 0 by writing 0 to it.

(2) ERLD (LD Access Error Detect) Bit

If an LD access error is detected on the SHwy bus, this bit is set to 1. It can be cleared to 0 by writing 0 to it.

If ERST = 1 or ERLD = 1, the SHwy error interrupt request (F1DMINT_N) becomes active (set to the "L" level). To clear the interrupt request, clear this bit to 0.

46.4.31 F1DMAC0/1-Data Transfer Status Register (F1DMAC0/1_DMDTSTS)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

46.4.33 DMA Transfer Modes

This processor supports three modes of DMA transfer: cycle stealing, pipeline and fly-by. Any one of these can be selected with the DMA transfer mode select bit (MDSEL) of DMA control register A (F1DMAC0/1_DMCNTAn).

(1) Cycle Stealing Mode

If the DMA transfer mode select bits (MDSEL) are set to 00, the cycle stealing mode is selected.

In this mode, the DMAC idly operates during one or more cycles between the start of read access and that of write access for 1-unit transfer. During this time, the CPU can access the target (source or destination).

(2) Pipeline Mode

If the DMA transfer mode select bits (MDSEL) are set to 01, the pipeline mode is selected.

In this mode, the DMAC continuously accesses the bus (for read/write operation). As a result, the CPU cannot access the target (source or destination) until the end of 1-operand transfer.

(3) Fly-by Mode

If the DMA transfer mode select bits (MDSEL) are set to 10, the fly-by mode is selected.

In this mode, the DMAC performs a single-address transfer by repeatedly starting read or write access. As a result, the CPU cannot access the target (source or destination) until the end of 1-operand transfer.

If the next DMA request is made while one operand is being transferred in fly-by mode, then the 1-operand transfer is followed by DMA transfer without the bus being released if the bus mastership keep function enable bit (BKEEP) for the arbitrated channel is 1.

The non-stop transfer option (DSEL = 11) cannot be selected for DMA fly-by mode.

Note: Pipeline or fly-by transfer across different slave spaces is not allowed. Also, pipeline or fly-by transfer across the SDRAM device channel is not allowed.

46.4.34 DMA Transfers

This processor supports three types of DMA transfer: single-operand, consecutive-operand and non-stop. Any one of these can be selected with the DMA transfer condition select bit (DSEL) of DMA control register A (F1DMAC0/1_DMCNTAn). These types of transfer are described below.

Table 46.15 and figure 46.18 show these types of transfer.

(1) Single-Operand Transfer

If the DMA transfer condition select bits (DSEL) are set to 00, single-operand transfer is performed.

Upon each DMA request, one operand is transferred. The size of each operand is based on the data count selected with the 1-operand transfer data count select bits (OPSEL) of the DMA mode register (F1DMAC0/1_DMMODn).

The 1-operand transfer is repeated. When the byte count reaches 0, the 1-DMA transfer ends.

(2) Consecutive-Operand Transfer

If the DMA transfer condition select bits (DSEL) are set to 01, consecutive-operand transfer is performed.

One DMA request causes operands to be transferred one after another until the 1-DMA transfer ends (i.e., the byte count reaches 0). The size of each operand is based on the data count selected with the 1-operand transfer data count select bit (OPSEL). Each time a 1-operand transfer completes, the channels are arbitrated. The transfer via the current channel continues automatically if no DMA request comes from another higher priority channel.

(3) Non-Stop Transfer

If the DMA transfer condition select bits (DSEL) are set to 11, non-stop transfer is performed.

Upon one DMA request, a non-stop transfer takes place continuously until the 1-DMA transfer ends (i.e., the byte count reaches 0). During this time, the channels are not arbitrated. Any DMA requests from channels with higher priority than the current one are not accepted.

During non-stop transfer, it is impossible to effectively set the 1-operand transfer data count select bits (OPSEL), establish fly-by mode and execute 2D addressing.

Table 46.15 DMA Transfers

DMA Transfer Condition Select Bits (DSEL)	DMA Transfer	Remarks
DSEL = "00"	Single-operand transfer • Upon each DMA request, one operand with a size based on the 1-operand transfer data count (OPSEL) is transferred. • The channels are arbitrated each time a 1-operand transfer completes.	
DSEL = "01"	Consecutive-operand transfer • One DMA request causes operands to be transferred one after another until the byte count reaches 0. • The channels are arbitrated each time a 1-operand transfer completes.	
DSEL = "11"	Non-stop transfer • Upon one DMA request, data are transferred continuously until the byte count reaches 0. • The channels are not arbitrated after the start of transfer.	OPSEL bits are invalid. Fly-by mode is not selectable. 2D addressing is not selectable.

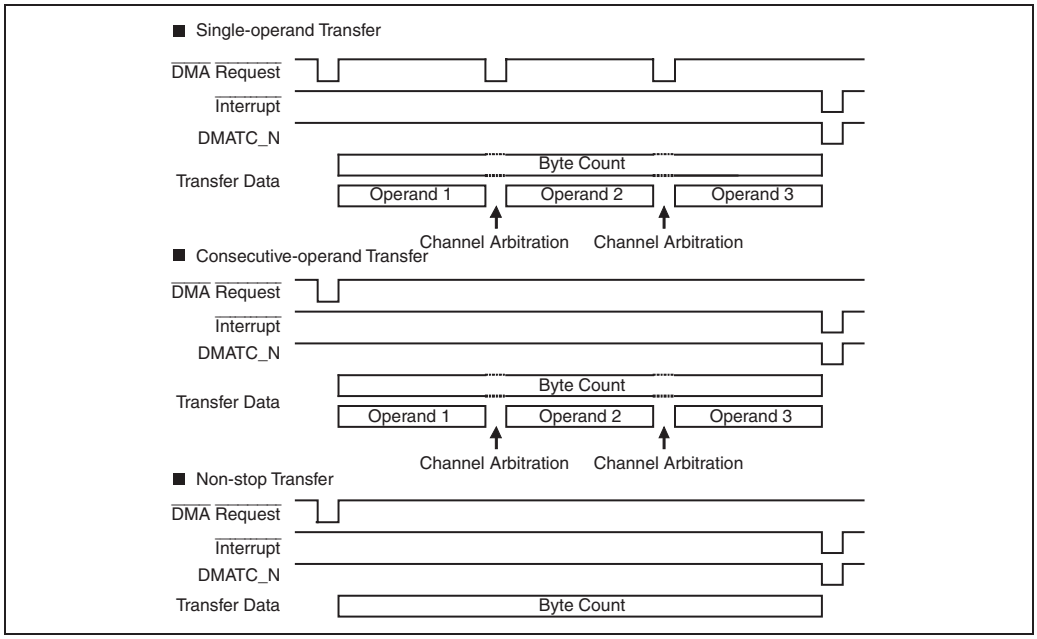

Figure 46.18 DMA Transfers

Table 46.16 shows the combinations of DMA transfer mode and DMA transfer condition.

Table 46.16 Combinations of DMA Transfer Mode and DMA Transfer Condition

		DMA Transfer		
		Single-operand transfer (DSEL="00")	**Consecutive-operand transfer (DSEL="01")**	**Non-stop transfer (DSEL="11")**
Transfer Mode	Cycle stealing mode (MDSEL = "00")	Possible	Possible	Possible
	Pipeline mode (MDSEL = "01")	Possible (*2)	Possible (*2)	Impossible
	Fly-by mode (MDSEL = "10")	Partially possible (*1)	Partially possible (*1)	Impossible

Notes: 1. In fly-by mode, single/consecutive-operand transfer between the module and SDRAM only is possible. In this mode, non-stop transfer is impossible.

2. Pipeline-type transfer between the modules or between the SDRAMs is impossible. If the non-stop transfer option is selected, pipeline-type transfer between the module and SDRAM is impossible.

46.4.35 DMA Startup

(1) Initializing the DMAC

Initialize the registers before setting the DMA transfer enable bit (DEN) to 1. Once a DMA transfer starts, the initial settings cannot be changed.

Below is an example procedure for DMAC initialization.

Setup Procedure

Set these registers:
(1) DMA mode register (F1DMAC0/1_DMMODn)
(2) DMA control register A (F1DMAC0/1_DMCNTAn)
(3) DMA control register B (F1DMAC0/1_DMCNTBn)
(4) DMA current source address register (F1DMAC0/1_DMCSADRn)
(5) DMA reload source address register (F1DMAC0/1_DMRSADRn)

When using the reload function, set these registers:
(6) DMA current destination address register (F1DMAC0/1_DMCDADRn)
(7) DMA reload destination address register (F1DMAC0/1_DMRDADRn)

When using the reload function, set these registers:
(8) DMA current byte count register (F1DMAC0/1_DMCBCTn)
(9) DMA reload byte count register (F1DMAC0/1_DMRBCTn)

When using the reload function, set this register:
(10) DMA interrupt control register (F1DMAC0/1_DMICNT)

When using interrupts, set this register:
(11) DMA common interrupt control register (F1DMAC0/1_DMICNTA)

When using interrupts, set these registers:
(12) DMA transfer enable bit (DEN)
(13) DMA start control register (F1DMAC0/1_DMSCNT)

(2) Starting DMA

DMA transfer via a channel is enabled by setting the DMA transfer enable bit (DEN) of DMA control register B (F1DMAC0/1_DMCNTBn) for that channel to 1 and by setting the DMAC module start bit (DMST) of the DMA start control register (F1DMAC0/1_DMSCNT) to 1.

When DMA transfer requests are generated, the priority levels of the channels are checked. A DMA request from the highest-priority channel is accepted and then a DMA transfer starts.

The presence or absence of a DMA request can be determined using the DMA request bit (DREQ) of DMA control register B (F1DMAC0/1_DMCNTBn).

At the start of DMA transfer after a DMA request is accepted, 1 is written to the channel-associated DMA arbitration status bit (DASTS) of DMA arbitration status register (F1DMAC0/1_DMASTS).

46.4.36 DMA Termination and Interrupts

(1) Terminating a DMA Transfer

When the value of the DMA current byte count register (F1DMAC0/1_DMCBCTn) reaches H'000 0000 (which indicates the completion of transferring all data), the DMA transfer end condition is detected. Then, the 1-DMA transfer completes. The following shows operations which are performed after the detection of the DMA transfer end condition.

- **Detecting the End of DMA Transfer:**
  1 is written to the channel-associated DMA transfer end condition detect bit (DEDET) of the DMA transfer end detect register (F1DMAC0/1_DMEDET).

- **Generating an Interrupt Request:**
  An interrupt request is generated to the interrupt controller according to the settings of the DMA interrupt control register (F1DMAC0/1_DMICNT) and DMA common interrupt control register (F1DMAC0/1_DMICNTA).

- **Output of the DMA End Signal:**
  The DMA end (DMATC_N) signal is output according to the settings of the DMA end signal output control bits (DTCM) of the DMA mode register (F1DMAC0/1_DMMODn).

- **Clearing the DMA Transfer Enable Bit (DEN):**
  If the DMA transfer enable clear bit (ECLR) of DMA control register B (F1DMAC0/1_DMCNTBn) is 1, the DEN bit of DMA control register B (F1DMAC0/1_DMCNTBn) is cleared to 0. Then, a DMA transfer is no longer performed via the relevant channel. If the ECLR bit is 0, the DEN bit is not cleared.

- **Reloading the Source Address:**
  If the DMA source address reload function enable bit (SRLOD) of DMA control register A (F1DMAC0/1_DMCNTAn) is 1, the value of the DMA reload source address register (F1DMAC0/1_DMRSADRn) is reloaded into the DMA current source address register (F1DMAC0/1_DMCSADRn).

- **Reloading the Destination Address:**
  If the DMA destination address reload function enable bit (DRLOD) of DMA control register A (F1DMAC0/1_DMCNTAn) is 1, the value of the DMA reload destination address register (F1DMAC0/1_DMRDADRn) is reloaded into the DMA current destination address register (F1DMAC0/1_DMCDADRn).

- **Reloading the Byte Count:**
  If the DMA byte count reload function enable bit (BRLOD) of DMA control register A (F1DMAC0/1_DMCNTAn) is 1, the value of the DMA reload byte count register (F1DMAC0/1_DMRBCTn) is reloaded into the DMA current byte count register (F1DMAC0/1_DMCBCTn).

Note: If reloading does not take place, set ECLR = 1 to clear the DEN bit.

(2) DMA Interrupt Requests

Interrupt request signals to the interrupt controller include the interrupt request signal (DMINT_N) for each channel and the common interrupt request signal (DMINTA_N) shared by the channels.

Figure 46.19 is a block diagram showing how these signals are generated.

If one of the DMA interrupt control bits (DINTM) of the DMA interrupt control register (F1DMAC0/1_DMICNT) is 1 when a DMA transfer ends, an interrupt request is generated via the channel associated with that bit. In addition, if one of the DMA common interrupt request signal control bits (DINTA) of the DMA common interrupt control register (F1DMAC0/1_DMICNTA) is 1, only the signal which is output over the channel associated with that bit serves as the common interrupt request signal. The generated interrupt request can be cleared by writing 1 to the DMA transfer end condition detect bit (DEDET) for the relevant channel.

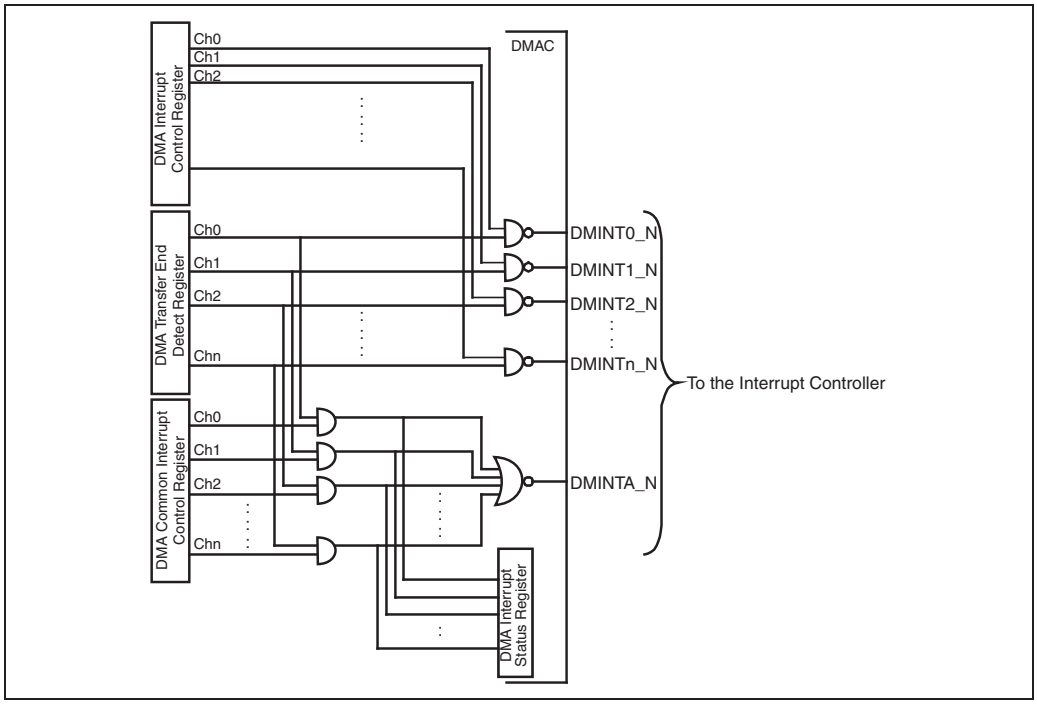

Figure 46.19 Generation of Channel-Associated Interrupt Request Signals and Common Interrupt Request Signal

(3) Output of the DMA End Signal

The DMA end signal (DMATC_N) is output differently depending on the settings of the channel-associated DMA end signal output control bits (DTCM) of the DMA mode register (F1DMAC0/1_DMMODn).

- If DTCM = 00, the DMATC_N signal is fixed at the "H" level and is not output as a valid signal when a DMA transfer ends.
- If DTCM = 01, the DMATC_N signal is output as a valid signal during the read cycle immediately before the end of DMA transfer (i.e., during the read cycle for the last 1-unit transfer).
- If DTCM = 10, the DMATC_N signal is output as a valid signal during the write cycle immediately before the end of DMA transfer (i.e., during the write cycle for the last 1-unit transfer).
- If DTCM = 11, the DMATC_N signal is output as an "L" pulse signal for one clock at the same time a DMA transfer end interrupt occurs.

If a DMA request comes from the on-chip peripheral circuit, the DMATC_N signal is fixed at the "H" level and is not output as a valid signal regardless of the settings of the DTCM bits. This signal should have no effect for fly-by mode. To make it invalid, set DTCM = 00. Figure 46.20 shows the DMA end signal output timing.

Note: For DMA transfer to an external device, the DMATC_N signal might become invalid (H) after the start of the last read or write access to the outside but before the end of access to the external bus.

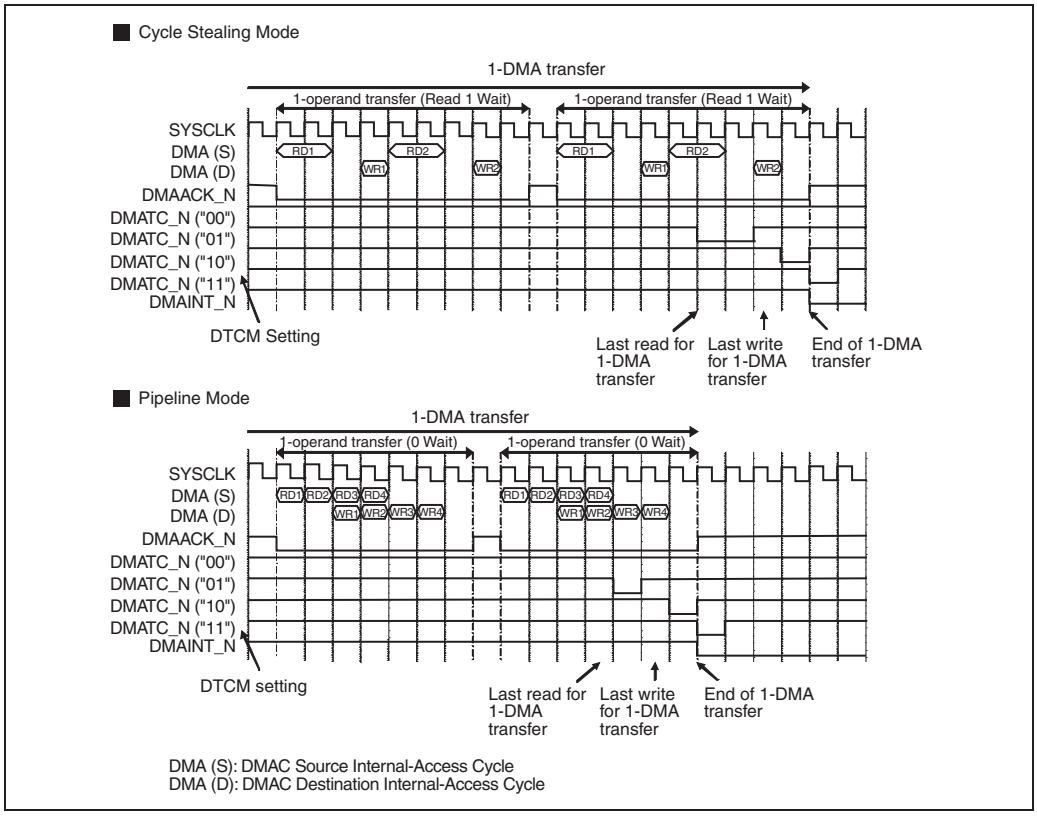

Figure 46.20 DMA End Signal Output Timing

(4) Suspending, Resuming and Aborting a DMA Transfer

(a) Suspending and Resuming a DMA Transfer

The DMAC (all channels) can be temporarily deactivated by clearing the DMAC module start bit (DMST) of the DMA start control register (F1DMAC0/1_DMSCNT) to 0. A channel can also be temporarily deactivated by clearing the DMA transfer enable bit (DEN) of DMA control register B (F1DMAC0/1_DMCNTBn) associated with that channel.

If the DMST or DEN bit is cleared to 0 while one operand is being transferred during single-operand or consecutive-operand transfer, this transfer completes and then no more transfers take place regardless of the transfer mode (cycle stealing, pipeline or fly-by).

If the DMS or DEN bit is cleared to 0 during non-stop transfer, the DMA transfer continues until the byte count reaches 0.

To reactivate the channel, set the DMST and DEN bits to 1. This resumes the DMA transfer operation.

(b) Aborting a DMA Transfer

To abort a channel, write 1 to the DMAC internal status clear bit (DSCLR) of DMA control register B (F1DMAC0/1_DMCNTBn) for that channel while a DMA transfer is temporarily suspended. This initializes the inside of the DMAC and aborts the DMA transfer. In this case, only the transfer status of the DMAC internal circuit is initialized. The registers are not initialized.

46.4.37 DMA Requests

(1) DMA Request Factors

There are a total of eight DMA request factors including the software trigger and DMA request signal inputs. Any one of these factors can be selected with the DMA request factor select bits (DCTG) of channel-associated DMA control register A (F1DMAC0/1_DMCNTAn).

(2) Sense Modes for DMA Requests

If a DMA request signal is selected with the DMA request factor select bits (DCTG = 000001 to 111111), the level sense mode (01/11) or edge sense mode (00/10) can be selected with the input sense mode select bits (STRG) of DMA control register A (F1DMAC0/1_DMCNTAn).*

Note: The level sense mode is only supported in this product.

46.4.38 Determination of DMA Channel Priorities

(1) Channel Priorities

The channels with fixed priorities are shown below. These channels are in descending order of priority from left to right with channel 0 being the highest-priority channel.

Channel 0 > Channel 1 > Channel 2 > … > Channel 6 > Channel 7

(2) Handling Multiplexed DMA Requests

The DMAC determines the channel priorities each time 1-operand transfer completes.

While a lower priority channel performs a data transfer, if a higher priority channel makes a DMA request, the higher priority channel starts a transfer after the end of the transfer involving the lower priority channel.

46.4.39 Reload Function

The reload function is implemented by setting the reload function enable bit of DMA control register A (F1DMAC0/1_DMCNTAn) for each channel and for each transfer parameter (source address, destination address and byte count).

The 2D function is implemented by setting the reload function enable bit (2DRLOD) of DMA control register A (F1DMAC0/1_DMCNTAn) for the six 2D registers (column setup, row setup, block setup, next-row offset, next-block offset and next-line offset registers).

When the DMA transfer end condition is detected, the DMA transfer parameters are reloaded automatically.

(1) Reload Register and Current Register

If not using the reload function, set data in the current register only. If using it, set data in both the reload register and current register.

Do not write to the current register while a 1-operand transfer is underway. If this is done, proper operation is not guaranteed. The reload register can be set during 1-operand transfer. It should be set before the last operand transfer in the DMA transfer process. If it is set during the last operand transfer, reloading might not complete by the end of the DMA transfer.

(2) Consecutive Data Transfer to Dispersed Areas

The reload function is available to enable consecutive data transfer to dispersed areas.

If values are written to the DMA reload source/destination address register (F1DMAC0/1_DMRSADRn F1DMAC0/1_DMRDADRn) or DMA reload byte count register (F1DMAC0/1_DMRBCTn) before the end of transfer, the next transfer parameters can be set without affecting the DMA transfer which is currently executed (via the current register). Therefore, two or more consecutive transfer blocks can be transferred over the same channel even though their destination areas or byte counts are different.

Figure 46.21 shows an example of using the reload function for block transfer to dispersed areas.

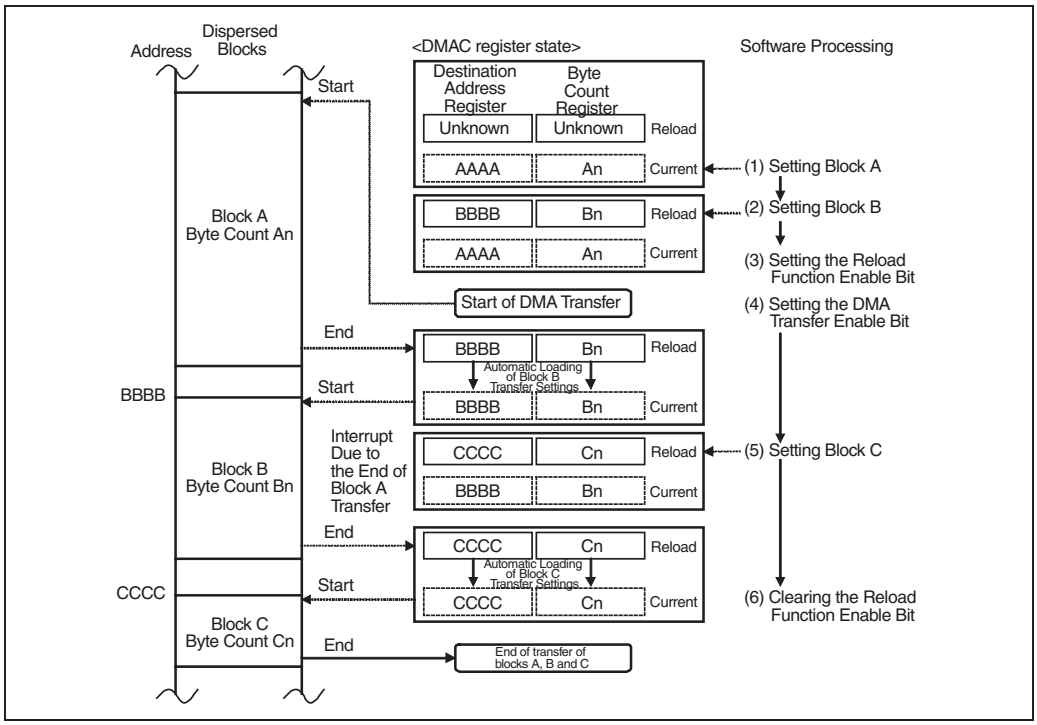

Figure 46.21 Example of Using the Reload Function for Block Transfer to Dispersed Areas

46.4.40 Rotate Function

If the rotate option is selected for addressing mode, the address is incremented. It can be selected for the work source address register or work destination address register. After 1-operand transfer, the address register for which this option has been selected contains the same value as the DMA current source address register (F1DMAC0/1_DMCSADRn) or DMA current destination address register (F1DMAC0/1_DMCDADRn) either of which was set at the start of the DMA transfer.

Figure 46.22 shows an example of using the rotate function for transfer (source: rotate, destination: increment).

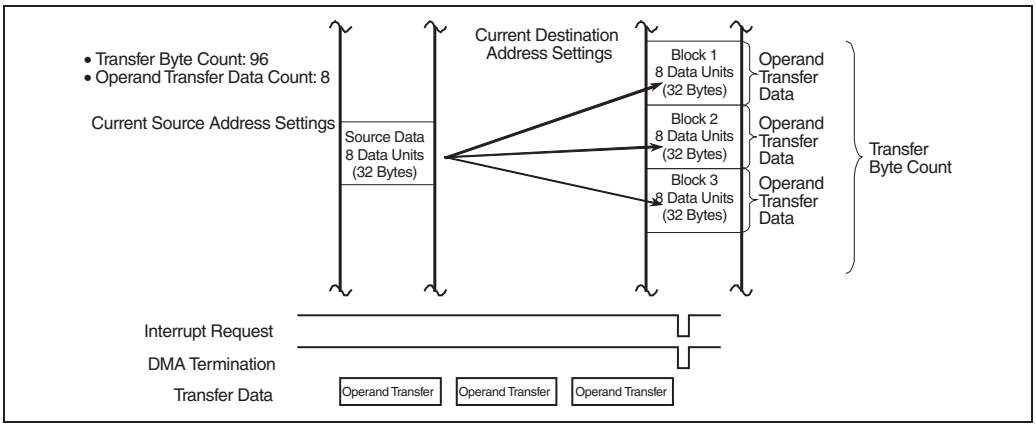

Figure 46.22 Example of Using the Rotate Function for Transfer (Source: Rotate, Destination: Increment)

46.4.41 Precautions in Using DMA

When performing a DMA transfer using the F1DMACs in this processor, observe the following precautions:

- Do not change the data width which is factory fixed at 64 bits (DMMODn.SZSEL = 3).
- Select the fly-by option (DMACNTAn.MDSEL = 2) for DMA transfer mode.
- Select the "H" level sense option (DMACNTAn.MDSEL = 2) for input sense mode.

Section 47 TS Interface (TSIF)

The transport stream interface (TSIF) is a module for receiving the MPEG2 transport stream (TS) used in two-segment broadcasting implemented as part of the digital terrestrial broadcasting services. The TSIF extracts packet data and controls PCR, which are required to decode the system layer of the MPEG2 standard.

47.1 Features

The TSIF has the following features.

- Serial data input
- Support for TS data transfer by DMA auto request
- Acquisition of TS packets
  Filters 67 kinds of PIDs (Packet ID) in total (The PID values of PAT and CAT packets are fixed. For PCR, video, and audio packets, the PID values are predefined.)
  Supports all valid packet receive mode (Null packet is deleted).
  Supports all packet receive mode including Null packet.
  Supports duplicate packet delete mode.
  Capable of specifying the endian type when TS packet data is read
  Supports timestamping TS packet data with timing of obtaining it
- TS data analysis
  Detects random access indicator.
  Detects discontinuity indicator.
  Detects video start code and short header.
- Extraction of PCR information
- Support for system clock generation

[Legend]

MPEG:	Moving picture expert group
TS:	Transport stream
PID:	Packet ID
PAT:	Program association table
CAT:	Conditional access table
PCR:	Program clock reference
ES:	Elementary stream

Figure 47.1 shows a block diagram of the TSIF.

The signals to transfer or control TS data are input as an input signal, and the TS packet data filtered by this module will be output as an output signal.

The serially input TS data is converted into 8-bit parallel data and the header of the TS packet is detected by the TS synchronous detection circuit. The TS filter circuit then determines and filters the PID of the TS packet according to the predefined PID table and stores the TS packet in the buffer for TS packets. Following these processes, only predefined TS packets are stored in the buffer and transferred to memories via a bus interface.

The analysis circuit of a TS header is a block that analyses the header of a TS packet, acquires the header information, and generates a trigger signal sent to other blocks. The ES data search circuit searches the start code and short header of an elementary stream (ES) contained in a TS packet. This result can be used as supplementary data to control the start timing of image decoding through the upper-level software that controls image decoding.

Based on the PCR information extracted from the TS packet, the PCR control unit outputs information needed for system clock control.

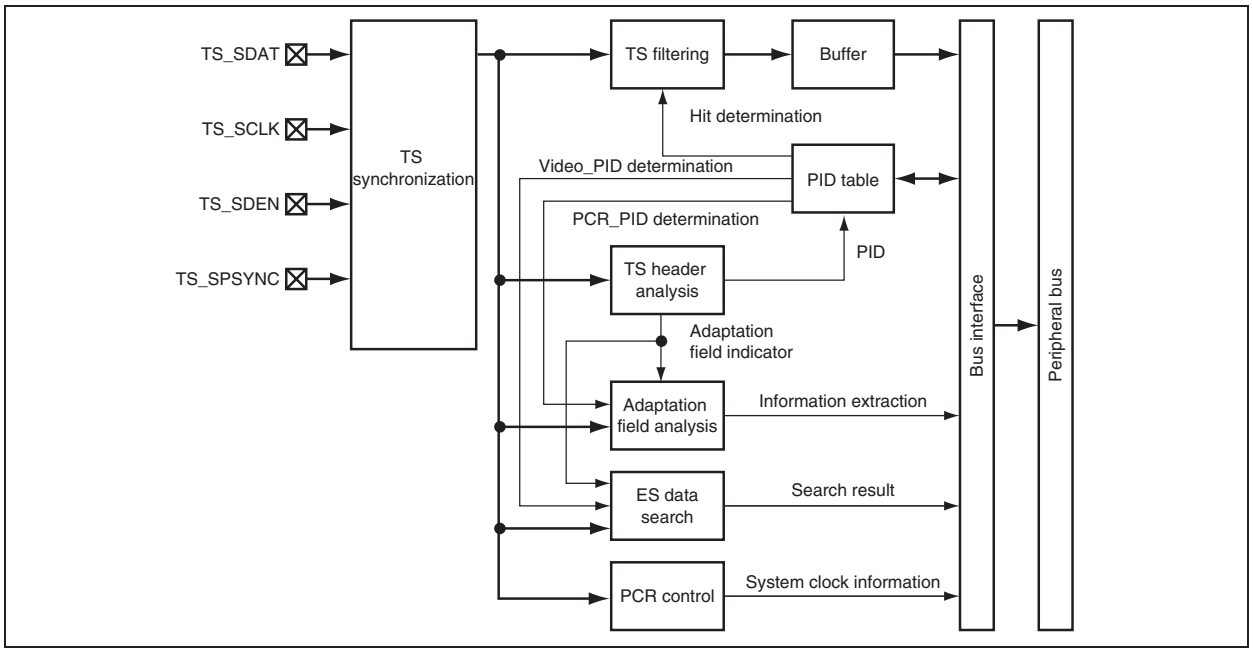

Figure 47.1 TSIF Block Diagram

47.2 Input/Output Pins

Table 47.1 shows the pin configuration.

Table 47.1 Pin Configuration

Pin Name	Function	I/O	Description
TS_SDAT	TS serial data	Input	Serial Input Pin of TS Packet Data
TS_SDAT2			Polarity inversion is enabled by register setting.
TS_SCK	TS serial clock	Input	Serial Input Clock Pin
TS_SCK2			Polarity inversion is enabled by register setting. The initial value is synchronized with the rising edge.
TS_SDEN	TS data enable	Input	Serial Input Enable Signal Pin
TS_SDEN2			Polarity inversion and On/Off setting are enabled by register setting. The initial value is On and enabled after the TS_SDEN signal is driven high.
TS_SPSYNC	TS data synchronization	Input	Byte Boundary Signal Pin
TS_SPSYNC2			Polarity inversion is enabled by register setting. The initial value is set on a byte boundary at the rising edge. If an LSI that does not have the TS_SPSYNC signal is connected, follow the method of handling synchronization signals in the LSI. Signals that have the same waveform of the TS_SDEN signal described in this chapter can be connected to this pin (see figure , Timing of Serial Data Input in , TSIF Module Signal Timing).

47.3 Register Descriptions

Table 47.2 shows the TSIF register configuration. Table 47.3 shows the register states in each operating mode.

Table 47.2 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
TSIF0 control register	TS0CTLR	R/W	H'FFE8 0000	32

47.3.1 TSIF Control Register (TSCTLR)

TSCTLR is a register for controlling the TSIF.

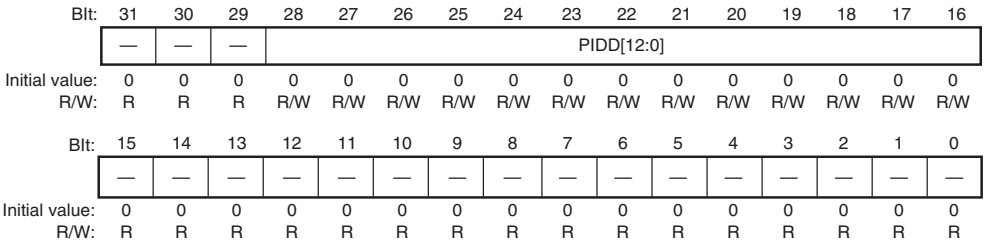
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	PLNGTH	TSDATP	TSCLKP	TSVLDP	–	PSYCP	–	–	SDENE	–	–	BUF4	TFA	DPDMD	DREQMD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R	R/W	R	R	R/W	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EN	PCRMD	FRCMD	FRCSEL	FRCLATCH	FRCADD[1:0]		FRCSTR	FRCPSC[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	PLNGTH	0	R/W	Byte Configuration Set of TS Packet Data 0: TS packet is 204-byte configuration. 1: TS packet is 188-byte configuration.
29	TSDATP	0	R/W	Input Polarity Set of TS Packet Data 0: TS data input is positive polarity. 1: TS data input is negative polarity (used after polarity inversion).
28	TSCLKP	0	R/W	Input Polarity Set of TS Clock 0: TS data clock input is positive polarity. (TS data is received at the rising edge.) 1: TS data clock input is negative polarity. (TS data is received at the falling edge.)
27	TSVLDP	0	R/W	Input Polarity Set of TS Packet Data Enable Signal 0: The TS_SDEN signal from the TS decoder is positive polarity (enabled at high). 1: The TS_SDEN signal from the TS decoder is negative polarity (enabled at low).
26	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
25	PSYCP	0	R/W	Input Polarity Set of TS Packet Data Sync Signal 0: TS packet sync signal TS_SPSYNC is positive polarity (sync byte at high). 1: TS packet sync signal TS_SPSYNC is negative polarity (sync byte at low).
24, 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
22	SDENE	0	R/W	TS Packet Data Enable Signal Enabled/Disabled 0: The TS_SDEN signal from the TS decoder is enabled. 1: The TS_SDEN signal from the TS decoder is disabled.
21 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18	TFA	0	R/W	Software Reset Signal in the TSIF This bit automatically enters the reset state on startup. Release the reset by writing 1. The TSIF internal registers are not initialized with this bit. When a reset is issued, confirm 0 first by reading this bit and release the reset. Note: Set this bit to 1 after TS_SCK of eight cycles or more is input. 0: The TSIF is reset internally (except internal registers). 1: Reset is released.
17	DPDMD	0	R/W	Duplicate Data of Consecutive TS Packets (Duplicate Packets) Delete When the PID of the previous consecutive packet matches continuity_counter, the data is deleted. However, when adaptation_field_control = ×0 (x: don't care), the data is not deleted. 0: Duplicate data valid mode Even when the PID of the consecutive packet and continuity_counter match, the data is not deleted. 1: Duplicate data delete mode When the PID of the previous consecutive packet and continuity_counter match, the data is deleted. Note that this is valid only when adaptation_field_control = ×1 (x: don't care).
16	DREQMD	0	R/W	After TS data transfer of one packet (188 or 192 bytes) by DMAC, selects whether the PEC bit in TSBUFCLRR is set to 1 automatically. 0: DMA interrupt transfer mode After TS data transfer of one packet (188 or 192 bytes), the PEC bit is not set to 1. 1: DMA auto-transfer mode After TS data transfer of one packet (188 or 192 bytes), the PEC bit is set to 1 and the internal buffer is cleared.
15	EN	0	R/W	Specifies the endian type for reading TS packet data from TSTSDR. 0: Big endian 1: Little endian
14	PCRMD	0	R/W	Specifies settings for displaying time indicated by TSPCRADC and TSTRPCRADC 0: Displays the time in 90 kHz units 1: Displays the time in 45 kHz units

Bit	Bit Name	Initial Value	R/W	Description
13	FRCMD	0	R/W	Clock setting of TSFRC 0: Displays the time in 90 kHz units 1: Displays the time in 45 kHz units It is necessary to make it FRCSEL=1 to validate this setting. It is invalid in the case of FRCSEL=0.
12	FRCSEL	0	R/W	The setting of the base clock of TSFRC 0: The divider clock set in FRCPSC is used. 1:The internal pre-scaler(FSCALER) is used.
11	FRCLATCH	0	R/W	Snapshot setting of the internal free-run counter It keeps a snapshot of the internal free-run counter by this setting. The kept value is readable in TSFRCL or TSFRCH. The snapshot is updated by overwriting in FRCLATCH=1. The internal free-run counter keeping is controlled by FRCSTR 0: The snapshot setting of TSFRCL/TSFRCH is off. 1: The snapshot setting of TSFRCL/TSFRCH is on. (The snapshot is updated when It overwrite in “1”).
10-9	FRCADD[1:0]	H’0	R/W	Determines whether to add a TSFRC value (timestamp) with timing of a PID match. 0x0: Does not add a TSFRC value to TSTSDR (TSTSDR reads 188-byte TS packet data) 0x1: Adds a TSFRC value to the 189th to 192nd bytes of TSTSDR (TSTSDR reads 188-byte TS packet data plus the 4-byte TSFRC value) 0x2: Reserved 0x3: Adds a 64bit of TSFRC value to the 189th to 196th bytes of TSTSDR (TSTSDR reads 188-byte TS packet data plus the 8-byte TSFRC value)
8	FRCSTR	0	R/W	Specifies the settings for the TSFRC operation 0: Stops the TSFRC counting operation 1: Performs the TSFRC counting-up operation
7 to 0	FRCPSC7 to FRCPSC0	H'00	R/W	Sets a division clock for TSFRC To set the clock to Bφ divided by n, set FRCPSC to n – 1. Example: To set the clock to 1 MHz (divided by 50) while Bφ is 50 MHz, set FRCPSC[7:0] to 49 (H'31). FRCSEL=0 is necessary to validate this setting. It is invalid in FRCSEL=1.



The table below shows the conditions where the TFA bit is reflected in the TSIF.

The TFA bit is reflected in the TSIF depending on the condition of the DREQMD bit with the following timing.

DREQMD Bit	TFA Bit	Reflection Timing
0	0 → 1	Reflected accordingly by register setting
	1 → 0	Reflected accordingly by register setting
1	0 → 1	Reflected accordingly by register setting
	1 → 0	Timing when the PEC bit is automatically set to 1

47.3.2 TSIF PID Data Register (TSPIDR)

TSPIDR is a register used to set the PID value that sets the section table of the PID filter. The settings to PIDD can be reflected by writing to TSCMDR after this register is written to.

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 16	PIDD12 to PIDD0	H'0000	R/W	Byte Configuration Set of TS Packet Data These bits set the PID value that sets the section table of the PID filter. The setting of this register can be reflected by writing to TSCMDR after setting PIDD.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

47.3.3 TSIF Command Register (TSCMDR)

TSCMDR is a register that sets the value set by TSPIDR to the PID table.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	PT[5]	—	—	ALLPIDMD	PIDMD	TFE	—	PPS	PT[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	PT[5]	0	R/W	Selecting a section for setting the PID table (see table 47.4) These bits are valid only when the PIDMD bit and the TFE bit are 0.
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	ALLPIDMD	0	R/W	PID Filter Mode Set ALLPIDMD PIDMD 0 0: A value set in the PID table is valid (PID filter mode). 0 1: All PIDs other than Null packet (PID = H'1FFF) are valid (all valid packet receive mode). 1 *: All PIDs including Null packet (PID = H'1FFF) are valid (all packet receive mode).
24	PIDMD	0	R/W	
23	TFE	0	R/W	Content of the PID Table Cleared 0: — 1: The content of the PID table is cleared.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	PPS	0	R/W	Selecting a section for setting the PID table (see table 43.4) These bits are valid only when the PIDMD bit and the TFE bit are 0.
20 to 16	PT4 to PT0	00000	R/W	
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Write a value to be set in the section table of the PID filter for TSPIDR while the PIDMD bit is 0. Then, writing one of the following values in table 43.4 sets a PID value in the specified select section.

In addition to the PID value set above, PIDs for PAT (fixed to H'0000) and CAT (fixed to H'0001) are set.

47.3.4 TSIF Interrupt Status Register (TSSTR)

TSSTR is a register that indicates the internal status of the TSIF. Each bit in TSSTR can be cleared by writing 0. Bits other than the SYNCF bit are set when a packet is received. Each bit in TSSTR (except for the SYNCF bit) is initialized by the TFA bit in TSCTLR.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	PID[12:0]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	CM1MF	CM0MF	–	ADCF	PIDF	STOF	RANDF	DISCF	SYNCF	OFEF	–	VSCF	VSHF	TSIFITF
Initial value:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 16	PID12 to PID0	H'0000	R/W	These bits indicate the PID of the TS packet input immediately before.
15 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	CM1MF	0	R/W	COMPARE MATCH1 matching flag The flag to show that “COMPARE MATCH COUNTER” counts down from a value set in TSCMCOR1 and became 0 It can’t write “1” by software 0:The value of TSCMCNT1 doesn’t become h’0000 0000. 1:The value of TSCMCNT1 became h’0000 0000 [A clear condition] It is written 0 to CM1MF
12	CM0MF	0	R/W	COMPARE MATCH0 matching flag The flag to show that “COMPARE MATCH COUNTER” counts down from a value set in TSCMCOR0 and became 0 It can’t write “1” by software 0:The value of TSCMCNT0 doesn’t become h’0000 0000. 1:The value of TSCMCNT0 became h’0000 0000 [A clear condition] It is written 0 to CM0MF
11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	ADCF	0	R/W	0: — 1: Indicates that PCRADC was updated (the PCR packet was input).
9	PIDF	0	R/W	0: — 1: Indicates that the set PID packet was received in the PID filter mode (ALLPIDMD = 0 and PIDMD = 0).
8	STOF	0	R/W	0: — 1: Indicates that the status of bits was updated (except this bit) by the completion of the next packet reception with the interrupt generated.
7	RANDF	0	R/W	0: — 1: Indicates that random_access_indicator of the TS packet input immediately before is 1.

Bit	Bit Name	Initial Value	R/W	Description
6	DISCF	0	R/W	0: — 1: Indicates that discontinuity_indicator of the PCR packet input immediately before shows the PCR discontinuous state.
5	SYNCF	1	R	Internal Synchronous/Asynchronous Mode State caused by Detection of the TS Packet Sync Signal When the sync signal (H'47) is detected three times consecutively in asynchronous mode, the TSIF enters the synchronous mode. When the sync signal is not detected four times consecutively in synchronous mode, it enters the asynchronous mode. The write value should always be 0. 0: Indicates that the TSIF is in synchronous mode (the TS packet is synchronized). 1: Indicates that the TSIF is in asynchronous mode (the TS packet is not synchronized).
4	OFEF	0	R/W	TSIF Internal Buffer Overflow 0: — 1: Indicates that an overflow error occurred in the internal buffer.
3	—	Undefined	R	Reserved The write value should always be 0.
2	VSCF	0	R/W	Video Packet Start Code Detection Flag 0: — 1: Indicates that the TS packet input immediately before is a video packet and its payload contains a start code (B'0000 0000 0000 0000 0000 0001 xxxx xxxx).
1	VSHF	0	R/W	Video Packet Short Header Detection Flag 0: — 1: Indicates that the TS packet input immediately before is a video packet and its payload contains a short header (B'0000 0000 0000 0000 1000 00xx xxxx xxxx).
0	TSIFINTF	0	R/W	TSIF Transfer Request Flag Indicates that the internal buffer contains one packet (188 bytes) of TS data. 0: — 1: Indicates that the internal buffer contains one packet of TS data.

47.3.5 TSIF TS Data Register (TSTSDR)

TSTSDR is a register to read TS packet data extracted by the set PID. Setting the EN bit in TSCTLR specifies the endian type.

When FRCADD[1:0] in TSCTLR is 2’b01, the TSFRC value (timestamp), which is recorded with the timing of a PID match, is stored in the 189th to 192nd bytes. This value can be used as packet management data.

It is stored in the 189th to 196th bytes at the time of FRCADD[1:0]=2'b11 setting.

After reading one packet (188 bytes) of TS data from this register, the PEC bit in TSBUFCLRR should be set to 1 (unless it is in DMA auto-transfer mode).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSD[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSD[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TSD31 to TSD0	H'0000 0000	R	FRCADD in TSCTLR = 00: • 1 to 188 bytes: TS Packet Data Extracted by the Set PID FRCADD in TSCTLR = 01: • 1 to 188 bytes: TS Packet Data Extracted by the Set PID • 189 to 192 bytes: TSFRC value recorded with timing of a PID match FRCADD in TSCTLR = 11: • 1 to 188 bytes: TS Packet Data Extracted by the Set PID • 189 to 196 bytes: TSFRC(H/L) value recorded with timing of a PID match

- TS packet data format

  [Big endian] EN bit in TSCTLR = 0:

Bit:	31	24	23	16	15	8	7	0
	TSDn[7:0]		TSDn + 1[7:0]		TSDn + 2[7:0]		TSDn + 3[7:0]	

(n = 0, 4, 8, ..., 180, 184)

  [Little endian] EN bit in TSCTLR = 1:

Bit:	31	24	23	16	15	8	7	0
	TSDn + 3[7:0]		TSDn + 2[7:0]		TSDn + 1[7:0]		TSDn[7:0]	

(n = 0, 4, 8, ..., 180, 184)

Note * Since the TSFRC(H/L) value, which is recorded with timing of a PID match and is in the 189th to 192nd(196th) bytes, is a 32-bit counter value, it is always read as longword data.

Bit:	31	0
	TSFRC[31:0] at PID matching	

47.3.6 TSIF Buffer Clear Register (TSBUFCLRR)

TSBUFCLRR is a register that clears the internal buffer of the TSIF after TS packet data is read.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PEC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PEC	0	R/W	Internal Buffer Clear This bit should be set to 1 immediately after TS packet data is read. When one packet of TS data is discarded because of a transfer error or such, this bit should be set to 1. This bit is automatically cleared to 0 after it has been set to 1. Do not access this register, while the DREQMD bit in TSCTLR is set to 1, or after TS packet data is read. 0: — 1: Clears the internal buffer after the TS packet is transferred (automatically returns to 0 after 1 is set). When one packet of data transferred is discarded because of a transfer error or such, 1 should always be set.

47.3.7 TSIF Interrupt Enable Register (TSINTER)

TSINTER is a register that controls an interrupt request from the TSIF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	CM1ME	0	R/W	0:- 1: Generates an interrupt when TSCMCNT1 counted down, and a value became h'0000 0000
12	CM0ME	0	R/W	0:- 1: Generates an interrupt when TSCMCNT0 counted down, and a value became h'0000 0000
11	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	ADCE	0	R/W	0: — 1: Generates an interrupt when PCRADC is updated (PCR packet is input).
9	PIDE	0	R/W	0: — 1: Generates an interrupt when the set PID packet is received in PID filter mode.
8	STOE	0	R/W	0: — 1: Generates an interrupt when the status is updated (interrupt time is over) by the completion of the next packet reception with the interrupt generated.
7	RANDE	0	R/W	0: — 1: Generates an interrupt when random_access_indicator of the TS packet input immediately before is 1.
6	DISCE	0	R/W	0: — 1: Generates an interrupt when discontinuity_indicator of the PCR packet input immediately before indicates PCR discontinuity.
5	SYNCE	0	R/W	0: — 1: Generates an interrupt when the TSIF is in asynchronous mode.

Bit	Bit Name	Initial Value	R/W	Description
4	OFEE	0	R/W	0: — 1: Generates an interrupt when an overflow error occurs in the internal buffer.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	VSCE	0	R/W	0: — 1: Generates an interrupt when the start code of a video packet is detected in the TS packet input immediately before.
1	VSHE	0	R/W	0: — 1: Generates an interrupt when the short header of a video packet is detected in the TS packet input immediately before.
0	TSIFINTE	0	R/W	0: — 1: Generates an interrupt when the internal buffer contains one packet (188 bytes) of TS data.

47.3.8 TSIF PSCALE Register (TSPSCALER)

TSPSCALER is a register that sets counter values 1 and 2 of the internal prescaler. When EXT_MODE = B'0, set the value of the PSCALE2 bit so that the value is equivalent to the value of the PSCALE1 bit plus 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	PSCALE2[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PSCALE1[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25 to 16	PSCALE2 9 to PSCALE2 0	H'000	R/W	These bits set counter value 2 of the internal prescaler.
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	PSCALE1 9 to PSCALE1 0	H'000	R/W	These bits set counter value 1 of the internal prescaler.

47.3.9 TSIF PSCALE_R Register (TSPSCALERR)

TSPSCALERR is a register that sets the ratio of counter values 1 and 2 of the internal prescaler.

When EXT_MODE = B'0, set the values of the PSCALE_R1 bit and the PSCALE_R2 bit so that the sum of these two bits is 9.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	PSCALE_R2[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	PSCALE_R1[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	PSCALE_R2 3 to PSCALE_R2 0	H'0	R/W	These bits set the ratio of counter value 2 of the internal prescaler.
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	PSCALE_R1 3 to PSCALE_R1 0	H'0	R/W	These bits set the ratio of counter value 1 of the internal prescaler.

After setting TSPSCALERR while TSPSCALER is H'0000 0000, set TSPSCALER.

When EXT_MODE = B'0, set TSPSCALER and TSPSCALERR so that the following equation is satisfied.

$$\left(\frac{PSCALE_R1 + PSCALE_R2}{PSCALE1 \times PSCALE_R1 + PSCALE2 \times PSCALE_R2}\right) \times B\phi = 90\ kHz$$

$$PSCALE_R1 + PSCALE_R2 = 9$$
$$PSCALE2 = PSCALE1 + 1$$

The examples below show register settings of TSPSCALER and TSPSCALERR corresponding to each operating frequency of the TSIF. When EXT_MODE = B'1, operating frequencies listed in table 47.5 are only supported.

Table 47.5 Setting Example of TSPSCALER and TSPSCALERR Corresponding to Each Operating Frequency

- EXT_MODE = B'0

Operating Frequency [MHz]	PSCALE2	PSCALE1	PSCALE_R2	PSCALE_R1
10.0	H’38	H’37	H’5	H’4
12.0	H’43	H’42	H’3	H’6
12.6	H’46	H’45	H’9	H’0
12.8	H’48	H’47	H’1	H’8
14.4	H’51	H’50	H’0	H’9
16.0	H’59	H’58	H’8	H’1
19.2	H’6B	H’6A	H’6	H’3
20.0	H’70	H’6F	H’1	H’8
27.0	H’97	H’96	H’0	H’9
33.0	H’B8	H’B7	H’3	H’6
48.0	H’10B	H’10A	H’6	H’3
50.0	H’116	H’115	H'7	H’2
54.0	H’12D	H’12C	H’0	H’9
66	H’16F	H’16E	H’6	H’3
83.4	H’1D0	H’1CF	H’3	H’6
100	H’22C	H’22B	H’5	H’4

- EXT_MODE = B'1

Operating Frequency [MHz]	PSCALE2	PSCALE1	PSCALE_R2	PSCALE_R1
13.5	H'000	H'001	H'0	H'1
27.0	H'000	H'002	H'0	H'1
40.5	H'000	H'003	H'0	H'1
54.0	H'000	H'004	H'0	H'1

Note: The operating frequency is a bus clock.

47.3.10 TSIF PCRADC Mode Register (TSPCRADCMDR)

TSPCRADCMDR is a register that sets the PCRADC mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	EXT_MODE	TR_SEL[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	EXT_MODE	0	R/W	Sets whether PCR_extension is included in the calculation of D_PCRADC. The EXT_MODE bit can be set to 1 only when this block operates at (13.5 × n) MHz (n = 1, 2, 3, 4). 0: PCR_extension is not included in the D_PCRADC calculation. 1: PCR_extension is included in the D_PCRADC calculation.
4	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	TR_SEL3 to TR_SEL0	H'00	R/W	These bits select a trigger signal for PCRADC to be input to the TSIF. Do not set two or more bits to 1. 0000: A trigger signal is not selected. 1000: An interrupt signal from DMAC channel 3 is selected as a trigger. 0100: An interrupt signal from DMAC channel 2 is selected as a trigger. 0010: An interrupt signal from DMAC channel 1 is selected as a trigger. 0001: An interrupt signal from DMAC channel 0 is selected as a trigger. Other than above: Setting prohibited

47.3.11 TSIF PCRADC Register (TSPCRADCR)

TSPCRADCR is a register that indicates the PCR value incremented by the internal clock (indicates time in a unit of 90 kHz).

After a reset is released, inputting a PCR packet starts count-up operation. Then, the counter value is corrected by using the PCR value in the stream each time a PCR packet is input.

This register is also updated in the packet asynchronous state.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D_PCRADC[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	D_CRADC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PCRADC31 to PCRADC0	H'0000 0000	R	These bits indicate the PCR value incremented by the internal clock. PCRMD in TSCTLR = 0: these bits indicate time in 90-kHz units PCRMD in TSCTLR = 1: these bits indicate time in 45-kHz units

47.3.12 TSIF TR_PCRADC Register (TSTRPCRADCR)

TSTRPCRADCR indicates the value of PCRADC read by a trigger signal for PCRADC selected by the TR_SEL bit (indicates time in a unit of 90 kHz).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TR_PCRADC[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TR_PCRADC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TR_PCRADC31 to TR_PCRADC0	H'0000 0000	R	These bits indicate the PCRADC value read by a trigger signal for PCRADC selected by the TR_SEL bit. PCRMD in TSCTLR = 0: these bits indicate time in 90-kHz units PCRMD in TSCTLR = 1: these bits indicate time in 45-kHz units

47.3.13 TSIF D_PCRADC Register (TSDPCRADCR)

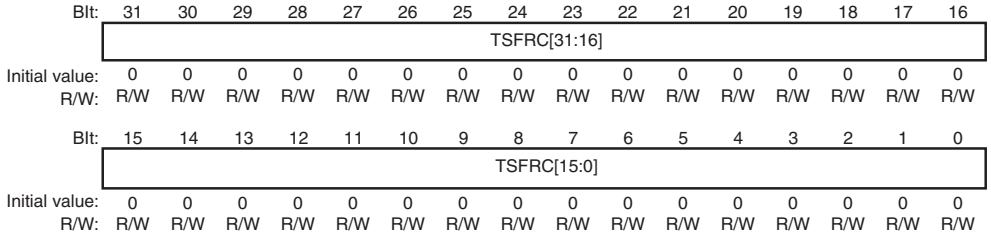
TSDPCRADCR indicates the value of the stream PCR minus PCRADC. After a reset is released and a second packet is input, the value of this register is valid.

When the value of the stream PCR minus PCRADC is greater than 32767 or smaller than –32768, the bits D_PCRADC[31:16] indicate H'8000. (The setting of PCRMD in TSCTLR does not affect D_PCRADC. D_PCRADC[31:16] and D_PCRADC[15:0] indicate a clock difference in a unit of 90 kHz and 27 MHz, respectively.)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D_PCRADC[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	D_PCRADC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	D_PCRADC31 to D_PCRADC0	H'0000 0000	R	These bits indicate the value of the stream PCR minus PCRADC.



47.3.14 TSIF Free Run Counter (TSFRCL)

TSFRCL is a 32-bit free run counter that counts up with a clock divided by setting FRCPSC[7:0] in TSCTLR or internal pre-scaler.

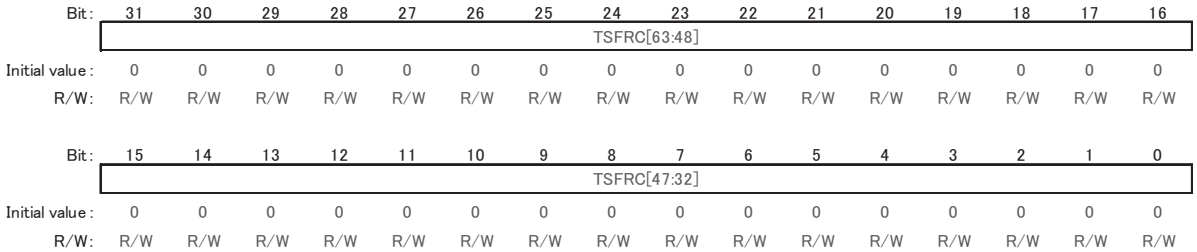
This counter starts counting up after choose clock in FRCSEL and FRCPSC in TSCTLR is set to 1.

TSFRCL is initialized to H'00000000 by a power-on reset, manual reset, R-standby or U-standby. Setting TFA in TSCTLR to 0 does not initialize this counter.

Setting FRCADD in TSCTLR to 01 stores the TSFRCL value (timestamp), which is recorded with timing of a PID match, in the 189th to 192nd bytes of TSTDR.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TSFRC31 to TSFRC0	H'0000 0000	R/W	Indicate the value of the free run counter.(lower)

47.3.15 TSIF Free Run Counter (TSFRCH)



TSFRCH links TSFRCL in free run counter of 32-bit and functions as it of 64-bit.

It is necessary to set 11 of FRCADD in TSCTLR to let it function as free run counter of 64-bit.

This counter starts counting up after choose clock in FRCSEL and FRCPSC in TSCTLR is set to 1.

TSFRCH is initialized to H'00000000 by a power-on reset, manual reset, R-standby or U-standby. Setting TFA in TSCTLR to 0 does not initialize this counter.

Setting FRCADD in TSCTLR to 11 stores the TSFRC(H/L) value (timestamp), which is recorded with timing of a PID match, in the 189th to 196th bytes of TSTDR.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TSFRC64 to TSFRC32	H'0000 0000	R/W	Indicate the value of the free run counter.(upper)

47.3.16 TSIF FSCALE Register (TSFSCALER)

TSFSCALER is a register that sets counter values 1 and 2 of the internal prescaler used in TSFRC. Set the value of the FSCALE2 bit so that the value is equivalent to the value of the FSCALE1 bit plus 1.

The specifications of the setting follow TSFSCALER.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	FSCALE2[9:0]									
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25 to16	FSCALE2 9 to FSCALE2 0	H'000	R/W	These bits set counter value 2 of the internal prescaler used in TSFRC.
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	FSCALE1 9 to FSCALE1 0	H'000	R/W	These bits set counter value 1 of the internal prescaler used in TSFRC.

47.3.17 TSIF FSCALE_R Register (TSFSCALERR)

TSFSCALERR is a register that sets the ratio of counter values 1 and 2 of the internal prescaler used in TSFRC.

Set the values of the FSCALE_R1 bit and the FSCALE_R2 bit so that the sum of these two bits is 9.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	FSCALE_R2[3:0]			
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	FSCALE_R1[3:0]			
Initial value :	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19 to 16	FSCALE_R2 3 to FSCALE_R2 0	H'0	R/W	These bits set the ratio of counter value 2 of the internal prescaler used TSFRC.
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	FSCALE_R1 3 to FSCALE_R1 0	H'0	R/W	These bits set the ratio of counter value 1 of the internal prescaler used TSFRC.

47.3.18 TSIF COMPARE MATCH Control Register (TSCMCTLR)

TSCMCTLR chooses Run/Stop of COMPARE MATCH COUNTER0 and COMPARE MATCH COUNTER1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31	PIDEX	0	R/W	This bit choose Use/Not_Use from choice section PID_34 to PID_64. 0: NOT use 1: use
30 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CM1GO	H'0	R/W	This bit choose Run/Stop COMPARE MATCH COUNTER1(TSCMCNT1). 0: TSCMCNT1 stops a count. 1: TSCMCNT1 starts counting.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	CM0GO	H'0	R/W	This bit choose Run/Stop COMPARE MATCH COUNTER0(TSCMCNT0). 0: TSCMCNT0 stops a count. 1: TSCMCNT0 starts counting.

47.3.19 TSIF COMPARE MATCH COUNTER0 (TSCMCNT0)

TSCMCNT0 is free run counter of 32-bit counting down in clock set in TSCTLR.FRCPSC[7:0] or internal prescaler used in TSFRC.

Countdown is started after setting of CM0GO=1 in TSCMCTLR.

As for TSCMCNT0, it is counted down by a value set by TSCMCOR0, and it is counted down by a value set again by TSCMCOR0 when it became H'0000_0000 if it is CM0GO=1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CMCNT0[31:16]

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMCNT0 31 to CMCNT0 0	H'0000 0000	R/W	There bits show a value of the COMPARE MATCH COUNTER0.

47.3.20 TSIF COMPARE MATCH COUNTER1 (TSCMCNT1)

TSCMCNT0 is one shot counter of 32-bit counting down in clock set in TSCTLR.FRCPSC[7:0] or internal prescaler used in TSFRC.

Countdown is started after setting of CM1GO=1 in TSCMCTLR.

TSCMCNT1 stops after having become H'0000_0000 by countdown.

It write 0 in CM1GO to run it again, and it is necessary to write 1 afterwards.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CMCNT1[31:16]

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMCNT1 31 to CMCNT1 0	H'0000 0000	R/W	There bits show a value of the COMPARE MATCH COUNTER1.

47.3.21 TSIF COMPARE MATCH CONSTANT Register0 (TSCMCOR0)

TSCMCOR0 sets a value at the time of a count down start of COMPARE MATCH COUNTER0 (TSCMCNT0).

It loads a value of TSCMCOR0 in TSCMCNT0 after setting of CM0GO=1 in TSCMCTLR.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSCOR0[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSCOR0[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TSCOR0 31 to TSCOR0 0	H'0000 0000	R/W	These bits set a value at the time of the countdown start of the COMPARE MATCH COUNTER0.

47.3.22 TSIF COMPARE MATCH CONSTANT Register1 (TSCMCOR1)

TSCMCOR1 sets a value at the time of a count down start of COMPARE MATCH COUNTER1 (TSCMCNT1).

It loads a value of TSCMCOR1 in TSCMCNT1 after setting of CM1GO=1 in TSCMCTLR.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSCOR1[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSCOR1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TSCOR1 31 to TSCOR1 0	H'0000 0000	R/W	These bits set a value at the time of the countdown start of the COMPARE MATCH COUNTER1.

47.3.23 TSIF TS PACKET COUNT Register (TSPCNT)

TSPCNT is 32-bit register showing the number of the TS packets begin to read in DMA from TSTSDR.

When it wrote 1 in TSPCNTPSH.PCTPH, TSPCNT is initialized to H'0000_0000.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PCNT[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PCNT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PCNT 31 to PCNT 0	H'0000 0000	R/W	These bits show a TS packet number read in DMA from TSTSDR. It stop count up with a value of H'FFFF_FFFF.

47.3.24 TSIF TS PACKET COUNT KEEP Register (TSPCNTKP)

TSPCNTKP is 32-bit register.

TSPCNTKP keeps the number of the TS packets which TSPCNT shows when It was written 1 in TSPCNTPSH.PCTPH.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PCNTKP[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PCNTKP[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PCNTKP 31 to PCNTKP 0	H'0000 0000	R/W	When It wrote 1 in TSPCNTPSH.PCTPH, It show a TS packet number read in DMA from TSTSDR.

47.3.25 TSIF TS PACKET COUNT PUSH Register (TSPCNTPSH)

TSPCNTPSH is 32-bit register.

It copy a value of TSPCNT at that time in TSPCNTKP when It write 1 in PCTPH.

When you want to copy it again, clear of the PCTPH is necessary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	PCTPH
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PCTPH	0	R/W	

47.4 Operation

47.4.1 TS Data Protocol

The TS packet supported by this LSI consists of 188-byte execution data including the sync byte and 16-byte Reed-Solomon code (parity data) for an error correction, with configuration of 204 bytes in total (figure 47.2). The TSIF supports TS data formats of both 188 bytes (without parity) and 204 bytes (with parity).

The data input pins consist of the following.

- Serial data (TS_SDAT) input
- Serial data clock (TS_SCK) input
- Synchronous (TS_SPSYNC) input
- Enable (TS_SDEN) input

Depending on the specifications of the LSI to be connected, the polarity of these pins can be switched by software (figure 47.3).

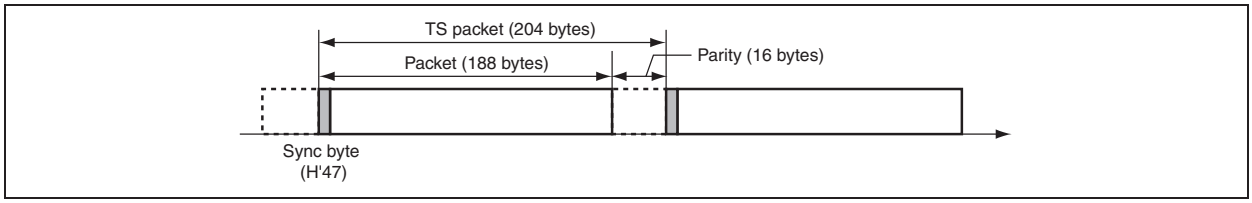

Figure 47.2 MPEG2-TS Packet Configuration

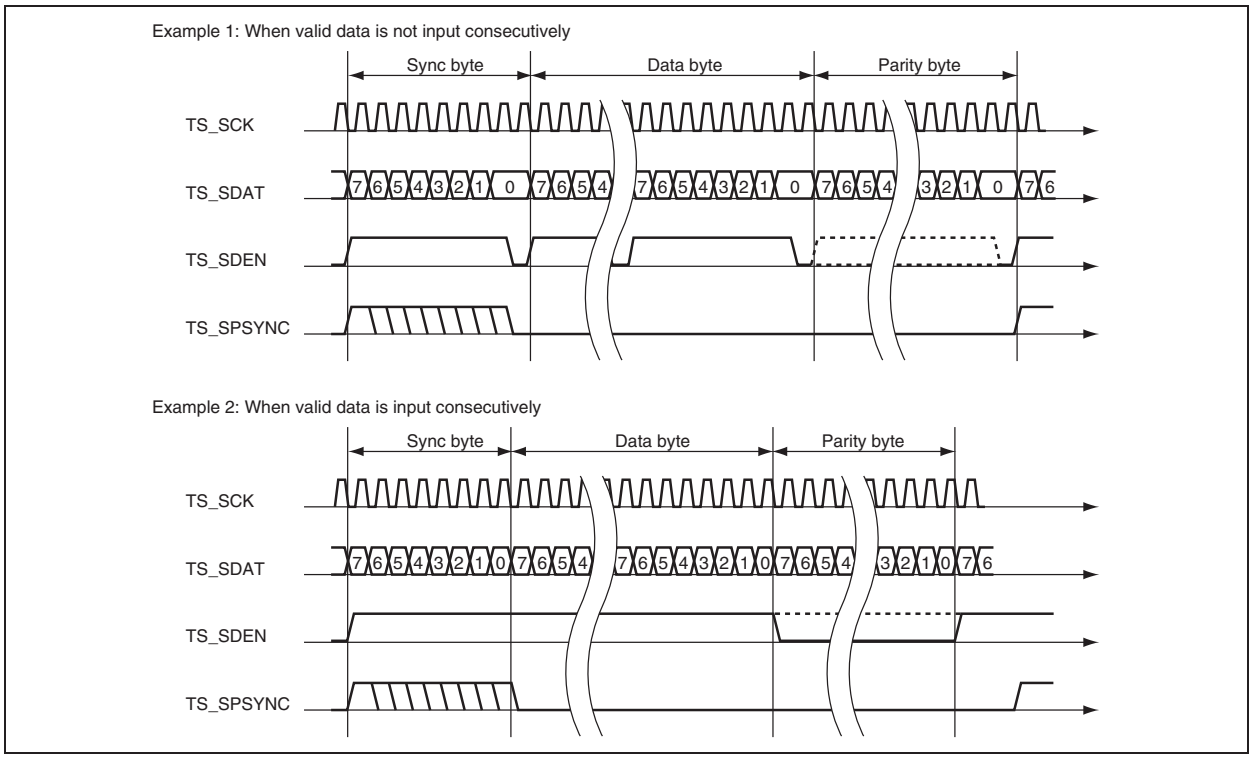

Figure 47.3 Timing of TS Data Serial Input

47.4.2 Synchronous Processing Unit

The function of synchronous processing is to synchronize packets for carrying out the subsequent PID filtering and such.

The TS packet data is constantly sent from a terrestrial station. The receiving terminal starts receiving the data regardless of the timing of the sender. This causes the receiving terminal to receive an incomplete packet. The synchronous processing is essential to identifying the start of TS packet data that are not played from the start and accurately process various data in the packet.

Moreover, as the signal quality of input data may deteriorate according to the transmission status, the TS packet data received via a tuner, OFDM demodulator, and the like may contain errors. The synchronous processing includes protection against such errors.

When the receiving terminal is started up, it searches for the sync byte (H'47). If the sync byte is detected, the receiving terminal checks whether or not the sync byte will appear again after one packet cycle (188 bytes or 204 bytes). If the sync byte appears twice consecutively, synchronization is confirmed. Once synchronized, even when the sync byte does not appear at a fixed position, an error is not generated immediately and the regular processing is continued.

When the sync byte has not appeared 4 times consecutively, the receiving terminal determines that synchronization is lost. Once synchronization is lost, the process for synchronization starts in the same way as when the receiving terminal is started up.

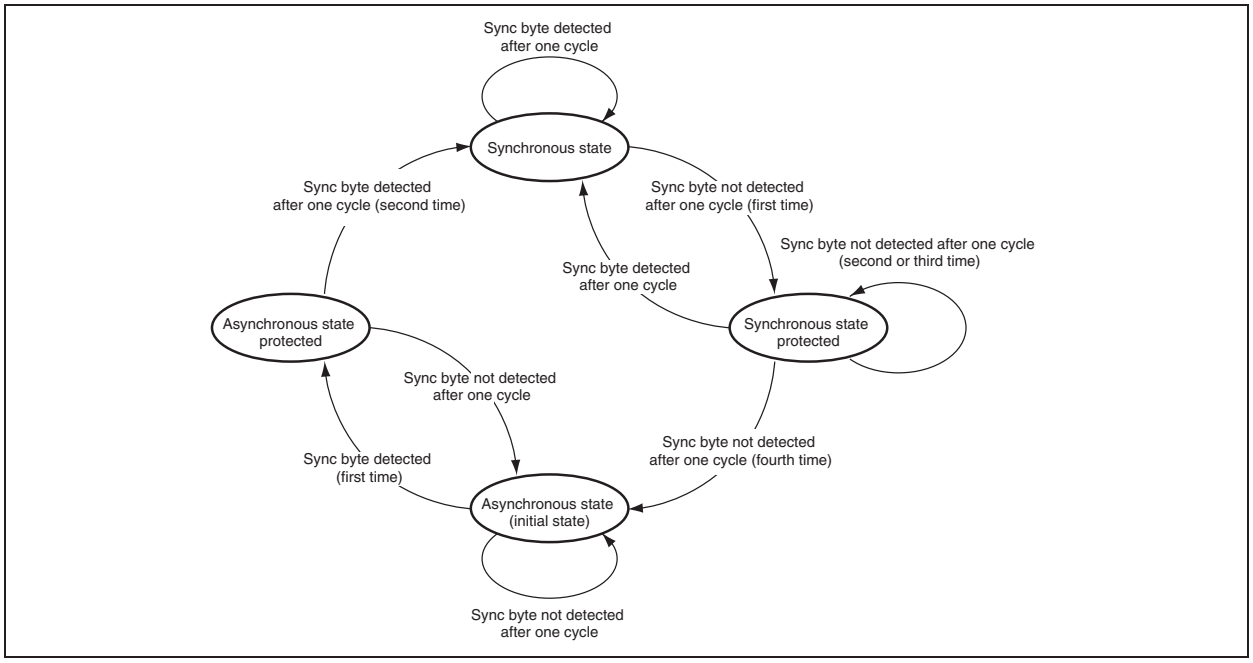

Figure 47.4 Detection State Configuration of Sync Byte

47.4.3 PID Filter Unit

PID filtering checks the PIDs of TS packets and if they match the predefined PID table values, the packets are stored in the buffer.

A total of 67 values can be registered as PID values. However, the values for PAT (H'0000) and CAT (H'0001) are fixed and not changeable. Even though the PID values for the PCR packet, video packet, and audio packet should be specified in the dedicated sections, respectively, another 62 PID values can be specified in any of the sections.

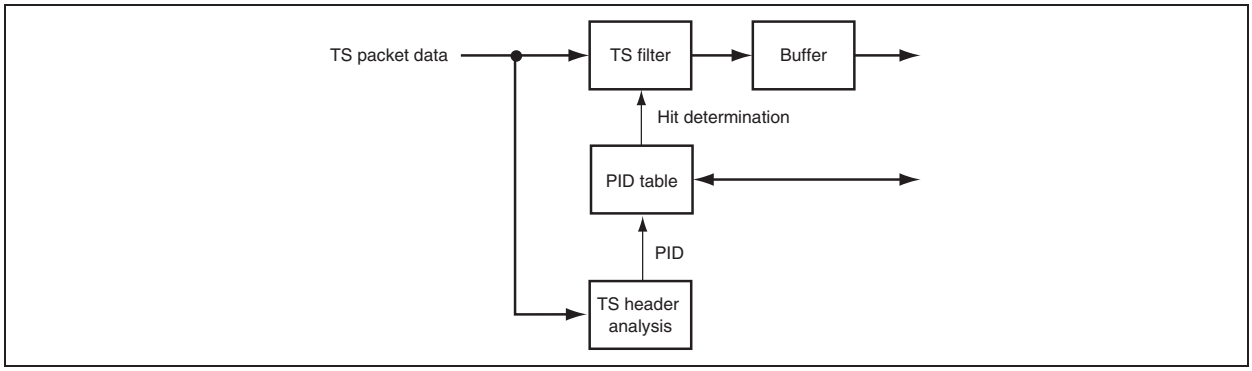

Figure 47.5 Block Diagram of PID Filtering

Table 47.6 PID Table

No.	Section	PID Value (12 Bits)	Description
1	Video	Any setting	Dedicated for video packet

66	CAT	Fixed to H'0001	Dedicated for CAT packet
67	PCR	Any setting	Dedicated for PCR packet

47.4.4 Bitstream Search Unit

The function of the bitstream search unit is to check the contents of the PCR and video packets to reduce the load of software. The functions listed below are available.

1. PCR discontinuity check

   PCR discontinuity (Discontinuity-indicator) is automatically detected and reflected in the status register. This is to reduce the delay in software processing if a PCR packet is input. PCR is a reference clock sent from a base station (broadcasting station) and may be switched to another PCR because of program changes and so on.
2. PCR_flag detection

   The PCR_flag is detected from the adaptation_field of the TS packet and reflected in the status register.
3. random_access_indicator detection

   The random_access_indicator is detected from the adaptation_field of the TS packet and reflected in the status register.
4. Duplicate packet delete

   The PID and continuity_counter are checked from consecutive TS packets to prevent duplicate TS data from being stored in the buffer.

5. Start code check

   When a start code (H'0000 01xx) is contained in a video stream, it is reflected in the status register. The start code marks the boundary in image data of the MPEG standard and is applied at the start of a sequence, image, and such.

6. Short header check

   When a short header (B'0000 0000 0000 0000 1000 00xx xxxx xxxx) is contained in a video stream, it is reflected in the status register.

These processes are performed in the adaptation field analysis unit and the ES data search unit.

At the time of TS header analysis for PID filtering, the presence of an adaptation field is analyzed. When hit information of a PCR packet or video packet in the PID table is input, the necessary process at each block is initiated.

Each result is reflected in the status register.

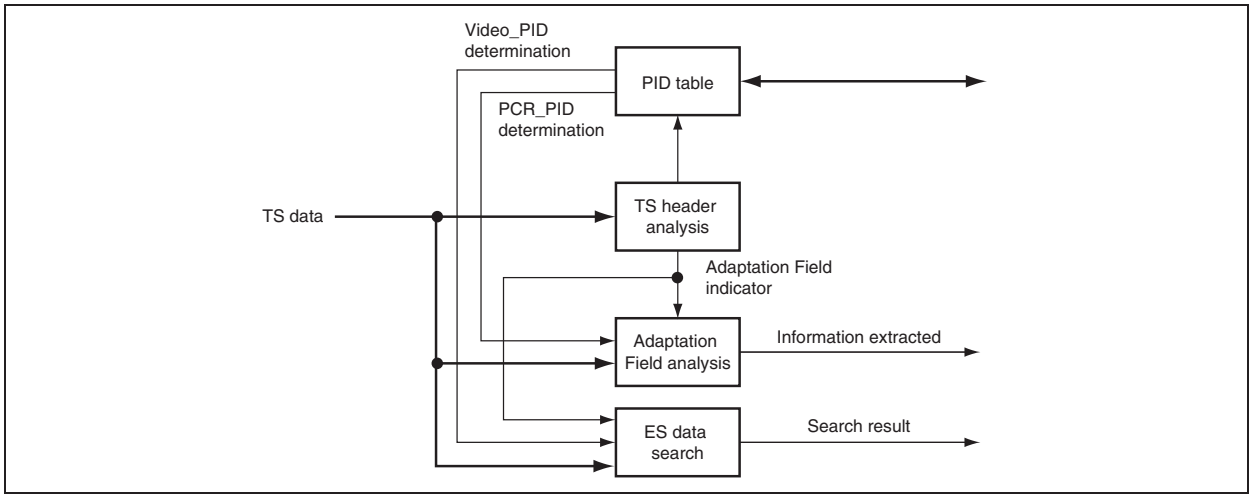

Figure 47.6 Block Diagram of Stream Search Unit

47.4.5 Process Flow

Figure 43.7 shows an outline of the process flow in the TSIF module.

Since the TSIF is in the reset state at power-on, it does not generate any signals until the initialization is completed. A TS packet ID (PID) to be extracted by the TSIF is set in the PID table. After other necessary settings have been completed, software reset is released and the TSIF is started up while a desired interrupt is allowed at the same time. After this, the TSIF waits until the necessary TS packet is extracted.

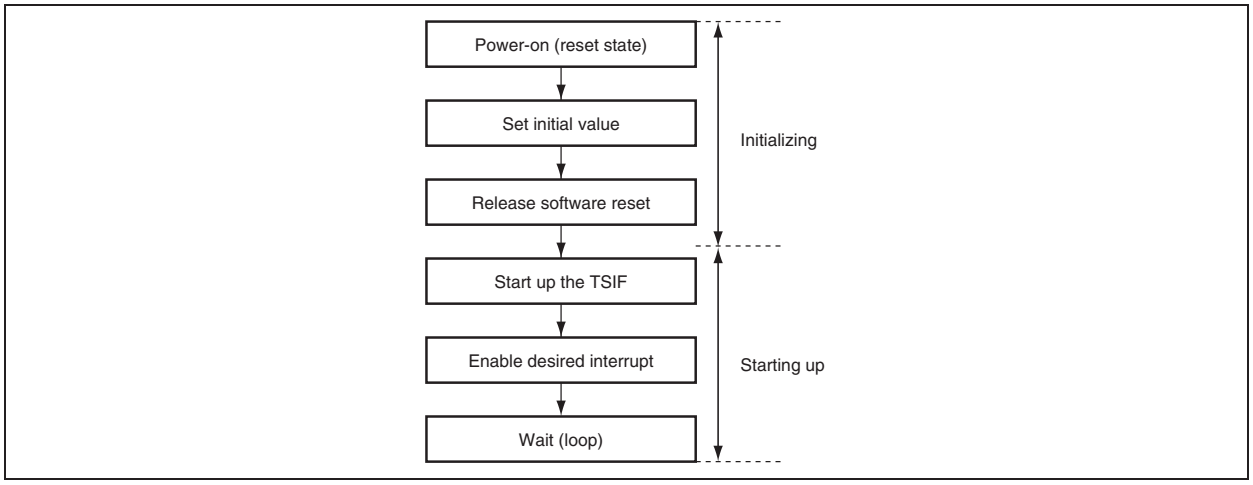

Figure 47.7 TSIF Process Flow

Two types of TS packet transfer are available as described below.

(1) DMA Interrupt Transfer Mode (figure 43.8)

The interrupt routine transfers the packet data stored in the buffer to a queue created in memory. Multiple queues must be created depending on the values of PIDs (e.g., video or audio). When an interrupt is generated, the TSSTR register is read first. If a status error is detected during reading, and the packet data is going to be discarded, the PEC bit in the TSBUFCLRR register should be set. The value of the PID bit in the TSSTR register should then be checked.

For example, if the packet is a video packet, it will be transferred to a video packet queue by DMA and so on. After 188-byte data is transferred or TS data plus TSFRC (192 bytes or 196bytes) is transferred, the PEC bit must be set to clear the internal buffer.

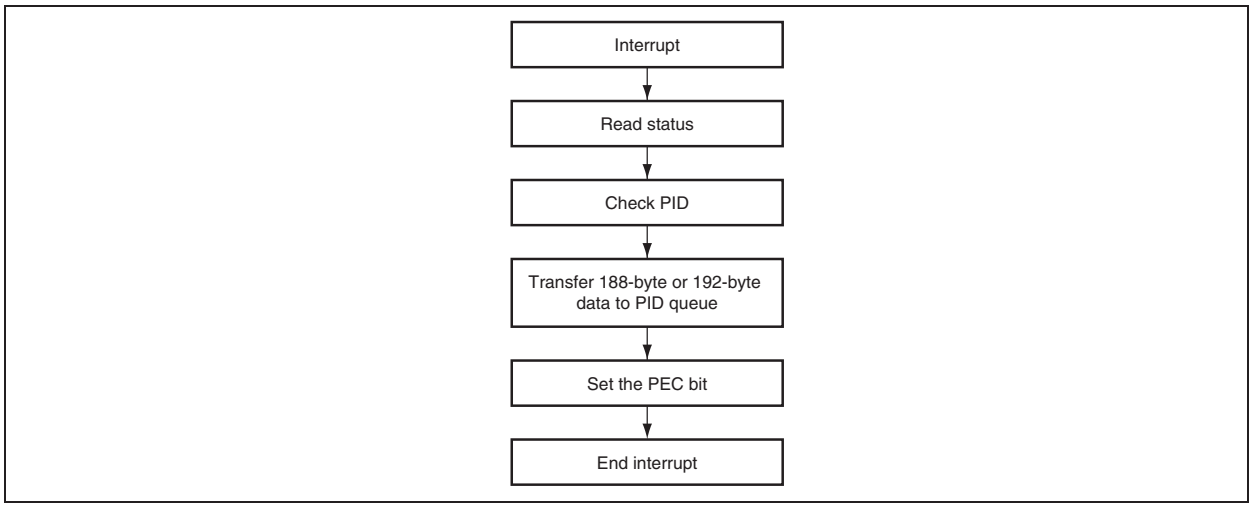

Figure 47.8 TSIF Interrupt Process Flow

(2) DMA Auto-Transfer Mode

To use this mode, the necessary setting should be made in the DMAC block before starting up the TSIF. When a single TS packet (188 bytes) is input or a single TS packet plus TSFRC (192 bytes or 196bytes) is input, the TSIF automatically issues a transfer request signal to the DMA and starts DMA transfer. Using this mode reduces the frequency of interrupts.

Section 48 High-Definition Multimedia Interface (HDMI)

This LSI has HDMI transmitter IP which is compliant with HDMI 1.3a specification.

48.1 Features

- HDMI version 1.3a, HDCP version 1.2 and DVI version 1.0 compliant transmitter
- Internal NV memory for HDCP Key
- Supports DTV from 480i to 1080i/60fps(or 1080p/30fps) HD resolution
- Programmable 2-way color space converter
- Compliant with EIA/CEA-861D
- Gamut metadata transmission
- Supports RGB, YCbCr digital video input (24bit RGB 888 / 24bit YCbCr 4:2:2) from LCDC(*1)
- Supports standard SPDIF input from FSI2(*2) for stereo or compressed audio up to 192KHz
- Programmable PLL characteristics, channel delay and transmitter pre-emphasis rate

Note: *1 : Please refer to section 40 “LCDC”.
*2 : Please refer to section 51 “FSI2/FMSI”.

48.2 Block Diagram

Figure 48.1 shows a block diagram of the HDMI transmitter.

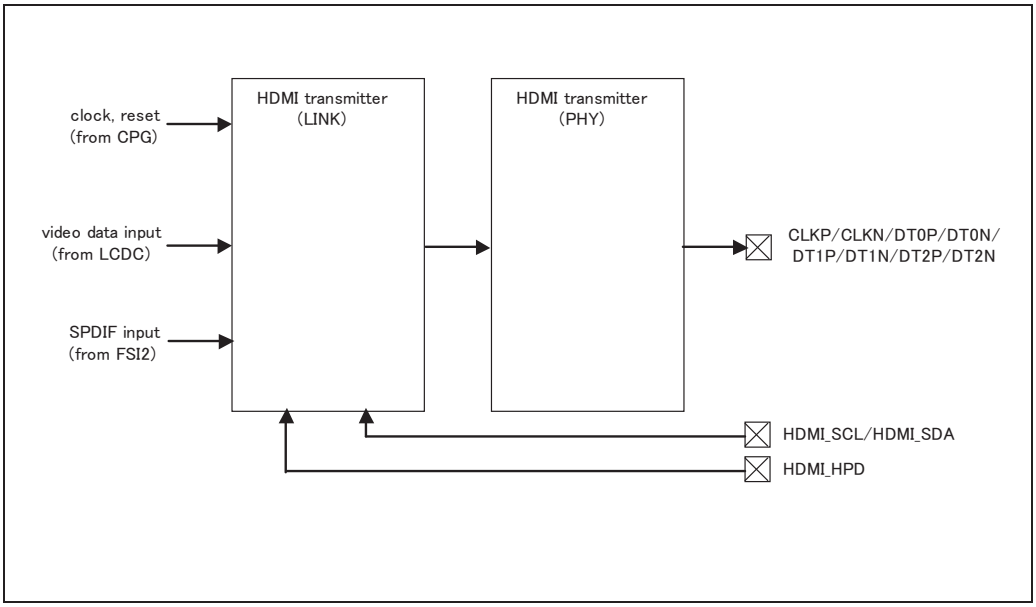

Figure 48.1 Block Diagram

48.3 Pin Configuration

Table 48.1 lists the pins of the HDMI transmitter.

Table 48.1 Pin List

Pin Name	Function	I/O	Description
TMDS_CLKP	Differential pin (plus) for Clock	Output	Differential pixel clock (plus) for HDMI cable interface signal TMDS_CLKP
TMDS_CLKN	Differential pin (minus) for Clock	Output	Differential pixel clock (minus) for HDMI cable interface signal TMDS_CLKN
TMDS_DT0P	Differential pin (plus) for Data0	Output	Differential serial data (plus) for HDMI cable interface signal TMDS_DT0P
TMDS_DT0N	Differential pin (minus) for Data0	Output	Differential serial data (minus) for HDMI cable interface signal TMDS_DT0N
TMDS_DT1P	Differential pin (plus) for Data1	Output	Differential serial data (plus) for HDMI cable interface signal TMDS_DT1P
TMDS_DT1N	Differential pin (minus) for Data1	Output	Differential serial data (minus) for HDMI cable interface signal TMDS_DT1N
TMDS_DT2P	Differential pin (plus) for Data2	Output	Differential serial data (plus) for HDMI cable interface signal TMDS_DT2P
TMDS_DT2N	Differential pin (minus) for Data2	Output	Differential serial data (minus) for HDMI cable interface signal TMDS_DT2N
TMDS_REXT	External Register	—	External Register (470 ohms to 2.5V)
HDMI_SCL	DDC signal	Inout	SCL signal for DDC line
HDMI_SDA	DDC signal	Inout	SDA signal for DDC line
HDMI_HPD	Hot Plug Detect	Input	Hot Plug Detect Input

Section 49 Consumer Electronics Control (CEC) Function

This LSI has control circuit for CEC signal which is specified by HDMI specification.

49.1 Features

- Clock source : RCLK(32.768KHz) is used for basic behavior clock.
- Data format
  - start bit : 1bit
  - data bit : 8bit
  - EOM bit : 1bit
  - ACK bit : 1bit
- Interrupt

  Transmission interrupt
  - 8 bit data transmission completion
  - 10 bit data transmission completion

  Transmission error interrupt
  - Arbitration Lost Detection
  - NACK reception (ACK reception for Broadcast transfer)

  Reception interrupt
  - 8 bit data reception completion
  - 10 bit data reception completion

  Reception error interrupt
  - Unacceptable signal reception
- Error detection

  Arbitration lost : During transmission, in either status bellow, arbitration lost is detected
  - At the changing CEC pins “Hi-Z” to “L” output, CEC pins is already “L” level.
  - At the changing CEC pins “L” output to “Hi-Z”, CEC pins is “L” level over acceptable range.

  Transmission error : CCBTA bit of CCBT2 register is matched with CTNACK bit of CECC2 register

  Reception acceptable range error : “L” or “H” period of reception data is out of acceptable range

- Function
  Digital filter : enable / disable can be selected
  Transmission stop condition: ACK / NACK can be selected
  Arbitration lost detection condition : either of following condition can be selected
    - During sending start bit and initiator address
    - During sending start bit and all of the data bit
- Transmission rising edge timing : can be selected from 8 phase
- Transmission falling edge timing : can be selected from 4 phase
- Receive data timing : detection timing can be selected from either of following
    - Detect only falling edge
    - Detect both rising and falling edge
- ACK output as reception : either of following can be selected
    - Program insertion : assigned by CCRBAO bit of CCRB2 register
    - Hardware insertion : output ACK in the case destination address is matched,
      output NACK in the case destination address is unmatched
- Acceptable range of start bit : +/-200us or +/-300us
- Acceptable range of data bit : either of following can be selected
    - From falling edge to rising edge +/-200us, from rising edge to falling edge +/- 350us
    - From falling edge to rising edge +/-300us, from rising edge to falling edge +/- 500us
- “L” pulse output, as reception error occurrence: output “L” pulse or not can be selected
- Waiting control of error “L” pulse output : either of following can be selected
    - In the case input CEC level is low as error occurrence, output “L” pulse synchronized with input CEC rising.
    - Output “L” pulse , regardless of input CEC level.

49.2 Block Diagram

Figure 49-1 shows a block diagram of CEC function.

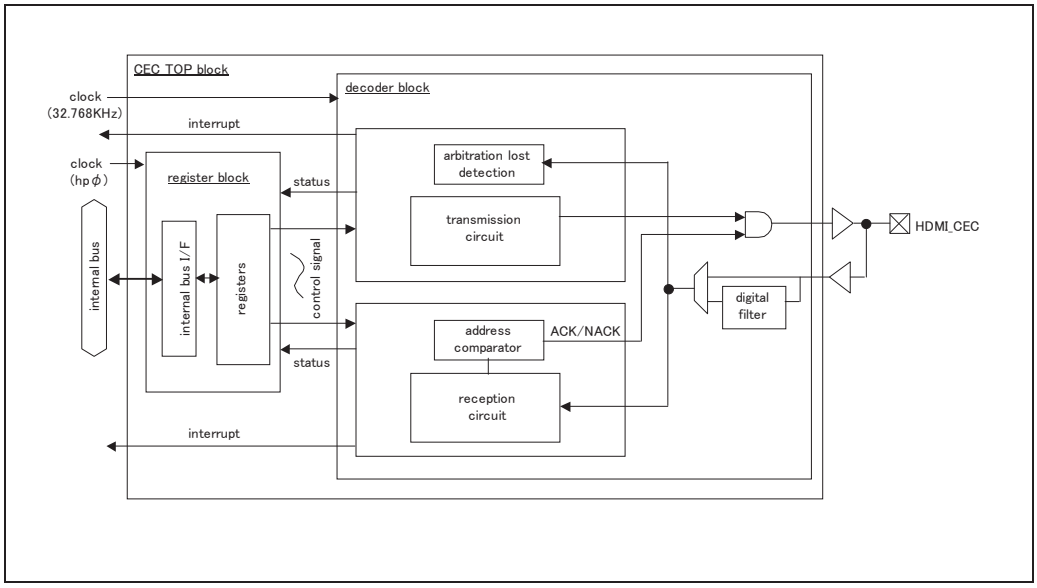

Figure 49-1 Block Diagram

49.3 Pin Configuration

Table 49.1 lists the pins of the CEC function.

Table 49-1 Pin List

Pin Name	Function	I/O	Description
HDMI_CEC	CEC	Inout	CEC control signal

49.4 Register Descriptions

Table 49-2 shows the CEC register configuration. Table 49-3 shows the register states in each operation mode.

Table 49-2 Register Configuration

Register	Abbreviation	R/W	Address	Access Size
CEC function control register 1	CECC1	R/W	H'E6BF 0000	8
CEC function control register 2	CECC2	R/W	H'E6BF 0001	8
CEC function control register 3	CECC3	R/W	H'E6BF 0002	8
CEC function control register 4	CECC4	R/W	H'E6BF 0003	8

49.4.1 CEC function control register 1 (CECC1)

CECC1

bit:	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	CECEN
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	–	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	CECEN	0	R/W	CEC function enable bit 0: CEC function disable 1: CEC function enable The CEC circuit is reset by setting CECEN "0".

49.4.2 CEC function control register 2 (CECC2)

CECC2

bit:	7	6	5	4	3	2	1	0
	CDATRNG	CSTRRNG	CFIL	CTABTS	CRACK	CTACKEN	CTNACK	CRRNG
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	CDATRNG	0	R/W	Data bit acceptable range specification bit 0: The period from falling edge to rising edge is +/- 200us The period from rising edge to falling edge is +/- 350us 1: The period from falling edge to rising edge is +/- 300us The period from rising edge to falling edge is +/- 500us
6	CSTRRNG	0	R/W	Start bit acceptable range specification bit 0: +/- 200us 1: +/- 300us

Bit	Bit Name	Initial Value	R/W	Description
5	CFIL	0	R/W	Digital filter enable bit 0: Digital filter disable 1: Digital filter enable
4	CTABTS	0	R/W	Arbitration lost detect condition select bit 0: During transmission of start bit and initiator address 1: During transmission of start bit and all of the data bit This bit selects the range of the arbitration lost detection at CEC rising edge. Except for CEC rising edge, the arbitration lost is detected regardless of this bit.
3	CRACK	0	R/W	Reception ACK output mode select bit 0: Program insertion 1: Hardware insertion When this bit is set to “0”, Output CCRBAO bit level in CCRB2 register as the reception ACK data. When this bit is set to “1”, if the received destination address is matched with the address selected by CRADR1 and CRADR2 registers, then output the ACK. And if the received destination address is not matched with the address selected by CRADR1 and CRADR2 registers, then output the NACK.
2	CTACKEN	0	R/W	Transmission NACK(ACK) stop control bit 0: Continue transmission regardless of NACK/ACK 1: Stop transmission by NACK/ACK reception When this bit is set to “1”, please select the stop condition by CTNACK bit.
1	CTNACK	0	R/W	Transmission NACK(ACK) stop condition select bit 0: Stop by ACK 1: Stop by NACK This bit is valid when CTACKEN bit is set to 1.
0	CRRNG	0	R/W	Reception edge detection select bit 0: Detect only falling edge 1: Detect rising and falling edge

49.4.3 CEC function control register 3 (CECC3)

CECC3

bit:	7	6	5	4	3	2	1	0
	–	–	–	–	CEOMI	CREGCLR	CRXDEN	CTXDEN
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	–	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
3	CEOMI	0	R/W	Disable EOM bit 0: EOM enable 1: EOM disable This bit select that stop or continue the transmission/reception when the EOM is “1”. Table 49-4 shows the behavior in the case EOM is “1”.
2	CREGCLR	0	R/W	CREGFLG clear bit When this bit is set to “1”, CREGFLG bit of CECC4 register is cleared to “0”. Before setting this bit to “1” next time, set this bit “0”.
1	CRXDEN	0	R/W	Enable reception register 0: reception stopped 1: reception permitted After 1 RCLK cycle of setting this bit, the reception is stopped or permitted.
0	CTXDEN	0	R/W	Enable transmission register 0: transmission stopped 1: transmission permitted After 1 RCLK cycle of setting this bit, the transmission is stopped or permitted.

Table 49-4 Behavior in the case EOM is "1"

CEOMI bit	Behavior in the case EOM is "1"	
	Reception	Transmission
0	Neglect the received data after the receiving EOM "1". (Wait for START bit)	Stop to transmit data after the transmitting EOM "1".
1	Reply ACK or NACK to the received data even after receiving EOM "1".	Transmit data even after the transmitting EOM "1".

When the CEOMI bit is "1", to stop the transmission, please set CTXDEN bit of CECC3 register.

49.4.4 CEC function control register 4 (CECC4)

CECC4

bit:	7	6	5	4	3	2	1	0
	CABTWEN	CREGFLG	CFALL[1:0]		CABTEN	CRISE[2:0]		
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	CABTWEN	0	R/W	Error "L" pulse output wait control bit 0: Output "L" pulse regardless of the CEC signal 1: Output "L" pulse at rising edge of the CEC signal This bit is valid when CABTEN bit is set to "1". In the case this bit is "1", when a reception error is detected during CEC input level is "L", error "L" pulse is output from next CEC rising edge. But when CEC rising edge is not detected within 3.6ms after an error occurrence, regarding the other devices output the error "L" pulse, this device doesn't output the error "L" pulse.
6	CREGFLG	0	R	CEC reception edge detection flag 0: The CEC "L" is not detected 1: The CEC "L" is detected When the CEC "L" is detected, this bit is set to "1". When CREGCLR bit of CECC3 register is set to "1", this bit is cleared to "0".
5, 4	CFALL[1:0]	00	R/W	CEC fall timing select bit Please refer Table 49-5.

Bit	Bit Name	Initial Value	R/W	Description
3	CABTEN	0	R/W	Error “L” pulse output enable bit 0: disable 1: enable When this bit is set to “1”, the received data bit is over the acceptable reception range, output 3.6ms “L” pulse. The “L” pulse output timing is selectable by CABTWEN bit.
2 to 0	CRISE[2:0]	000	R/W	CEC rise timing select bit Please refer Table 49-6.

Table 49-5 CEC fall timing in transmission

CFALL[1:0] bit	CEC fall timing	
	Start bit	Data bit
00b	The standard value (*1)	The standard value (*2)
01b	The standard value – 2 RCLK cycles	The standard value – 7 RCLK cycles
10b	The standard value – 3 RCLK cycles	The standard value – 9 RCLK cycles
11b	The standard value – 5 RCLK cycles	The standard value – 11 RCLK cycles

*1 : 4.5ms from the falling edge of start bit
*2 : 2.4ms from the bit start event

Table 49-6 CEC rising timing in transmission

CRISE[2:0] bit	CEC rise timing (common to start bit and data bit)
000b	The standard value (*)
001b	The standard value – 1 RCLK cycle
010b	The standard value – 2 RCLK cycles
011b	The standard value – 3 RCLK cycles
100b	The standard value – 4 RCLK cycles
101b	The standard value – 5 RCLK cycles
110b	The standard value – 6 RCLK cycles
111b	The standard value + 1 RCLK cycle

* : Start bit : 3.7ms from the falling edge of start bit
Data bit (logical 0) : 1.5ms from the bit start event
Data bit (logical 1) : 0.6ms from the bit start event

49.4.5 CEC flag register (CECFLG)

CECFLG

bit:	7	6	5	4	3	2	1	0
	CRSTFLG	CTD8FLG	CRD8FLG	CTNACKFLG	CTABTFLG	CRERRFLG	CTFLG	CRFLG
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	CRSTFLG	0	R	Start bit detect flag 0: The start bit is not detected or 8th bit is received 1: The start bit is detected
6	CTD8FLG	0	R	8th data transmit flag 0: The 8th bit is not transmitted or the 10th bit is transmitted 1: The 8th bit is transmitted
5	CRD8FLG	0	R	8th data receive flag 0: The 8th bit is not received or the 10th bit is received 1: The 8th bit is received
4	CTNACKFLG	0	R	Transmission NACK detect flag 0: NACK or ACK are not detected 1: NACK is detected (in the case Directly address transmission) ACK is detected (in the case Broadcast transmission) When CTXDEN bit of CECC3 register (stop the transmission), this bit is cleared to “0”.
3	CTABTFLG	0	R	Arbitration lost detect flag 0: Not detected 1: Detected When CTXDEN bit of CECC3 register (stop the transmission), this bit is cleared to “0”.
2	CRERRFLG	0	R	Reception error detect flag 0: Not detected 1: Reception error (out of the acceptable range) is detected When CRXDEN bit of CECC3 register (stop the reception), this bit is cleared to “0”.
1	CTFLG	0	R	Transmission state flag 0: Waiting 1: During transmission

Bit	Bit Name	Initial Value	R/W	Description
0	CRFLG	0	R	Reception state flag 0: Waiting 1: During reception When CABTEN bit of CECC4 register is set to “1” (error “L” output is permitted) and the error “L” pulse is output, this bit is also set to “1”.

49.4.6 CEC interrupt factor select register (CISEL)

CISEL

bit:	7	6	5	4	3	2	1	0
	CRISELS	CTISEL2	CTISEL1	CTISEL0	CRISELM	CRISEL2	CRISEL1	CRISEL0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	CRISELS	0	R/W	Reception start bit interrupt enable 0: disable 1: enable
6	CTISEL2	0	R/W	Transmission error interrupt enable 0: disable 1: enable
5	CTISEL1	0	R/W	Transmission 10th bit interrupt enable 0: disable 1: enable
4	CTISEL0	0	R/W	Transmission 8th bit interrupt enable 0: disable 1: enable
3	CRISELM	0	R/W	Reception interrupt mode select bit 0: The reception 8th/10th bit interrupt occurs regardless of destination address 1: Only in the case that the destination address is matched or the broadcast address, the reception 8th/10th bit interrupt occurs.

Bit	Bit Name	Initial Value	R/W	Description
2	CRISEL2	0	R/W	Reception error interrupt enable 0: disable 1: enable
1	CRISEL1	0	R/W	Reception 10th bit interrupt enable 0: disable 1: enable
0	CRISEL0	0	R/W	Reception 8th bit interrupt enable 0: disable 1: enable

Please set CISEL register when CECEN bit of CECC1 register is “0”.

49.4.7 CEC transmission buffer register 1 (CCTB1)

CCTB1

bit:	7	6	5	4	3	2	1	0
	CCTB1[7:0]							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	CCTB1[7:0]	All 0	R/W	Please set transmission data

Please set CCTB1 register either of the following terms.

- When CTXDEN bit of CECC3 register is “0” (stop transmission)
- When CTXDEN bit of CECC3 register is “1” and CTD8FLG bit of CECFLG register is “1” (during the transmission EOM or ACK bit)

Please don’t set CCTB1 register when CTXDEN is “1” and CTD8FLG is “0”(during the transmission from 1st to 8th bit).

49.4.8 CEC transmission buffer register 2 (CCTB2)

CCTB2

bit:	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	CCTBA	CCTBE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
1	CCTBA	0	R	Transmission ACK/NACK input bit 0: ACK is detected 1: NACK is detected Please read this bit after 10th bit (ACK bit) transmission (after CTD8FLG bit of CECFLG register is changed form "1" to "0").
0	CCTBE	0	R/W	Transmission EOM bit 0: The data block is continued 1: The data block is finished

Please set CCTBE bit either of the following terms.

- When CTXDEN bit of CECC3 register is "0" (stop transmission)
- When CTXDEN bit of CECC3 register is "1" and CTD8FLG bit of CECFLG register is "1" (during the transmission EOM or ACK bit)

Please don't set CCTBE bit when CTXDEN is "1" and CTD8FLG is "0"(during the transmission from 1st to 8th bit).

CCRB1

bit:	7	6	5	4	3	2	1	0
	CCRB1[7:0]							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

49.4.9 CEC reception buffer register 1 (CCRB1)

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	CCRB1[7:0]	All 0	R	Received data is set

Please read CCRB1 register after receiving the 8th bit data.
(After CRD8FLG bit of CECFLG register is changed from "0" to "1")

49.4.10 CEC reception buffer register 2 (CCRB2)

CCRB2

bit:	7	6	5	4	3	2	1	0
	–	–	–	–	–	CCRBAI	CCRBAO	CCRBE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	–	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	CCRBAI	0	R	Reception ACK input bit 0: ACK is detected 1: NACK is detected Please read this bit after 10th bit (ACK bit) reception (after CRD8FLG bit of CECFLG register is changed form “1” to “0”).
1	CCRBAO	0	R/W	Reception ACK output bit 0: Output ACK 1: Output NACK This bit is valid when CRACK bit of CECC2 register is “1” (program insertion).
0	CCRBE	0	R	Reception EOM bit 0: The data block is continued 1: The data block is finished Please read this bit after 10th bit (ACK bit) reception (after CRD8FLG bit of CECFLG register is changed form “1” to “0”).

Please set CCRBAO bit either of the following terms.

- When CRXDEN bit of CECC3 register is “0” (stop transmission)
- When CRXDEN bit of CECC3 register is “1” and receiving from the start bit to EOM bit

Please don’t set CCRBAO bit during receiving ACK bit.

49.4.11 CEC reception follower address register 1 (CRADR1)

CRADR1

bit:	7	6	5	4	3	2	1	0
	CRADRI17	CRADRI16	CRADRI15	CRADRI14	CRADRI13	CRADRI12	CRADRI11	CRADRI10
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description	
7	CRADRI17	0	R/W	Address 0111b select bit	0: not selected
6	CRADRI16	0	R/W	Address 0110b select bit	1: selected
5	CRADRI15	0	R/W	Address 0101b select bit	
4	CRADRI14	0	R/W	Address 0100b select bit	
3	CRADRI13	0	R/W	Address 0011b select bit	
2	CRADRI12	0	R/W	Address 0010b select bit	
1	CRADRI11	0	R/W	Address 0001b select bit	
0	CRADRI10	0	R/W	Address 0000b select bit	

Please select reception follower address of this device.
Please set CRADR1 register when CECEN bit of CECC1 register is “0”.

49.4.12 CEC reception follower address register 2 (CRADR2)

CRADR2

bit:	7	6	5	4	3	2	1	0
	CRADRI27	CRADRI26	CRADRI25	CRADRI24	CRADRI23	CRADRI22	CRADRI21	CRADRI20
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description	
7	CRADRI27	0	R/W	Address 1111b select bit	0: not selected
6	CRADRI26	0	R/W	Address 1110b select bit	1: selected
5	CRADRI25	0	R/W	Address 1101b select bit	
4	CRADRI24	0	R/W	Address 1100b select bit	
3	CRADRI23	0	R/W	Address 1011b select bit	
2	CRADRI22	0	R/W	Address 1010b select bit	
1	CRADRI21	0	R/W	Address 1001b select bit	
0	CRADRI20	0	R/W	Address 1000b select bit	

Please select reception follower address of this device.
Please set CRADR2 register when CECEN bit of CECC1 register is “0”.

In the case that CRADRI27 bit is set to “1”, when the follower address is “1111b”(broadcast) and CRACK bit of CECC2 register is “1” (the hardware insertion of ACK output in the reception), ACK is replied.

In this section, it may be represented as “destination address is matched” that received destination address is matched to the address selected by CRADR1 or CRADR2 registers.

49.4.13 CEC interrupt factor register (CINTR)

CINTR

bit:	7	6	5	4	3	2	1	0
	CINT7	CINT6	CINT5	CINT4	CINT3	CINT2	CINT1	CINT0
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	CINT7	0	R	Interrupt factor 7 0: Reception 8th bit interrupt is not detected 1: Reception 8th bit interrupt is detected This bit is cleared to “0” by writing “1” to CINTCLR7 bit of CINTCLR register.
6	CINT6	0	R	Interrupt factor 6 0: Reception 10th bit interrupt is not detected 1: Reception 10th bit interrupt is detected This bit is cleared to “0” by writing “1” to CINTCLR6 bit of CINTCLR register.
5	CINT5	0	R	Interrupt factor 5 0: Reception error interrupt is not detected 1: Reception error interrupt is detected This bit is cleared to “0” by writing “1” to CINTCLR5 bit of CINTCLR register.
4	CINT4	0	R	Interrupt factor 4 0: Reception start bit interrupt is not detected 1: Reception start bit interrupt is detected This bit is cleared to “0” by writing “1” to CINTCLR4 bit of CINTCLR register.

Bit	Bit Name	Initial Value	R/W	Description
3	CINT3	0	R	Interrupt factor 3 0: Transmission 8th bit interrupt is not detected 1: Transmission 8th bit interrupt is detected This bit is cleared to “0” by writing “1” to CINTCLR3 bit of CINTCLR register.
2	CINT2	0	R	Interrupt factor 2 0: Transmission 10th bit interrupt is not detected 1: Transmission 10th bit interrupt is detected This bit is cleared to “0” by writing “1” to CINTCLR2 bit of CINTCLR register.
1	CINT1	0	R	Interrupt factor 1 0: Transmission NACK interrupt is not detected 1: Transmission NACK interrupt is detected This bit is cleared to “0” by writing “1” to CINTCLR1 bit of CINTCLR register.
0	CINT0	0	R	Interrupt factor 0 0: Arbitration lost interrupt is not detected 1: Arbitration lost interrupt is detected This bit is cleared to “0” by writing “1” to CINTCLR0 bit of CINTCLR register.

49.4.14 CEC interrupt factor clear register (CINTCLR)

CINTCLR

bit:	7	6	5	4	3	2	1	0
	CINTCLR7	CINTCLR6	CINTCLR5	CINTCLR4	CINTCLR3	CINTCLR2	CINTCLR1	CINTCLR0
Initial value:	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7	CINTCLR7	—	W	CEC interrupt factor clear bit 7 0 : no operation 1: Clear CINT7 bit and the interrupt factor indicated by CINT7
6	CINTCLR6	—	W	CEC interrupt factor clear bit 6 0 : no operation 1: Clear CINT6 bit and the interrupt factor indicated by CINT6

Bit	Bit Name	Initial Value	R/W	Description
5	CINTCLR5	–	W	CEC interrupt factor clear bit 5 0 : no operation 1: Clear CINT5 bit and the interrupt factor indicated by CINT5
4	CINTCLR4	–	W	CEC interrupt factor clear bit 4 0 : no operation 1: Clear CINT4 bit and the interrupt factor indicated by CINT4
3	CINTCLR3	–	W	CEC interrupt factor clear bit 3 0 : no operation 1: Clear CINT3 bit and the interrupt factor indicated by CINT3
2	CINTCLR2	–	W	CEC interrupt factor clear bit 2 0 : no operation 1: Clear CINT2 bit and the interrupt factor indicated by CINT2
1	CINTCLR1	–	W	CEC interrupt factor clear bit 1 0 : no operation 1: Clear CINT1 bit and the interrupt factor indicated by CINT1
0	CINTCLR0	–	W	CEC interrupt factor clear bit 0 0 : no operation 1: Clear CINT0 bit and the interrupt factor indicated by CINT0

49.4.15 CEC interrupt mode select register (CINTSEL)

CINTSEL

bit:	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	CINTSEL
Initial value:	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	–	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	CINTSEL	1	R/W	CEC interrupt mode select bit 0: Output the interrupt signals until the interrupt factors are cleared by CINTCLR register 1: Output the interrupt signals for 1 RCLK cycle

49.5 Operation

49.5.1 CEC input/output timing and the specification value

RCLK(32.768KHz) clock is used for source clock of CEC operations for transmission and reception.

Therefore, in the case of the transmission, an output signal is changed at the timing which is created by source clock and which is the nearest as CEC specification value. Also in the case of the reception, an input signal is sampled at the timing which is created by source clock.

An acceptable reception range or an output timing may be expressed by the values in some sections. The nearest timing which is created by source clock is also used for these values.

49.5.2 Digital filter

CEC input signals are transmitted to the internal circuit synchronized with the source clock RCLK. In the case that CFIL bit of CECC2 register is “1”, if the input CEC level is matched two RCLK cycles, the input level is transmitted to the internal circuit.

Figure 49-2 shows the timing diagram of digital filter.

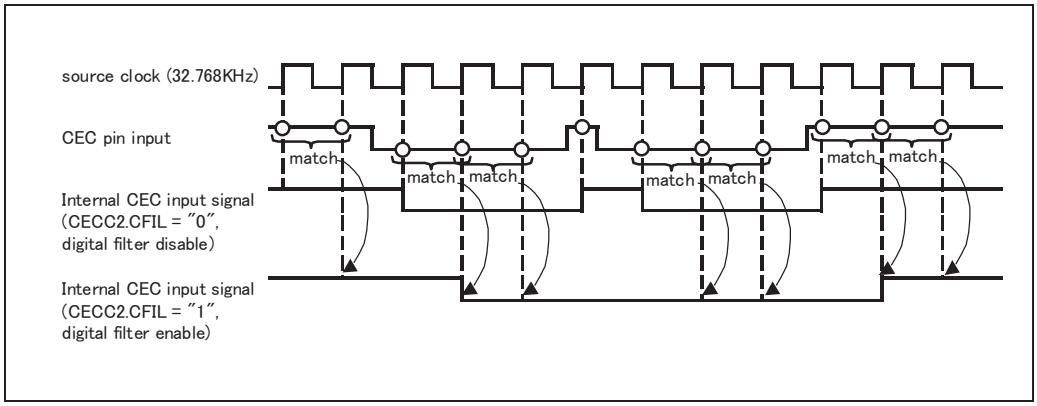

Figure 49-2 Digital filter

49.5.3 Data reception

49.5.3.1 Start bit decision

The decision timing of start and data bit can be selected by CRRNG bit of CECC2 register. The acceptable range of start bit can be selected by CSTRRNG bit of CECC2 register. Figure 49-3 shows the acceptable range of start bit.

When acceptable start bit is detected, CRSTFLG bit of CECFLG register is set to “1” (detect start bit).

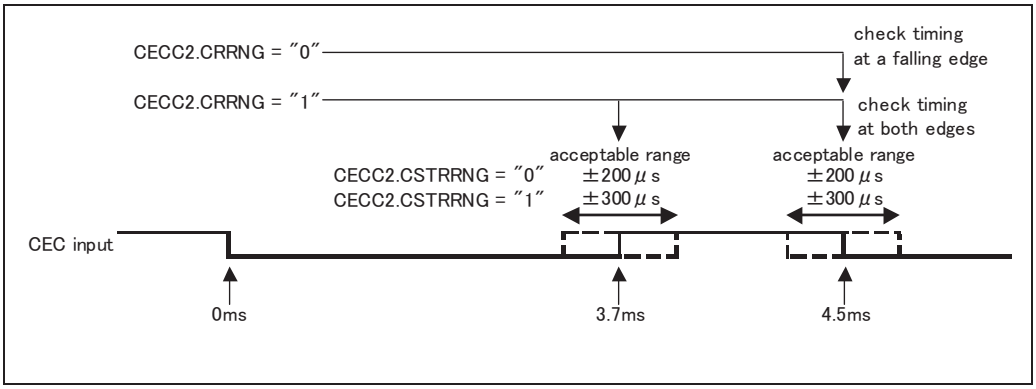

Figure 49-3 Acceptable range of start bit

49.5.3.2 Data bit decision

The decision timing of start and data bit can be selected by CRRNG bit of CECC2 register. The acceptable range of data bit can be selected by CDATRNG bit of CECC2 register. Figure 49-4 and Figure 49-5 shows the acceptable range of data bit.

When CRRNG bit of CECC2 register is “0”, if the CEC rising edge is before 1.05ms, the received data is judged as “1”, and if the CEC rising edge is after 1.05ms, the received data is judged as “0”.

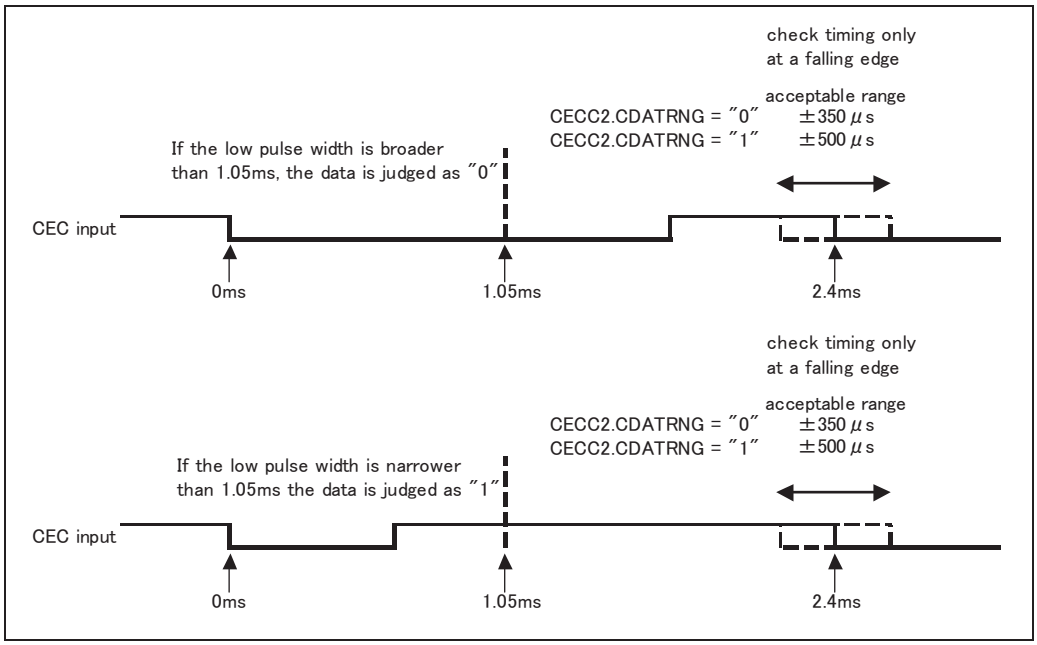

Figure 49-4 Acceptable range of data bit (CECC2.CRRNG = “0”)

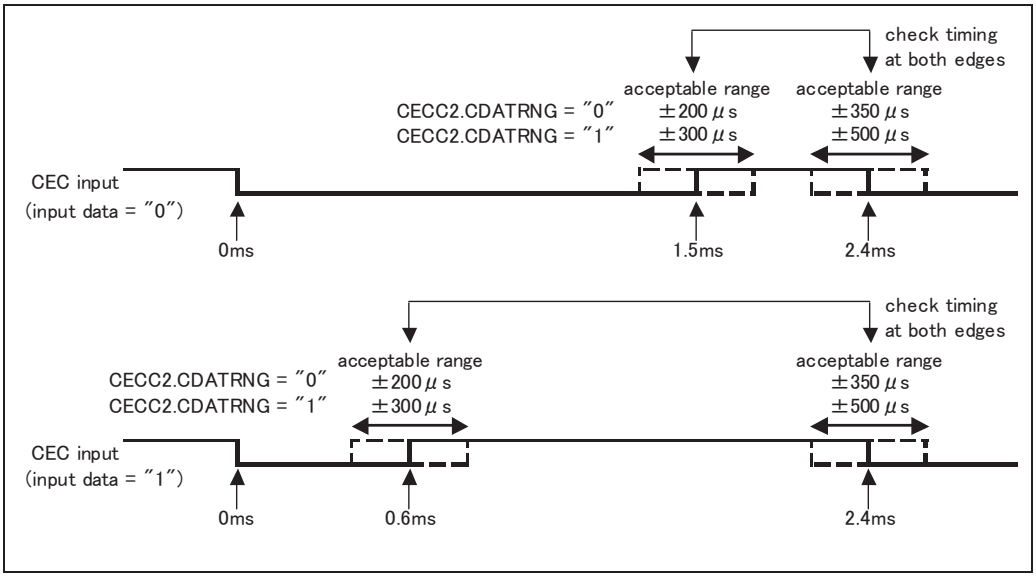

Figure 49-5 Acceptable range of data bit (CECC2.CRRNG = "1")

If the data reception timing is out of the acceptable range, reception error occurs. And it causes following operation.

- CRERRFLG bit of CECFLG register is set to "1"(reception error).
- In the case that CABTEN bit of CECC4 register is "1", 3.6ms "L" pulse is transmitted.

When CABTEN bit of CECC4 register is "1", output timing of error "L" pulse can be selected by CABTWEN bit of CECC4 register. Figure 49-6 shows output timing of error "L" pulse.

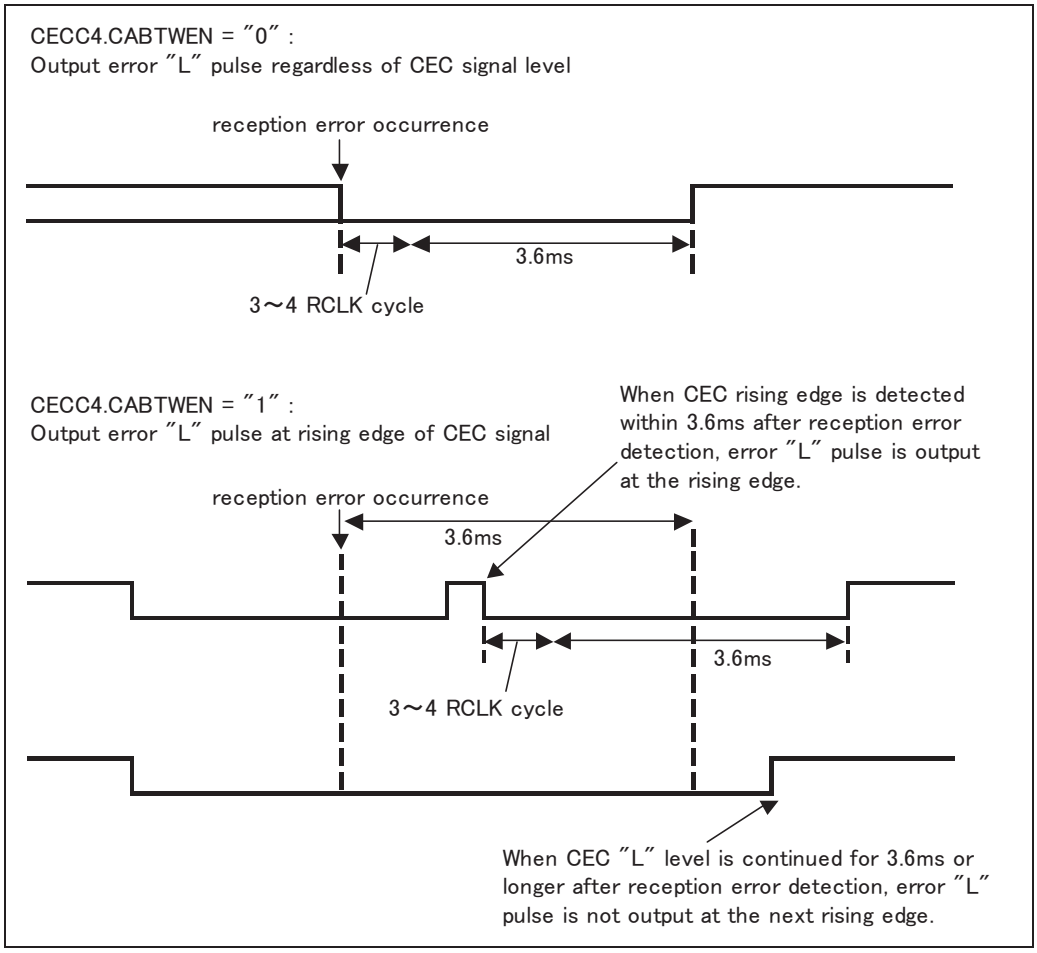

Figure 49-6 Error "L" pulse at reception error (CECC4.CABTEN = "1")

49.5.3.3 ACK bit output

ACK bit value which is transmitted at 10th bit can be selected.

In the case that CRACK bit of CECC2 register is "0" (program insertion), the value which is set to CCRBAO bit of CCRB2 register is output as ACK data.

In the case that CRACK bit is “1” (hardware insertion), the ACK or NACK output is decided by the relation between a received Destination address and the address selected by CRADR1 or CRADR2 registers.

Table 49-7 shows ACK or NACK output conditions.

Table 49-7 ACK output

CRACK bit	CCRBAO bit	Destination Address		ACK output
		Received Destination Address	The own address selected by CRADR1 or CRADR2 registers	
0	0	-	-	ACK
	1	-	-	NACK
1	-	Directly address (0000b～1110b)	Match with received address	ACK
			Not match with received address	NACK
		Broadcast address (1111b)	1111b(match with received address)	ACK
			0000b～1110b	NACK

49.5.3.4 Example of reception sequence

Figure 49-7 shows an example of reception sequence. Figure 49-8 shows an example of reception sequence (error occasion case, changing from “error L pulse disable” to “enable”).

When a reception error is detected, CRERRFLG bit of CECFLG register is set to “1”. When a reception is stopped by a reception error, please set “0” to CRXDEN bit of CECC3 register (reception stop), then CRERRFLG is set to “0”. For restarting reception, please wait for more than 1 RCLK cycle after setting CRXDEN bit “0”, and then set CRXDEN bit “1”(reception permit).

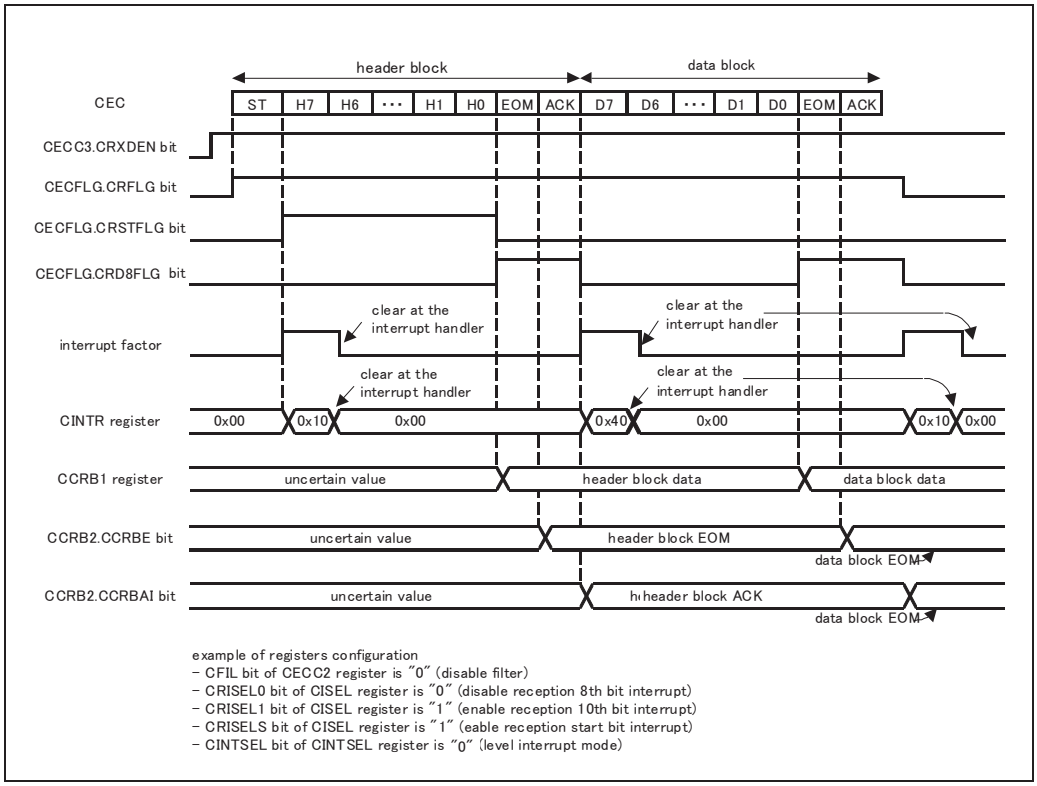

Figure 49-7 Example of reception sequence

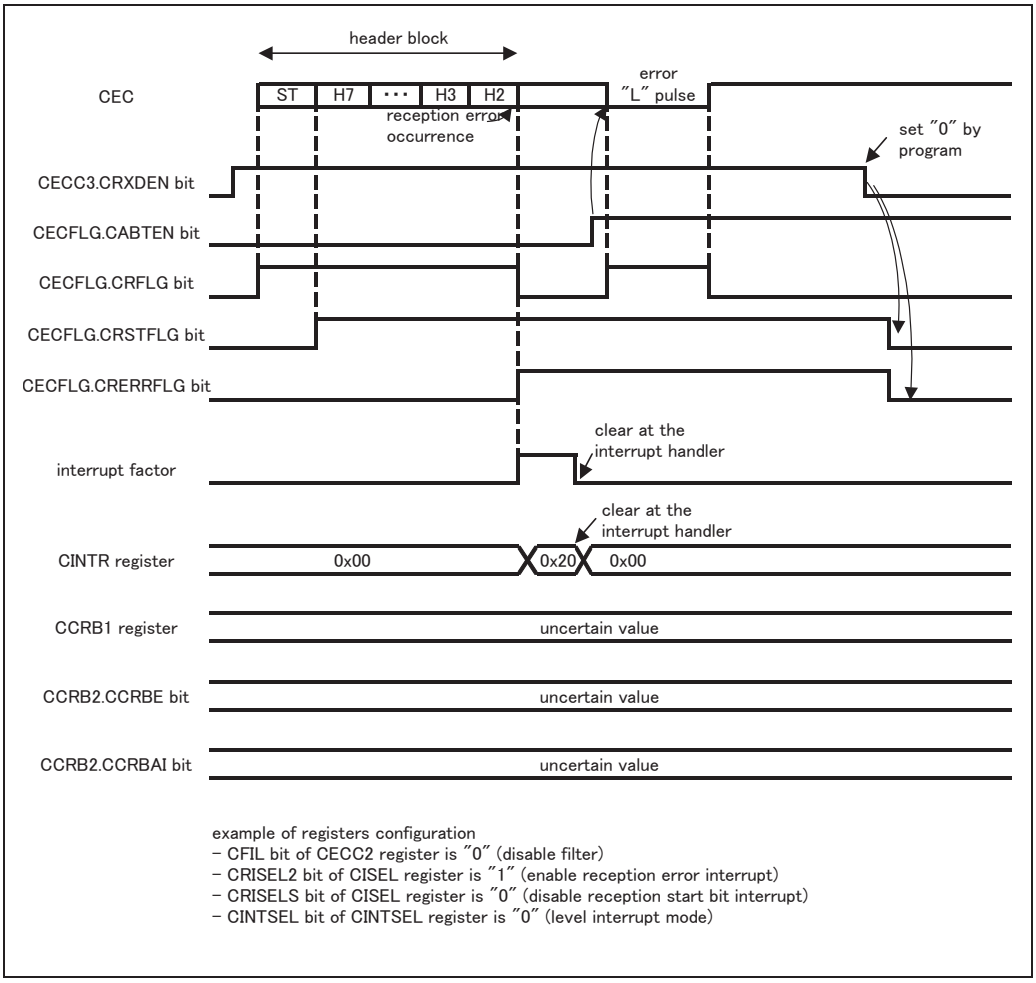

Figure 49-8 Example of reception sequence
(In the case that reception error occurs, and error "L" pulse is changed from disable to enable)

49.5.4 Data transmission

49.5.4.1 Transmission timing select

The rise timing or fall timing of transmission signal can be selected.

The rise timing of transmission signal can be selected by CRISE[2:0] bit of CECC4 register.

Figure 49-9 shows rise timing of transmission signal.

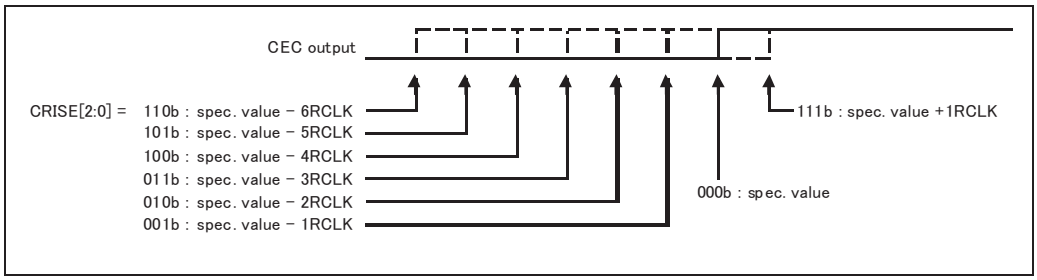

Figure 49-9 Rise timing of transmission signal

The fall timing of transmission signal can be selected by CFALL[1:0] bit of CECC4 register.

Figure 49-10 shows fall timing of transmission signal.

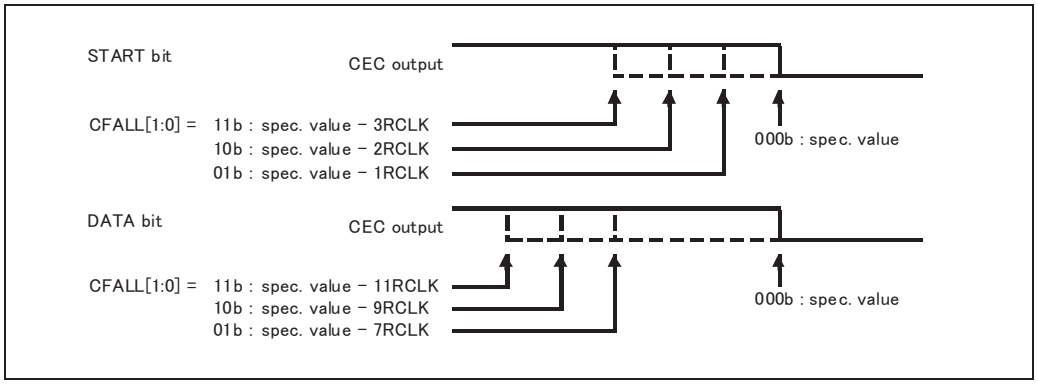

Figure 49-10 Fall timing of transmission signal

49.5.4.2 Arbitration lost detection

During a data transmission, an arbitration lost is detected in the following case

- When this LSI make CEC signal Hi-Z, CEC signal becomes “L” by an external factor.

The range that arbitration lost can be detected at CEC rising edge can be selected by CTABTS bit of CECC2 register. Figure 49-11 shows the range of the arbitration lost detection.

When an arbitration lost is detected, CTABTFLG bit of CECFLG register is set to “1” (arbitration lost detected).

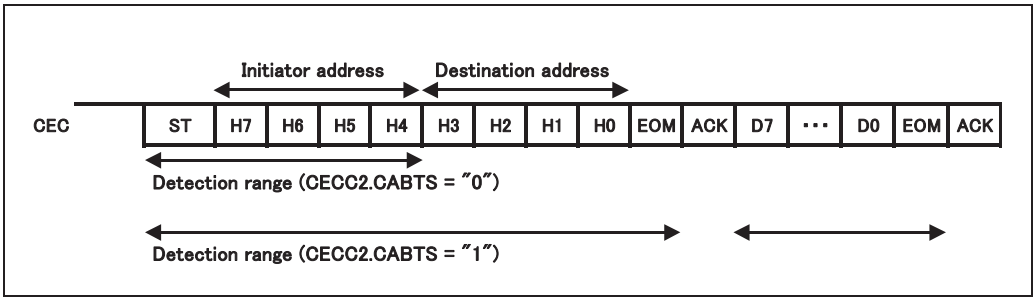

Figure 49-11 The range of arbitration lost detection

49.5.4.3 Example of transmission sequence

Figure 49-12 shows an example of transmission sequence. Figure 49-13 shows an example of transmission sequence (in the case of receiving NACK). And Figure 49-14 shows an example of transmission sequence (in the case of arbitration lost detection).

After transmission completion, please set “0” to CTXDEN bit of CECC3 register (transmission stop). Even in the case continuous transmission, after 1 frame (a header and some data blocks) transmission, please set “0” to CTXDEN. And then, after waiting for more than 1 RCLK cycle, please set CTXDEN bit “1”(transmission permit) again.

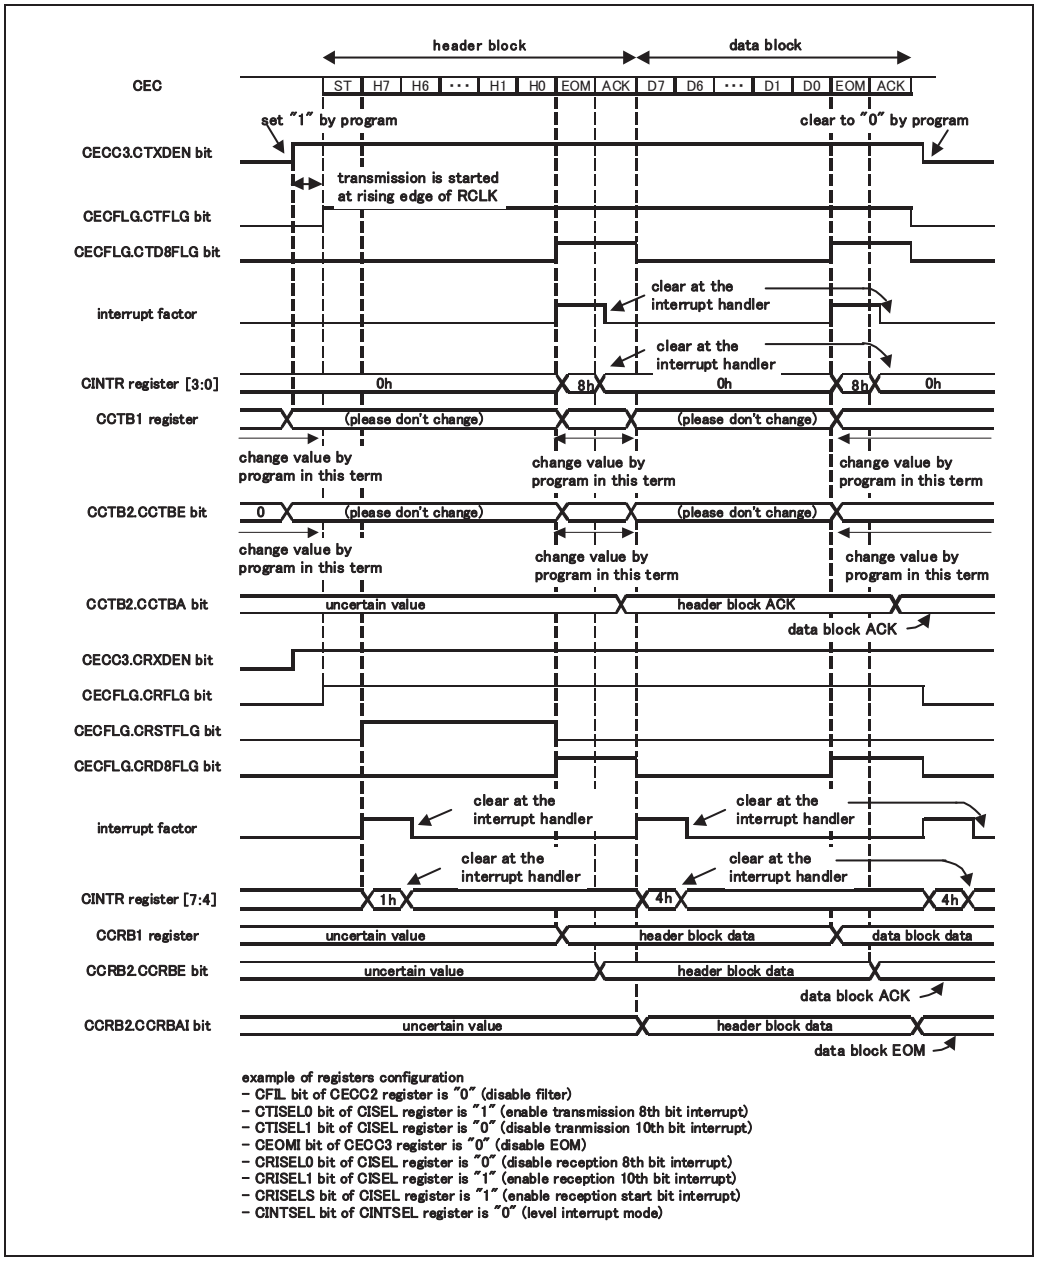

Figure 49-12 Example of transmission sequence

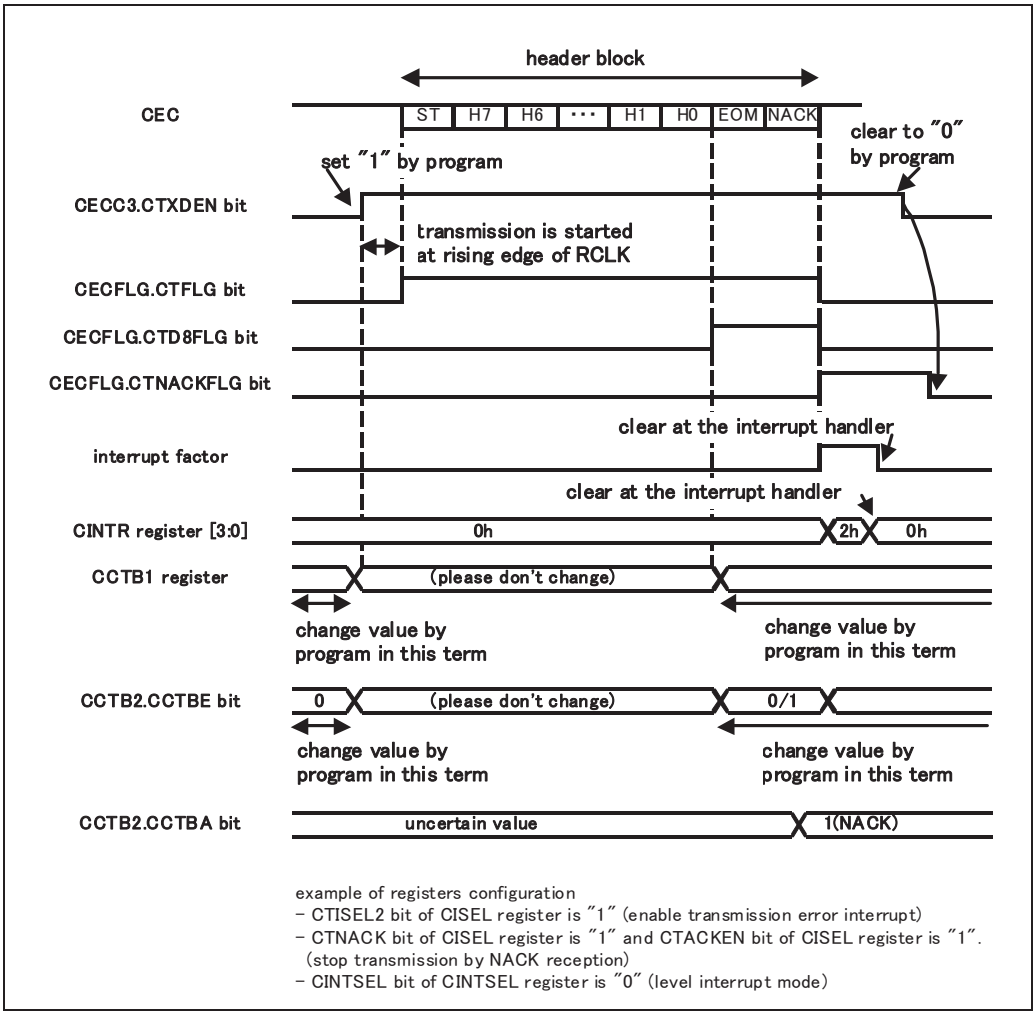

Figure 49-13 Example of transmission sequence (receive NACK)

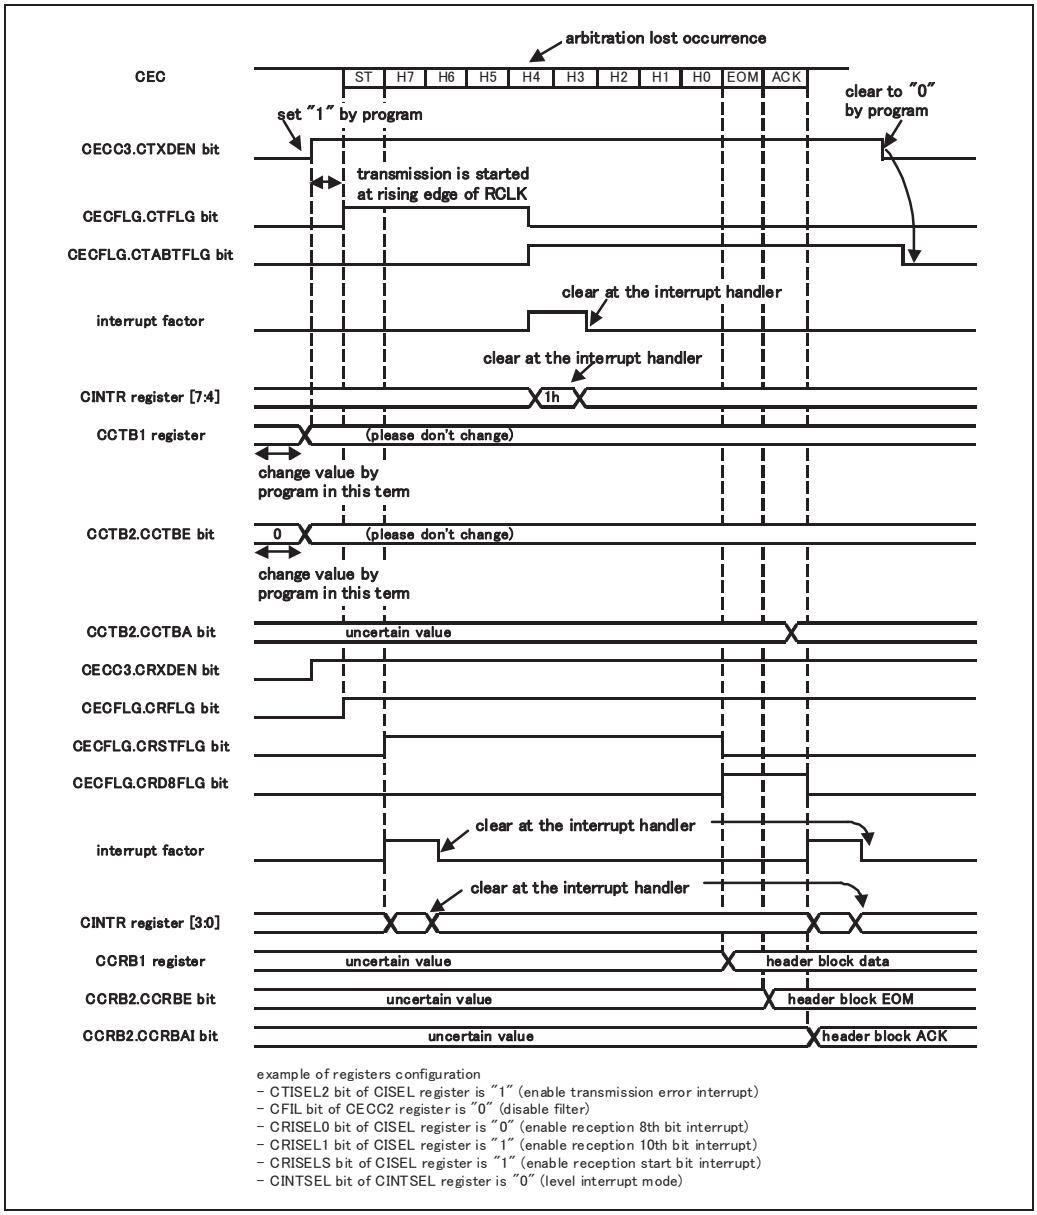

Figure 49-14 Example of transmission sequence (arbitration lost detection)

49.6 Interrupt

CEC function has CEC1 interrupt and CEC2 interrupt.

Table 49-8 and Table 49-9 show the interrupt factor of CEC function. CEC1 interrupt request and CEC2 interrupt request occurs by these interrupt factors. In the case that CRISELM bit of CISEL register is “1”, reception 8th/10th bit interrupt occurs only following cases.

- Destination address matches with the address selected by CRADRI1 register or CRADRI2 register.
- Destination address is Broadcast address (1111b)

Table 49-8 CEC1 interrupt factor

Interrupt type	Interrupt factor	Interrupt request timing	Enable bit
Transmission interrupt	Transmission 8th bit	CECFLG.CTD8FLG bit changes “0” to 1”	CTISEL0
	Transmission 10th bit	CECFLG.CTD8FLG bit changes “1” to “0”	CTISEL1
Transmission error interrupt	Arbitration lost	CECFLG.CTABTFLG bit changes “0” to “1”	CTISEL2
	NACK reception (Directly address) ACK reception (Broadcast address)	CECFLGCTNACKFLG bit changes “0” to “1”	

Table 49-9 CEC2 interrupt factor

Interrupt type	Interrupt factor	Interrupt request timing	Enable bit
Reception interrupt	Reception 8th bit	CECFLG.CRD8FLG bit changes “0” to 1”	CRISEL0
	Reception 10th bit	CECFLG.CRD8FLG bit changes “1” to “0”	CRISEL1
	Start bit detection	CECFLG.CRSTFLG bit changes “0” to “1”	CRISELS
Reception error interrupt	Out of acceptable range	CECFLGCRERRFLG bit changes “0” to “1”	CRISEL2

Figure 49-15 shows block diagram of CEC function interrupt. In the case that CINTSEL bit is "1", interrupt request is maintained until CINT[7:0] bits of CINTR register are cleared by CINTCLR register.

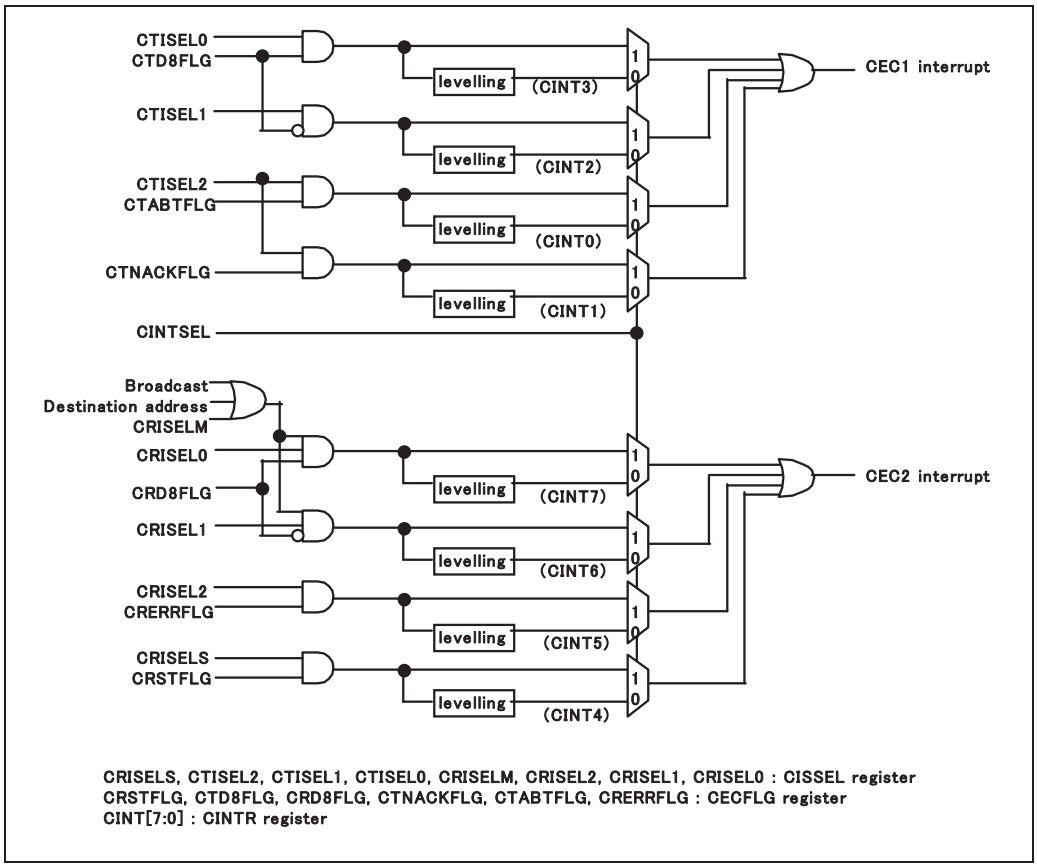

Figure 49-15 Interrupt of CEC function

49.7 Notes for using CEC function

49.7.4.1 Operation of register bits

CEC register bits are operated synchronously with RCLK. When register bit is written by program, the value is changed immediately. But internal circuit acts at RCLK clock timing. Therefore, in the case continuously writing same bit or reading bits which is influenced other bits, please wait for more than 1 RCLK cycle.

Example 1 : In the case continuously writing same bit

(1) Set a bit “0”

(2) Wait 1 RCLK cycle

(3) Change the bit to “1”

Example 2 : In the case reading bits which is influenced other bits

In the case, after stopping reception, reading CRERRFLG bit of CECFLG register “0” (error not detected)

(1) Set CRXDEN bit of CECC3 register “0”(reception stop)

(2) Wait 1 RCLK cycle

(3) Read CRERRFLG bit of CECFLG register

Section 50 Sound Processing Unit 2 (SPU2)

The sound processing unit 2 (SPU2) is a dedicated unit for sound and audio processing, which consists of two DSPs that are specially designed to process audio CODECs such as AAC or MP3 and to perform pre- and post-sound processing and two bus bridges (SPU–DMAC) each of which has a DMAC that can be started by the DSP and system CPU.

The SPU2 is enhanced to support direct access from the system CPU to DSP I/O peripheral modules and access from the DSP to SPU2 external spaces in order to perform pre- and post-processing as well as audio CODEC processing by the DSP.

50.1 Features

Table 50.1 shows the SPU2 functions and features.

Table 50.1 MAC Functions and Features

Component	Item	Description
DMAC	Number of channels	• 3 channels
	Transfer data length	• SHwy: 1 longword (4 bytes), 8 longwords (32 bytes) • DSP-P RAM: 32 bits/32 bits × 8 bursts • DSP-X/Y RAM: 24 bits 16 bits × 16/24 bits × 8 bursts (aligned mode) 24 bits × 10/11 bursts (seamless mode)
	Max. transfer count	• 65,535 (16 bits)
	Address mode	• Dual address mode
	Addressing	• Upper 9 bits fixed (base address) • Fixed/23-bit (8-MByte) increment
	Transfer request	• Auto request
	Priority order	• Fixed (Ch0>Ch1>Ch2)
	Interrupt request	• Interrupt requests can be generated to the SH and DSP at the end of data transfer. Both of interrupt sources and interrupt requests can be masked.
	Data swap	• DMA transfer data can be swapped. (Byte swap, word swap, byte-word swap)
	• A DMAC that supports all the above functions is integrated with a DSP. • The SPU2 has two sets of DSPs and DMACs. • With more than one DSP, transfers between the DSP-X/Y and memory are complete within the SPU without using the SHwy.	

Component	Item	Description
Bus bridge	DSP interface	• Supports DMA transfers between the external memory and the DSP. • Provides direct access to the DSP memory from the CPU in target through mode. • Provides access to the external space (such as the CPU registers) of the SPU2 from the DSP in bus-through mode. • Provides access to the SPU2 registers from the DSP.
Bus bridge	IO interface	• Arbitrates access to the SPU2 registers and external peripheral modules from the DSP and the CPU. • Can be connected with peripheral modules.

Figure 50.1 shows a block diagram of the SPU2.

As shown in the figure, the SPU2 has two DSPs.

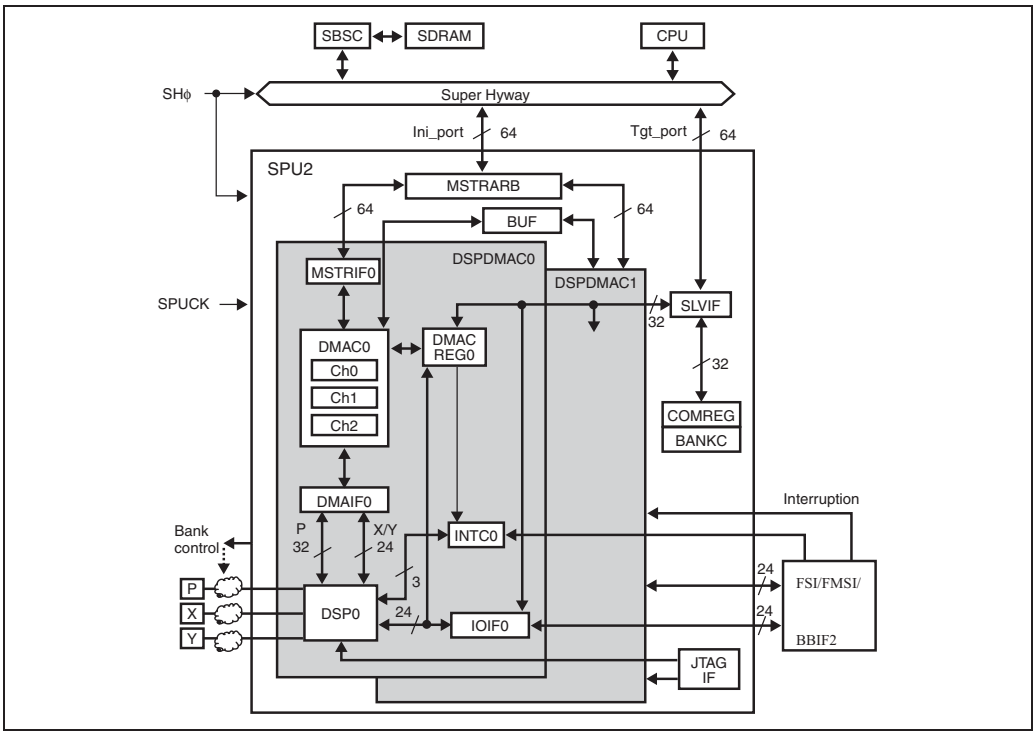

Figure 50.1 SPU2 Block Diagram

Table 50.2 gives a brief description of each block in the SPU2.

Table 50.2 Overview of SPU2 Sub Modules

Module Abbreviation		Overview
SLVIF		• SHwy target interface • One port regardless of the number of DSPs
COMREG		• Global registers shared between the CPU and all integrated DSPs
BANKC		• Memory bank controller used to control memory shared among the DSPs
JTAGIF		• JTAG debug interface supporting multi-core systems
MSTRARB		• SHwy initiator interface • Arbiter that grants SHwy bus mastership to one port when more than one DSP is equipped
BUF		• DMA data buffer used for DMA data communication between the DSPs
DSPDMAC		• One DSPDMAC module integrated (including the following sub modules) when one DSP is equipped.
	DMACREG	• Register used mainly to start a DMAC
	INTC	• DSP interrupt controller • Controls the one-hot condition of the SPU2 internal interrupt sources and two SPU2 external sources.
	IOIF	• DSP-IO interface • Arbitrates access to the DSP-IO space from the DSP and CPU.
	MSTRIF	• Bus master interface that supports SHwy initiator ports • Issues bus commands when a DMAC is started. • Issues bus commands in bus-through mode.
	DMAC	• 3-channel DMA controller
	DMAIF	• DSP's DMA interface
	DSP	• 24-bit DSP dedicated for audio processing

50.2 Register Descriptions

The table below shows the SPU2 register configuration.

Table 50.3 Register Configuration

Register Name	Abbreviation	R/W		Access Size (Bit)		Physical Address	DSP Address
		CPU	DSP	CPU	DSP		
PRAM bank control register 0	PBANKC0	R/W	R	32	24	H'FE2F FC00	H'FF00

50.2.1 PRAM Bank Control Register 0 (PBANKC0)

PBANKC0 is a 32-bit readable/writable register that controls which bank in the program memory (DSP0-PRAM) for one of the SPU2's on-chip DSPs (DSP0) is used. PBANKC0 can be written only by the CPU.

Each of this register indicates the availability of a bank that consists of 32 bits x 8 Kwords. If 1 is set in bit N, then it means DSP0 uses bank N. This product has 40 Kwords of program memory that can be used by DSP0 and DSP1. In the initial state, DSP0 is set to use all of the 40-Kword memory.

Do not set 1 in the same bit position of PBANKC0[4:0] and PBANKC1[4:0].

The register value should be changed after the CPU resets the DSP and before it clears the reset state.

For details, see section 50.3.3, DSP Memory Allocation.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 5	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
4 to 0	PBANKC0 [4:0]	H'1F	R/(W)*	PRAM Bank Control bits for DSP0 0: DSP0 does not use bank N. 1: DSP0 uses bank N.

Note: * Writable only by the CPU.

50.2.2 PRAM Bank Control Register 1 (PBANKC1)

PBANKC1 is a 32-bit readable/writable register that controls which bank in the program memory (DSP1-PRAM) for one of the SPU2's on-chip DSPs (DSP1) is used. PBANKC1 can be written only by the CPU.

Each of this register indicates the availability of a bank that consists of 32 bits × 8 Kwords. If 1 is set in bit N, then it means DSP1 uses bank N. This product has 40 Kwords of program memory that can be used by DSP0 and DSP1. In the initial state, DSP0 is set not to use any of the 40-Kword memory. Refer to the description of the PBANKC0 register to specify the bank to be used by DSP1.

The register value should be changed after the CPU resets the DSP and before it clears the reset state.

For details, see section 50.3.3, DSP Memory Allocation.

4 to 0	PBANKC1 [4:0]	H'00	R/(W)*	PRAM Bank Control bits for DSP1 0: DSP1 does not use bank N. 1: DSP1 uses bank N.

Note: * Writable only by the CPU.

50.2.3 XRAM Bank Control Register 0 (XBANKC0)

XBANKC0 is a 32-bit readable/writable register that controls which bank in the X memory (DSP0-XRAM) for one of the SPU2's on-chip DSPs (DSP0) is used.

Each of this register indicates the availability of a bank that consists of 24 bits × 8 Kwords. If 1 is set in bit N, then it means DSP0 uses bank N. This product has 56 Kwords of memory that can be used by DSP0 and DSP1. In the initial state, DSP0 is set to use all of the 56-Kword memory.

Before the CPU changes the register value, it has to make sure that all of the SPU2's on-chip DSPs are ready for switching banks.

For details, refer to section 50.3.3, DSP Memory Allocation.

31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
6 to 0	XBANKC0 [6:0]	H'7F	R/W	XRAM Bank Control bits for DSP0 0: DSP0 does not use bank N. 1: DSP0 uses bank N.

50.2.4 XRAM Bank Control Register 1 (XBANKC1)

XBANKC1 is a 32-bit readable/writable register that controls which bank in the X memory (DSP1-XRAM) for one of the SPU2's on-chip DSPs (DSP1) is used.

Each bit in this register indicates the availability of a bank that consists of 24 bits × 8 Kwords. If 1 is set in bit N, then it means DSP1 uses bank N. In the initial state, DSP1 is set not to use any bank. Refer to the description of the XBANKC0 register to specify the bank to be used by DSP1.

Before the CPU changes the register value, it has to make sure that all of the SPU2's on-chip DSPs are ready for switching banks.

For details, see section 50.3.3, DSP Memory Allocation.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 0	XBANKC1 [6:0]	H'00	R/W	XRAM Bank Control bits for DSP1 0: DSP1 does not use bank N. 1: DSP1 uses bank N.

50.2.5 SPU Software Reset Register (SPUSRST)

SPUSRST is a 32-bit readable/writable register that controls operation of the registers (SPU software reset) in the SPU.

When the SPUSRST bit is set to 0, the registers in the SPU2 are initialized. As these registers include the DSPRST and DSPCORERST registers, the DSP are also initialized.

When issuing a software reset by writing 0 to any bit in this register, read this register after the write to make sure the bit is written to 0, and then clear the reset by writing 1 to the bit.

When accessing a DSP as a SHwy target, set 1 to make the SPU2 operational. However, host access to SPU2 registers, such as to set the SPUSRST bit to 1 to clear the reset, is always guaranteed.

The BUF3SRST to BUF0SRST bits are software reset registers used to clear buffers for inter-DSP communication and are numbered according to the buffer number. For example, the BUF3SRST bit initializes the DMABUF3 register to 0.

When clearing buffers, reset after the DMA transfer on the channel that is used in an inter-DSP communication is stopped by interrupting the transfer or when it is complete.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	BUF3SRST	1	R/W	DMABUF3 Software Reset bit 0: DMABUF3 is reset. 1: DMABUF3 operates normally.
6	BUF2SRST	1	R/W	DMABUF2 Software Reset bit 0: DMABUF2 is reset. 1: DMABUF2 operates normally.
5	BUF1SRST	1	R/W	DMABUF1 Software Reset bit 0: DMABUF1 is reset. 1: DMABUF1 operates normally.
4	BUF0SRST	1	R/W	DMABUF0 Software Reset bit 0: DMABUF0 is reset. 1: DMABUF0 operates normally.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SPUSRST	1	R/(W)*	SPU2 Software Reset bit 0: SPU2 is reset. 1: SPU2 operates normally.

Note: * Writable only by the CPU.

50.2.6 SPU Address Register (SPUADR)

SPUADR is a 32-bit read-only register that indicates the upper 12 bits (bits 32 to 20) of the physical address of the SPU2.

The DSP can start the DMAC involving the DSP memory by setting the value read from this register in the SBAR or DBAR register (see the description later), even if the SPU2 mapping address varies depending on products. This allows the program more portable.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SPUADR[31:20]												—	—	—	—
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	SPUADR [31:20]	—	R	SPU2 Mapping Address bits These bits indicate the upper 12 bits of the SPU2 mapping address.
19 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

50.2.7 SHwy Endian Register (ENDIAN)

ENDIAN is a 32-bit read-only register that indicates the endian of the SHwy. Reading this register returns the value specified by the MD5 pin in bit 0. This register is useful in cases such as if you want to change data swap methods for the SPU2's on-chip DMAC depending on the endian of the SHwy, allowing the program more portable.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ENDIAN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ENDIAN	—	R	SHwy Endian bit This bit indicates the endian of the SHwy, which is specified by the MD5 pin. 0: The SHwy operates in big endian mode. 1: The SHwy operates in little endian mode.

50.2.8 Global Common Registers 0 to 7 (GCOM0 to 7)

GCOM0 to 7 are 32-bit readable/writable registers that can be controlled by the CPU and all of the SPU2's on-chip DSPs. These registers are mainly used as communication registers for inter-DSP communication.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	GCOMn[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GCOMn[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	GCOMn[23:0]	H'00 0000	R/W	Global Common bits (n=0 to 7) The CPU and all of the SPU2's on-chip DSP can control these bits to use mainly as communication registers for inter-DSP communication.

50.2.9 Internal Transfer Buffer Registers 0 to 3 (DMABUF0 to 3)

DMABUF0 to 3 are read-only registers that are used as temporary buffers for DMA transfers (inter-DSP transfers) within the SPU2 without using the SHwy.

When an inter-DSP transfer is performed by setting the IM1 bit in the CHCR register to 1, the address of this register should be specified as the source or destination address. The CHCR.DAM or CHCR.SAM bit should also be set to 1 to fix the address.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BUFn[23:8]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BUFn[7:0]								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8*	BUFn[23:0]	H'00 0000	R	Buffer for intra-SPU2 DMA transfer (n=0 to 3) When a DMA transfer is performed within the SPU2 without using the SHwy by setting the CHCRn.IM bit to 1, the address of this register should be specified as the source or destination address.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: * DSP: 23 to 0

Two DMA channels should be used for inter-DSP transfers. For example, if inter-DSP communication is to be performed from DSP0-XRAM to DSP1-XRAM as shown in figure 50.2, both DMAC0 and DMAC1 should be started. The source and destination addresses should be set as shown in table 50.5.

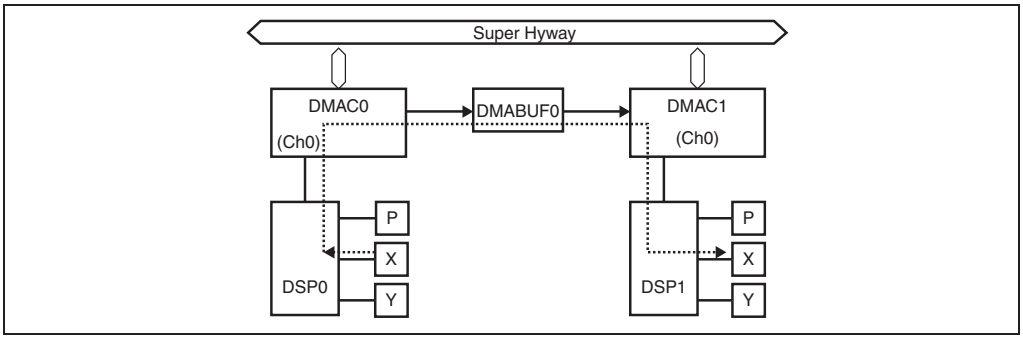

Figure 50.2 Example of Inter-DSP Transfer

Table 50.5 Example of Inter-DSP Communication Setting

Example of Setting for Transfer from DSP0-XRAM to DSP1-XRAM (SHwy Bypassed)	Source Address (SBAR00, SAR00)	Destination Address (DBAR01, DAR01)
DMAC0 CH0	DSP0-XRAM	DMABUF0/1/2/3 (fixed)
DMAC1 CH0	DMABUF0/1/2/3 (fixed)	DSP1-XRAM

50.2.10 DSP Full Reset Register (DSPRST)

DSPRST is a 32-bit readable/writable register. Only the CPU can write to this register.

The SPU2's on-chip DSP has two reset control bits, the DSPRST bit in this register and the DSPCORERST bit in the DSPCORERST register, that can be used to control DSP full reset and DSP core reset respectively.

The SPU2's on-chip DSP can be divided into DSP core, DSP memory shell, and DSP debug module. While the DSPRST bit in this register is 1, all FFs in them except the DSP debug module are initialized.

While this bit is 1, the DSP memory shell is also initialized and the DSP-P/X/YRAM cannot be accessed. Therefore, when downloading a DSP program, set this bit to 0 to clear the DSP initialized state. When doing it, however, do not write 0 to the DSPCORERST register described below.

Note that setting this register to 1 does not initialize the DMAC control registers such as SAR or CHCR and the SPU2 registers such as DSP-CPU communication registers (e.g. COM0). These registers must be initialized individually.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSP RST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DSPRST	1	R/(W)*	DSPn Reset bit 0: Activates the DSP (i.e., clears the DSP reset). 1: Resets the DSP.

Note: * Writable only by the CPU.

50.2.11 DSP Core Reset Register (DSPCORERST)

DSPCORERST is a 32-bit readable/writable register. Only the CPU can write to this register.

The SPU2's on-chip DSP can be divided into DSP core, DSP memory shell, and DSP debug module. While the DSPCORERST bit is 1, only the DSP core is initialized.

While this bit is 1, the DSP memory shell is not initialized and DSP memory access such as to download DSP programs is still available. To reset when downloading them, follow the steps below.

1. Initial sate (after a power-on reset)
   DSPRST = 1 (DSP full reset)
   DSPCORERST = 1
2. DSP reset control 1
   DSPRST = 0 (clear the DSP full reset.)
   DSPCORERST = 1 (initial value: initializes the DSP core only.)
   Download the desired data to the DSP-P/X/Y.
3. DSP reset control 2
   DSPRST = 0 (clear the DSP full reset.)
   DSPCORERST = 0 (clear the DSP core reset, start a program fetch.)

Note that similarly to the DSPRST register, setting the DSPCORERST register to 1 does not initialize the DMAC control registers such as SAR or CHCR and the SPU2 registers such as DSP-CPU communication registers (e.g. COM0). These registers must be initialized individually.

31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DSPCORERST	1	R/(W)*	DSP Core Reset bit 0: Activates the DSP core (i.e., clears the DSP core reset). 1: Resets the DSP core.

Note: * Writable only by the CPU.

50.2.12 DSP Hold Register (DSPHOLD)

DSPHOLD is a 32-bit read-only register. The STOP_ACK bit indicates the DSP core status.

The HOLD_ACK bit is the acknowledge status of the hold request when the DSP makes access with wait state to I/O peripheral modules. When this bit is 1, the DSP is in hold state.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	STOP_ACK	1	R	STOP Acknowledge bit This bit is set when the DSP core is reset. 0: The DSP core is normal. 1: The DSP core is reset.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	HOLD_ACK	0	R	DSP Hold Acknowledge bit 0: The DSP core is active. 1: The DSP core is in hold state.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

50.2.13 DSP Restart Register (DSPRESTART)

DSPRESTART is a 32-bit readable/writable register. Only the CPU can write to this register.

The HALT_ACK bit is set to 1 when the DSP is in halt state. To clear this halt state, set the RESTART bit to 1. When the DSP detects the restart signal and the halt signal from the DSP is negated, the RESTART bit is automatically updated to 0.

31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	RESTART	0	R/(W)*	DSP Restart bit This bit can be used to clear the DSP halt state. 0: Does not restart the DSP. 1: Restarts the DSP.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	HALT_ACK	0	R	DSP Halt Acknowledge bit 0: The DSP is active. 1: The DSP is in halt state.

Note: * Writable only by the CPU.

50.2.14 CPU Interrupt Source Mask Register (IEMASKC)

IEMASKC is a 32-bit readable/writable register that masks various interrupt sources to the CPU individually. If this register masks an interrupt source, the interrupt source is not enabled even if the corresponding interrupt is unmasked by the IMASKC register described later. Thus, the interrupt does not occur.

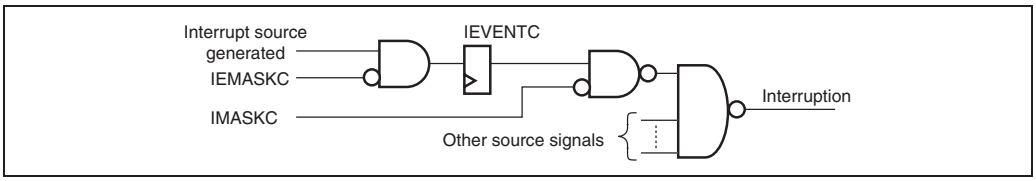

Figure 50.3 CPU Interrupt Source Mask

12	DSPIEMASKC	1	R/W	Mask bit for the source of the DSP register setting interrupt to the CPU Set this bit to 0 when the DSPIEVENTC bit in the IEVENTC register should be set. 0: Does not mask the interrupt source (i.e., enables the interrupt source). 1: Masks the interrupt source (i/e., disables the interrupt source).

Bit	Bit Name	Initial Value	R/W	Description
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CH2IEMASKC	1	R/W	Mask for the source of the CH2 transfer end interrupt related to CPU interrupt Set this bit to 0 when the interrupt source should be generated after CH2 DMA transfer is complete. 0: Does not mask the interrupt source (i.e., enables the interrupt source). 1: Masks the interrupt source (i.e., disables the interrupt source).
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CH1IEMASKC	1	R/W	Mask for the source of the CH1 transfer end interrupt related to CPU interrupt Set this bit to 0 when the interrupt source should be generated after CH1 DMA transfer is complete. 0: Does not mask the interrupt source (i.e., enables the interrupt source). 1: Masks the interrupt source (i.e., disables the interrupt source).
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CH0IEMASKC	1	R/W	Mask for the source of the CH0 transfer end interrupt related to CPU interrupt Set this bit to 0 when the interrupt source should be generated after CH0 DMA transfer is complete. 0: Does not mask the interrupt source (i.e., enables the interrupt source). 1: Masks the interrupt source (i.e., disables the interrupt source).

50.2.15 CPU Interrupt Signal Mask Register (IMASKC)

IMASKC is a 32-bit readable/writable register that masks various interrupts to the CPU individually.

To generate an interrupt request signal for an interrupt source, set the related bit in this register to 0 and also set the related mask bit in the IEMASKC register above to 0. If the IEMASKC register masks an interrupt source, the interrupt request signal does not occur even if the IMASKC register unmasks the interrupt signal.

12	DSPIMASKC	1	R/W	Mask bit for the DSP register setting interrupt to the CPU If the DSP set the DSPEVENTC bit in the IEVNTC register to 1 and also sets this mask bit to 0, then the interrupt request is generated to the CPU. 0: Does not mask the interrupt (i.e., enables the interrupt request signal). 1: Masks the interrupt (i.e., disables the interrupt request signal).
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CH2IMASKC	1	R/W	Mask bit for the CH2 transfer end interrupt 0: Does not mask the interrupt (i.e., enables the interrupt request signal). 1: Masks the interrupt (i.e., disables the interrupt request signal).

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CH1IMASKC	1	R/W	Mask bit for the CH1 transfer end interrupt 0: Does not mask the interrupt (i.e., enables the interrupt request signal). 1: Masks the interrupt (i.e., disables the interrupt request signal).
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CH0IMASKC	1	R/W	Mask bit for the CH0 transfer end interrupt 0: Does not mask the interrupt (i.e., enables the interrupt request signal). 1: Masks the interrupt (i.e., disables the interrupt request signal).

50.2.16 CPU Interrupt Source Register (IEVENTC)

IEVENTC is a 32-bit readable/writable register that indicates the source of an interrupt to the CPU. The CPU can only clear the register to 0. Even it attempts to write 1 to the register, the register remains unchanged. When using the interrupt handler to clear the interrupt source related to one CHIEVENTC bit, set the other CHIEVENTC bits to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	DSPIEVENTC	0	R/W*1	Source of the DSP register setting interrupt to the CPU Only the DSP can write to this bit. If the IEMASKC and IMASKC registers cancel the mask and the DSP sets this bit to 1, the interrupt request is generated to the CPU. The CPU can write nothing but 0. 0: The DSP register setting interrupt is not generated. 1: The DSP register setting interrupt is generated.
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CH2IEVENTC	0	R/W*2	Source of the CH2 transfer end interrupt 0: The CH2 transfer end interrupt is not generated. 1: The CH2 transfer end interrupt is generated.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	CH1IEVENTC	0	R/W*2	Source of the CH1 transfer end interrupt 0: The CH1 transfer end interrupt is not generated. 1: The CH1 transfer end interrupt is generated.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CH0IEVENTC	0	R/W*2	Source of the CH0 transfer end interrupt 0: The CH0 transfer end interrupt is not generated. 1: The CH0 transfer end interrupt is generated.

Note: *1 Only the DSP can write 1 to the DSPIEVENTC bit. The CPU can only clear it to 0.
*2 The CPU can only clear the CHIEVENTC bits to 0. Even if it attempts to write 1 to these bits, they remain unchanged.

50.2.17 DSP Interrupt Source Mask Register (IEMASKD)

IEMASKD is a 32-bit readable/writable register that masks various interrupt sources to the DSP individually. If this register masks an interrupt source, the interrupt source is not enabled even if the IMASKD register described later unmasks the interrupt. Thus, that interrupt does not occur.

11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	CH2IE MASKD	1	R/W	Mask bit for the source of the CH2 transfer end interrupt related to DSP interrupt To generate the interrupt source after the completion of CH2 DMA transfer, set this mask bit to 0. 0: Does not mask the interrupt source (i.e., enables the interrupt source). 1: Masks the interrupt source (i.e., disables the interrupt source).
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CH1IE MASKD	1	R/W	Mask bit for the source of the CH1 transfer end interrupt related to DSP interrupt To generate the interrupt source after the completion of CH1 DMA transfer, set this mask bit to 0. 0: Does not mask the interrupt source (i.e., enables the interrupt source). 1: Masks the interrupt source (i.e., disables the interrupt source).
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CH0IE MASKD	1	R/W	Mask bit for the source of the CH1 transfer end interrupt related to DSP interrupt To generate the interrupt source after the completion of CH0 DMA transfer, set this mask bit to 0. 0: Does not mask the interrupt source (i.e., enables the interrupt source). 1: Masks the interrupt source (i.e., disables the interrupt source).

50.2.18 DSP Interrupt Mask Register (IMASKD)

IMASKD is a 32-bit readable/writable register that masks various interrupts to the DSP individually.

To generate an interrupt request signal for an interrupt source, set the related source bit in this register to 0 and also set the related source mask bit in the IEMASKD register above to 0. If the IEMASKD register masks an interrupt source, the interrupt request signal does not occur even if the IMASKD register clears the interrupt mask.

8	CH2IMASKD	1	R/W	Mask bit for the CH2 transfer end interrupt 0: Does not mask the interrupt (i.e., enables the interrupt request signal). 1: Masks the interrupt (i.e., disables the interrupt request signal).
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	CH1IMASKD	1	R/W	Mask bit for the CH1 transfer end interrupt 0: Does not mask the interrupt (i.e., enables the interrupt request signal). 1: Masks the interrupt (i.e., disables the interrupt request signal).
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CH0IMASKD	1	R/W	Mask bit for the CH0 transfer end interrupt 0: Does not mask the interrupt (i.e., enables the interrupt request signal). 1: Masks the interrupt (i.e., disables the interrupt request signal).

50.2.19 DSP Interrupt Set Register (IESETD)

IESETD is a 32-bit readable/writable register that indicates the source of an interrupt to the DSP. When using the interrupt handler to clear an interrupt source, this register is updated by writing 0 to each bit of the IECLRD register.

When an interrupt whose source can be identified by this register occurs, int[2] of the interrupt signal int[2:0] to the DSP is asserted. If int[2] is asserted and the DSP accepts it, the DSP program counter jumps to the interrupt vector irq3 to handle the interrupt.

Similarly to int[2], interrupts to the DSP from SPU2 peripheral modules are assigned to int[1:0] and these interrupts are handled by jumping to irq2 with int[1] and to irq1 with int[0].

21	DSP1IESETD	0	R/(W)*	Source bit of the register setting interrupt from DSP1 0: The register setting interrupt to the DSP is not generated by DSP1. 1: The register setting interrupt to the DSP is generated by DSP1.
20	DSP0IESETD	0	R/(W)*	Source bit of the register setting interrupt from DSP0 0: The register setting interrupt to the DSP is not generated by DSP0. 1: The register setting interrupt to the DSP is generated by DSP0.
19 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	CPUIESETD	0	R/(W)*	Source of the CPU register setting interrupt to the DSP Only the CPU can write to this bit. When the IEMASKD and IMASKD registers clear the masks and the CPU sets this bit to 1, the interrupt request is generated to the DSP. 0: The CPU register setting interrupt is not generated. 1: The CPU register setting interrupt is generated.
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	BTIESETD	0	R/W	Source of the bus-through access end interrupt 0: The bus-through access end interrupt is not generated. 1: The bus-through access end interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CH2IESETD	0	R/W	Source of the CH2 transfer end interrupt 0: The CH2 transfer end interrupt is not generated. 1: The CH2 transfer end interrupt is generated.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CH1IESETD	0	R/W	Source of the CH1 transfer end interrupt 0: The CH1 transfer end interrupt is not generated. 1: The CH1 transfer end interrupt is generated.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CH0IESETD	0	R/W	Source of the CH0 transfer end interrupt 0: The CH0 transfer end interrupt is not generated. 1: The CH0 transfer end interrupt is generated.

Note: * Each DSP can write 1 to the DSPnIESETD bit only. It should write 1 to the DSPnIESETD bit corresponding the number of the DSP to which an interrupt request should be sent. Even if it writes 0 to the bit, the bit value remains unchanged (0 is no written). Only the CPU can write 1 to the CPUIESETD bit. Even if it writes 0 to the bit, the bit value remains unchanged (0 is no written).

50.2.20 DSP Interrupt Clear Register (IECLRD)

IECLRD is a 32-bit readable/writable register that is used to clear the source of an interrupt to the DSP. To clear an interrupt source with the interrupt handler, write 0 to the bit related to that source and also write 1 to the other bits. If you write 0 to a bit not related to that source, an inappropriate interrupt source might be cleared.

Only one source can be cleared at a time. Even if interrupts by more than one interrupt source are detected by reading this register, clear only one source, perform the processing related to the source, and then return to the main routine. In this case, another interrupt should be detected immediately after returning to the main routine. If you clear more than one source at a time, more interrupts are to be generated than expected and interrupts without interrupt sources may be detected.

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	DSP1IECLRD	0	R/(W)*	Bit for clearing the source of the register setting interrupt to the DSP from DSP1 0: The register setting interrupt to the DSP from DSP1 is absent (cleared). 1: The register setting interrupt to the DSP from DSP1 is present.
20	DSP0IECLRD	0	R/(W)*	Bit for clearing the source of the register setting interrupt to the DSP from DSP0 0: The register setting interrupt to the DSP from DSP0 is absent (cleared). 1: The register setting interrupt to the DSP from DSP0 is present.

Bit	Bit Name	Initial Value	R/W	Description
19 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	CPUIECLRD	0	R/(W)*	Bit for clearing the source of the CPU register setting interrupt to the DSP 0: The CPU register setting interrupt is absent (cleared). 1: The CPU register setting interrupt is present.
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	BTIECLRD	0	R/(W)*	Bit for clearing the source of the bus-through access end interrupt 0: The bus-through access end interrupt is absent (cleared). 1: The bus-through access end interrupt is present.
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CH2IECLRD	0	R/(W)*	Bit for clearing the source of the CH2 transfer end interrupt destined to the DSP. 0: The CH2 transfer end interrupt is absent (cleared). 1: The CH2 transfer end interrupt is present.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CH1IECLRD	0	R/(W)*	Bit for clearing the source of the CH1 transfer end interrupt destined to the DSP. 0: The CH1 transfer end interrupt is absent (cleared). 1: The CH1 transfer end interrupt is present.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	CH0IECLRD	0	R/(W)*	Bit for clearing the source of the CH0 transfer end interrupt destined to the DSP. 0: The CH0 transfer end interrupt is absent (cleared). 1: The CH0 transfer end interrupt is present.

Note: * Only writing 0 is reflected on each DSP. Write 0 to the bit related to the source to be cleared and write 1 to the other bits. Only one source can be cleared at a time.

50.2.21 DMAC Operation Register (OR)

OR is a 32-bit readable/writable register that includes the master enable bit to control all transfer channels apart from the CHCR.DE bit that enables or disables one channel at a time.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DME	0	R/W	DMA Master Enable This bit enables or disables all transfer channels. 0: Disables all transfer channels. 1: Enables all transfer channels.

50.2.22 CPU-DSP Communication Registers 0 to 7 (COM0 to 7)

COM0 to COM7 are 32-bit readable/writable registers that are used for communication between the CPU and the DSP. Both of them can write to these registers. These registers contain 192 bits (24 bits x 8) whose usages are defined according to system-specific needs. These register values do not affect to the SPU2 operation at all.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	COMn[23:16]

23 to 0	COMn[23:0]	H'00 0000	R/W	Bits for communication between the CPU and the DSP (n = 0 to 7) These bits can be defined for communication between the CPU and the DSP.

50.2.23 Bus-Through Address High Register (BTADRU)

BTADRU is a 32-bit readable/writable register that specifies the upper address when the DSP accesses SPU2 external registers or SDRAM. This upper address is concatenated with the lower address specified in the BTADRL register below to access the SPU2 external space.

For details, see 50.2.29, Bus-Through Mode Control Register (BTCTRL).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

15 to 0	BTADR[31:16]	H'0000	R/W	Upper bits of the bus-through address These bits specify the upper address (16 bits) when the DSP accesses the SPU2 external space in bus-through mode.

50.2.24 Bus-Through Address Low Register (BTADRL)

BTADRL is a 32-bit readable/writable register that specifies the lower address when the DSP accesses SPU2 external registers or SDRAM. This lower address is concatenated with the upper address specified in the BTADRU register above to access the SPU2 external space.

For details, see section, 50.2.29 Bus-Through Mode Control Register (BTCTRL).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	BTADR[15:0]	H'0000	R/W	Lower bits of the bus-through address These bits specify the lower address (16 bits) when the DSP accesses the SPU2 external space in bus-through mode.

50.2.25 Bus-Through Write Data High Register (WDATU)

WDATU is a 32-bit readable/writable register that specifies the upper bits of write data when the DSP makes write access to SPU2 external registers or SDRAM.. These upper bits of data are concatenated with the lower bits of data specified in the WDATL register below to make write access to the SPU2 external space.

For details, see section 50.2.29, Bus-Through Mode Control Register (BTCTRL).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	WDAT[31:16]	H'0000	R/W	Upper bits of write data in bus-through write mode These bits specify the upper 16 bits of write data when the DSP makes 32-bit write access to the SPU2 external space in bus-through mode.

50.2.26 Bus-Through Write Data Low Register (WDATL)

WDATL is a 32-bit readable/writable register that specifies the lower bits of write data when the DSP makes write access to SPU2 external registers or SDRAM.. These lower bits of write data are concatenated with the upper bits of write data specified in the WDATU register above to make write access to the SPU2 external space.

For details, see section 50.2.29, Bus-Through Mode Control Register (BTCTRL).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	WDAT[15:0]	H'0000	R/W	Lower bits of write data in bus-through write mode These bits specify the lower 16 bits of write data when the DSP makes 32-bit write access to the SPU2 external space in bus-through mode. For 32-bit access: Specify the lower 16 bits of 32-bit data. For 16-bit access: Specify 16 bits. For 8-bit access: Specify 8 bits in bits[7:0].

50.2.27 Bus-Through Read Data High Register (RDATU)

RDATU is a 32-bit read-only register that contains the upper bits of read data when the DSP makes 32-bit read access to the SPU2 external registers or SDRAM.

For details, see section 50.2.29, Bus-Through Mode Control Register (BTCTRL).

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	RDAT{31:16}	H'0000	R	Upper bits of read data in bus-through read mode These bits contain the upper 16 bits of read data when the DSP makes 32-bit read access to the SPU2 external space in bus-through mode.

50.2.28 Bus-Through Read Data Low Register (RDATL)

RDATL is a 32-bit read-only register that contains the lower bits of read data when the DSP makes 32-bit read access to the SPU2 external registers or SDRAM and the whole read data bits when it makes 16-/8-bit read access.

For details, see section 50.2.29, Bus-Through Mode Control Register (BTCTRL).

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	RDAT[15:0]	H'0000	R	Lower bits of read data in bus-through read mode These bits contain the lower 16 bits of read data when the DSP makes 32-bit read access to the SPU2 external space and contain the whole read data bits when it makes 16-/8-bit access in bus-through mode. In 8-bit read access, bit 8 out of bits[15:8] is updated to 0 and read data are contained in bits[7:0].

50.2.29 Bus-Through Mode Control Register (BTCTRL)

BTCTRL is a register that can be read and written only by the DSP, which controls bus-through mode. The CPU can only read it. Bus-through mode refers to the way in which the DSP accesses the SPU2 external registers or SDRAM.

This register controls the type (read/write) and size of access in bus-through mode.

Write 1 to either of the BTR or BTW bit at a time. When the desired access is complete after writing 1 to the bit, it returns to 0 automatically.

In read access, the BTR bit returns to 0 automatically when the RDATU/RDATL register stores the read data.

In write access, the BTW bit returns to 0 automatically when the response packet to the store access to the Super Hyway is received. Therefore, you should read the data at the same address as the target write access in order to make sure if the write data is written completely.

R/W:	R	R	R/(W)*	R/(W)*	R	R	R	R	R	R	R	R/(W)*	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13, 12	BTS[1:0]	00	R/(W)*	These bits specify the access size in bus-through mode. 00: 32 bits (LOAD4/STORE4) 01: 16 bits (LOAD2/STORE2) 10: 8 bits (LOAD1/STORE1) 11: Setting prohibited
11 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	BTW	0	R/(W)*	Control bit for write access in bus-through mode Do not set this bit and the BTR bit to 1 at a time. Also, do not set this bit to 1 when the BTR bit is 1. 0: No write access is in progress or the write access is complete. 1: Starts a write access or the write access is in progress.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	BTR	0	R/(W)*	Control bit for read access in bus-through mode Do not set this bit and the BTW bit to 1 at a time. Also, do not set this bit to 1 when the BTW bit is 1. 0: No read access is in progress or the read access is complete. 1: Starts a read access or the read access is in progress.

Note: * Writable only by the DSP.

Figure 50.5 shows a flow chart of a memory access in bus-through mode. If you do not need to make sure if the data is written completely in write access, you can perform other processing after writing 1 to the BTW bit in the BTCTL register.

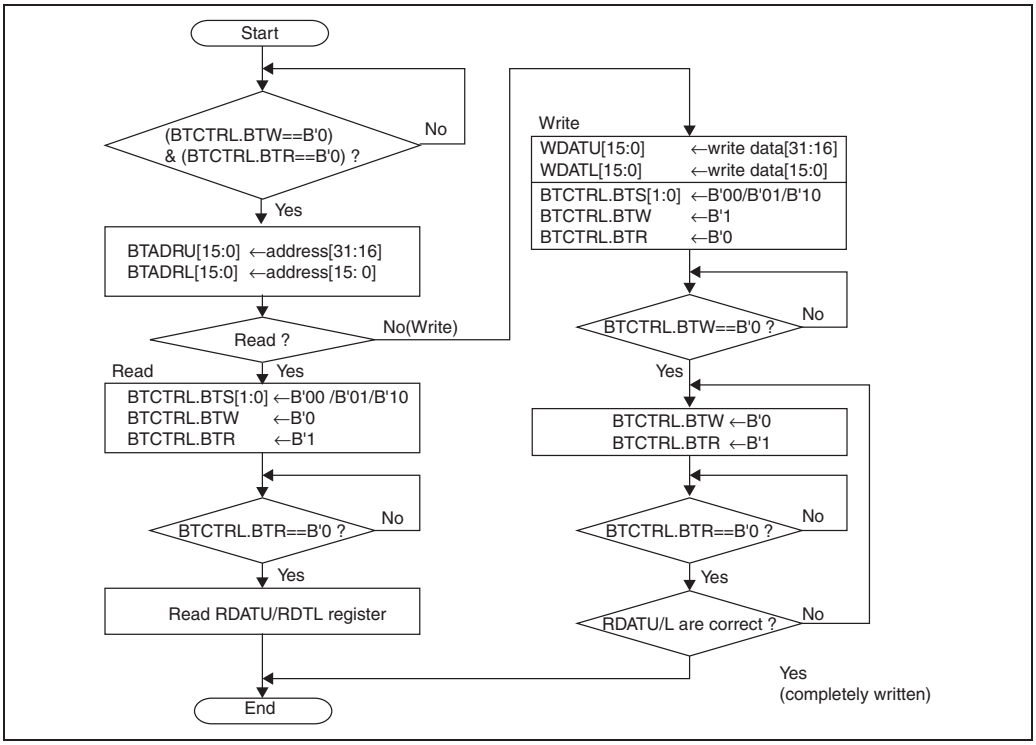

Figure 50.5 Flow Chart of Accessing SPU2 External Space in Bus-Through Mode (Example of Polling Register)

50.2.30 SPU Status Register (SPUSTS)

SPUSTS is a 32-bit read-only register. By reading this register, you can check the DMA transfer status and determine if there is any ongoing bus-through access at the time when it is read.

The DMA_ON bit is 1 while there is ongoing DMA transfer or bus-through access from the DSP to the SPU2 external space. To check if DMA transfer is stopped after setting the DME bit in the OR register or the DE bit in the CHCR register (that corresponds to the channel to stop) to 0, confirm that the DMA_ON bit is set to 0. To check that for a specific channel, confirm also that the CH_SEL bit is set to B'11.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22	DMA_ON	0	R	DMA Enable 0: No DMA transfer. 1: DMA/BT transfer is present (DMA transfer or bus-through access in progress).
21, 20	CH_SEL[1:0]	00	R	DMA Channel 00: CH0 DMA transfer in progress 01: CH1 DMA transfer in progress 10: CH2 DMA transfer in progress 11: No DMA transfer, or bus-through access in progress
19	BT_ON	0	R	DMA Enable 0: No bus-through access. 1: Bus-through access is present (bus-through in progress).

Bit	Bit Name	Initial Value	R/W	Description
18 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

50.2.31 Source Base Address Register 0 to 2 (SBAR0 to 2)

SBARn is a 32-bit readable/writable register that consists of the source base address bits SBARn[8:0] that specify the upper9 bits of the source address for DMA transfer.

DSPn reads from/writes to the upper 24 bits in this register. Do not specify addresses in the P2 space. Specifying H'Axxx xxxx is considered an error by the SHwy packet router and the transfer fails (specify H'0xxx xxxx instead).

Bit	Bit Name	Initial Value	R/W	Description
31 to 23[*1]	SBARn[8:0]	H'000	R/W	Source base address bits for specifying the upper 9 bits of the source address. Note that transfer of data which is continuous across an 8-Mbyte boundary in memory space is impossible. A write is prohibited during DMA transfer.
22 to 0[*2]	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: *1 DSP: 23 to 15
*2 DSP: 14 to 0

50.2.32 Source Address Registers 0 to 2 (SAR0 to 2)

SARn is a 32-bit readable/writable register that consists of the source address bits SARn[22:2] that specify the bits [22:2] of the source address for DMA transfer. It supported only data transfer that are performed in 4- or 32-byte units.

Note that transfer of data which is continuous across an 8-Mbyte boundary in memory space is impossible.

To use the source as a ring buffer, set the address within the ring buffer in this register.

31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 2	SARn[22:2]	H'00 0000	R/W	Source base address bits for specifying the bits [22:2] of the source address. Note that transfer of data which is continuous across an 8-Mbyte boundary in memory space is impossible. A write is prohibited during DMA transfer.
1, 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

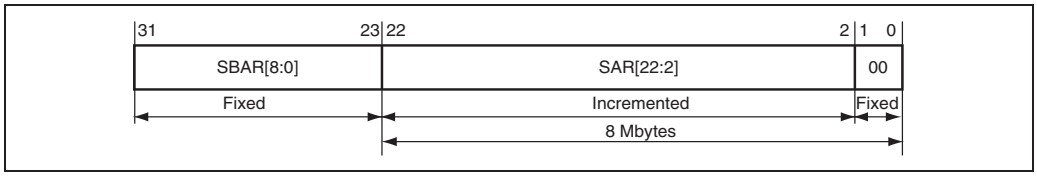

Figure 50.6 Source Address Configuration

50.2.33 Destination Base Address Registers 0 to 2 (DBAR0 to 2)

DBARn is 32-bit readable/writable registers that consists of the destination base address bits DBARn[8:0] that specify the upper 9 bits of the destination address for DMA transfer.

DSPn reads from/writes to the upper 24 bits in this register.

Do not specify addresses in the P2 space. Specifying H'Axxx xxxx is considered an error by the SHwy packet router and the transfer fails (specify H'0xxx xxxx instead).

Bit	Bit Name	Initial Value	R/W	Description
31 to 23*1	DBARn[8:0]	H'000	R/W	Destination Base Address bits for specifying the upper 9 bits of the destination address. Note that transfer of data which is continuous across an 8-Mbyte boundary in memory space is impossible. A write is prohibited during DMA transfer.
22 to 0*2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: *1 DSP: 23 to 15
*2 DSP: 14 to 0

50.2.34 Destination Address Registers 0 to 2 (DAR0 to 2)

DARn is a 32-bit readable/writable register that consists of the destination address bits DARn[22:2] that specify the bits [22:2] of the destination address for DMA transfer. It supported only data transfer that are performed in 32-bit or 32-byte units.

Note that transfer of data which is continuous across an 8-Mbyte boundary in memory space is impossible.

To use the destination as a ring buffer, set the address within the ring buffer in this register.

31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 2	DARn[22:0]	H'00 0000	R/W	Destination Base Address bits for specifying the bits [22:2] of the destination address. Note that transfer of data which is continuous across an 8-Mbyte boundary in memory space is impossible. A write is prohibited during DMA transfer.
1, 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

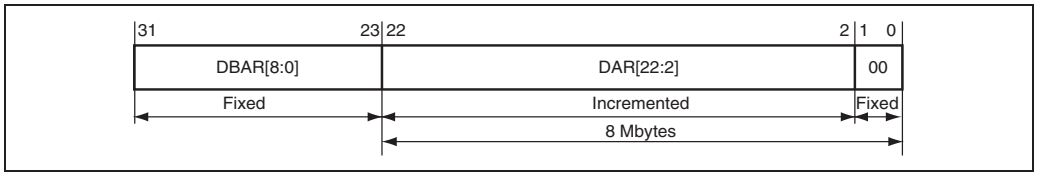

Figure 50.7 Destination Address Configuration

50.2.35 Transfer Count Registers 0 to 2 (TCR0 to 2)

TCRn is a 32-bit readable/writable register that specifies the amount of DMA transfer.

TCR is set to 1 for 4-byte transfer. Specifying H'FFFF for 4-byte transfer permits 4-byte transfer to take place a maximum of 65,535 times.

TCR is also set to 1 for 24-bit transfer which does not involve the SuperHyway. An example of this is DMA transfer from the DSP-XRAM to the DSP-YRAM.

If the transfer size for the SuperHyway is specified as 32 bytes with the TS bit in CHCRn, then the TCRn is decremented by 8. In this case, specify a multiple of 8 in the TCRn.

If the TS bit of the CHCRn is set to B'111 and seamless transfer mode is selected, then specify a multiple of 24 (H'18) in the TCR.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	TCRn[15:0]	H'0000	R/W	This bit specifies the amount of transfer. TCR = 1 means 4-byte transfer. The remaining amount of transfer is indicated during transfer. A write is prohibited during transfer.

50.2.36 SHwy Priority Registers 0 to 2 (SHPRI0 to 2)

SHPRIn is a 32-bit readable/writable register whose 4 bits are used to set the SHwy process priority when the transfer destination or source address is specified as an address in memory space under management by the CPU.

The greater the set value, the higher the SHwy process priority (H'F: highest priority, H'0: lowest priority). The priority can be specified for each DMA channel.

If both the transfer source and destination addresses are specified as addresses in the SPU memory space, the SHwy is not accessed and thus the priority value for the channel is ignored.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

3 to 0	SHPRIn[3:0]	H'E	R/W	These bits specify the SHwy process priority.

50.2.37 Channel Control Registers 0 to 2 (CHCR0 to 2)

CHCRn is a 32-bit readable/writable register that controls the address mode, transfer size, etc.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	SWAP[1:0]		DAM	SAM	—	—	IM[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W

	—	TS[2:0]			—	—	RINGC[1:0]		—	—	—	TE	—	—	—	DE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R/(W)*	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23, 22	SWAP[1:0]	00	R/W	Swap bits These bits specify how to swap DMA transfer data. 00: No swap 01: Byte swap 10: Word swap 11: Byte-word swap
21	DAM	0	R/W	Destination Address Mode This bit specifies whether to increment or fix the transfer destination address. 0: Increments the address. 1: Fixes the address.
20	SAM	0	R/W	Source Address Mode This bit specifies whether to increment or fix the transfer source address. 0: Increments the address. 1: Fixes the address.
19, 18	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
17, 16	IM[1:0]	00	R/W	Intra-SPU2 Transfer Mode (inter-DSP transfer) Set this bit to transfer data within the SPU2 space without using the SHwy. When this bit is set to B'10 or B'11, set the TS bit to B'000. 00: Normal transfer mode 01: Normal transfer mode 10: Intra-SPU2 transfer mode (the source is used as a buffer) 11: Intra-SPU2 transfer mode (the destination is used as a buffer)
15	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 12	TS[2:0]	All 0	R/W	Transfer Size These bits specify the unit of transfer. 000: Single transfer mode 1 (specify B'000 for iner-DSP transfer) 001: Single transfer mode 2 010: Single transfer mode 3 011: Single transfer mode 4 100: Burst alignment transfer mode 1 101: Burst alignment transfer mode 2 110: Burst alignment transfer mode 3 111: Burst seamless transfer mode
11, 10	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9, 8	RINGC[1:0]	00	R/W	Ring Buffer Control These bits enables/disables ring buffer. For details, refer to section 50.6 Modulo Addressing. 00: Off (LSA/LEA disabled) 01: Setting prohibited 10: Enabled (the ring buffer is the source) Specify an address within the ring buffer in SAR. 11: Enabled (the ring buffer is the destination) Specify an address within the ring buffer in DAR.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	TE	0	R/(W)*	Transfer End Flag This bit is set to 1 when TCR reaches 0 and transfer ends. 0: Transfer is in progress or interrupted (this bit is retained as 0 even if you try to write 1 to it). 1: Transfer is complete (write 0 to the bit to clear it).
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DE	0	R/W	DMA Transfer Enable This bit specifies enables or disables DMA transfer over the channel. Both this bit and the DME bit in the OR register to start the transfer. 0: Disables the transfer. 1: Enables the transfer.

Note: * Only 0 can be written to clear the flag.

Table 50.6 shows the TS encoding and transfer targets.

Table 50.6 TS Bit Encoding and Transfer Targets

	Transfer Source (Read)			Transfer Destination (Write)		
		DSP memory			DSP memory	
CHCRn.TS	SHwy	P	X/Y	SHwy	P	X/Y
000	32 bits (LOAD4)	32 bits	32 bits of data which includes 24 bits of read data and H’00 concatenated to the least significant bit	32 bits (STORE4)	32 bits	Upper 24 bits of transfer source data
001	32 bits (LOAD4)	32 bits	32 bits of data which includes 24 bits of read data and H’00 concatenated to the most significant bit	32 bits (STORE4)	32 bits	Lower 24 bits of transfer source data
010	32 bits (LOAD4)	32 bits	32 bits of data which includes 24 bits of read data and H’00 concatenated to the least significant bit	32 bits (STORE4)	32 bits	24 bits of data which includes upper 16 bits of transfer source data and H’00 concatenated to the least significant bit ({16 bits, H'00})
011	32 bits (LOAD4)	32 bits	32 bits of data which includes 24 bits of read data and H’00 concatenated to the most significant bit	32 bits (STORE4)	32 bits	24 bits of data which includes lower 16 bits of transfer source data and H’00 concatenated to the most significant bit ({H'00, 16 bits})
100	64 bits×4 (LOAD32)	32 bits×8	{24 bits,H'00}×8	64 bits×4 (STORE32)	32 bits×8	Upper 24 bits of transfer source data × 8

	Transfer Source (Read)			Transfer Destination (Write)		
		DSP memory			DSP memory	
CHCRn.TS	SHwy	P	X/Y	SHwy	P	X/Y
101	64 bits×4 (LOAD32)	32 bits×8	{H'00,24 bits}×8	64 bits×4 (STORE32)	32 bits×8	Lower 24 bits of transfer source data x 8
110	64 bits×4 (LOAD32)	—*1	{24 bits,H'00}×16	64 bits×4 (STORE32) If the transfer source is X/Y, upper 16 bits x 16 is changed to 64 bits x 4.	—*1	{16 bits,H'00}×16
111	64 bits×4 (LOAD32)	—*1	{24 bits,H'00}×N (10or11) (Transfer destination is SHwy only)*2	64 bits×4 (STORE32)	—*1	24 bits×n (10or11) (Transfer source is SHwy only)*2

Note: *1 Do not specify the PRAM. If you specify, transfer data is undetermined.

*2 If TS = B'111, specify the source and destination of transfer as SHwy→SHwy, SHwy→DSP-X/Y, or DSP-X/Y→SHwy.

Intra-SPU2 transfer mode (inter-DSP transfer) is a mode in which data transfer, for example from the DSP0-XRAM to DSP1-XRAM, is complete within the SPU2 without using the SHwy. Since transfer in this mode is performed via the dedicated buffers (BUF0 to 3) in the SPU2, two DMACs, one for each of the data transmitting side and the data receiving side should be started. The DSP memory is the source and BUF0 to 3 are the destination during data transmission while the DSP memory is the destination and BUF0 to 3 are the source during data reception. Thus, set the IM bit in the CHCR register to B'11 on the data transmitting side and to B'10 on the data receiving side.

When the TS bit in the CHCR register to H'4 to 6, set a multiple of 8 in the TCR register. When the TS bit in the CHCR register to H'7, set a multiple of 24 (H'18) in the TCR register.

The SWAP[1:0] bits specify the method of swapping DMA transfer data. SHwy bus data is swapped by the specified method.

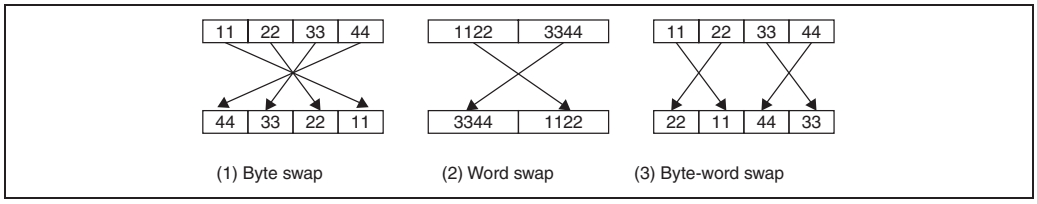

Figure 50.8 Data Swapping Methods

50.2.38 Loop Start Address Registers 0 to 2 (LSA0 to 2)

LSA0 to 2 are 32-bit readable/writable registers. Each of these registers specifies the loop start address by its word address when the source or destination is used as a ring buffer during DMA transfer on DMA channels 0 to 2.

The ring buffer is used only for the DSP data X/Y memory (XRAM/YRAM) and either the source or destination can be used as a ring buffer for one transfer. The maximum size of ring buffer is 48 Kbytes (24 bits x 16 Kwords) and the space for it is from the address specified by this register to the end address specified by the registers LEA0 to 2 below.

The value set in this register is valid only if the RINGC[1:0] bits in the CHCR register are set to B'10 or B'11.

For details, see section 50.6, Modulo Addressing.

15 to 2	LSAn[15:2]	H'0000	R/W	Loop Start Address bits of ring buffer Specify the address by its word address (physical address[15:2]).
1, 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

50.2.39 Loop End Address Registers 0 to 2 (LEA0 to 2)

LEA0 to 2 are 32-bit readable/writable registers. Each of these registers specifies the loop end address by its word address when the source or destination is used as a ring buffer during DMA transfer on DMA channels 0 to 2.

The ring buffer is used only for the DSP data X/Y memory (XRAM/YRAM) and either the source or destination can be used as a ring buffer for one transfer. The maximum size of ring buffer is 48 Kbytes (24 bits x 16 Kwords) and the space for it is from the address specified by the registers LSA0 to 2 above to the end address specified by this register.

The value set in this register is valid only if the RINGC[1:0] bits in the CHCR register are set to B'10 or B'11.

For details, see section 50.6, Modulo Addressing.

50.3 Memory Description

The SPU2 memory configuration is shown in figure 50.9. In this figure, the SPU2 is allocated to the physical space from H'00 0000 to H'1F FFFF (21 bits: 2 Mbytes).

Each DSP's instruction RAM (PRAM), data RAM (X/YRAM), and DSP-IO peripheral module space and the SPU register (SPUREG) are mapped to this space.

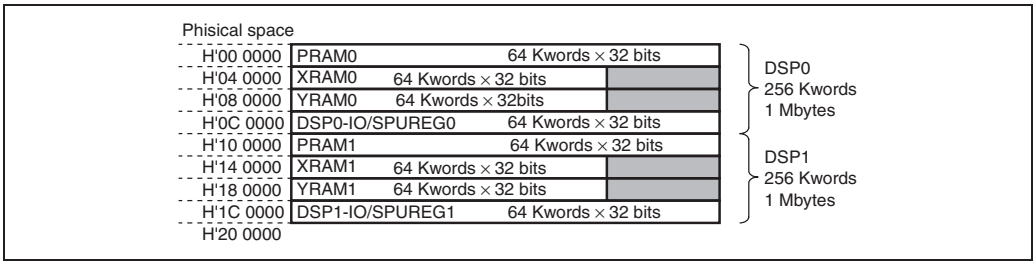

Figure 50.9 SPU2 Memory Configuration (Basic Two-DSP Configuration)

50.3.1 DSP Instruction RAM Areas

The DSP instruction RAM (PRAM) configuration is shown in figure 50.10. The PRAM is mapped to a 256-Kbyte space (64 Kwords × 32 bits).

This product has 160-Kbyte (40 Kwords × 32 bits) of instruction RAM.

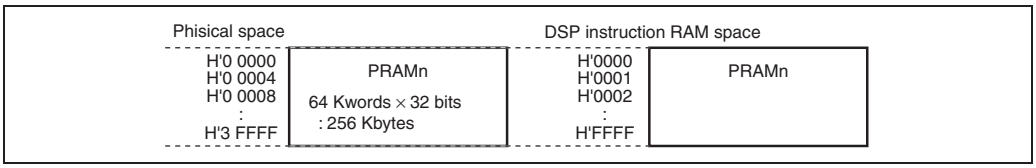

Figure 50.10 DSP Instruction RAM (PRAM) Configuration

50.3.2 DSP Data RAM Areas

The DSP data RAM (XRAM and YRAM) configurations are shown in figure 50.11. Both the XRAM and YRAM consist of 192-Kbyte (64 Kwords × 24 bits) of space.

This product has 168-Kbyte (56 Kwords × 24 bits) of data RAM.

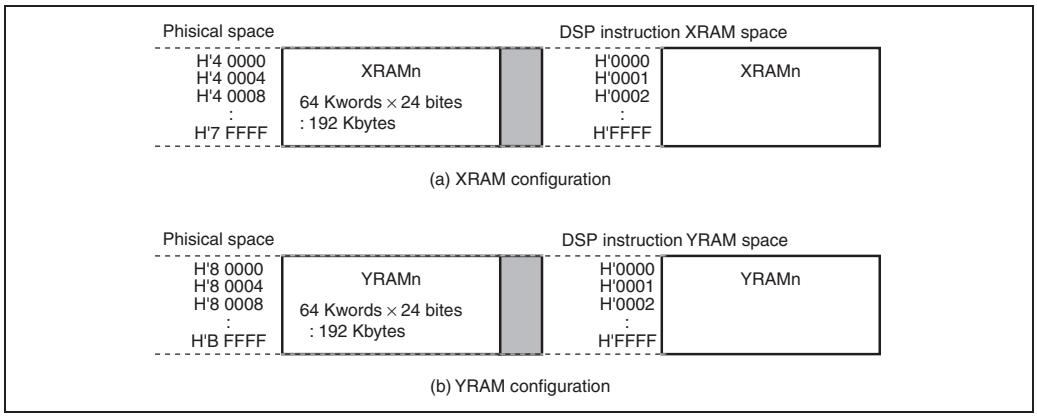

Figure 50.11 DSP Data RAM (XRAM/YRAM) Configurations

50.3.3 DSP Memory Allocation

The SPU2 can change memory allocation for DSP0 and DSP1 by switching memory banks. The PRAM and XRAM are allocated in this way.

DSP0 and DSP1 can map 32 bits×40 Kwords (= 160 Kbytes) of PRAM and 24 bits×56 Kwords (= 168 Kbytes) of XRAM.

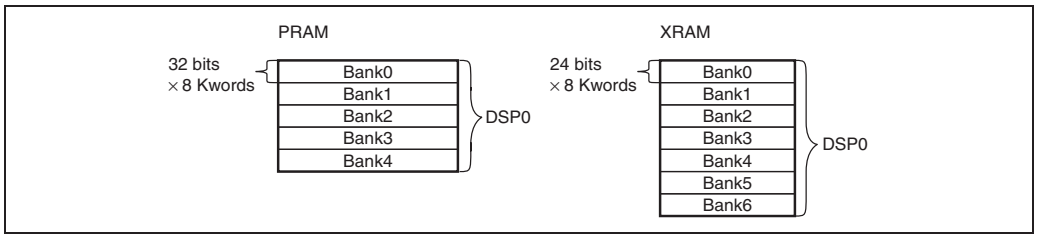

Figure 50.12 Initial Memory Allocation

In the initial state, DSP0 is set to use all of the PRAM (40 Kwords) and XRAM (56 Kwords), DSP1 is set to use no banks in the PRAM and XRAM.

Specify the banks to be used by DSP0 and DSP1.

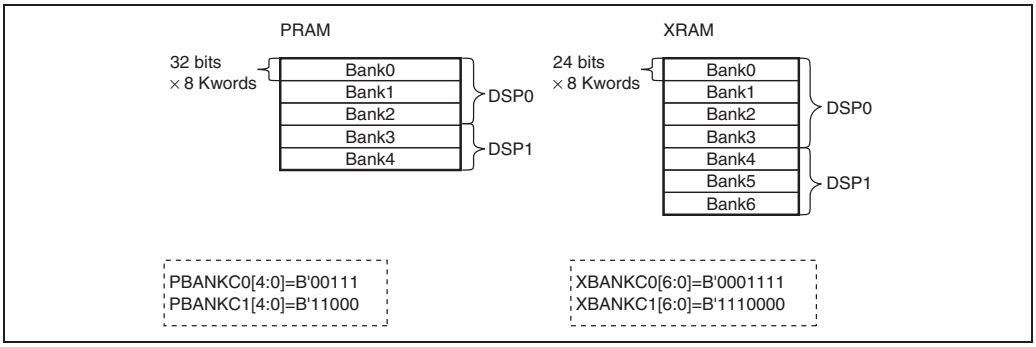

Figure 50.13 Example of Memory Allocation

(1) Example of Switching PRAM Banks

Figure 50.14 shows an example of switching PRAM banks. Figure 50.15 and 50.16 show examples of PRAM memory allocation.

In this example, application A is switched to application C for DSP0 and application B is switched to application D for DSP1. Reset the DSP core before switching application.

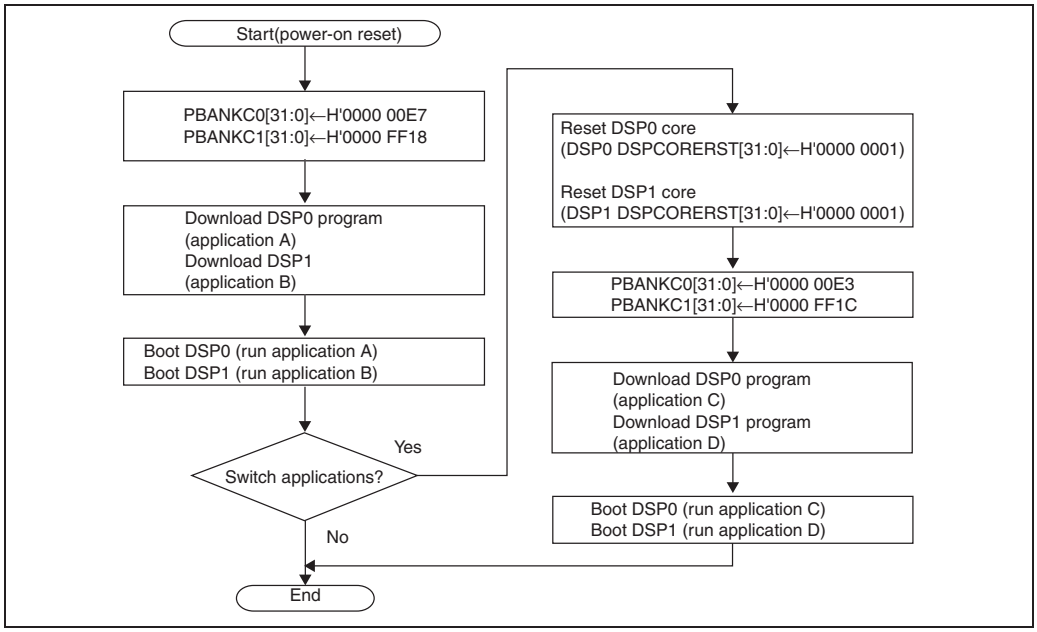

Figure 50.14 Example of Procedure for Switching PRAM Banks

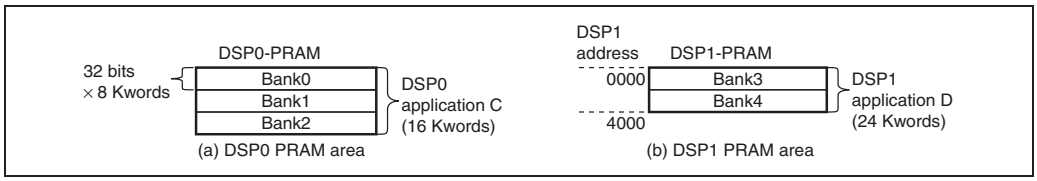

Figure 50.15 Program Areas for Application A and B (Initial Memory Allocation)

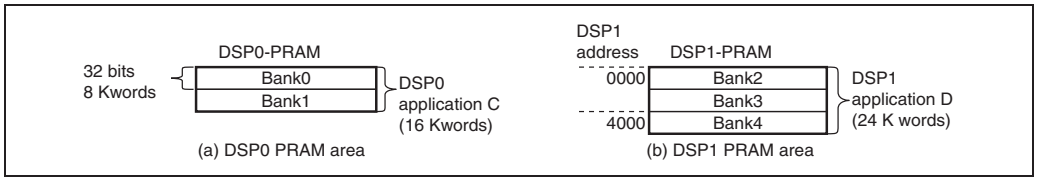

Figure 50.16 Program Areas for Application C and D (Modified Memory Allocation)

(2) Example of Switching XRAM Banks

The XRAM, similarly to the PROM, can be allocated between DSP0 and DSP1. This product has 56 Kwords (8 Kwords×7 banks) of XRAM. Adjust XRAM allocation depending on applications by controlling the XBANKC0 and XVANKC1 registers.

50.3.4 DSP I/O Area

The DSP I/O space configuration is shown in figure 50.17. 64 Kwords are mapped to this space like the XRAM and YRAM and the addressing unit for the YRAM is used for addressing this space.

The SPU registers are mapped to the I/O space, which can be accessed by both the CPU and the DSP.

However, the peripheral area can be accessed only by the DSP.

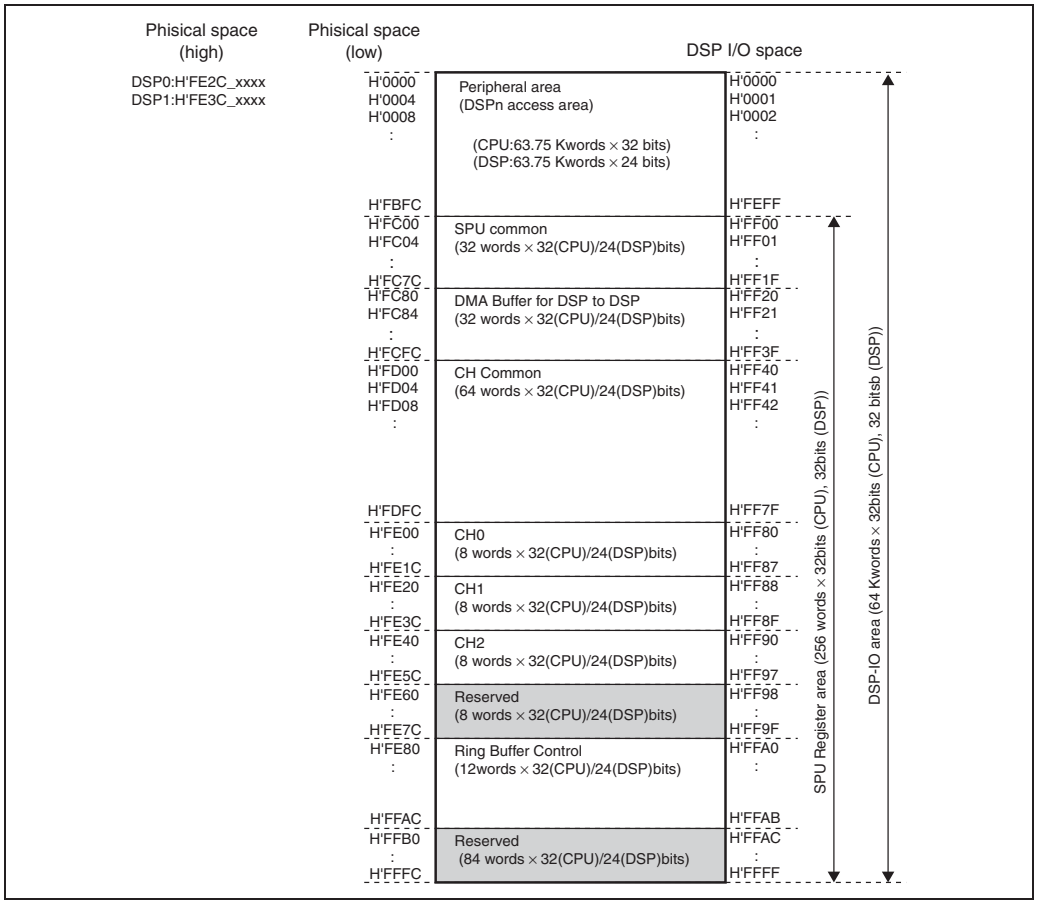

Figure 50.17 DSP I/O Space Configuration

The FSI is mapped from H'0000 to H'00FF in the DSP I/O space.

50.3.5 Interrupt Interface Specifications

The SPU2 outputs the same number of interrupt request signals to the CPU as that of the on-chip DSPs. These signals should be cleared at the beginning of the interrupt handler after the event occurs. The masks for the interrupt request signals to the CPU are controlled by the IMASKC register. The interrupt sources are controlled by the IEMASKC and IEVENTC registers.

When clearing an interrupt source, write 0 to the bit corresponding to the source to be cleared and 1 to the other bits.

Each DSP has three interrupt signals to the DSP in the SPU2. One of them is assigned to the source in the SPU2 and the other two have input pins for the SPU2 external peripheral modules.

When the DSP accepts an interrupt, it asserts the acknowledge signal for 1 cycle. To assert spui_int_dsp0[1] by the SPU2 external peripheral modules, spui_int_dsp0[1] should be negated by assertion of spuo_int_ack_dsp0[1]. Similarly, spui_int_dsp0[0] should also be negated by assertion of spuo_int_ack_dsp0[0].

To reassert them, they should be negated for at least 1 cycle.

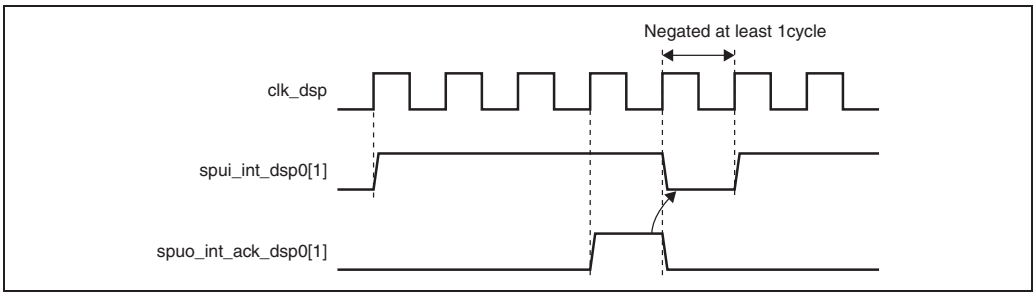

Figure 50.18 Interrupt Signal Timing

When the DSP is interrupted, one bit of the interrupt signals to the DSP (int[2:0]) is asserted.

If the interrupt is generated by the SPU2 internal source, int[2] is asserted. When int[2] is accepted by the DSP, the program counter of the DSP jumps to the interrupt vector irq3 to execute interrupt handling.

Interrupts from the SPU2 peripheral modules are assigned to int[1:0] and they are handle by jumping to irq2 with int[1] or to irq1 with int[0].

50.4 Start Procedures

50.4.1 Procedure for Starting the DSP

The procedure for starting the DSP is shown in figure 50.19. To start the DSP after a hardware reset, follow the flow chart below to download a DSP program. The procedure for starting the DSP is common to both of the DSPs in this product and there is no restriction on the order of starting them.

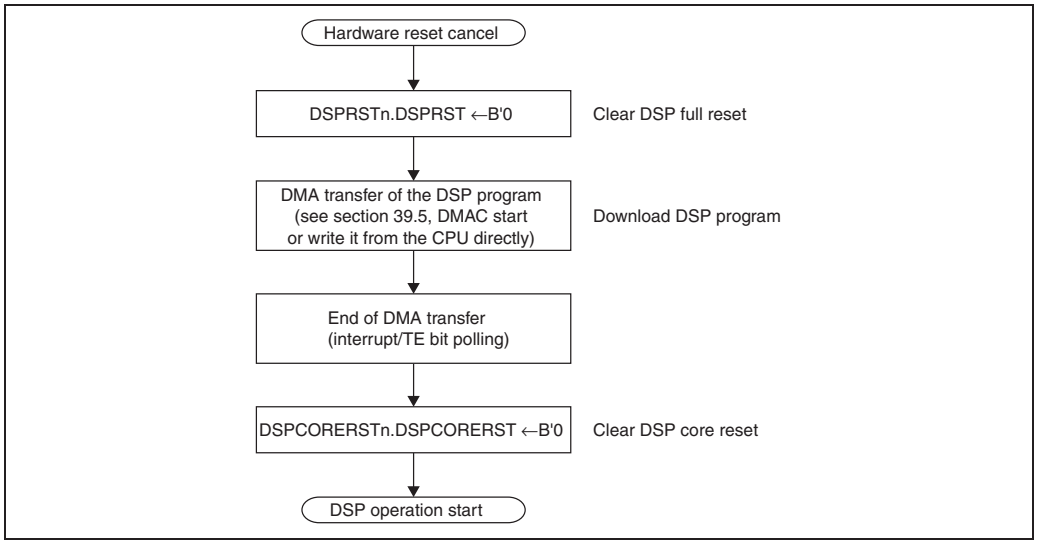

Figure 50.19 Procedure for Starting the DSP

50.5 DMAC Start

An example procedure for setting the registers for starting the DMAC is shown in figure 50.20.

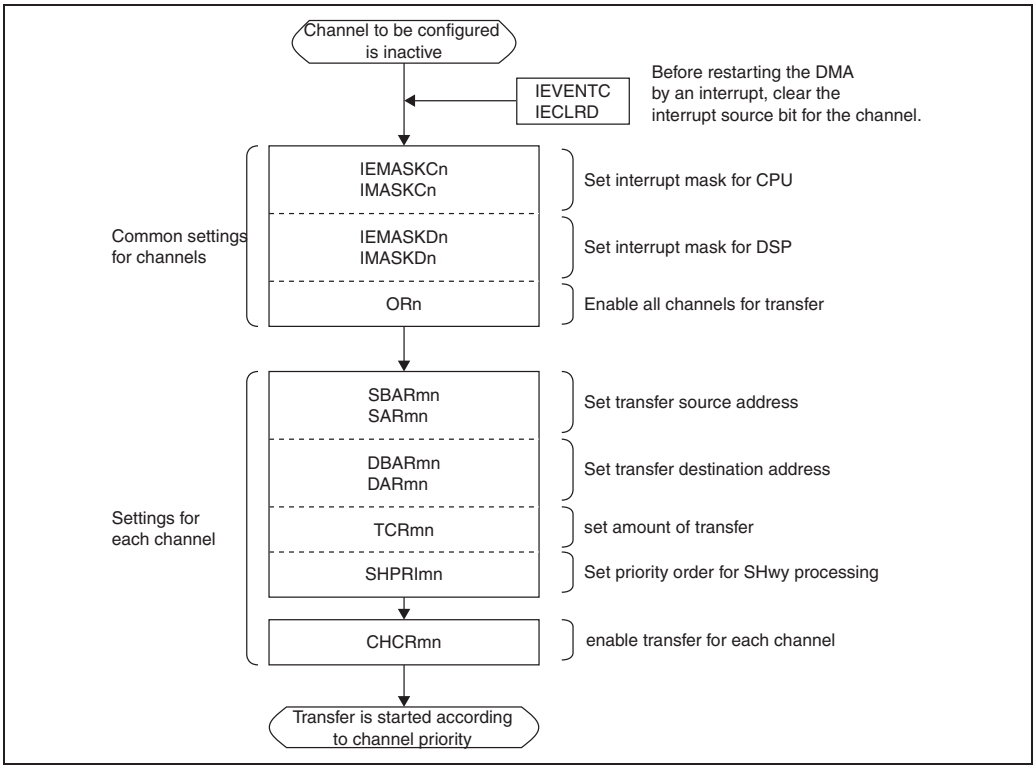

Figure 50.20 Recommended Procedure for Starting the DMAC

50.6 Modulo Addressing

Table 50.7 shows the SPU2-DMAC modulo addressing specifications.

Table 50.7 SPU2-DMAC Modulo Addressing Specifications

Item	Description
Target memory	• DSP-XRAM or DSP-YRAM
Target range	• 96 bytes to 48 Kbytes (24 bits×16 Kwords)
	• The ring buffer size should be determined by the LEA−LSA in 32-word (96-byte) units.
DMA channel	• Supported on all channels (CH0, CH1, CH2)
Source/destination selection	• Modulo addressing supported for source or destination only (DMA transfer between ring buffers is unsupported.)
Ring end address	• When the DMA source is used as a ring buffer, the data in the address specified by LEA0 to 2 are not transferred.
	• When the DMA destination is used as a ring buffer, data are not stored in the address specified by LEA0 to 2.
Address for starting DMA (source/destination)	• When using the DMA source as a ring buffer, specify an address in the ring buffer as the source address for starting DMA transfer (LSA can be specified , but not LEA).
	• When using the DMA destination as a ring buffer, specify an address in the ring buffer as the destination address for starting DMA transfer (LSA can be specified, but not LEA).

Figure 50.21 shows an example of modulo addressing. When using the DSP-XRAM for the DMA source as a ring buffer, specify an address in the ring buffer area for starting DMA transfer.

When the data one word before LEA are transferred in the Nth DMA transfer, the next transfer starts from the address specified by LSA.

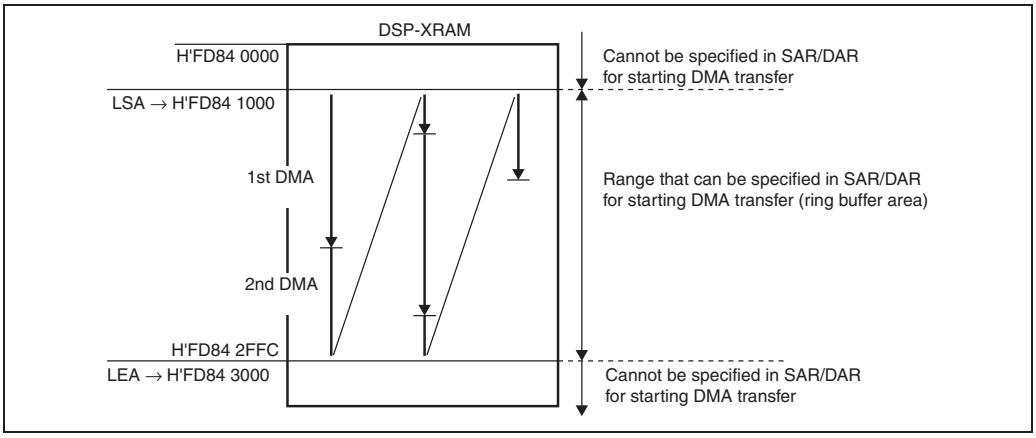

Figure 50.21 Example of Modulo Addressing

50.7 Restrictions

Table 50.8 shows the restrictions on the use of the SPU2.

Table 50.8 SPU2 Usage Restrictions

	Restrictions	
No.	**Item**	**Description**
1	Unit of access	Only 32-bit access to the SPU registers from the CPU is guaranteed.
2	Register setting	If the CHCR.DE and OR.DME bits are set to 1 and DMA transfer via a DMA channel is enabled, a write to the SPU registers via that DMA channel should not be performed. However, the CHCR.TE bit can be cleared to 0. Also, the CHCR.DE bit can be negated to interrupt the DMA transfer.
3	DMA transfer area	The SARn and DARn registers should be specified so that data starting at address H'0000 0000 can be transferred in 8-Mbyte units or less. Data transfer across an 8-Mbyte boundary in which the 24th bit produces a carry is not guaranteed.
4	Intra-SPU2 transfer (inter-DSP transfer)	Two DMA channels should be used if a transfer is performed in the SPU2 without using the SHwy. Also, the CHCR.TS bit should be set to 0.
5	LD32/ST32 transfer	If CHCR.TS = B’100/B’101/B’110 is specified, TCRn should be a multiple of 8 (H’0018).
6	Seamless transfer	If CHCR.TS = B’111 is specified, TCRn should be a multiple of 24 (H’0018).
7	Bus through mode	When the DSP accesses the SPU2 external space in bus-through mode, the SPU2 external address should be specified in the BTADRU register.
8	Initiator source	When more than one DSP is included and the SHwy initiator port is implemented with one port, initiator source 0 and 1 should have the same value.

Section 51 FIFO-Buffered Serial Interface 2 (FSI2/FMSI)

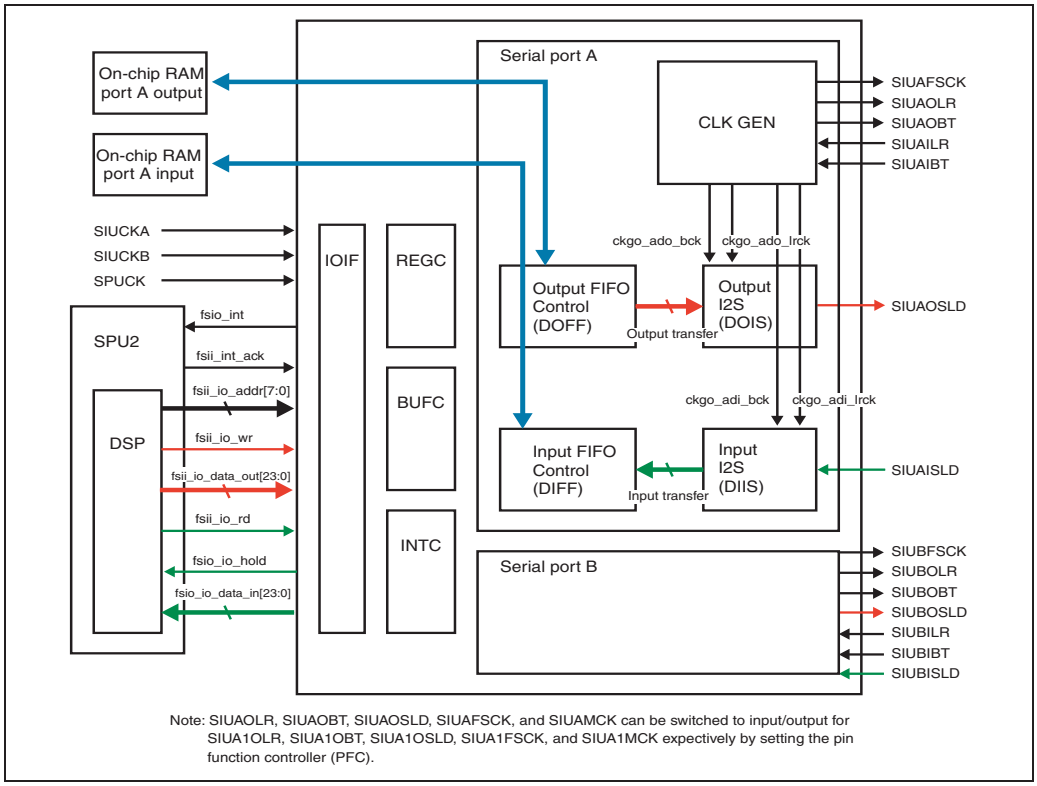
The FIFO-buffered serial interface 2 (FSI2) and the FIFO-incorporating melody and serial interface (FMSI) are sound I/O interfaces that support both analog and digital connections. It has an output function that outputs 24-bit data output from the audio processing circuit with 3 lines: LR clock, bit clock, and serial clock lines, and an input function that converts input 3-line data to 24-bit data. It supports continuous I/O operation by managing FIFO states and generating interrupts. FSI2 supports an SPDIF interface.

These modules act as peripheral circuits of the SPU2 (Sound Processing Unit 2) audio processing circuit.

51.1 Features

The functions and features are listed in table 51.1.

Table 51.1 List of FSI2 Functions



Classification	Item	Details
Operating frequency	Sampling frequency (fs)	8kHz to 96kHz (max.) SPDIF up to 192kHz[stream]
	Audio clock	Clock signal (at 32 f_S, 64 f_S, 128 f_S, 256 f_S, or 512 f_S) used to generate the LR clock and bit clock 512 kHz to 49.15 MHz (max.) (64 × 8 kHz to 512 × 96kHz)
	DSP clock	FSI2 operating frequency: 120MHz(max)
DSP/IO	Data bus width	24 bits
Supported I/O format	Monaural (1 channel)	MONO, MONO Delay
	Stereo (2 channels)	I2S, PCM
	Multi-channel (1 to 8 channels)	TDM, TDM Delay

Classification	Item	Details
Output interface	3-line serial output (× 2: ports A and B)	Master operation (generates the LR and bit clocks from the audio clocks: 64 fs, 128 fs, 256 fs, 512 fs)
		LR clock (fs): 8 kHz to 9 6kHz
		Bit clock:
		32 bits/fs, 64 bits/fs, 128 bits/fs, 256 bis/fs, 512 bits/fs (monaural)
		64 bits/fs, 128 bits/fs, 256 bits/fs, 512 bits/fs (stereo)
		256 bits/fs, 512 bits/fs (multi-channel)
		Slave operation (can operate with the external LR and bit clocks)
		LR clock (fs): 8 kHz to 96 kHz
		Bit clock:
		32 bits/fs, 64 bits/fs, 128 bits/fs, 256 bits/fs, 512 bits/fs (monaural)
		64 bits/fs, 128 bits/fs, 256 bits/fs, 512 bits/fs (stereo)
		256 bits/fs, 512 bits/fs (multi-channel)
Input interface	3-line serial input (× 1: ports A)	Master operation
		Supports the same LR and bit clocks as the output interface.
		Slave operation
		Supports the same LR and bit clocks as the output interface.
FIFO	FIFO status	State, number of stored sample data, overflow, underflow
	FIFO clear	Clears the address pointer.
	Interrupt source condition select	Output operation:
		(1) Empty.
		(2) More than half of data areas are free.
		(3) Data areas for more than 1 sample are free.
		Input operation:
		(1) Full.
		(2) More than half of data areas are occupied.
		(3) Data areas for more than 1 sample are occupied.

Classification	Item	Details
Interrupt	Interrupt control	Can generate interrupt requests externally. Supports masks for interrupt sources and interrupt signals.
Muting	Mute mode	Normal muting and muting at zero crossing

Figure 51.1 shows a block diagram of the FSI2.

Serial port B has the same structure and interface as serial port A.

Note: SIUAOLR, SIUAOBT, SIUAOSLD, SIUAFSCK, and SIUAMCK can be switched to input/output for SIUA1OLR, SIUA1OBT, SIUA1OSLD, SIUA1FSCK, and SIUA1MCK expectively by setting the pin function controller (PFC).

Figure 51.1 Block Diagram

The followings are the brief descriptions of each block.

(1) Serial Port A

Serial port A is a module that consists of 5 modules: CLK GEN, data output FIFO control, data input FIFO control, data output I2S, and data input I2S, and performs I/O operations for audio data

(a) CLK GEN

CLK GEN selects the master clock generated internally or the slave clock supplied external and outputs it to the internal modules (DOIS, DIIS).

(b) Data Output FIFO Control (DOFF)

A FIFO to which data from the DSP is written is called output FIFO. The DOFF controls access to the DP-RAM. The FIFO states are reflected on the FIFO status register (A_DOFF_ST).

The output FIFO control register (A_DOFF_CTL) can be used to select the condition for generating the FIFO interrupt source (A_DOFF_CTL.IHC).

The FIFO clear (A_DOFF_CTL.CLR) initializes the access pointer to the on-chip RAM and the error history.

(c) Data Output I2S (DOIS)

The DOIS controls a counter based on the rising and falling edges of the LR clock generated from the CLK GEN to request data to the DOFF.

It also determines the channel number associated with data and stores data into the corresponding channel buffer. It reads data at the next LR clock and shifts it to the left to output serial data.

(d) Data Input FIFO Control (DIFF)

A FIFO to which external data is written is called input FIFO. The DIFF controls access to the DP-RAM. The FIFO states are reflected on the FIFO status register (A_DIFF_ST).

The input FIFO control register (A_DIFF_CTL) can be used to select the condition for generating the FIFO interrupt source (A_DIFF_CTL.IHC).

The FIFO clear (A_DIFF_CTL.CLR) initializes the access pointer to the on-chip RAM and the error history.

(e) Data Input I2S (DIIS)

The DIIS controls a counter based on the rising and falling edges of the LR clock generated from the CLK GEN to store the parallel converted signal to each channel buffer. The stored data are concatenated the channel number and written to input FIFOs.

(f) BP-IF (Biphase mark Interface)

The BP-IF outputs the Biphase mark format after modulating the SPDIF format (IEC60958) from 64 bit/fs to 128bit/fs.

(g) SPTR (SPDIF Transfer Return)

IF FSI2 treats SPDIF format, the SPTR makes the user's data, the state of channel and so on including in the audio data, and outputs to the BP-IF and the DOIS.

(2) Serial Port B

Serial port B has the same structure and interface as serial port A and operates independently.

(3) Other Management Modules

These modules control registers for major functions.

(a) INTC

This module controls interrupt signals. It aggregates 4 interrupt sources generated internally and outputs as one interrupt signal externally. Interrupt events are triggered based on the FIFO capacity. The condition can be changed.

Interrupt source and interrupt signal masks can be used to control how to handle those triggered events.

(b) BUFC

The BUFC block controls data reads/writes between the DSP and FIFOs. To read input data continuously, data are prefetched from FIFOs. Data are output with 4 waits on the initial read, but the following reads can be performed continuously with one wait by controlling the buffer pointer and reading data stored in buffers.

(c) REGC

This module manages registers that are not used by INTC and BUFC. It is used to manage format, clock, and MUTE settings.

(d) IOIF

This module selects read data of INTC, BUFC, and REGC.

Table 51.2 summarizes the number of wait cycles for the registers accessible from the DSP-IO.

Table 51.2 Wait Cycles for FSI2 Register Read/Write

Register	Read	Write
A_DIDT	Initial read (4 waits)	Prohibited
B_DIDT	2nd and following reads (1 wait)	
Other registers	1 wait	No wait

51.2 Input/Output Pins

Table 51.3 shows the FSI2 pin configurations.

Table 51.3 Pin Configurations

FSI2 Block	Pin Name	Function	Input/Output	Description
Port A	FSIACK	Port A master clock input	Input	Master clock input pin for port A
	FSIAILR	Port A sound input L/R clock	Input	Sound input L/R clock pin (slave)
	FSIAIBT	Port A sound input bit clock	Input	Sound input bit clock pin (slave)
	FSIAISLD	Port A sound input serial data	Input	Sound input serial data pin
	FSIAOMC	Port A master clock output	Output	Master clock output pin for port A
	FSIAOLR	Port A sound output L/R clock	Output	Sound output L/R clock pin (master)
	FSIAOBT	Port A sound output bit clock	Output	Sound output bit clock pin (master)
	FSIAOSLD	Port A sound output serial data	Output	Sound output serial data pin
	FSIASPDIF	Port A sound output SPDIF data	Output	Sound output SPDIF pin
Port B	FSIBCK	Port B master clock input	Input	Master clock input pin for port B
	FSIBSPDIF	Port A sound output SPDIF data	Output	Connect to the HDMI

51.3 Register Descriptions

Table 51.4 shows the FSI2 register configuration.

Table 51.4 Register Configuration

Type	Register Name	Abbreviation	R/W (Common to CPU/DSP)	Access Size		Physical Address	DSP Address
				CPU	DSP		
Port A	Port A output serial format register	A_DO_FMT	R/W	32	24	H'FE3C0000	H'0000

Note: The port A and port B registers have the same functions and settings.

51.3.1 Port A/B Output Serial Format Register (A_DO_FMT/B_DO_FMT)

A_DO_FMT/B_DO_FMT is a 32-bit readable/writable register. It selects the format from MONO, MONO_Delay, PCM, I2S, TDM, and TDM_Delay that is used in output operations on serial ports A/B.

When TDM and TDM_Delay modes are selected, it also specifies the number of channels (1 to 8 channels).

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0

3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	NCH[2:0]	000	R/W	These bits specify the number of channels in TDM and TDM_Delay modes. When selecting the modes other than TDM and TDM_Delay, specify B'000. 000: 1 channel 001: 2 channels 010: 3 channels 011: 4 channels 100: 5 channels 101: 6 channels 110: 7 channels 111: 8 channels

51.3.2 Port A/B Output FIFO Control Register (A_DOFF_CTL/B_DOFFCTL)

A_DOFF_CTL/B_DOFF_CTL is a 32-bit readable/writable register that selects the conditions for generating interrupt sources of serial ports A/B. The FIFO clear initializes the access pointer to the on-chip RAM and the history of overflow and underflow errors.

21, 20	IHC[1:0]	01	R/W	Interrupt Source Condition Select 00: Empty. 01: More than half of data areas are free. 10: Data areas for more than 1 sample are free. 11: Setting prohibited (Full state)
19 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CLR	0	R/(W)*	FIFO Clear This bit initializes the access pointer and the error history. This bit is always read as 0. 0: When only the interrupt source condition is changed, the write value should be 0. 1: Clears FIFOs.

Note: * f 1 is written to the CLR bit, it is asserted for 1 pulse and cleared to 0.

51.3.3 Port A/B Output FIFO Status Register (A_DOFF_ST/B_DOFF_ST)

A_DOFF_ST/B_DOFF_ST is a 32-bit readable/writable register. It can be used to read the output FIFO states for serial ports A/B, the number of stored sample data, and the history of overflow and underflow errors.

The OF and UF bits clear the history when they are written to 0.

Bit:	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R/(W)*	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
31, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	ST[1:0]	00	R	FIFO State 00: Empty state. 01: Less than half of data areas are occupied. 10: More than half of data areas are occupied. 11: Full state.
19 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
16 to 8	SZ[8:0]	H'000	R	Number of Sample Data These bits indicate the number of sample data stored in FIFOs. The maximum value varies depending on the number of channels selected for the format. The maximum number of sample data for each channel is shown below (if 256 words of DP-RAM is connected). If more data than the maximum number in the parenthesis are written, an overflow occurs. FIFOs are used in 4-channel units in 3-channel mode and in 8-channel units in 5- to 7-channel mode, meaning that more FIFOs than the required size of DP-RAM are used. The DSP should take into account the maximum number of writes for these extra FIFOs. 1 channel: 256 (256 × 1 = 256) 2 channels: 128 (128 × 2 = 256) 3 channels: 64 (64 × 3 = 192) 4 channels: 64 (64 × 4 = 256) 5 channels: 32 (32 × 5 = 160) 6 channels: 32 (32 × 6 = 192) 7 channels: 32 (32 × 7 = 224) 8 channels: 32 (32 × 8 = 256)
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	OF	0	R/(W)*	FIFO Error History 0: No error has occurred. 1: Overflow has occurred.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	UF	0	R/(W)*	FIFO Error History 0: No error has occurred. 1: Underflow has occurred.

Note: * The FIFO error history is cleared by writing 0 to this bit and retained by writing 1 to it.

51.3.4 Port A Input Serial Format Register (A_DI_FMT)

A_DI_FMT is a 32-bit readable/writable register that selects the format used in I/O operations of serial ports A from MONO, MONO_Delay, PCM, I2S, TDM, and TDM_Delay.

When TDM and TDM_Delay are selected, the number of channels should be specified.

Bit:	23	22	21	20	19	18	17	16

31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 4	FMT[2:0]	011	R/W	Format Select 000: MONO (1 channels 001: MONO Delay (1 channel) 010: PCM (2 channels) 011: I2S (2 channels) 100: TDM (1 to 8 channels) 101: TDM Delay (1 to 8 channels) 110: Setting prohibited 111: Setting prohibited
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	NCH[2:0]	000	R/W	These bits specify the number of channels for the TDM and TDM_Delay formats. When selecting the modes other than TDM and TDM_Delay, specify B'000. 000: 1 channel 001: 2 channels 010: 3 channels 011: 4 channels 100: 5 channels 101: 6 channels 110: 7 channels 111: 8 channels

51.3.5 Port A Input FIFO Control Register (A_DIFF_CTL)

A_DIFF_CTL is a 32-bit readable/writable register that sets the condition for generating interrupt sources of serial port A input FIFOs. The FIFO clear initializes the access pointer to the on-chip RAM.

It also deletes the history of overflow and underflow errors.

Bit:	23	22	21	20	19	18	17	16

21, 20	IHC[1:0]	01	R/W	Condition for generating interrupt source 00: Full state 01: Number of data is over half the FIFO capacity. 10: More than 1 sample of data is in FIFOs. 11: Setting prohibited (empty state)
19 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	CLR	0	R/(W)*	FIFO Clear This bit initializes the access pointer and the error history. This bit is always read as 0. 0: When only the interrupt source condition is changed, the write value should be 0. 1: Clears FIFOs.

Note: * If 1 is written to the CLR bit, it is asserted for 1 pulse and cleared to B'0.

51.3.6 Port A Input FIFO Status Register (A_DIFF_ST)

A_DIFF_ST is a 32-bit readable/writable register. It can be used to read the input FIFO states for serial ports A, the number of stored sample data, and the history of overflow and underflow errors.

The OF and UF bits clear the history when they are written to 0.

Bit:	23	22	21	20	19	18	17	16

0	UF	0	R/(W)*	FIFO Error History 0: No error has occurred. 1: Underflow has occurred.

Note: * The FIFO error history is cleared by writing 0 to this bit and retained by writing 1 to it.

51.3.7 Port A/B Clock Set Register (A_ACK_MD/B_ACK_MD)

A_ACK_MD/B_ACK_MD is a 32-bit readable/writable register. It generates the master clock used by serial ports A/B and selects master/slave operation of the LR and bit clocks used internally.

The master clock is generated from the external audio clock. The block diagram is shown in figure 51.2.

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14 to 12	ACKMD[1:0]	000	R/W	These bits specify the audio clock to generate the master LR clock. Select the audio clock (fs) to be input for the sampling frequency (fs). 000: 512 fs 001: 256 fs 010: 128 fs 011: 64 fs 100: 32 fs Note: When selecting SPDIF(PCM or stream), select 512 fs/256 fs/128 fs.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10 to 8	BPFMD[1:0]	001	R/W	These bits set the division ratio of the master bit clock. Some settings are unavailable depending or the format and the input audio clock. Refer to table 51.5. 000: 32bit/fs 001: 64bit/fs 010: 128bit/fs 011: 256bit/fs 100: 512bit/fs 101: Reserve 110: Reserve 111: 16bit/fs

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	DIMD	0	R/W	DIIS Module Master/Slave Select 0: Slave operation 1: Master operation
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DOMD	0	R/W	DOIS Module Master/Slave Select 0: Slave operation 1: Master operation

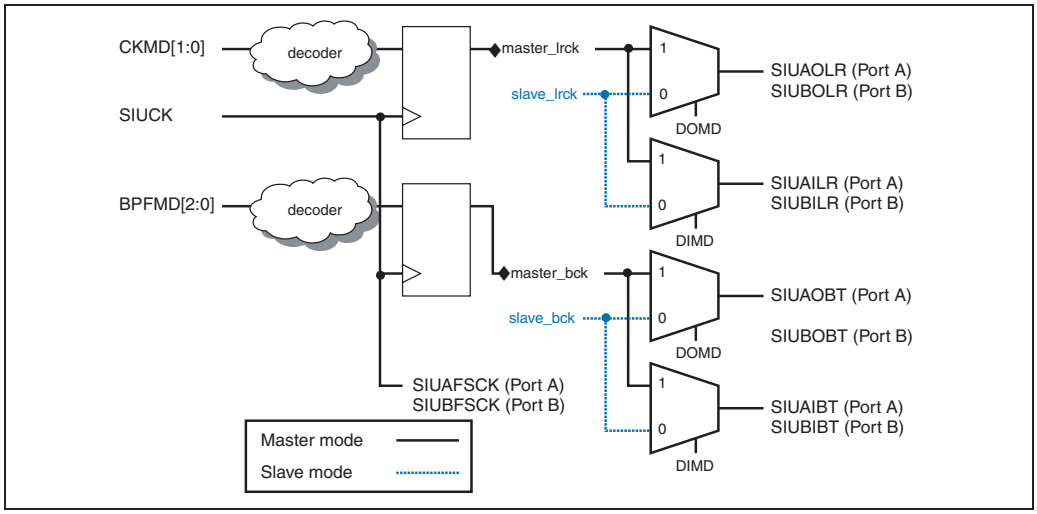

Figure 51.2 Master Clock Generation, I/O Operations, Master/Slave Selection

Table 51.5 List of Supported Formats

	MONO, MONO Delay	I2S, PCM	TDM, TDM Delay
Operating Clock	**BPFMD**	**BPFMD**	**BPFMD**
Master	64 bit/fs	64 bit/fs	(*)

	128 bit/fs	128 bit/fs	
	64 bit/fs	64 bit/fs	
	32 bit/fs		
Slave	512 bit/fs	512 bit/fs	512 bit/fs
	256 bit/fs	256 bit/fs	256 bit/fs
	128 bit/fs	128 bit/fs	
	64 bit/fs	64 bit/fs	
	32 bit/fs		

Note: * In TDM/TDM Delay modes, select 256 fs and 512 fs.

51.3.8 Port A/B Clock Invert control register (A_ACK_RV/B_ACK_RV)

A_ACK_RV/B_ACK_RV is a 32-bit readable/writable register that selects inversion of the master and slave clocks for serial ports A/B. They can be inverted according to the external interface specifications.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0

7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	LRS	0	R/W	Slave LR Clock Inversion 0: Clock not inverted 1: Clock inverted
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	BRS	0	R/W	Slave Bit Clock Inversion 0: Clock not inverted 1: Clock inverted

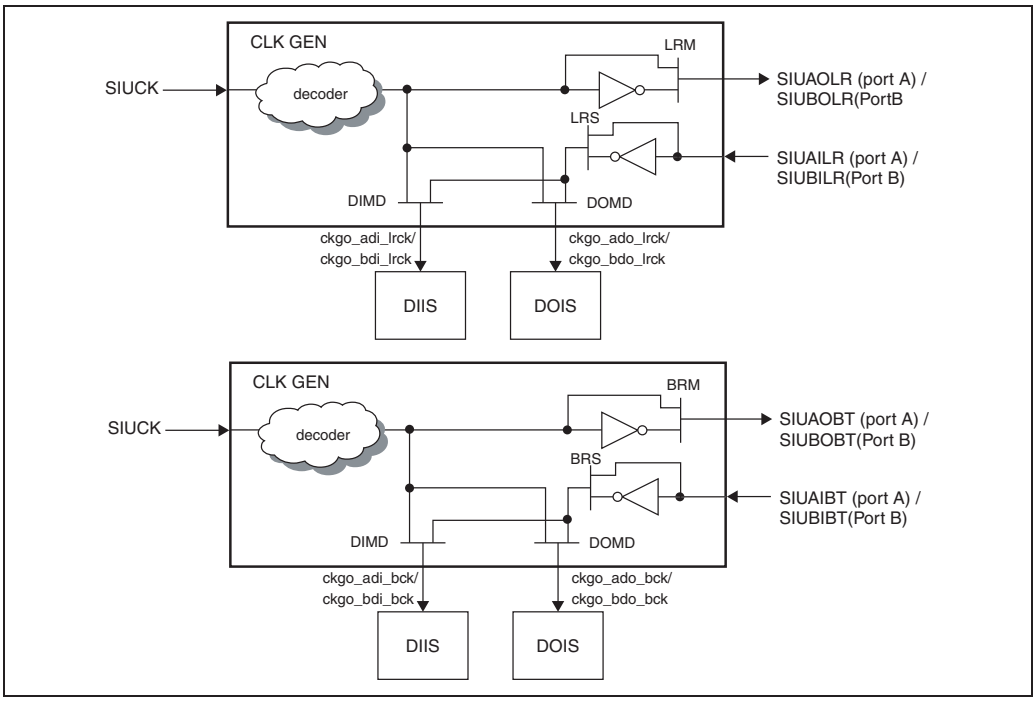

Figure 51.3 Master/Slave Clock Inversion Selector

Only one clock system (master output, bit and LR clocks for slave input pins) can be generated for one serial port. Thus, master-master and slave-slave operations with different formats and different bit and LR clocks cannot be performed on the same serial port.

To perform simultaneous input and output operations with different formats, bit clocks, and LR clocks, configure those operations for port A and port B separately.

51.3.9 Port A Read Data Register (A_DIDT)

A_DIDT is a 32-bit read-only register that can be used to read data stored in serial ports A input FIFOs. If FIFOs are empty, a read causes an underflow error.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
									DIDT[23:16]

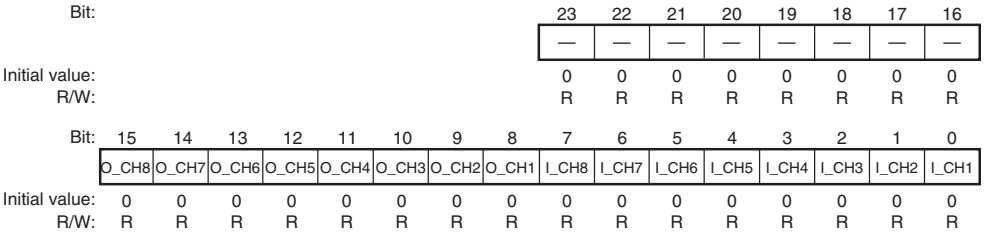
	DIDT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DIDT[31:0]	H'00 0000	R	These bits contain data from input FIFOs. This register is read-only.

51.3.10 Port A/B Write Data Register (A_DODT/B_DODT)

A_DODT/B_DODT is a 32-bit write-only register that can be used to write data to serial ports A/B output FIFOs. If FIFOs are full, a write causes an overflow error.



Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
									DODT[23:16]

	DODT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DODT[31:0]	H'00 0000	W	These bits contain data to output FIFOs. This register is write-only.

51.3.11 Port A/B MUTE State (A_MUTE_ST/B_MUTE_ST)

A_MUTE_ST/B_MUTE_ST is a 32-bit read-only register that indicates the MUTE state for each channel in I/O operations on ports A/B.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	O_CH8	0	R	Port A Output MUTE State 0: Channel 8 MUTE disabled 1: Channel 8 MUTE on
14	O_CH7	0	R	Port A Output MUTE State 0: Channel 7 MUTE off 1: Channel 7 MUTE on
13	O_CH6	0	R	Port A Output MUTE State 0: Channel 6 MUTE off 1: Channel 6 MUTE on
12	O_CH5	0	R	Port A Output MUTE State 0: Channel 5 MUTE off 1: Channel 5 MUTE on
11	O_CH4	0	R	Port A Output MUTE State 0: Channel 4 MUTE off 1: Channel 4 MUTE on
10	O_CH3	0	R	Port A Output MUTE State 0: Channel 3 MUTE off 1: Channel 3 MUTE on

Bit	Bit Name	Initial Value	R/W	Description
9	O_CH2	0	R	Port A Output MUTE State 0: Channel 2 MUTE off 1: Channel 2 MUTE on
8	O_CH1	0	R	Port A Output MUTE State 0: Channel 1 MUTE off 1: Channel 1 MUTE on
7	I_CH8	0	R	Port A Input MUTE State 0: Channel 8 MUTE off 1: Channel 8 MUTE on *Port B is reserve bit

3	I_CH4	0	R	Port A Input MUTE State 0: Channel 4 MUTE off 1: Channel 4 MUTE on *Port B is reserve bit
2	I_CH3	0	R	Port A Input MUTE State 0: Channel 3 MUTE off 1: Channel 3 MUTE on *Port B is reserve bit
1	I_CH2	0	R	Port A Input MUTE State 0: Channel 2 MUTE off 1: Channel 2 MUTE on

Bit	Bit Name	Initial Value	R/W	Description
				*Port B is reserve bit
0	I_CH1	0	R	Port A Input MUTE State 0: Channel 1 MUTE off 1: Channel 1 MUTE on *Port B is reserve bit

51.3.12 Port A/B DMA control register [Output] (A_OUT_DMA/B_OUT_DMAC)

A_OUT_DMAC/B_OUT_DMAC is a 32-bit readable/writable register that can be accessed by CPU.

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 4	VDMD	00	R/W	Setting valid data 00: Package in front 01: Package in the back 10: Stream mode(16bit * 2) 11: Reserve When using PCM format or SPDIF (IEC60958) format, set “10”. When using SPDIF (IEC61937) format, set “10”
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DMA_ON	0	R/W	DMA active bit 0: DMA Off 1: DMA On

1) Package in front

Byte address	31	0
0–3	dat0[23:0]	don't care
4–7	dat1[23:0]	don't care
8–C	dat2[23:0]	don't care

2) Package in the back

Byte address	31	0
0–3	don't care	dat0[23:0]
4–7	don't care	dat1[23:0]
8–C	don't care	dat2[23:0]

3) Stream mode (16bit * 2)

Byte address	31	0
0–3	dat0[15:0]	dat1[15:0]
4–7	dat2[15:0]	dat3[15:0]
8–C	dat4[15:0]	dat5[15:0]

51.3.13 Port A/B output control register (A_OUT_SEL/B_OUT_SEL)

A_OUT_SEL/B_OUT_SEL is a 32-bit readable/writable register that control serial output. When using SPDIF (IEC60958) format, set “00” to SO_MD bits.

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	FCLR	0	R/W	Clear frame number of SPDIF 0: Keep value 1: Initialize value.
19 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	DMMD	0	R/W	Select SPDIF output timing when output data 1/2 full of FIFO. 0: Output Biphase only 1: Output Biphase and serial data
3 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1 to 0	SO_MD	01	R/(W)*	Port A Output FIFO Interrupt 00: serial output (OFF) Biphase output (OFF) 01: serial output (ON) Biphase output (OFF) 10: serial output (OFF) Biphase output (ON) 11: serial output (ON) Biphase output (ON)

51.3.14 Port A/B output SPDIF state register (A_OUT_SPST/B_OUT_SPST)

A_OUT_SPST/B_OUT_SPST is a 32-bit readable/writable register. This register change state information of channel and value of interrupt.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	FSIZE	00000000	R	Count value of sample of SPDIF (IEC:60958) 00000000: ready 00000001: first frame … 11000000: last frame (192)
7 to 0	ESIZE	01100000	R/W	Set value of interrupt frame of SPDIF (IEC:60958) 00000000: ready 00000001: first frame … 11000000: last frame (192)

51.3.15 Port A DMA control register [Input] (A_IN_DMAC)

A_OUT_DMAC is a 32-bit readable/writable register that can be accessed by CPU.

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	VDMD	0	R/W	Setting valid data 0: Package in front 1: Package in the back
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DMA_ON	0	R/W	DMA active bit 0: DMA Off 1: DMA On

51.3.16 Port A input control register (A_IN_SEL)

A_IN_SEL is a 32-bit readable/writable register that control serial input.

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SI_MD	1	R/W	Select serial input mode 0: SI-IF (Off) 1: SI-IF (On)

51.3.17 Port A/B master clock control register (A_MST_CTLR/B_MST_CTLR)

A_MST_CTLR/B_MST_CTLR is a 32-bit readable/writable register that fix signal in SPDIF mode.

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	BP	0	R/W	Fix the signal of Biphase output 0: Fix Low (On) 1: Fix Low (Off)
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SE	0	R/W	Fix the master clock 0: Fix Low (On) 1: Fix Low (Off)

51.3.18 Timer set register (TMR_CTL)

TMR_CTL is a 32-bit readable/writable register that counts value of sample, Output of port A, port A and Input of port A. If value of counter is overflow, FSI2 interrupt occur.

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	AI	1101	R/W	Sampling frequency of Port A input 0000: 1 0001: 2 0010: 4 0011: 8 0100: 16 0101: 32 0110: 64 0111: 128 1000: 256 1001: 512 1010: 1024 1011: 2048 1100: 4096 1101: 8192 1110: 16384 1111: 32768
19 to 16	AO	1101	R/W	Sampling frequency of Port A output same function (bit 31 to 20)
15 to 12	—	1101	R	Reserved These bits are always read as 1101. The write value should always be 1101.
11 to 8	BO	1101	R/W	Sampling frequency of Port B output same function (bit 31 to 20)
0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

51.3.19 Timer clear register (TMR_CLR)

TMR_CLR is a 32-bit readable/writable register that clear the value of counter.

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	AI_CLR	0	R/W	Clear the value of counter for Port A input. 0: keep 1: clear
19 to 17	—	All 0	R	Reserved These bits are always read as 1101. The write value should always be 1101.
16	AO_CLR	0	R/W	Clear the value of counter for Port A output. 0: keep 1: clear
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	BO_CLR	0	R/W	Clear the value of counter for Port B output. 0: keep 1: clear
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

51.3.20 Interrupt clear register (INT_CLR)

INT_CLR is a 32-bit readable/writable register that clear interrupts to CPU.

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	CPIC	0	R/W	Clear the interrupt to CPU. 0: keep 1: clear
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

51.3.21 CPU Interrupt State Register (CPU_INT_ST)

CPU_INT_ST is a 32-bit readable/writable register that retains 4 interrupt sources separately. Only writing 0 to clear is accepted. Writing 1 does not change the bit value. To clear a specific interrupt source, write 0 to the corresponding bit and 1 to the other bits.

The interrupt state register is set if the specified interrupt condition matches the FIFO state while the corresponding interrupt mask is cleared. If an interrupt source is cleared at the same time as the interrupt source occurs, the interrupt condition takes precedence.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	IIB	—	—	—	IOB	—	—	—	IIA	—	—	—	IOA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/(W)*	R	R	R	R/(W)*	R	R	R	R/(W)*	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	IESTTAI	0	R/W	Factor of timer interrupt for port A input 0: Clear 1: Keep
19	IESTOEBO	0	R/W	Factor of end interrupt for port B output 0: Clear 1: Keep
18	IESTOEAO	0	R/W	Factor of end interrupt for port A output 0: Clear 1: Keep
17	IESTTBO	0	R/W	Factor of timer interrupt for port B 0: Clear 1: Keep
16	IESTTAO	0	R/W	Factor of timer interrupt for port A 0: Clear 1: Keep

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	IESTSEBO	0	R/W	Factor of next SPDIF stream interrupt for port B 0: Clear 1: Keep
10	IESTBEBO	0	R/W	Factor of interrupt that update information of SPDIF parameter for port B 0: Clear 1: Keep
9	IESTEBO	0	R/W	Factor of FIFO Error interrupt for port B output 0: Clear 1: Keep
8	IESTBO	0	R/W	Factor of FIFO state interrupt for port B output 0: Clear 1: Keep
7 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	IESTEAI	0	R/W	Factor of FIFO Error interrupt for port A input 0: Clear 1: Keep
4	IESTAI	0	R/W	Factor of FIFO state interrupt for port A input 0: Clear 1: Keep
3	IESTSEAO	0	R/W	Factor of next SPDIF stream interrupt for port A 0: Clear 1: Keep
2	IESTBEAO	0	R/W	Factor of interrupt that update information of SPDIF parameter for port B 0: Clear 1: Keep
1	IESTEAO	0	R/W	Factor of FIFO Error interrupt for port A output 0: Clear

Bit	Bit Name	Initial Value	R/W	Description
				1: Keep should always be 0.
0	IESTAO	0	R/W	Factor of FIFO state interrupt for port B output 0: Clear 1: Keep

Note: * Writing 0 to this bit clears the interrupt source. Writing 1 does not change the bit value.

51.3.22 CPU Interrupt Source Mask Set Register (CPU_IEMSK)

IEMASK is a 32-bit readable/writable register that masks the interrupt source for each FIFO. If this register masks an interrupt source, the interrupt source is not enabled even if the IMASK register below unmasks the interrupt signal. Thus, the interrupt does not occur.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	IEMSKTBI	0	R/W	Port A Input Timer Interrupt Request Mask 0: Disabled(Mask) 1: Enabled
19	IEMSKOEBO	0	R/W	Port B output End Interrupt Request Mask 0: Disabled(Mask) 1: Enabled
18	IEMSKOEAO	0	R/W	Port A output End Interrupt Request Mask 0: Disabled(Mask) 1: Enabled
17	IEMSKTBO	0	R/W	Port B Output Timer Interrupt Request Mask 0: Disabled(Mask) 1: Enabled
16	IEMSKTAO	0	R/W	Port A Output Timer Interrupt Request Mask 0: Disabled(Mask) 1: Enabled
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value

Bit	Bit Name	Initial Value	R/W	Description
				should always be 0.
11	IEMSKSEBO	0	R/W	Port B output next SPDIF stream Request Mask 0: Disabled(Mask) 1: Enabled
10	IEMSKBEBO	0	R/W	Port B Output update information of SPDIF Request Mask 0: Disabled(Mask) 1: Enabled
9	IEMSKEBO	0	R/W	Port B output FIFO Error Request Mask 0: Disabled(Mask) 1: Enabled
8	IEMSKBO	0	R/W	Port B output FIFO status Request Mask 0: Disabled(Mask) 1: Enabled
7 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	IEMSKEAI	0	R/W	Port A input FIFO Error Request Mask 0: Disabled(Mask) 1: Enabled
4	IEMSKAI	0	R/W	Port A input FIFO status Request Mask 0: Disabled(Mask) 1: Enable
3	IEMSKSEAO	0	R/W	Port A output next SPDIF stream Request Mask 0: Disabled(Mask) 1: Enabled
2	IEMSKBEAO	0	R/W	Port A Output update information of SPDIF Request Mask 0: Disabled(Mask) 1: Enabled
1	IEMSKEAO	0	R/W	Port A output FIFO Error Request Mask 0: Disabled(Mask) 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
0	IEMSKAO	0	R/W	Port A output FIFO status Request Mask 0: Disabled(Mask) 1: Enabled

51.3.23 CPU Interrupt Signal Mask Set Register (CPU_IMSK)

CPU_IMASK is a 32-bit readable/writable register that masks the interrupt signal for each FIFO to the DSP. If an interrupt source for a FIFO whose interrupt signal is unmasked, the interrupt request signal occurs.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0

R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	IMSKTAI	0	R/W	Port A Input Timer Interrupt Signal Mask 0: Disabled(Mask) 1: Enabled
19	IMSKOEBO	0	R/W	Port B output End Interrupt Request Mask 0: Disabled(Mask) 1: Enabled.
18	IMSKOEAO	0	R/W	Port A output End Interrupt Request Mask 0: Disabled(Mask) 1: Enabled.
17	IMSKTBO	0	R/W	Port B Output Timer Interrupt Request Mask 0: Disabled(Mask) 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
16	IMSKTAO	0	R/W	Port A Output Timer Interrupt Request Mask 0: Disabled(Mask) 1: Enabled
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	IMSKSEBO	0	R/W	Port B output next SPDIF stream Request Mask 0: Disabled(Mask) 1: Enabled
10	IMSKBEBO	0	R/W	Port B Output update information of SPDIF Request Mask 0: Disabled(Mask) 1: Enabled
9	IMSKEBO	0	R/W	Port B output FIFO Error Request Mask 0: Disabled(Mask) 1: Enabled
8	IMSKBO	0	R/W	Port B output FIFO status Request Mask 0: Disabled(Mask) 1: Enabled
7 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	IMSKEAI	0	R/W	Port A input FIFO Error Request Mask 0: Disabled(Mask) 1: Enabled
4	IMSKAI	0	R/W	Port A input FIFO status Request Mask 0: Disabled(Mask) 1: Enable
3	IMSKSEAO	0	R/W	Port A output next SPDIF stream Request Mask 0: Disabled(Mask) 1: Enabled
2	IMSKBEAO	0	R/W	Port A Output update information of SPDIF Request Mask 0: Disabled(Mask)

Bit	Bit Name	Initial Value	R/W	Description
				1: Enabled
1	IMSKEAO	0	R/W	Port A output FIFO Error Request Mask 0: Disabled(Mask) 1: Enabled
0	IMSKAO	0	R/W	Port A output FIFO status Request Mask 0: Disabled(Mask) 1: Enabled

51.3.24 DSP Interrupt State Register (DSP_INT_ST)

DSP_INT_ST is a 32-bit readable/writable register that retains 4 interrupt sources separately. Only writing 0 to clear is accepted. Writing 1 does not change the bit value. To clear a specific interrupt source, write 0 to the corresponding bit and 1 to the other bits.

The interrupt state register is set if the specified interrupt condition matches the FIFO state while the corresponding interrupt mask is cleared. If an interrupt source is cleared at the same time as the interrupt source occurs, the interrupt condition takes precedence.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

R/W:	R	R	R	R/(W)*	R	R	R	R/(W)*	R	R	R	R/(W)*	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	IESTTAI	0	R/W	Factor of timer interrupt for port A input 0: Clear 1: Keep
19	IESTOEBO	0	R/W	Factor of end interrupt for port B output 0: Clear 1: Keep
18	IESTOEAO	0	R/W	Factor of end interrupt for port A output 0: Clear 1: Keep
17	IESTTBO	0	R/W	Factor of timer interrupt for port B 0: Clear 1: Keep
16	IESTTAO	0	R/W	Factor of timer interrupt for port A 0: Clear 1: Keep

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	IESTSEBO	0	R/W	Factor of next SPDIF stream interrupt for port B 0: Clear 1: Keep
10	IESTBEBO	0	R/W	Factor of interrupt that update information of SPDIF parameter for port B 0: Clear 1: Keep
9	IESTEBO	0	R/W	Factor of FIFO Error interrupt for port B output 0: Clear 1: Keep
8	IESTBO	0	R/W	Factor of FIFO state interrupt for port B output 0: Clear 1: Keep
7 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	IESTEAI	0	R/W	Factor of FIFO Error interrupt for port A input 0: Clear 1: Keep
4	IESTAI	0	R/W	Factor of FIFO state interrupt for port A input 0: Clear 1: Keep
3	IESTSEAO	0	R/W	Factor of next SPDIF stream interrupt for port A 0: Clear 1: Keep
2	IESTBEAO	0	R/W	Factor of interrupt that update information of SPDIF parameter for port B 0: Clear 1: Keep
1	IESTEAO	0	R/W	Factor of FIFO Error interrupt for port A output 0: Clear

Bit	Bit Name	Initial Value	R/W	Description
				1: Keep should always be 0.
0	IESTAO	0	R/W	Factor of FIFO state interrupt for port B output 0: Clear 1: Keep

Note: * Writing 0 to this bit clears the interrupt source. Writing 1 does not change the bit value.

51.3.25 DSP Interrupt Source Mask Set Register (DSP_IEMSK)

DSP_IEMASK is a 32-bit readable/writable register that masks the interrupt source for each FIFO. If this register masks an interrupt source, the interrupt source is not enabled even if the DSP_IMASK register below unmasks the interrupt signal. Thus, the interrupt does not occur.

Bit:	23	22	21	20	19	18	17	16

1	TSOA	0	R/W	Port A Output MUTE 0: MUTE off 1: MUTE on
0	TYOA	0	R/W	Port A Output MUTE Mode Set 0: Normal MUTE 1: Zero cross MUTE

51.3.28 Clock Reset Set Register (ACK_RST)

ACK_RST is a 32-bit readable/writable register. During reset, it masks the LR and bit clocks that are output from the clock-generating block. Clear the reset after setting formats and clocks by follow the operation flow.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	CRB	—	—	—	CRA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	PBCR	0	R/W	Port B Clock Reset 0: Issues a reset. 1: Clear the reset.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PACR	0	R/W	Port A Clock Reset 0: Issues a reset. 1: Clears the reset.

Note: * This bit should be asserted for longer than the audio clock period so that the counter synchronized with it is reset.

51.3.29 Software Reset Set Register (SOFT_RST)

SOFT_RST is a 32-bit readable/writable register that initializes the internal registers.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	SRB	—	—	—	SRA	—	—	—	IR	—	—	—	SR
Initial value:	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1
R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	PBSR	1	R/W	Port B Software Reset This bit performs a port B FIFO clear. 0: Issues a reset. 1: Clears the reset.
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	PASR	1	R/W	Port A Software Reset This bit performs a port A FIFO clear. 0: Issues a reset. 1: Clears the reset.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	IR	1	R/W	Interrupt Reset This bit negates the interrupt signal without receiving an acknowledge. 0: Issues a reset. 1: Clears the reset.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value

Bit	Bit Name	Initial Value	R/W	Description
				should always be 0.
0	FSISR	1	R/W	Software Reset This bit initializes all registers. 0: Issues a reset. 1: Clears the reset.

51.3.30 FIFO Size Register (FIFO_SZ)

FIFO_SZ is a 32-bit read-only register that indicates the on-chip RAM capacity.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	BI[2:0]			—	BO[2:0]			—	AI[2:0]			—	AO[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	BO[2:0]	000	R	Port B Output FIFO Capacity These bits indicate the on-chip RAM capacity. 000: 256 words 001: 512 words 010: 1024 words 011: 2048 words 111: Out-of-spec capacity is set (error) Note: No value other than listed above is output.

Bit	Bit Name	Initial Value	R/W	Description
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 4	AI[2:0]	000	R	Port A Input FIFO Capacity These bits indicate the on-chip RAM capacity. 000: 256 words 001: 512 words 010: 1024 words 011: 2048 words 111: Out-of-spec capacity is set (error) Note: No value other than listed above is output.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2 to 0	AO[2:0]	000	R	Port A Output FIFO Capacity These bits indicate the on-chip RAM capacity. 000: 256 words 001: 512 words 010: 1024 words 011: 2048 words 111: Out-of-spec capacity is set (error) Note: No value other than listed above is output.

51.3.31 Clock select register (CLK_SEL)

CLK_SEL is a 32-bit readable/writable register that select clock for FSI2.This register access from CPU only by HPB bus only.

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DSPS	0	R/W	Select FSI2 clock. 0: Bus clock(HP clock) 1: DSP clock(SPU clock)

Note: Not change this register value while FSI2 transfer data.

51.3.32 Swap select register (SWAP_SEL)

SWAP_SEL is a 32-bit readable/writable register that select clock for FSI2.This register access from CPU only by HPB bus only.

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1 to 0	BW	0	R/W	Select SWAP mode. 00: normal 01: Byte swap 10: Word swap 11: Byte word swap

Note: Not change this register value while FSI2 transfer data.

51.3.33 HPB software reset register (HPB_SRST)

SWAP_SEL is a 32-bit readable/writable register that select clock for FSI2.This register access from CPU only by HPB bus only.

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	HPBSR	1	R/W	HPB reset 0: Reset to HPB block 1: normal
19 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
16	DSPSR	0	R/W	DSP reset 0: Reset to DSP block 1: normal
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: Not change this register value while FSI2 transfer data.

51.3.34 SPDIF (60958) Port A/B channel state register (A_SP_CHST00, A_SP_CH01/ B_SP_CHST00, B_SP_CH01)

A_SP_CHST00, A_SP_CHST01, B_SP_CHST00 and B_SP_CHST01 are 32-bit readable/writable registers that set value of channel state by 1block.

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14	ST	0	R/W	Audio identification 0: Audio 1: except for audio Note: Set value “1”, when using stream mode.
13	ST	0	R/W	Copyright protection 0: protection 1: non-protection
12 to 10	ST	000	R/W	Select emphasis 000: non-emphasis 001: emphasis (50/15 micro sec) 010: reserve 011: reserve
9 to 8	—	00	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	ST	0	R/W	Category code 00000000: 2 channel general format 10000000: 2 channel CD 01000000: 2 channel PCM encoder/decoder 11000000: 2 channel DAT

51.3.35 SPDIF (60958) Port A/B user data register (A_SP_USD00 - A_SP_USD23/ B_SP_USD00 - B_SP_USD23)

A_SP_USD00 - A_SP_USD23, B_SP_USD00 - B_SP_USD22 and B_SP_USD23 are 32-bit readable/writable registers that set value of channel state by 1block.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	US	All 0	R/W	User data

51.3.36 SPDIF (61937) Port A/B preamble pa register (A_SP_PA/ B_SP_PA)

A_SP_PA and B_SP_PA are 32-bit readable/writable registers that set value of preamble data.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	PA	All 0	R/W	Preamble pa paremeter (IEC61937)

51.3.37 SPDIF (61937) Port A/B preamble pb register (A_SP_PB/ B_SP_PB)

A_SP_PB and B_SP_PB are 32-bit readable/writable registers that set value of preamble data.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	PB	All 0	R/W	Preamble pb paremeter (IEC61937)

51.3.38 SPDIF (61937) Port A/B preamble pc register (A_SP_PC/ B_SP_PC)

A_SP_PC and B_SP_PC are 32-bit readable/writable registers that set value of preamble data.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	PC	All 0	R/W	Preamble pc paremeter (IEC61937)

51.3.39 SPDIF (61937) Port A/B preamble pd register (A_SP_PD/ B_SP_PD)

A_SP_PD and B_SP_PD are 32-bit readable/writable registers that set value of preamble data.

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	PD	All 0	R/W	Preamble pd paremeter (IEC61937)

51.3.40 Port A/B Pause cycle register (A_SP_PS/ B_SP_PS)

A_SP_PS and B_SP_PS are 32-bit readable/writable registers that set value of pause cycle (IEC60958).

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	PS	All 0	R/W	Set value of pause frame.

Do not set it excluding the following value.

Stream format	Value of 1 frame for pause
AC-3 data	3 frame(Recommend)
MPEG-1 layer 1 data	32 frame(Must)
MPEG-1 layer 2 or 3 data	
MPEG-2 without extension	
MPEG-2 data with extension	
MPEG-2 layer 1 low sampling frequency	64 frame(Must)
MPEG-2 layer 2 or 3 low sampling frequency	
MPEG-2 AAC	32 frame(Recommend)
MPEG-2 AAC and half-rate low sampling frequency	64 frame(Recommend)
MPEG-2 AAC and quarter-rate low sampling frequency	128 frame(Recommend)
MPEG-4 AAC	32 frame(Recommend)
MPEG-4 AAC and half-rate low sampling frequency	64 frame(Recommend)
MPEG-4 AAC and quarter-rate low sampling frequency	128 frame(Recommend)
MPEG-4 AAC double-rate high sampling frequency	16 frame(Recommend)

51.3.41 Port A/B Pause length register (A_SP_PL/ B_SP_PL)

A_SP_PL and B_SP_PL are 32-bit readable/writable registers that set value of pause all frame (IEC60958).

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	PL	All 0	R/W	Set value of pause frame.

Do not set it excluding the following value.

Stream format	Value of 1 frame for pause
AC-3 data	3 frame(1 frame) x N*
MPEG-1 layer 1 data	32 frame(1 frame) x N*
MPEG-1 layer 2 or 3 data	
MPEG-2 without extension	
MPEG-2 data with extension	
MPEG-2 layer 1 low sampling frequency	64 frame(1 frame) x N*
MPEG-2 layer 2 or 3 low sampling frequency	
MPEG-2 AAC	32 frame(1 frame) x N*
MPEG-2 AAC and half-rate low sampling frequency	64 frame(1 frame) x N*
MPEG-2 AAC and quarter-rate low sampling frequency	128 frame(1 frame) x N*
MPEG-4 AAC	32 frame(1 frame) x N*
MPEG-4 AAC and half-rate low sampling frequency	64 frame(1 frame) x N*
MPEG-4 AAC and quarter-rate low sampling frequency	128 frame(1 frame) x N*
MPEG-4 AAC double-rate high sampling frequency	16 frame(1 frame) x N*

Note: N = 1,2,3,… Set value of all of frame is 65535 frame or less.

51.3.42 Port A/B Frame size register (A_SP_FS/ B_SP_FS)

A_SP_FS and B_SP_FS are 32-bit readable/writable registers that set value of frame (IEC60958), when using SPDIF stream data.

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	PL	All 0	R/W	Set value of frame while 1 frame.

Do not set it excluding the following value.

Stream format	Value of 1 frame
Null-data	3frame to 4096frame(Recommend)
AC3 data	1536 frame
Pause	-
MPEG-1 layer 1 data	384 frame
MPEG-1 layer 2 or 3 data, or MPEG-2 without extension	1152 frame
MPEG-2 data with extension	1152 frame
MPEG-2 AAC ADTS	1024 frame
MPEG-2 layer 1 low sampling frequency	768 frame
MPEG-2 layer 2 or 3 low sampling frequency	2304 frame
MPEG-2 AAC ADTS low sampling frequency	2048/4096 frame
MPEG-4 AAC	1024/2048/4096/512 frame

51.3.43 Interrupt select register (INT_SEL)

INT_SEL is 32-bit readable/writable registers that select redirection which DSP of SPU2 or INTC.

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 2	FMSI_SEL	00	R/W	Select redirection for FMSI 01: DSP of SPU2 only 10: INTC only
1 to 0	FSI_SEL	00	R/W	Select redirection for FSI2 01: DSP of SPU2 only 10: INTC only

51.4 Interface Specifications

51.4.1 FSI2 and SPU2 Connection Interface Specifications

The FSI2 uses an 8-bit address space (H'00 to H'FF). The FSI2 registers can be read and written via the SPU2 DSP/IO bus.

(1) BUFC Specifications

Figure 51.5 shows the data flow from read requests to the A_DIDT and B_DIDT registers to the data output.

To read data stored in input FIFOs continuously, the fsio_io_hold signal is maintained when the A_DIDT or B_DIDT register is read. When a read request is sent to the FSI2, the hold signal is not driven low and the read request is kept asserted until data are stored in buffers in the control block. Thus, data requests are generated continuously and the next data to be read are stored in the control block buffers.

Data can be read continuously with one wait like other registers by prefetching data in the control block buffers.

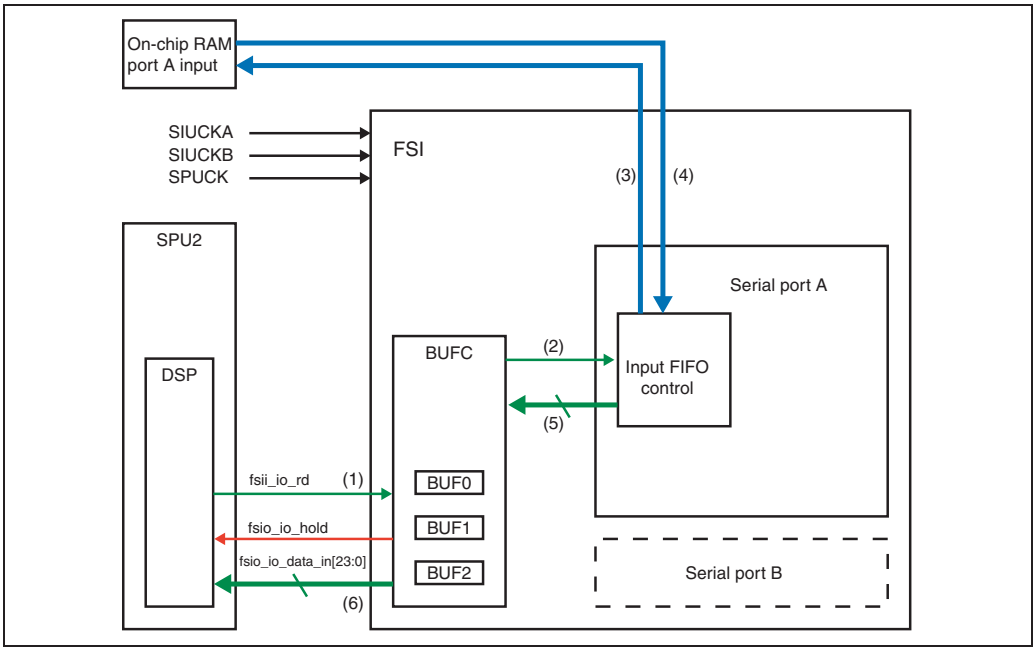

Figure 51.5 Block Diagram of Input FIFO Read Request

51.4.2 Clock Interface Specifications

A block diagram of clock signals is shown in figure 51.6.

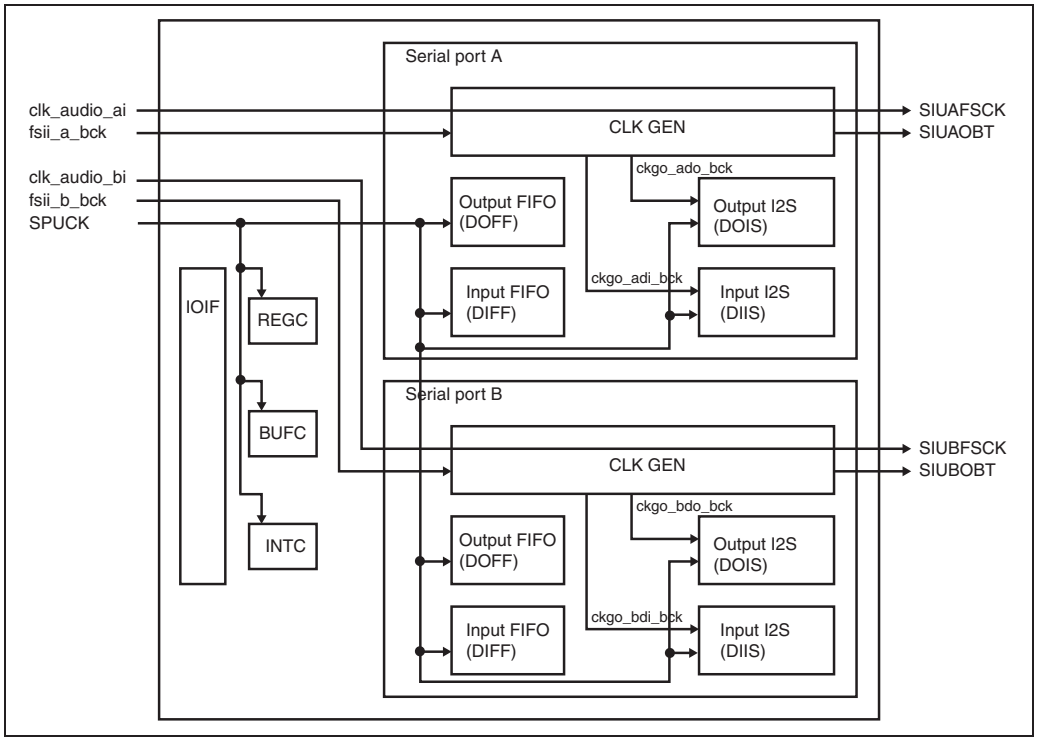

Figure 51.6 Block Diagram of FSI2 Clock Inputs

51.4.3 Reset Interface Specifications

Table 51.6 lists the FSI2 resets.

Table 51.6 FSI2 Rest Type, Initialization Register and Block

			Initializing Module							
Reset Name	**Register**	**Initialization Register**	**INTC**	**BUFC**	**REGC**	**CLK GEN**	**Output FIFO**	**Input FIFO**	**Output I2S**	**Input I2S**
Hardware reset	—	All registers	√							
Software reset	SOFT_RST.SR	All registers except software reset	√							√ (except FFs synchronized with the Bitclk)
Port A reset	SOFT_RST.SRA	Performs a port A FIFO clear.	—	—	—	—		√ (Port A only)		
Port B reset	SOFT_RST.SRB	Performs a port B FIFO clear.	—	—	—	—		√ (Port B only)		
Clock reset A	CLK_RST.CRA	—	—	—	—	√ (Port A)	—	—	—	—
Clock reset B	CLK_RST.CRB	—	—	—	—	√ (Port B)	—	—	—	—

Port B output FIFO clear	B_DOFF_CTL.CLR	—	—	—	—	—	√ (Port B)	—	—	—
Port B input FIFO clear	B_DIFF_CTL.CLR	—	—	√ (Port B)	—	—	—	√ (Port B)	—	—

[Legend] √: Reset, —: Register retained

(1) Hardware Reset

Initializes all registers and modules.

(2) Software Reset

Initializes all registers except the software reset register (SOFT_RST.SR) and all modules. In master operation, the bit clock that is used for asynchronous passing may be fixed due to a clock reset, perform a software reset after resetting ports A/B (see (8) Procedures for Initializing the FSI2).

(3) Port A/B Reset

These are the reset signals to initialize the FFs that are synchronized with the bit clock.

Since the bit clock is used for asynchronous passing, this reset requires to wait for longer than 1 bit clock cycle after a register write to perform it.

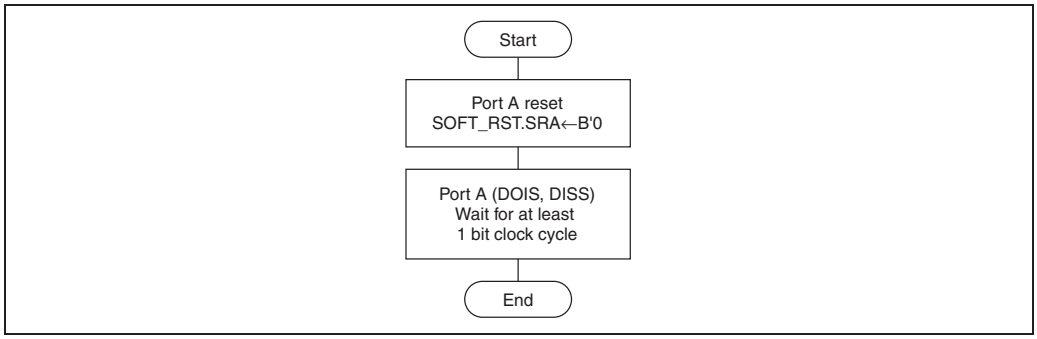

Figure 51.7 Flow of Port A Reset

(4) Clock Reset A/B

These are the reset signals to initialize the FFs that are synchronized with the audio clock.

Since the audio clock is used for asynchronous passing, this reset requires to wait for longer than 1 audio clock cycle after a register write to perform it.

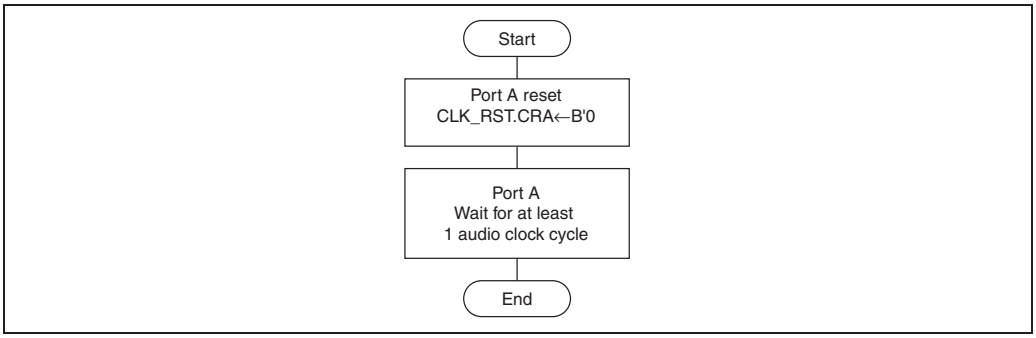

Figure 51.8 Flow of Clock Reset A

(5) Interrupt Reset

Negates the interrupt signal (fsio_int) when the corresponding register is written.

(6) Port A/B Output FIFO Clear

Clears the address pointer of the FIFO control block and the error history.

(7) Port A/B Input FIFO Clear

Clears the address pointer of the FIFO control block, the error history, and buffers for continuous 1-wait reads.

(8) Procedures for Initializing the FSI2

The procedures for initializing the FSI2 are shown in figure 51.9. There are two types of procedures: one by using a hardware reset and another by using a software reset. To achieve the same effect as a hardware reset, perform a software reset after port A/B reset (initializing the FFs that are synchronized with the bit clock).

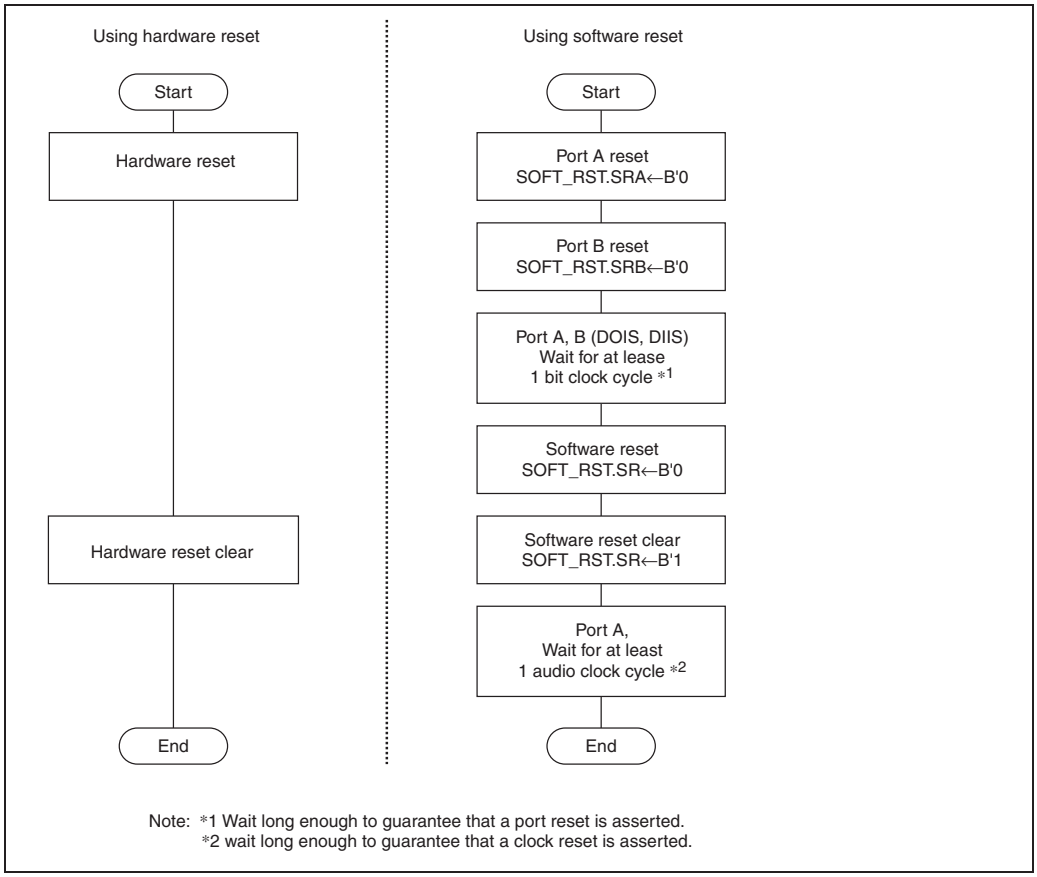

Figure 51.9 Operation Flow of FSI2 Initial States

51.4.4 Interrupt Interface Specifications

The FSI2 has an interrupt signal line for external modules. The positive interrupt signal is connected to SPU2 and the negative interrupt signal is connected to the CPU (INTC).

In normal operation, SPU2 handles interrupts and the CPU interrupt signal is not used.

The CPU interrupt signal is used for debugging where DSP programs of SPU2 are not started.

Table 51.7 shows the pin configurations in normal operation.

Table51.7 Interrupt Pin Configurations

Pin Name	Input/Output	Function	Polarity
fsio_int	Output	Interrupt requests to SPU2	High
fsii_int_ack	Input	In response to a request, SPU2 returns a 1-pulse acknowledge and the FSI2 drives fsio_int low.	High

In normal operation, the external interrupt signal (fsio_int) is asserted by any of four interrupt sources. Once the interrupt signal is asserted after it is negated by fsii_int_ack, it is never asserted again until at least one interrupt source is cleared (int_set=0).

Figure 51.10 shows a timing chart of the interrupt signal.

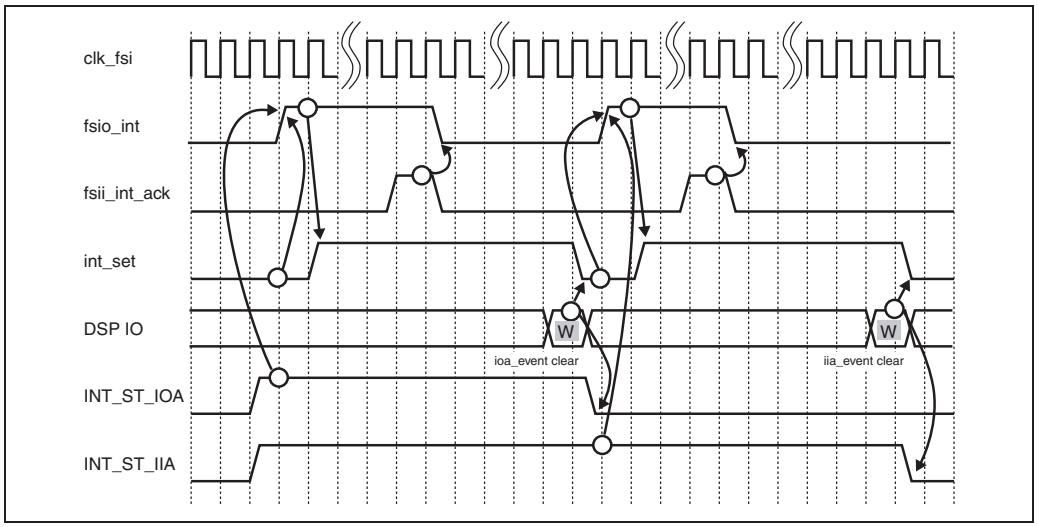

Figure 51.10 Timing Chart of Interrupt Signal

If all masks for interrupt sources and signals are cleared, the interrupt status registers (INT_ST.IOA, INT_ST.IIA) function as the interrupt request signals (int_ioa, int_iia).

SPU2 clears the source (int_st_ioa) at the end of interrupt handling. By this clearing, the interrupt control signal (int_set) is B'0 and is asserted again when another source occurs.

51.5 MUTE Specifications

The FSI2 has normal MUTE and zero cross MUTE functions for input/output operations. The MUTE circuits are implemented for output FIFOs and input FIFOs.

(1) Normal MUTE

The normal MUTE mutes on a per sample data basis. It is turned on (outputs 0) for channel 1 first 2 samples after it is enabled. Similarly, it is turned off for channel 1 first 2 samples after it is disabled.

Figure 51.11 shows the 2-channel audio output and the MUTE signal.

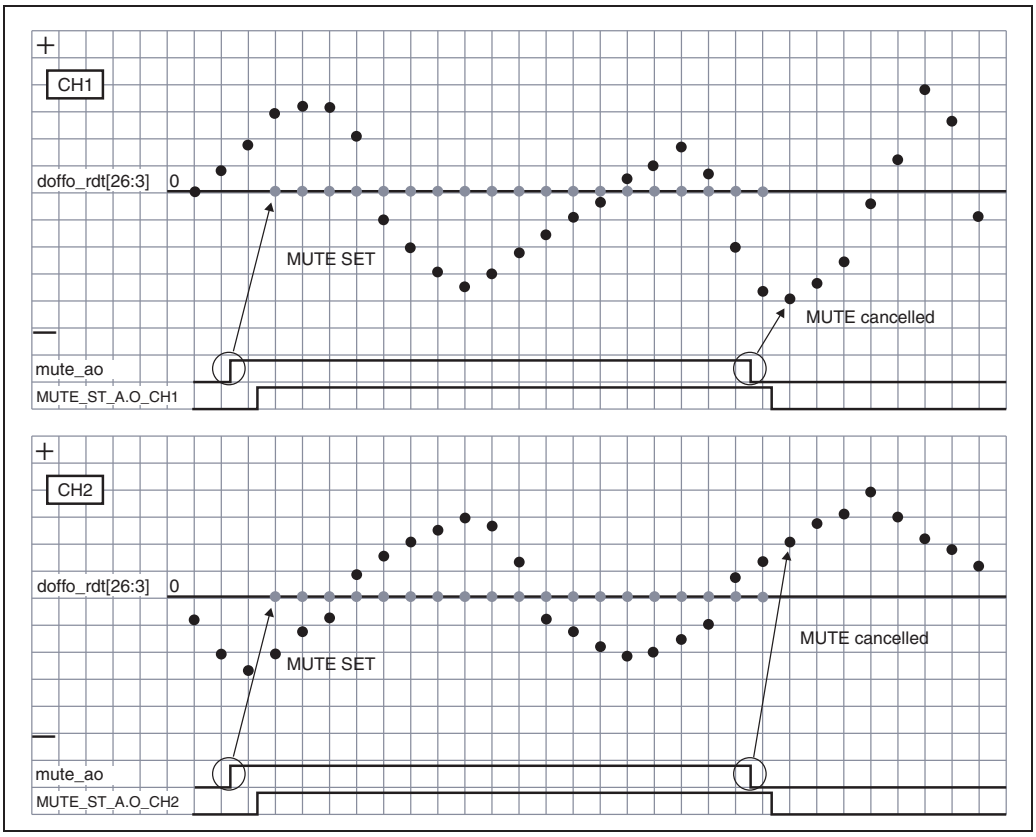

Figure 51.11 Normal MUTE Specification (Output Operation)

When the MUTE signal is asserted in input operation, the conversion module (input I2S) takes data written to input FIFOs and writes 0 to the on-chip RAM.

(2) Zero Cross MUTE

If the zero cross MUTE function is enabled, it compares current data to the previous one on each channel independently.

The conditions for turning on the mute are (1) the previous data is 0, (2) current data is 0, and (3) the sign of current data does not match the one of the previous data.

If any of these conditions ((1) to (3)) is satisfied, the mute is turned on (0 is output) until the zero cross MUTE function is disabled.

The mute (outputting 0) is turned off, just like it is turned on, if any of the conditions ((1) to (3)) is satisfied when current data is compared to the previous one on each channel independently.

Figure 51.12 shows the 2-channel audio output and zero cross MUTE signal.

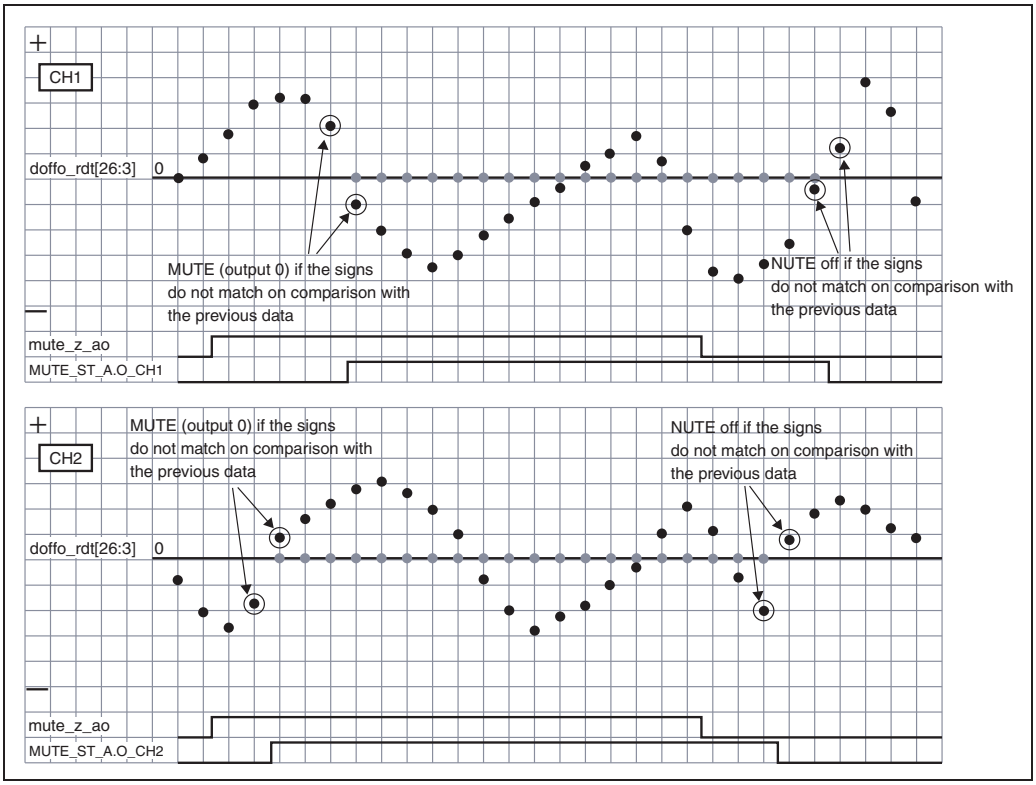

Figure 51.12 Zero Cross MUTE Specification (Output Operation)

Even if the zero cross MUTE function is enabled, the mute (outputting 0) is not turned on unless any of the conditions (1) to (3) is met.

Even if any of the conditions (1) to (3) is met, the mute (outputting 0) is not turned off unless the zero cross MUTE function is disabled.

After the zero cross MUTE function is enabled, it can be switched to the normal MUTE function to turn on/off the mute forcibly.

When the MUTE signal is asserted in input operation, the conversion module (input I2S) compares data written to input FIFOs to determine if the conditions (1) to (3) are met and writes 0 to the on-chip RAM.

51.6 FIFO Overflow/Underflow Specifications

When an underflow or overflow error occurs, the FIFO contains the error related information in a register. This section describes underflows and overflows in the output FIFOs and input FIFOs.

An output FIFO underflow occurs when the output I2S requests data (req) while the FIFO is empty. When it occurs, the output FIFO outputs H'00 0000 and the channel number [2:0]. An overflow occurs when the DSP tries to write more data than the FIFO capacity. Such write operations are ignored. No overflow occurs under management by the DSP.

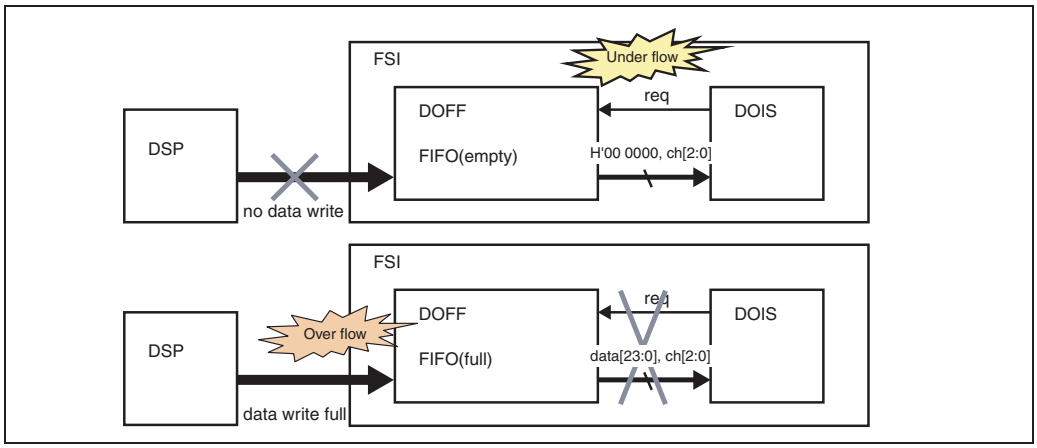

Figure 51.13 Output FIFO Underflow/Overflow

An input FIFO overflow occurs if 3-line serial data is input to the FIFO externally when it is full. The write to the input FIFO that caused an overflow is ignored. An underflow occurs when a read request is issued by the DSP while the input FIFO is empty. When it occurs, the read request returns 0. No underflow occurs under management by the DSP.

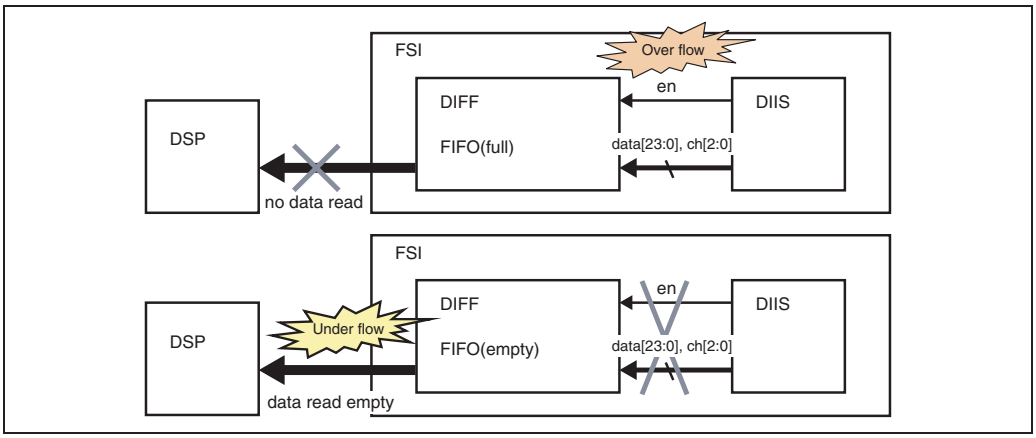

Figure 51.14 Input FIFO Overflow/Underflow

51.7 FIFO Clear

The FSI2 has a FIFO clear function for input and output separately. This function does the following:

(1) Clearing the UF/OF error history

Clears the FIFO status to 0.

(2) Clearing the address pointer of the FIFO control

Initializes the counter that controls the on-chip RAM access. When a FIFO clear is performed, the address pointer returns to the start address and data prior to the clear is overwritten.

(3) Clearing data prefetched by the BUFC block and the buffer pointer

Clears data prefetched by the BUFC block for continuous reads and the buffer pointer.

(4) Masking the FIFO control block

Can be enabled for the request (CH0) corresponding to the second sample after a FIFO clear. This is because the state of the mask is determined by the request (output) and enable (input) after the format and clock settings is fixed.

51.8 Serial Data Formats

All formats for 3-line serial data are shown below. The internal modules (DOIS, DIIS) operate based on the falling edge of the LR clock (CH0) that is inverted on the rising edge of the bit clock. Although the master clock is generated according to the specification in master operation, the inversion register needs to be set properly if the external LR and bit clocks are input directly in slave operation. Along with serial data formats, the inversion settings for slave operation are shown below for reference.

The MONO and MONO_Delay serial data formats are shown below.

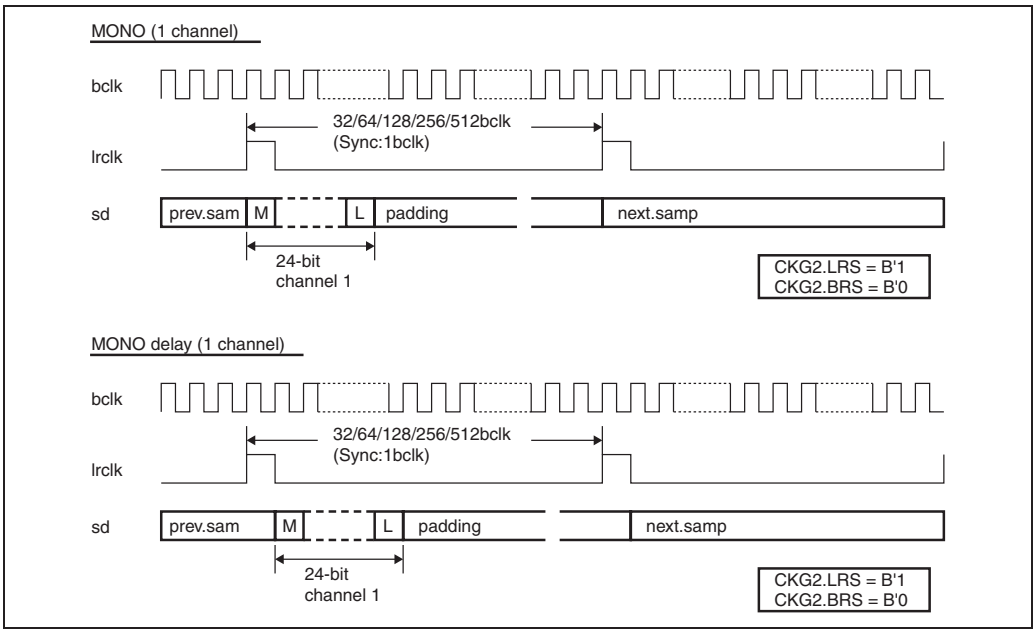

Figure 51.15 MONO and MONO_Delay Formats

The PCM and I2S serial data formats are shown below.

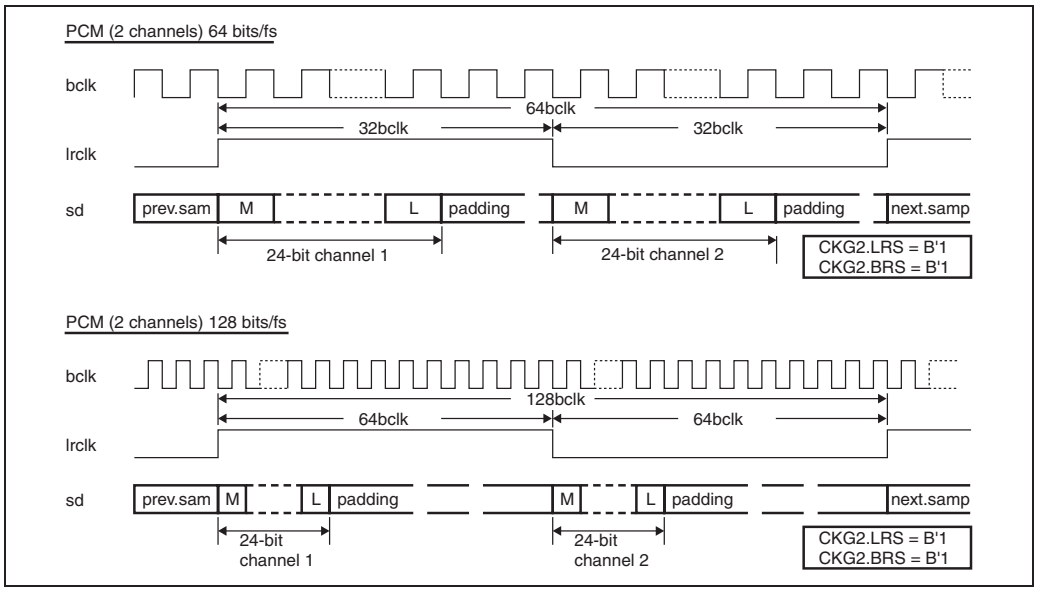

Figure 51.16 PCM Formats

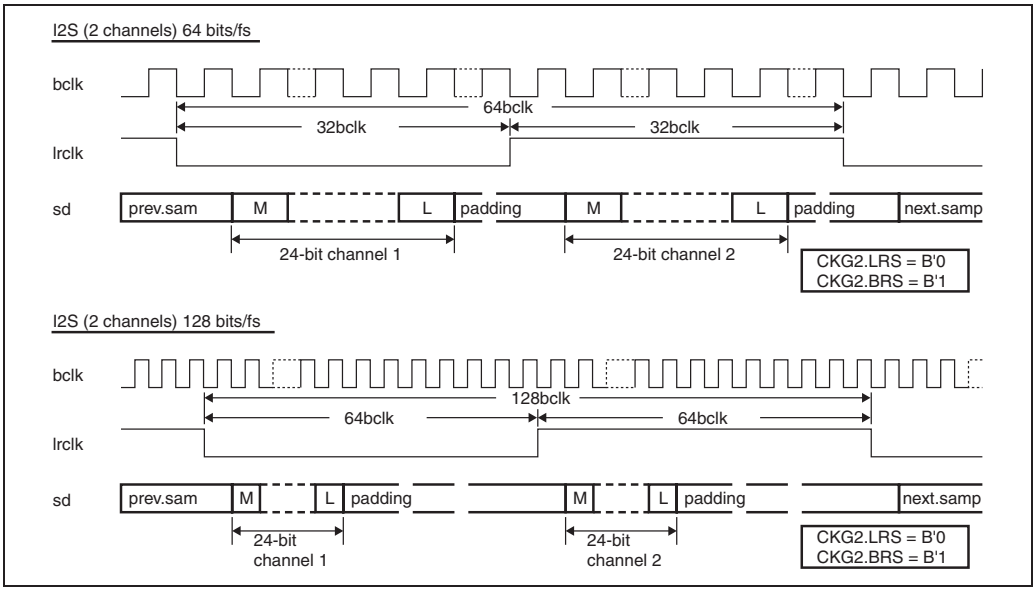

Figure 51.17 I2S Formats

The TDM and TDM_Delay serial data formats are shown below.

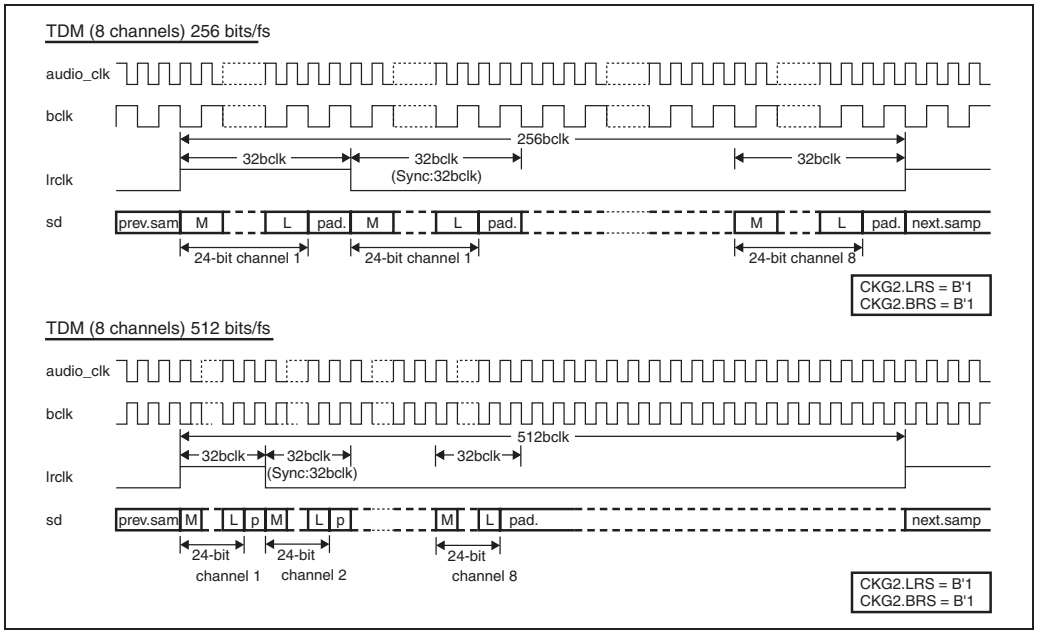

Figure 51.18 TDM Formats

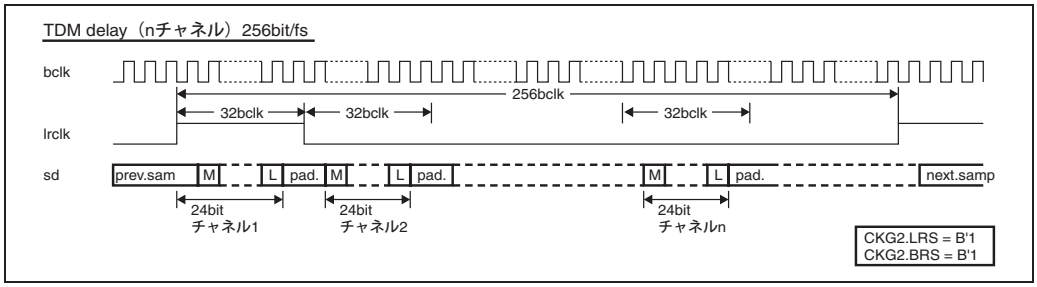

Figure 51.19 TDM Delay Formats

51.9 Operation Flows

51.9.1 Procedure for Starting the FSI2

A flow chart for starting the FSI2 for serial port A is shown in figure 51.20. This flow chart is applicable for serial port B.

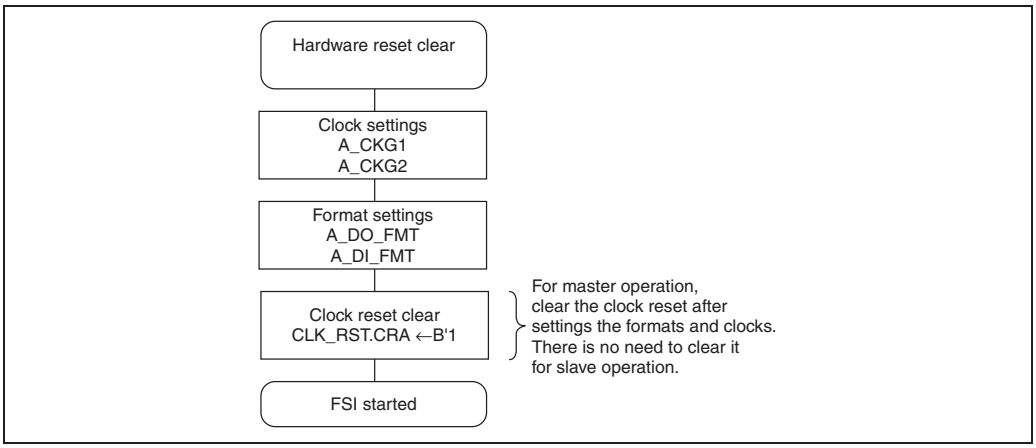

Figure 51.20 Flow for Starting FSI2 (Port A)

Use the steps above to start the FSI2. The configured bit and LR clocks are input to the conversion block (DOIS and DIIS modules), and data requests generated and data writes are started in the FIFO control block (DOFF and DIFF modules).

51.9.2 Procedure for Restarting the FSI2

A flow chart for restarting the FSI2 for serial port A is shown below. This flow chart is applicable for serial port B. To reconfigure transfer format and clock setting, follow the steps in this flow.

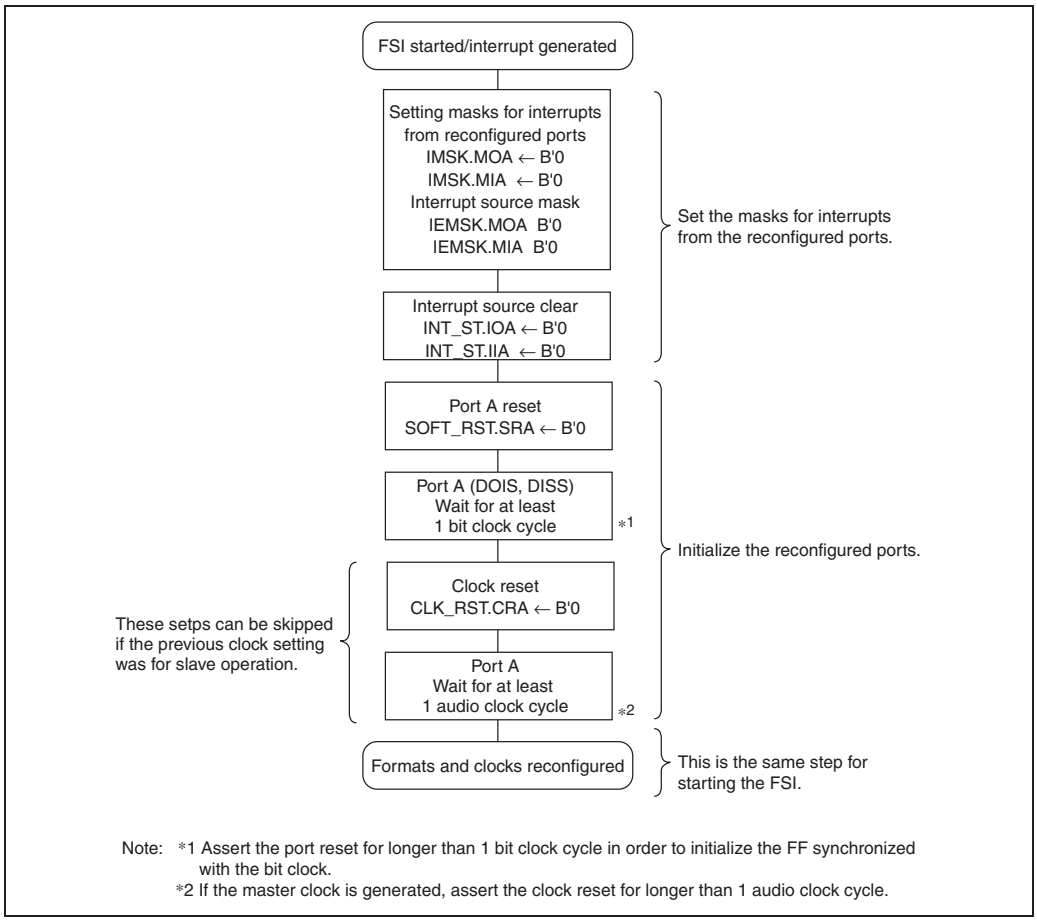

Figure 51.21 Flow for Restarting FSI2 (Port A)

Perform a port reset to initialize the port after setting the masks for the reconfigured port.

After initializing the port, return to the steps in section 51.9.1, Procedure for Starting the FSI2 to reconfigure the format and clock settings.

51.9.3 Procedure for Configuring Initial Interrupt Setting

A flow for configuring the initial interrupt setting after the FSI2 is started is shown in figure 51.22.

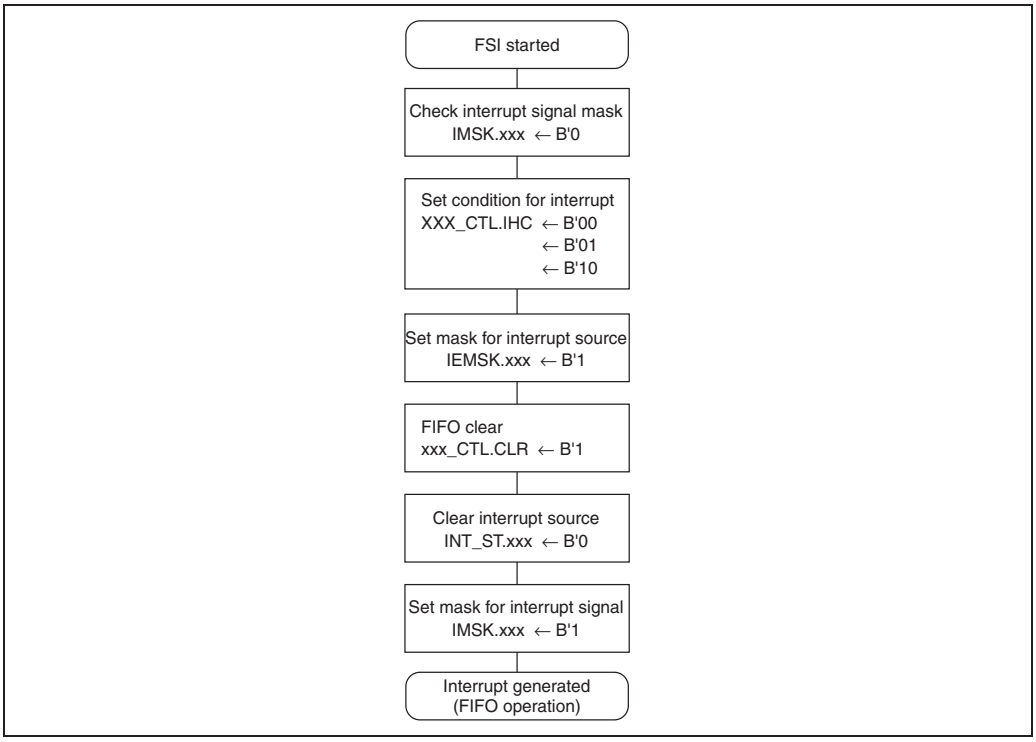

Figure 51.22ow for Configuring Initial Interrupt Setting

Interrupt settings can be configured for ports A/B and input/output (4 modes) independently. "xxx" in the figure indicates any signal to be transferred.

After checking if the mask for the signal to be transferred is set, select the interrupt condition and set the interrupt source mask, then perform a FIFO clear. Clear the interrupt source that may be generated and retained before the FIFO clear, clear the signal mask.

An interrupt signal occurs based on the FIFO capacity after a FIFO clear. Use this flow to configure interrupts if audio data are used for input and output operation initially.

51.9.4 Example of DSP Operation Flow

Figure 51.23 shows an example of the operation flow that the DSP follows to transfer audio data continuously after it accepts an interrupt.

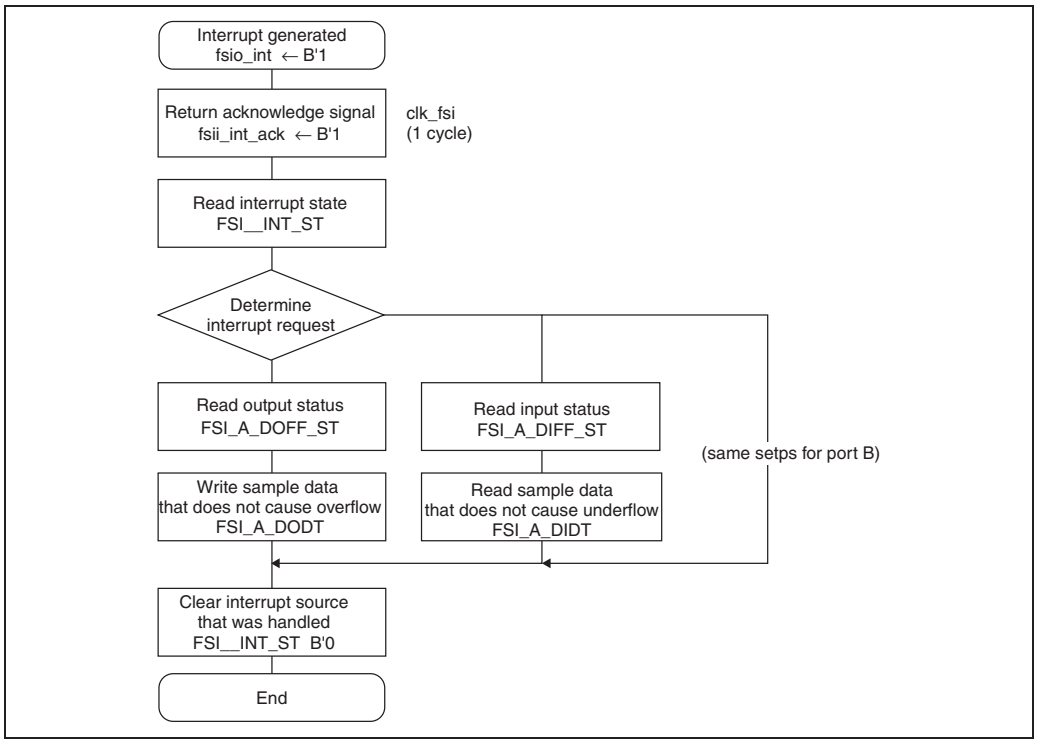

Figure 51.23ample of DSP Operation Flow

The DSP that accepts the interrupt signal returns an acknowledge signal for one cycle to the FSI2. Then, it reads the interrupt state to determine which FIFO caused the interrupt and handles the interrupt adequately. When it is handled, the DSP clears the interrupt source and exits the flow. Clearing the interrupt source allows the FSI2 to assert a new interrupt signal.

51.10 Restrictions

Table 51.8 shows the restrictions that apply to the use of the FSI2.

Table 51.8 Usage Restrictions

	Restrictions	
No.	**Item**	**Description**
1	Clock setting for master operation	In TDM and TDM Delay modes, the LR clock cannot be generated from 64 fs and 128 fs of audio clock, so they should not be set.
2		The bit clock setting (BPFMD register) is restricted by the input audio clock and format (any bit clock faster than the audio clock cannot be generated).
3	Timing for generating interrupt signal	An interrupt signal is generated 2 cycles (clk_fsi) after the FIFO status matches the interrupt source condition (match event) while all masks are cleared.
4	Worst case overflow/underflow	In the worst case such as system clock: 4MHz, fs: 96kHz (bit_clk = 50MHz), TDM (8 channels), overflow and underflow errors occur about 10 system clock cycles after the output interrupt (FIFO empty) and input interrupt (FIFO full) signals are generated. To enable continuous operation in such a worst case, select the half of the FIFO capacity as the level for generating interrupt. Additionally, the system clock should be nearly equal to the bit clock for stable continuous operation. In this case, the number of cycles from the FIFO full state to generating an overflow is extended from 10 cycles to about 100 cycles by using the system clock that is ten times faster (40MHz) and to about 700 cycles by selecting the half of the FIFO capacity as the level for generating interrupt. Consequently, it takes about 70000 cycles (product of the two cycle counts) until an overflow occurs by doing the both.
5	FIFO status read	Since the FIFO status is read with 1 wait, the result indicates the status that is 1 cycle (clk_fsi) old.
6	Simultaneous input and output operations	Simultaneous operation such as master-master or slave-slave operation is not allowed on the same serial port with different formats and LR/bit clocks (one serial port has only one I/O system)
7	Port reset	When performing an internal reset of the DOIS and DIIS modules due to the change in formats or clocks, the reset should be asserted longer than the input bit clock.
8	Clock reset	Since the counter for generating the master clock is synchronized with the audio clock, a reset should be asserted longer than the audio clock to reset the counter for reconfiguration.

51.11 FMSI (FIFO-incorporating Melody and Serial Interface)

The FMSI is an audio interface that incorporates a FIFO controller sporting both serial and parallel interfaces. A parallel port has been added as an expansion circuit for the FSI module. As well as incorporating existing FSI functionality, interrupt functionality has been strengthened, and 16-bit transmission formats are handled.

This module acts as a peripheral circuit of the SPU2 (Sound Processing Unit 2) audio processing circuit.

51.11.1 Characteristics of the FMSI Module

Characteristics and functions of the FMSI are described in table 51.9.

Table 51.9 List of FMSI Characteristics and Functions

Classification	Item	Details
Operating frequencies	Sampling frequency (f_S)	8 kHz to 96 kHz (max.)
	Audio clock	Clock signal (at 32 f_S, 64 f_S, 128 f_S, 256 f_S, or 512 f_S) used to generate the LR clock and bit clock
		256 kHz to 49.15 MHz (32 × 8 kHz to 512 × 96 kHz)
	IO bus clock	Operating frequency of the FMSI (100 MHz, max.)
	Sync. clock for the parallel interface	Operating frequency of the HPB (100 MHz, max.)
DSP/IO	Width of the IO bus	24 bits
Clock control	Control of the audio clock input to the interface section	Master operation (operation is to generate the LR and bit clocks from the audio clock)
		Slave operation (operation is to generate the LR and bit clocks from an external audio clock)
Output interface	Three-line serial output	Data width: 16 or 24 bits
		Formats Monaural (1 channel): Mono or mono with delay Stereo (2 channels): PCM or I2S Multi-channel (1 to 8 channels): TDM or TDM with delay
	Parallel output (MSU)	Data width: 16 bits
		Number of channels: 1

Classification	Item	Details
Input interface	Three-line serial input	Handles data in the same formats as the three-line serial output.
	Parallel input (SCUV)	Data width: 16 or 24 bits Number of channels: 2
FIFO	Capacity	Connected to external DP-RAM 24 bits × 256 words
	FIFO state information	Indicates the FIFO state (sampling data, underflow, or overflow)
	FIFO clearing	Initializes the FIFO state
	Interrupt source condition select	Controlled by the number of samples Output operation: Space equivalent to more than xxx samples is empty. Input operation: Data is equivalent to xxx or more samples.
Timer	Timer control	Interrupt generation is based on the counting of sampling periods.
Interrupts	Interrupt control	Single output for interrupt signals from all sources Control of source masking and signal masking
Direct transfer	Control of direct transfer	Continuous operation by DSP IO without reading and writing of registers 1. Parallel input (SCUV) to serial output 2. Serial input to parallel output (MSU) Note: This is with equal sampling frequencies.
Muting	Mute mode	Normal muting and muting at zero crossing

51.12 FMSI Block Diagram

Figure 51.24 shows a block diagram of the FMSI.

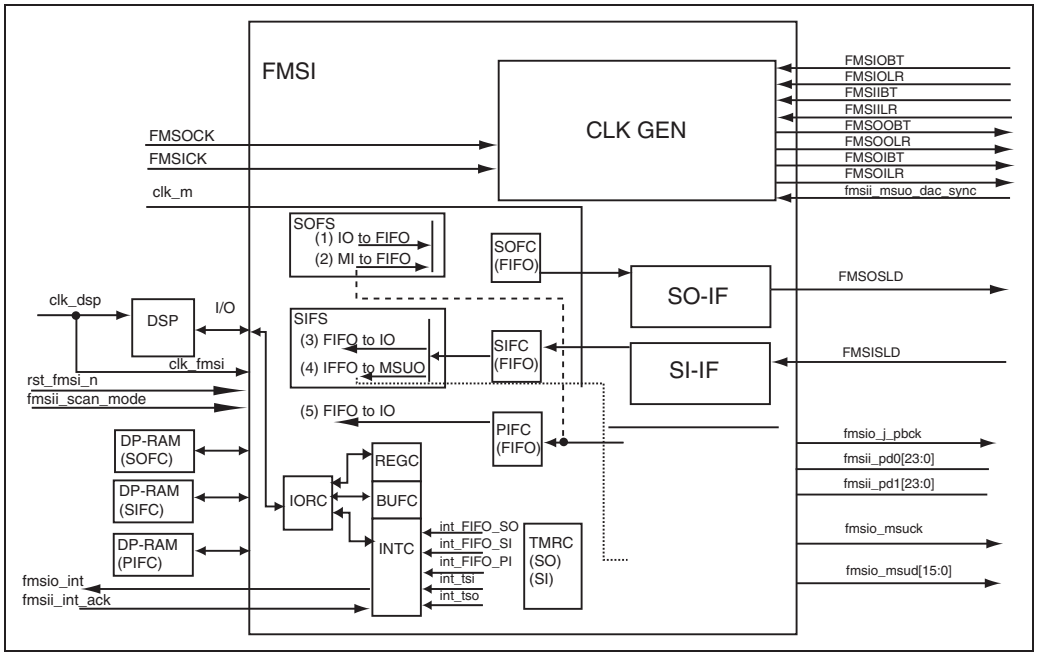

Figure 51.24 FMSI Block Diagram

The following provides an overview of modules comprising the FMSI.

51.12.1 CLK GEN (Clock Generation)

The CLK GEN generates the audio clock (for the LR clock and bit clock) used for the interface block (SO-IF, SI-IF, MI-IF, and MSUO-IF). The CLK GEN includes the following two systems for serial output (parallel input) and serial input (parallel output).

- SO system: For SO-IF (operating clock: clk_fmsi, FMSOCK or FMSIOBT)
- SI system: For SI-IF (operating clock: clk_fmsi, FMSICK or FMSIIBT)

51.12.2 SO-IF (Serial Output Interface)

The SO-IF issues a read request to the FIFO (SOFC) and performs serial conversion of read data with the operating clocks, clk_fmsi and ckgo_sdo_bck. A read request synchronized with clk_fmsi and serial conversion synchronized with ckgo_sdo_bck are performed asynchronously by switching the clocks.

51.12.3 SI-IF (Serial Input Interface)

The SI-IF performs parallel conversion of serial data and writes data to the FIFO (SIFC) with the operating clocks, clk_fmsi and ckgo_sdi_bck. Parallel conversion synchronized with ckgo_sdi_bck and data write synchronized with clk_fmsi are performed asynchronously by switching the clocks.

51.12.4 SOFC (Serial Output FIFO Control)

The SOFC is a serial output FIFO controller that controls accesses to a DP-RAM connected externally. The SOFC monitors the DP-RAM usage size (number of samples) and error history. A MUTE circuit is included. The operating clock is clk_fmsi.

51.12.5 SOFS (Serial Output FIFO Select)

The SOFS selects the DSP-IO bus or direct transfer MI-IF via which serial output data is to be written. The operating clock is clk_fmsi.

51.12.6 SIFC (Serial Input FIFO Control)

The SIFC is a serial input FIFO controller that controls accesses to a DP-RAM connected externally. The SIFC monitors the DP-RAM usage size (number of samples) and error history. A MUTE circuit is included. The operating clock is clk_fmsi.

51.12.7 SIFS (Serial Input FIFO Select)

The SOFS selects the DSP-IO bus or direct transfer MSUO-IF for serial input data. The operating clock is clk_fmsi.

51.12.8 PIFC (Parallel Input FIFO Control)

The PIFC is a parallel input FIFO controller that controls accesses to a DP-RAM connected externally. The PIFC monitors the DP-RAM usage size (number of samples) and error history. A MUTE circuit is included. The operating clock clk_fmsi.

51.12.9 TMRC (Timer Control)

The TMRC counts the sampling frequency cycles for the SO (MI) and SI (MSUO) systems. If the counter value exceeds the value specified by the register, an interrupt source is generated.

51.12.10 INTC (Interrupt Control)

This module controls interrupt signals. Interrupt sources generated internally are collected into one interrupt signal to be output externally. Interrupt sources can be masked individually.

51.12.11 BUFC (Buffer Control)

The BUFC block controls data reads/writes between the DSP and FIFOs. To read input data continuously, data are prefetched from FIFOs. Data are output with 4 waits on the initial read, but the following reads can be performed continuously with one wait by controlling the buffer pointer and reading data stored in buffers.

51.12.12 REGC (Register Control)

This module manages registers that are not used by INTC and BUFC. It is used to manage format, clock, and MUTE settings.

51.12.13 IORC (Input Output Register Control)

This module selects read data of INTC, BUFC, and REGC.

51.13 Input/Output Pins

Table 51.10 shows the FMSI pin configuration.

Table 51.10 FMSI Pin Configuration

Pin Name	I/O	Function
FMSOCK	Input	Audio clock input pin for SO-IF and MI-IF
FMSICK	Input	Audio clock input pin for SI-IF
FMSOOLR	Output	Output LR clock pin (master)
FMSOOBT	Output	Output bit clock pin (master)
FMSOILR	Output	Input LR clock pin (master)
FMSOIBT	Output	Input bit clock pin (master)
FMSIOLR	Input	Output LR clock pin (slave)
FMSIOBT	Input	Output bit clock pin (slave)
FMSIILR	Input	Input LR clock pin (slave)
FMSIIBT	Input	Input bit clock pin (slave)
FMSOSLD	Output	Output serial data pin
FMSISLD	Input	Input serial data pin

51.14 Register Descriptions

Figure 51.25 shows a schematic of FMSI address mapping. Table 51.11 shows the FMSI register configuration. The FMSI is mapped in the SPU2 (DSP1-IO) peripheral module area, which can be accessed by the CPU and DSP.

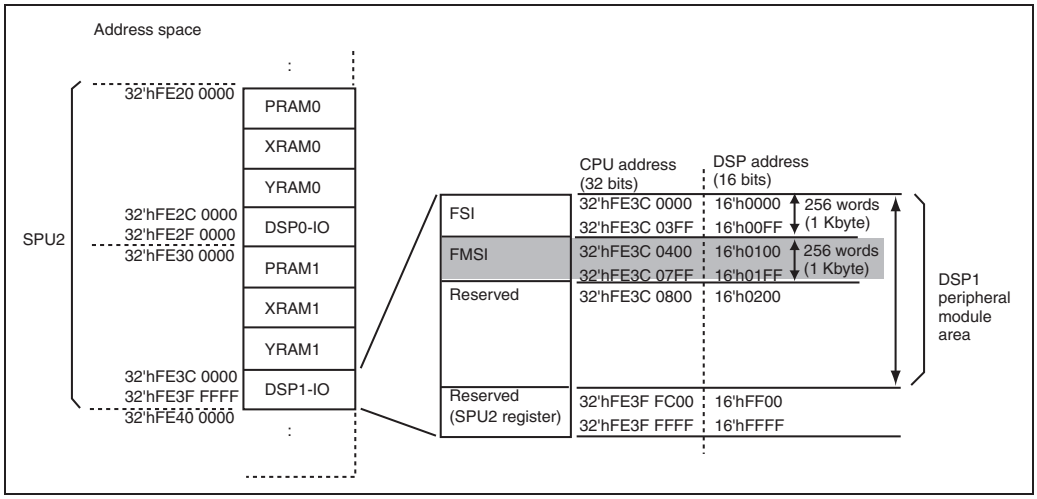

Figure 51.25 FMSI Address Space

The FMSI has 256 words (1 Kbyte) of address space.

Table 51.11 FMSI Register Configuration

Register Name	Abbrev.	R/W	Physical Address	DSP Address	Access Size		Dynamic/ Static
					CPU	DSP	
Serial output format register	S_DO_FMT	R/W	H'FE3C 0400	H'0100	32	24	S
Serial output FIFO control register	S_DOFF_CTL	R/W	H'FE3C 0404	H'0101	32	24	S/D*
Serial output FIFO status register	S_DOFF_ST	R/W	H'FE3C 0408	H'0102	32	24	D
Serial input format register	S_DI_FMT	R/W	H'FE3C 040C	H'0103	32	24	S
Serial input FIFO control register	S_DIFF_CTL	R/W	H'FE3C 0410	H'0104	32	24	S/D*
Serial input FIFO status register	S_DIFF_ST	R/W	H'FE3C 0414	H'0105	32	24	D
Serial input FIFO read register	S_DIDT	R	H'FE3C 0420	H'0108	32	24	D
Serial output FIFO write register	S_DODT	W	H'FE3C 0424	H'0109	32	24	D
Serial MUTE state register	S_MUTE_ST	R	H'FE3C 0428	H'010A	32	24	D
Parallel input format register	P_DI_FMT	R/W	H'FE3C 044C	H'0113	32	24	S
Parallel input FIFO control register	P_DIFF_CTL	R/W	H'FE3C 0450	H'0114	32	24	S/D*
Parallel input FIFO status register	P_DIFF_ST	R/W	H'FE3C 0454	H'0115	32	24	D
Parallel input FIFO read register	P_DIDT	R	H'FE3C 0460	H'0118	32	24	D
Parallel MUTE state register	P_MUTE_ST	R	H'FE3C 0468	H'011A	32	24	D
SO-IF and MI-IF operating clock set register	SOMI_CKG_ MD	R/W	H'FE3C 05C0	H'0170	32	24	S

Register Name	Abbrev.	R/W	Physical Address	DSP Address	Access Size		Dynamic/ Static
					CPU	DSP	
SO-IF and MI-IF operating clock invert register	SOMI_CKG_RV	R/W	H'FE3C 05C4	H'0171	32	24	S
SI-IF and MSUO-IF operating clock set register	SIMO_CKG_MD	R/W	H'FE3C 05C8	H'0172	32	24	S
SI-IF and MSUO-IF operating clock invert register	SIMO_CKG_RV	R/W	H'FE3C 05CC	H'0173	32	24	S
Clock system set register	CKG_SMD	R/W	H'FE3C 05D0	H'0174	32	24	S
Timer count set register	TMR_CTL	R/W	H'FE3C 05D8	H'0176	32	24	D
Timer count clear register	TMR_CLR	R/W	H'FE3C 05DC	H'0177	32	24	D
Direct serial transfer set register	DRCT_SRL	R/W	H'FE3C 05E0	H'0178	32	24	S
Interrupt state register	INT_ST	R/W	H'FE3C 0600	H'0180	32	24	D
Interrupt source mask register	IEMSK	R/W	H'FE3C 0605	H'0181	32	24	D
Interrupt signal mask register	IMSK	R/W	H'FE3C 0608	H'0182	32	24	D
MUTE set register	MUTE	R/W	H'FE3C 060C	H'0183	32	24	D
Clock reset register	CLK_RST	R/W	H'FE3C 0610	H'0184	32	24	S
Software reset register	SOFT_RST	R/W	H'FE3C 0614	H'0185	32	24	S
FIFO size register	FIFO_SZ	R	H'FE3C 0618	H'0186	32	24	S

Note: The (FIFO) CLR bit (bit 0) is a static bit; however, all the other bits in the register, that is, interrupt monitoring condition setting bits can be modified dynamically.

There are two types of registers, dynamic and static. Static registers should not be modified when the FSI is in operation (during continuous operation).

The CPU can write/read data to/from the lower bits (23 to 0) in registers. The upper bits are read as 0 and cannot be modified.

For setting the FMSI operation, also see a description of the register for selecting the FSI/FMSI interrupt acknowledge destination in section 51.3.43.

51.14.1 Serial Output Format Register (S_DO_FMT)

S_DO_FMT is a 24-bit readable/writable register that sets the bus width and selects the format to be used from MONO, MONO_Delay, PCM, I2S, TDM, and TDM_Delay.

When TDM and TDM_Delay modes are selected, this register specifies the number of channels (1 to 8 channels).

Bit:	23	22	21	20	19	18	17	16
	—	—	—	BWS	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	FMT[2:0]			—	NCH[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	BWS	0	R/W	Bus Width Select Selects the bus width for serial transfer. 0: 24 bits 1: 16 bits
19 to 7	—	All 0	R	Reserved
6 to 4	FMT	011	R/W	Format Selects the serial output format. 000: MONO (1 channel) 001: MONO Delay (1 channel) 010: PCM (2 channels) 011: I2S (2 channels) 100: TDM (1 to 8 channels) 101: TDM Delay (1 to 8 channels) 110: Setting prohibited 111: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
3	—	0	R	Reserved
2 to 0	NCH	000	R/W	Number of Channels Specifies the number of channels in TDM and TDM_Delay modes. 000: 1 channel 001: 2 channels 010: 3 channels 011: 4 channels 100: 5 channels 101: 6 channels 110: 7 channels 111: 8 channels When selecting the modes other than TDM and TDM_Delay, specify 000.

51.14.2 Serial Output FIFO Control Register (S_DOFF_CTL)

S_DOFF_CTL is a 24-bit readable/writable register that specifies the conditions for generating interrupt sources and initializes the FIFO (SOFC). Interrupt control can be selected from rough control that is conventionally used for FSI-IP and control using the number of samples.

Bit:	23	22	21	20	19	18	17	16
	—	—	IHC[1:0]		—	—	—	ISC[8]
Initial value:	0	0	0	1	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ISC[7:0]								—	—	—	IMS	—	—	—	CLR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	IHC	01	R/W	Interrupt Happening Condition Selects an interrupt source generation condition (rough control). 00: Empty state 01: More than half of the FIFO is free. 10: Has storage capacity for one or more samples. 11: Setting prohibited (Full state) (Data storage amount when more than half of the FIFO is free) 1 channel: 127 samples (127 words) or less 2 channels: 63 samples (126 words) or less 3 or 4 channels: 31 samples (3 channels: 93 words, 4 channels: 124 words) or less 5 to 8 channels: 15 samples (5 channels: 75 words, 6 channels: 90 words, 7 channels: 105 words, 8 channels: 120 words) or less
19 to 17	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
16 to 8	ISC	h'000	R/W	Interrupt Sample Condition Specifies an interrupt source generation condition by the number of samples that can be stored in free areas (control by the number of samples). (Example: format: ch1) h'100: Empty state h'080: Has storage capacity for 80 or more samples. h'001: Has storage capacity for one or more samples. h'000: Setting prohibited (Full state) The set value must not exceed the upper limit for the number of channels. (Settable values) 1 channel: 0 to 256 samples (h'0 to h'100) 2 channels: 0 to 128 samples (h'0 to h'80) 3 or 4 channels: 0 to 64 samples (h'0 to h'40) 5 to 8 channels: 0 to 32 samples (h'0 to h'20)
7 to 5	—	All 0	R	Reserved
4	IMS	0	R/W	Interrupt Mode Select Selects interrupt control mode. 0: Rough control (IHC) 1: Control by the number of samples (ISC)
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0*	CLR	0	W	Clear Clears the FIFO. Initializes the access pointer and the error history. 0: When only the interrupt source generation condition is changed, the write value should be 0. 1: Clears the FIFO. This bit is always read as 0.

Note: If 1 is written to the CLR bit, the bit is asserted for one pulse and then cleared to 0.

51.14.3 Serial Output FIFO Status Register (S_DOFF_ST)

S_DOFF_ST is a 24-bit read-only register (the OF and UF bits can be written to). It can be used to read the serial output FIFO states, the number of stored sample data, and the history of overflow and underflow errors. For procedure for clearing the OF and UF bits, refer to section 51.18.2, Error Flag Clear.

Bit:	23	22	21	20	19	18	17	16
	—	—	ST[1:0]		—	—	—	SZ[8]
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SZ[7:0]								—	—	—	OF	—	—	—	UF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/(W)*	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	ST	00	R	Status Indicates the FIFO status. 00: Empty state 01: Less than half of the FIFO is used. 10: Half or more of the FIFO is used. 11: Full state
19 to 17	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
16 to 8	SZ	h'000	R	Size Number of sample data Indicates the number of sample data stored in the FIFO. The maximum value depends on the number of channels selected for the format. The maximum number of sample data for each number of channels is shown below. If more samples than the maximum number of samples in the parentheses are written, an overflow occurs. 1 channel: 256 (256 × 1 = 256 words) 2 channels: 128 (128 × 2 = 256 words) 3 channels: 64 (64 × 3 = 192 words) 4 channels: 64 (64 × 4 = 256 words) 5 channels: 32 (32 × 5 = 160 words) 6 channels: 32 (32 × 6 = 192 words) 7 channels: 32 (32 × 7 = 224 words) 8 channels: 32 (32 × 8 = 256 words) FIFOs are used in 4-channel units in 3-channel mode and in 8-channel units in 5- to 7-channel mode, meaning that more FIFOs than the required size of DP-RAM are used. For the DSP, the maximum number of writes must be taken into account.
7 to 5	—	All 0	R	Reserved
4*	OF	0	R/W	Overflow Indicates the FIFO error history. 0: No error has occurred. 1: Overflow has occurred.
3 to 1	—	All 0	R	Reserved
0*	UF	0	R/W	Underflow Indicates the FIFO error history. 0: No error has occurred. 1: Underflow has occurred.

Note: The FIFO error history is cleared by writing 0 to this bit and retained by writing 1 to it.

51.14.4 Serial Input Format Register (S_DI_FMT)

S_DI_FMT is a 24-bit readable/writable register that sets the bus width and selects the format to be used from MONO, MONO_Delay, PCM, I2S, TDM, and TDM_Delay.

When TDM and TDM_Delay modes are selected, this register specifies the number of channels (1 to 8 channels).

Bit:	23	22	21	20	19	18	17	16
	—	—	—	BWS	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	FMT[2:0]			—	NCH[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	BMS	0	R/W	Bus Width Select Selects the bus width for serial transfer. 0: 24 bits 1: 16 bits
19 to 7	—	All 0	R	Reserved
6 to 4	FMT	011	R/W	Format Selects the serial input format. 000: MONO (1 channel) 001: MONO Delay (1 channel) 010: PCM (2 channels) 011: I2S (2 channels) 100: TDM (1 to 8 channels) 101: TDM Delay (1 to 8 channels) 110: Setting prohibited 111: Setting prohibited.

Bit	Bit Name	Initial Value	R/W	Description
3	—	0	R	Reserved
2 to 0	NCH	000	R/W	Number of Channels Specifies the number of channels in TDM and TDM_Delay modes. 000: 1 channel 001: 2 channels 010: 3 channels 011: 4 channels 100: 5 channels 101: 6 channels 110: 7 channels 111: 8 channels When selecting the modes other than TDM and TDM_Delay, specify 000.

51.14.5 Serial Input FIFO Control Register (S_DIFF_CTL)

S_DIFF_CTL is a 24-bit readable/writable register that specifies the conditions for generating interrupt sources and initializes the FIFO (SIFC). Interrupt control can be selected from rough control that is conventionally used for FSI-IP and control using the number of samples.

Bit:	23	22	21	20	19	18	17	16
	—	—	IHC[1:0]		—	—	—	ISC[8]
Initial value:	0	0	0	1	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ISC[7:0]								—	—	—	IMS	—	—	—	CLR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	IHC	01	R/W	Interrupt Happening Condition Interrupt source generation condition (rough control) 00: Full state 01: Amount of data in the FIFO equals or exceeds half the FIFO capacity. 10: One or more sample data is in the FIFO. 11: Setting prohibited (empty state) (Data storage amount when half or more of the FIFO space is free) 1 channel: 128 samples (128 words) or more 2 channels: 64 samples (128 words) or more 3 or 4 channels: 32 samples (3 channels: 96 words, 4 channels: 128 words) or more 5 to 8 channels: 16 samples (5 channels: 80 words, 6 channels: 96 words, 7 channels: 112 words, 8 channels: 128 words) or more
19 to 17	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
16 to 8	ISC	h'000	R/W	Interrupt Sample Condition Specifies an interrupt source generation condition by data size (control by the number of samples). h'xxx: xxx or more sample data are in the FIFO. h'001: One or more sample data is in the FIFO. h'000: No data (Empty state) The set value must not exceed the upper limit for the number of channels specified for the pertinent format. (Settable values) 1 channel: 0 to 256 samples (h'0 to h'100) 2 channels: 0 to 128 samples (h'0 to h'80) 3 or 4 channels: 0 to 64 samples (h'0 to h'40) 5 to 8 channels: 0 to 32 samples (h'0 to h'20)
7 to 5	—	0	R	Reserved
4	IMS	0	R/W	Interrupt Mode Select Selects interrupt control mode. 0: Rough control (IHC) 1: Control by the number of samples (ISC)
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0*	CLR	0	W	Clear Clears the FIFO. Initializes the access pointer and the error history. 0: When only the interrupt source generation condition is changed, the write value should be 0. 1: Clears the FIFO. This bit is always read as 0.

Note: If 1 is written to the CLR bit, the bit is asserted for one pulse and then cleared to 0.

51.14.6 Serial Input FIFO Status Register (S_DIFF_ST)

S_DIFF_ST is a 24-bit read-only register (the OF and UF bits can be written to). It can be used to read the serial input FIFO states, the number of stored sample data, and the history of overflow and underflow errors. For procedure for clearing the OF and UF bits, refer to section 51.18.2, Error Flag Clear.

Bit:	23	22	21	20	19	18	17	16
	—	—	ST[1:0]		—	—	—	SZ[8]
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SZ[7:0]								—	—	—	OF	—	—	—	UF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/(W)*	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	ST	00	R	Status Indicates the FIFO status. 00: Empty state 01: Less than half of the FIFO is used. 10: Half or more of the FIFO is used. 11: Full state
19 to 17	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
16 to 8	SZ	h'000	R	Size Number of sample data Indicates the number of sample data stored in FIFOs. The maximum value depends on the number of channels selected for the format. The maximum number of sample data for each number of channels is shown below. If more samples than the maximum number of samples in the parentheses are read, an underflow occurs. 1 channel: 256 (256 × 1 = 256 words) 2 channels: 128 (128 × 2 = 256 words) 3 channels: 64 (64 × 3 = 192 words) 4 channels: 64 (64 × 4 = 256 words) 5 channels: 32 (32 × 5 = 160 words) 6 channels: 32 (32 × 6 = 192 words) 7 channels: 32 (32 × 7 = 224 words) 8 channels: 32 (32 × 8 = 256 words) FIFOs are used in 4-channel units in 3-channel mode and in 8-channel units in 5- to 7-channel mode, meaning that more FIFOs than the required size of DP-RAM are used. For the DSP, the maximum number of reads must be taken into account.
7 to 5	—	All 0	R	Reserved
4*	OF	0	R/W	Overflow Indicates the FIFO error history. 0: No error has occurred. 1: Overflow has occurred.
3 to 1	—	All 0	R	Reserved
0*	UF	0	R/W	Underflow Indicates the FIFO error history. 0: No error has occurred. 1: Underflow has occurred.

Note: The FIFO error history is cleared by writing 0 to this bit and retained by writing 1 to it.

51.14.7 Serial Input FIFO Read Register (S_DIDT)

S_DIDT is a 24-bit read-only register that can be used to read data stored in the serial input FIFO. If the FIFO is empty, a read causes an underflow error.

Bit:	23	22	21	20	19	18	17	16
	DIDT[23:16]							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R*	R*	R*	R*	R*	R*	R*	R*

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DIDT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R*	R*	R*	R*	R*	R*	R*	R*	R	R	R	R	R	R	R	R

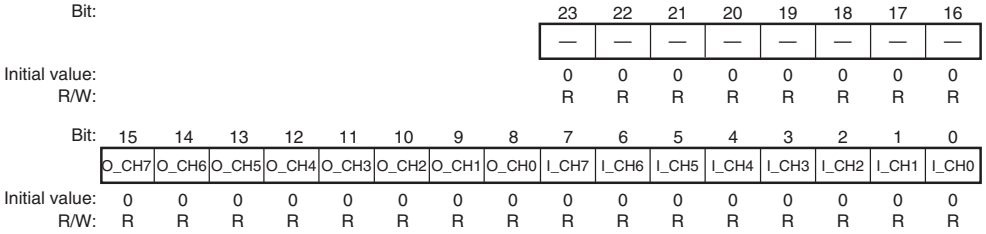
* In 16-bit transfer mode, valid data is output to bits 23 to 8.

Bit	Bit Name	Initial Value	R/W	Description
23 to 0	DIDT	h'00 0000	R	Read-only register used to read data stored in the serial input FIFO.

51.14.8 Serial Output FIFO Write Register (S_DODT)

S_DODT is a 24-bit write-only register that can be used to write data to the serial output FIFO. If the FIFO is full, a write causes an overflow error.

Bit:	23	22	21	20	19	18	17	16
	DODT[23:16]							
Initial value:	0	0	0	0	0	0	0	0
R/W:	W*	W*	W*	W*	W*	W*	W*	W*



Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DODT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W*	W*	W*	W*	W*	W*	W*	W*	W	W	W	W	W	W	W	W

* In 16-bit transfer mode, write valid data in bits 23 to 8.

Bit	Bit Name	Initial Value	R/W	Description
23 to 0	DODT	h'00 0000	W	Write-only register used to write data to the serial output FIFO.

51.14.9 Serial MUTE State Register (S_MUTE_ST)

S_MUTE_ST is a 24-bit read-only register that indicates the MUTE state for each channel in serial I/O operation.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	O_CH7	O_CH6	O_CH5	O_CH4	O_CH3	O_CH2	O_CH1	O_CH0	I_CH7	I_CH6	I_CH5	I_CH4	I_CH3	I_CH2	I_CH1	I_CH0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
23 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	O_CH7	0	R	Serial Output MUTE State (Same name for bits 14 to 8) 0: Channel 8 MUTE off 1: Channel 8 MUTE on
14	O_CH6	0	R	0: Channel 7 MUTE off 1: Channel 7 MUTE on
13	O_CH5	0	R	0: Channel 6 MUTE off 1: Channel 6 MUTE on
12	O_CH4	0	R	0: Channel 5 MUTE off 1: Channel 5 MUTE on
11	O_CH3	0	R	0: Channel 4 MUTE off 1: Channel 4 MUTE on
10	O_CH2	0	R	0: Channel 3 MUTE off 1: Channel 3 MUTE on
9	O_CH1	0	R	0: Channel 2 MUTE off 1: Channel 2 MUTE on
8	O_CH0	0	R	0: Channel 1 MUTE off 1: Channel 1 MUTE on

Bit	Bit Name	Initial Value	R/W	Description
7	I_CH7	0	R	Serial Input MUTE State (Same name for bits 6 to 0) 0: Channel 8 MUTE off 1: Channel 8 MUTE on
6	I_CH6	0	R	0: Channel 7 MUTE off 1: Channel 7 MUTE on
5	I_CH5	0	R	0: Channel 6 MUTE off 1: Channel 6 MUTE on
4	I_CH4	0	R	0: Channel 5 MUTE off 1: Channel 5 MUTE on
3	I_CH3	0	R	0: Channel 4 MUTE off 1: Channel 4 MUTE on
2	I_CH2	0	R	0: Channel 3 MUTE off 1: Channel 3 MUTE on
1	I_CH1	0	R	0: Channel 2 MUTE off 1: Channel 2 MUTE on
0	I_CH0	0	R	0: Channel 1 MUTE off 1: Channel 1 MUTE on

51.14.10 Parallel Input Format Register (P_DI_FMT)

P_DI_FMT is a 24-bit readable/writable register that specifies the bus width and the number of channels for data transfer.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	BWS	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	NCH
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	BWS	0	R/W	Bus Width Select Selects the bus width of the MI-IF module. 0: 24 bits 1: 16 bits (the lower 8 bits are invalid.)
19 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	NCH	1	R/W	Number of Channel Selects the number of channels of the MI-IF module. 0: 1 channel 1: 2 channels

51.14.11 Parallel Input FIFO Control Register (P_DIFF_CTL)

P_DIFF_CTL is a 24-bit readable/writable register that sets the condition for generating interrupt sources and initializes the FIFO (PIFC). Interrupt control can be selected from rough control that is conventionally used for FSI-IP and control using the number of samples.

Bit:	23	22	21	20	19	18	17	16
	—	—	IHC[1:0]		—	—	—	ISC[8]
Initial value:	0	0	0	1	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ISC[7:0]								—	—	—	IMS	—	—	—	CLR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	IHC	01	R/W	Interrupt Happening Condition Interrupt source generation condition (rough control) 00: Full state 01: Amount of data in the FIFO equals or exceeds half the FIFO capacity. 10: One or more sample data is in the FIFO. 11: Setting prohibited (empty state) (Data storage amount when half or more of the FIFO space is used) 1 channel: 128 samples (128 words) or more 2 channels: 64 samples (128 words) or more 3 or 4 channels: 32 samples (3 channels: 96 words, 4 channels: 128 words) or more 5 to 8 channels: 16 samples (5 channels: 80 words, 6 channels: 96 words, 7 channels: 112 words, 8 channels: 128 words) or more
19 to 17	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
16 to 8	ISC	h'000	R/W	Interrupt Sample Condition Interrupt source generation condition (control by the number of samples) Specifies the interrupt source generation condition by data size. h'xxx: xxx or more sample data are in the FIFO. h'001: One or more sample data is in the FIFO. h'000: No data (Empty state) The set value must not exceed the upper limit for the number of channels specified for the pertinent format. Settable values: 1 channel: 0 to 256 samples (h'0 to h'100) 2 channels: 0 to 128 samples (h'0 to h'80) 3 or 4 channels: 0 to 64 samples (h'0 to h'40) 5 to 8 channels: 0 to 32 samples (h'0 to h'20)
7 to 5	—	All 0	R	Reserved
4	IMS	0	R/W	Interrupt Mode Select Selects interrupt control. 0: Rough control (IHC) 1: Control by the number of samples (ISC)
3 to 1	—	All 0	R	Reserved
0*	CLR	0	W	Clear Clears the FIFO. Initializes the access pointer and the error history. 0: When only the interrupt source generation condition is changed, the write value should be 0. 1: Clears the FIFO. This bit is always read as 0.

Note: If 1 is written to the CLR bit, the bit is asserted for one pulse and then cleared to 0.

51.14.12 Parallel Input FIFO Status Register (P_DIFF_ST)

P_DIFF_ST is a 24-bit read-only register (the OF and UF bits can be written to). It can be used to read the parallel input FIFO states, the number of stored sample data, and the history of overflow and underflow errors. For procedure for clearing the OF and UF bits, refer to section 51.18.2, Error Flag Clear.

Bit:	23	22	21	20	19	18	17	16
	—	—	ST[1:0]		—	—	—	SZ[8]
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SZ[7:0]								—	—	—	OF	—	—	—	UF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/(W)*	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21, 20	ST	00	R	Status Indicates the FIFO status. 00: Empty state 01: Less than half of the FIFO is used. 10: Half or more of the FIFO is used. 11: Full state
19 to 17	—	All 0	R	Reserved
16 to 8	SZ	h'000	R	Size Number of sample data Indicates the number of sample data stored in the FIFO. The maximum number of sample data 1 channel: 256 (256 × 1 = 256 words) 2 channels: 128 (128 × 2 = 256 words)
7 to 5	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
4*	OF	0	R/W	Overflow Indicates the FIFO error history. 0: No error has occurred. 1: Overflow has occurred.
3 to 1	—	All 0	R	Reserved
0*	UF	0	R/W	Underflow Indicates the FIFO error history. 0: No error has occurred. 1: Underflow has occurred.

Note: The FIFO error history is cleared by writing 0 to this bit and retained by writing 1 to it.

51.14.13 Parallel Input FIFO Read Register (P_DIDT)

P_DIDT is a 24-bit read-only register that can be used to read data stored in the parallel input FIFO. If the FIFO is empty, a read causes an underflow error.

Bit:	23	22	21	20	19	18	17	16
	DIDT[23:16]							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R*	R*	R*	R*	R*	R*	R*	R*

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DIDT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R*	R*	R*	R*	R*	R*	R*	R*	R	R	R	R	R	R	R	R

Note: * In 16-bit transfer mode, valid data is output to bits 23 to 8.

Bit	Bit Name	Initial Value	R/W	Description
23 to 0	DIDT	h'00 0000	R	Read-only register used to read data stored in the parallel input FIFO.

51.14.14 Parallel MUTE State Register (P_MUTE_ST)

P_MUTE_ST is a 24-bit read-only register that indicates the MUTE state for each channel in parallel input operation.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

* In 16-bit transfer mode, write valid data in bits 23 to 8.

Bit	Bit Name	Initial Value	R/W	Description
23 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	I_CH1	0	R	Parallel Input MUTE State (Same name for bit 0) 0: Channel 2 MUTE off 1: Channel 2 MUTE on
0	I_CH0	0	R	0: Channel 1 MUTE off 1: Channel 1 MUTE on

51.14.15 SO-IF and MI-IF Operating Clock Set Register (SOMI_CKG_MD)

SOMI_CKG_MD is a 24-bit readable/writable register. It generates the master clock and selects audio clock used in the SO-IF and MI-IF modules.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	MSUSYNCS	—	—	—	—
Initial value:	0	0	0	1	0	0	0	0
R/W:	R	R	R	R/(W)*2	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	ACKMD[2:0]			—	BPFMD[2:0]			—	—	—	DIPMD	—	—	—	DOSMD
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R	R/(W)*1	R/(W)*1	R/(W)*1	R	R/(W)*1	R/(W)*1	R/(W)*1	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20*2	MSUSYNCS	1	R/W	MSU SYNC Select Selects the synchronization clock for generating the reference clock for the MI-IF module. 1: Generates the reference clock using serial LR clock. 0: Generates the reference clock using the MSU sync signal.
19 to 15	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
14 to 12*[1]	ACKMD	000	R/W	Audio Clock Mode Specifies the audio clock used for generating the master LR clock. Select the audio clock (fs) to be input in terms of a multiple of the sampling frequency (fs). 000: 512 fs 001: 256 fs 010: 128 fs 011: 64 fs 100: 32 fs Setting these bits is not necessary for slave operation.
11	—	0	R	Reserved
10 to 8*[1]	BPFMD	001	R/W	Bit/Fs Mode Sets the division ratio of the master bit clock. 111: 16 bit/fs 000: 32 bit/fs 001: 64 bit/fs 010: 128 bit/fs 011: 256 bit/fs 100: 512 bit/fs 101: Setting prohibited 110: Setting prohibited Setting these bits is not necessary for slave operation.
7 to 5	—	All 0	R	Reserved
4	DIPMD	0	R/W	Data Input Parallel Mode Selects master or slave operation for the MI-IF module. 0: Slave operation 1: Master operation
3 to 1	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
0	DOSMD	0	R/W	Data Output Serial Mode Selects master or slave operation for the SO-IF module. 0: Slave operation 1: Master operation

Notes: 1. Some values cannot be set depending on the format and transfer bus width. For the formats and the ACKMD and BPFMD bit settings, refer to section 51.19.
2. For the clock to the MI-IF module, the settings of the MSUSYNCS bit take precedence. (When MSUSYNCS is 1, the set value of DIPMD is ignored.)

51.14.16 SO-IF and MI-IF Operating Clock Invert Register (SOMI_CKG_RV)

SOMI_CKG_RV is a 24-bit readable/writable register that specifies whether to invert bit clocks and LR clocks. In master mode, set the bits according to the formats of the external ADC and the DAC. In slave operation, set the bits so that the external clock is input to the circuit at the falling edge of the LR clock and the rising edge of the bit clock. Figure 51.3 shows the relation among clock inversion, the master/slave selector, and the clock setting registers in terms of the LR clock.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0

R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
23 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	LRM	0	R/W	LR Clock Reverse Master Specifies whether to invert the master LR clock. 0: Clock not inverted 1: Clock inverted
11 to 9	—	All 0	R	Reserved
8	BRM	0	R/W	Bit Clock Reverse Master Specifies whether to invert the master bit clock. 0: Clock not inverted 1: Clock inverted
7 to 5	—	All 0	R	Reserved
4	LRS	0	R/W	LR Clock Reverse Slave Specifies whether to invert the slave LR clock. 0: Clock not inverted 1: Clock inverted

Bit	Bit Name	Initial Value	R/W	Description
3 to 1	—	All 0	R	Reserved
0	BRS	0	R/W	Bit Clock Reverse Slave Specifies whether to invert the slave bit clock. 0: Clock not inverted 1: Clock inverted

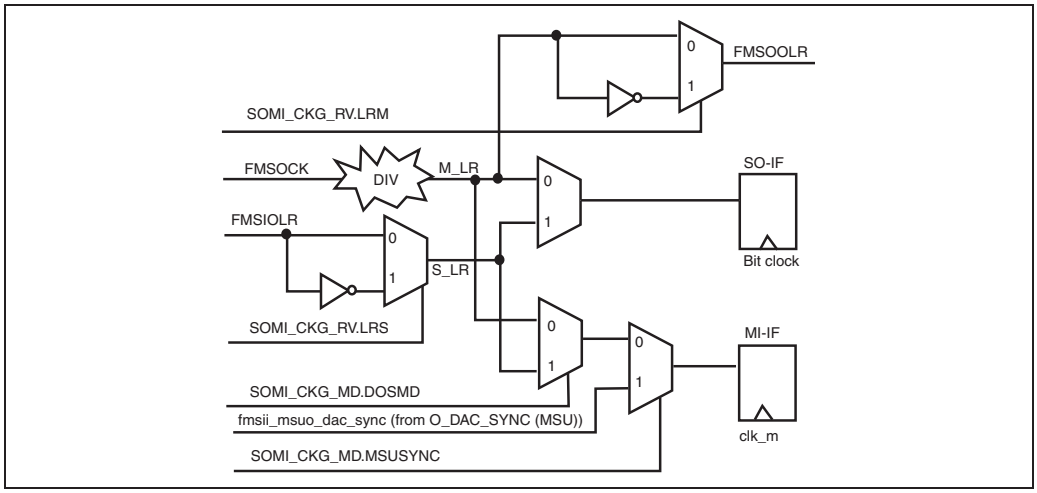

Figure 51.26 LR Clock Selector for SO-IF and MI-IF Modules (Inversion, Master/Slave)

51.14.17 SI-IF and MSUO-IF Operating Clock Set Register (SIMO_CKG_MD)

SIMO_CKG_MD is a 24-bit readable/writable register. It generates the master clock and selects audio clock used in the SI-IF module.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	MSUOG	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	ACKMD[2:0]			—	BPFMD[2:0]			—	—	—	DOPMD	—	—	—	DISMD
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R	R/(W)*1	R/(W)*1	R/(W)*1	R	R/(W)*1	R/(W)*1	R/(W)*1	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	MSUOG	0	R/W	Controls the timing signal to be output to the MSU. 0: Gated (fixed to low) until SI-IF ® MSUO-IF is selected. 1: Output regardless of the mode.
19 to 15	—	All 0	R	Reserved
14 to 12	ACKMD*	000	R/W	Audio Clock Mode Specifies the audio clock used to generate the master LR clock. Select the audio clock (fs) to be input in terms of a multiple of the sampling frequency (fs). 000: 512 fs 001: 256 fs 010: 128 fs 011: 64 fs 100: 32 fs Setting these bits is not necessary for slave operation.
11	—	0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	BPFMD*	001	R/W	Bit/Fs Mode Sets the division ratio of the master bit clock. 111: 16 bit/fs 000: 32 bit/fs 001: 64 bit/fs 010: 128 bit/fs 011: 256 bit/fs 100: 512 bit/fs 101: Setting prohibited 110: Setting prohibited Setting these bits is not necessary for slave operation.
7 to 5	—	All 0	R	Reserved
4	DOPMD	0	R/W	Data Output Parallel Mode Selects master or slave operation for the MSUO-IF module. 0: Slave operation 1: Master operation
3 to 1	—	All 0	R	Reserved
0	DISMD	0	R/W	Data Input Serial Mode Selects master or slave operation for the SI-IF module. 0: Slave operation 1: Master operation

Note: Some values cannot be set depending on the format and transfer bus width. For the formats and the ACKMD and BPFMD bit settings, refer to section 51.19.

51.14.18 SI-IF and MSUO-IF Operating Clock Invert Register (SIMO_CKG_RV)

SIMO_CKG_RV is a 24-bit readable/writable register that specifies whether to invert bit clocks and LR clocks. In master mode, set the bits according to the formats of the external ADC and DAC. In slave operation, set the bits so that the external clock is input to the circuit at the falling edge of the LR clock and the rising edge of the bit clock. Figure 51.4 shows the relation among clock inversion, the master/slave selector, and the clock setting registers in terms of the LR clock.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
23 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	LRM	0	R/W	LR Clock Reverse Master Specifies whether to invert the master LR clock. 0: Clock not inverted 1: Clock inverted
11 to 9	—	All 0	R	Reserved
8	BRM	0	R/W	Bit Clock Reverse Master Specifies whether to invert the master bit clock. 0: Clock not inverted 1: Clock inverted
7 to 5	—	All 0	R	Reserved
4	LRS	0	R/W	LR Clock Reverse Slave Specifies whether to invert the slave LR clock. 0: Clock not inverted 1: Clock inverted

Bit	Bit Name	Initial Value	R/W	Description
3 to 1	—	All 0	R	Reserved
0	BRS	0	R/W	Bit Clock Reverse Slave Specifies whether to invert the slave bit clock. 0: Clock not inverted 1: Clock inverted

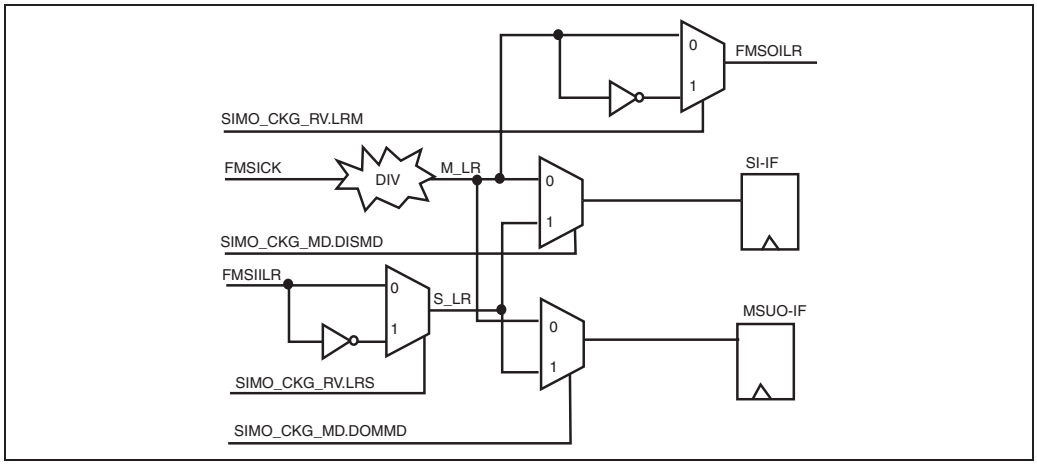

Figure 51.27 LR Clock Selector for SI-IF and MSUO-IF Modules (Inversion, Master/Slave)

51.14.19 Clock System Set Register (CKG_SMD)

CKG_SMD is a 24-bit readable/writable register. The FMSI has two clock systems. Set this register to operate the FMSI with only one clock system.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	MSMD	—	—	—	SSMD
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	MSMD	0	R/W	Master Synchronism Mode Master mode 0: Two clock systems 1: One clock system
19 to 17	—	All 0	R	Reserved
16	SSMD	0	R/W	Slave Synchronism Mode Slave mode 0: Two clock systems 1: One clock system
15 to 0	—	All 0	R	Reserved

Figure 51.28 shows the external audio clock pins of the FMSI. In master mode operation with one clock system, FMSOCK is valid and the signals that have the same phases as (FMSOOBT, FMSOOLR) and (FMSOIBT, FMSOILR) are output as the master output clocks. In slave mode operation with one clock system, FMSIOBT and FMSIOLR are valid.

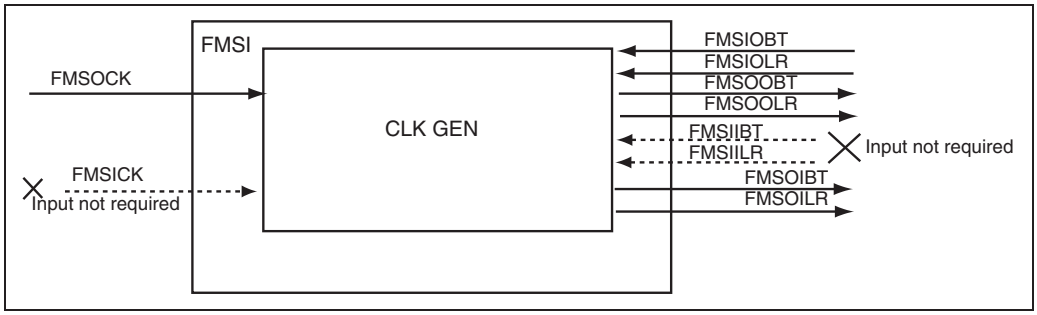

Figure 51.28 FMSI Audio Clock Pins

In operation with one clock system, the master clock is generated using the SOMI_CKG_MD register. The operation clock invert registers SOMI_CKG_RV and SIMO_CKG_RV can be set. Note that, however, the same value must be set for these two registers because the outputs have the same phase.

In operation with one clock system, SOMI_CKG_RV is used to set slave clock inversion.

51.14.20 Timer Count Set Register (TMR_CTL)

TMR_CTL is a 24-bit readable/writable register that controls timer operation. The counter counts the number of samples transferred in master/slave operation of the SO and SI systems. When the counter value reaches the set value, an interrupt source is generated.

Bit:	23	22	21	20	19	18	17	16
	SI[3:0]				SO[3:0]			
Initial value:	1	0	1	1	1	0	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
23 to 20	SI	1011	R/W	Sampling Frequency for the SI System Sets the value of the counter at which an interrupt source is to be generated. 0000: 1 0001: 2 0010: 4 0011: 8 0100: 16 0101: 32 0110: 64 0111: 128 1000: 256 1001: 512 1010: 1024 1011: 2048 1100: 4096 1101: 8192 1110: 16384 1111: 32768

Bit	Bit Name	Initial Value	R/W	Description
19 to 16	SO	1011	R/W	Sampling Frequency for the SO System Sets the value of the counter at which an interrupt source is to be generated. (The settings are the same as for bits 23 to 20.)
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SOM	0	R/W	Sampling Frequency Setting for Counting for the SO System 0: SO-IF 1: MI-IF

51.14.21 Timer Count Clear Register (TMR_CLR)

TMR_CLR is a 24-bit readable/writable register that clears the counter and the interrupt source that is asserted on a counter overflow.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	SI_CLR	—	—	—	SO_CLR
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	SI_CLR	0	R/W	Clears the counter for the SI system. 0: Retains a count value. 1: Clears the counter and the interrupt source.
19 to 17	—	All 0	R	Reserved
16	SO_CLR	0	R/W	Clears the counter for the SO system. 0: Retains a count value. 1: Clears the counter and the interrupt source.
15 to 0	—	All 0	R	Reserved

Figure 51.29 shows a block diagram of the timer control circuit.

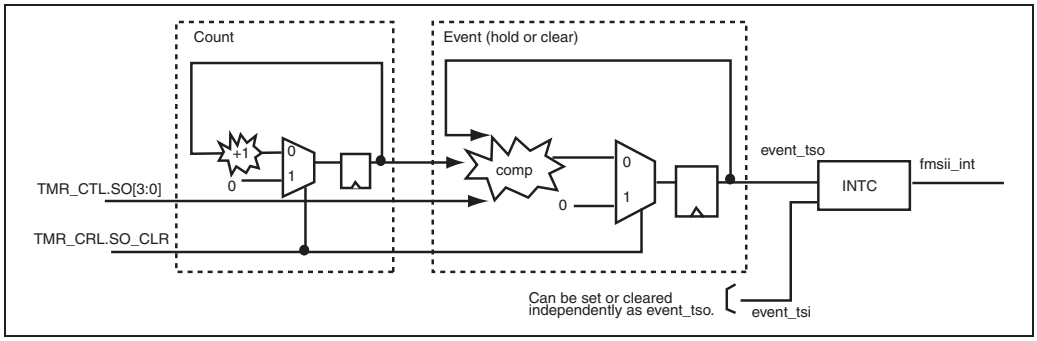

Figure 51.29 Block Diagram of the Timer Control Circuit

The interrupt source for the interrupt control block (INTC) is asserted when the counter overflows and held asserted until cleared. In the interrupt handling routine, clear the counter before clearing the interrupt source.

51.14.22 Direct Serial Transfer Set Register (DRCT_SRL)

DRCT_SRL is a 24-bit readable/writable register that sets direct transfer of parallel and serial data at the same sampling frequency without reading and writing registers (I/O).

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	SIMD[1:0]		—	—	—	SOMD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
23 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	SIMD	00	R/W	Serial Input Mode Select 00: IO (3) Serial input → DSP-IO 10: MSUO-IF (4) Serial input → parallel (MSU) output Other than those above: Reserved. (Setting prohibited.)
3 to 1	—	All 0	R	Reserved
0	SOMD	0	R/W	Serial Output Mode Select 0: IO (1) DSP-IO → serial output 1: MI-IF (2) Parallel (SCUV) input → serial output

51.14.23 Interrupt State Register (INT_ST)

INT_ST is a 24-bit readable/writable register that retains 6 sources of the FIFO and timer interrupts separately. Only writing 0 to clear is accepted. Writing 1 does not change the bit value. To clear a specific interrupt source, write 0 to the corresponding bit and 1 to the other bits.

The interrupt state register is set if the specified interrupt condition matches the FIFO and timer status while the corresponding interrupt mask is cleared. If an interrupt source is cleared at the same time as the interrupt source occurs, the interrupt condition takes precedence.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	IESTATSI	—	—	—	IESTATSO
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/(W)*	R	R	R	R/(W)*

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	IESTAEPI	IESTAPI	—	—	IESTAESI	IESTASI	—	—	IESTAESO	IESTASO
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20*	IESTATSI	0	R/W	SI System Timer Interrupt Event Status 1: Clears the interrupt source. 0: Retains the interrupt source.
19 to 17	—	All 0	R	Reserved
16*	IESTATSO	0	R/W	SO System Timer Interrupt Event Status 1: Clears the interrupt source. 0: Retains the interrupt source.
15 to 10	—	All 0	R	Reserved
9*	IESTAEPI	0	R/W	Parallel Input FIFO Error Status 1: Clears the interrupt source. 0: Retains the interrupt source.
8*	IESTAPI	0	R/W	Parallel Input FIFO Interrupt Event Status 1: Clears the interrupt source. 0: Retains the interrupt source.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved
5*	IESTAESI	0	R/W	Serial Input FIFO Error Status 1: Clears the interrupt source. 0: Retains the interrupt source.
4*	IESTASI	0	R/W	Serial Input FIFO Interrupt Event Status 1: Clears the interrupt source. 0: Retains the interrupt source.
3, 2	—	All 0	R	Reserved
1*	IESTAESO	0	R/W	Serial Output FIFO Error Status 1: Clears the interrupt source. 0: Retains the interrupt source.
0*	IESTASO	0	R/W	Serial Output FIFO Interrupt Event Status 1: Clears the interrupt source. 0: Retains the interrupt source.

Note: Writing 0 to this bit clears the interrupt source. Writing 1 does not change the bit value.

51.14.24 Interrupt Source Mask Register (IEMSK)

IEMSK is a 24-bit readable/writable register that masks the interrupt source for each FIFO. If this register masks an interrupt source, the interrupt source is not enabled even if the IMSK register described below unmasks the interrupt signal. Thus, the interrupt does not occur.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	IEMSKTSI	—	—	—	IEMSKTSO
Initial value:	0	0	0	0	0	0	0	0

51.14.26 MUTE Set Register (MUTE)

MUTE is a 24-bit readable/writable register that enables the MUTE function. Set MUTE on/off after selecting MUTE mode.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MUTEPI	MUTETPI	—	—	MUTESI	MUTETSI	—	—	MUTESO	MUTETSO
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
23 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	MUTEPI	0	R/W	Mute Parallel Input Enables parallel input MUTE. 0: MUTE off 1: MUTE on
9	MUTETPI	0	R/W	Mute Type Parallel Input Selects parallel input MUTE mode. 0: Normal MUTE 1: Zero cross MUTE
7, 6	—	All 0	R	Reserved
5	MUTESI	0	R/W	Mute Serial Input Enables serial input MUTE. 0: MUTE off 1: MUTE on
4	MUTETSI	0	R/W	Mute Type Serial Input Selects serial input MUTE mode. 0: Normal MUTE 1: Zero cross MUTE
3, 2	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
1	MUTESO	0	R/W	Mute Serial Output Enables serial output MUTE. 0: MUTE off 1: MUTE on
0	MUTETSO	0	R/W	Mute Type Serial Output Selects serial output MUTE mode. 0: Normal MUTE 1: Zero cross MUTE

51.14.27 Clock Reset Register (CLK_RST)

CLK_RST is a 24-bit readable/writable register that resets the counter for generating the master clock. To operate the FMSI in master mode, set the formats and clocks before releasing the reset. During reset, the LR and bit clocks are not output to the external and internal IF blocks. However, when the frequency division ratio of the bit clock frequency to fs is 1:1, the bit clock pulses continue to be applied.

Bit:	23	22	21	20	19	18	17	16

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	SICR	—	—	—	SOCR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/(W)*	R	R	R	R/(W)*

Bit	Bit Name	Initial Value	R/W	Description
23 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4*	SICR	0	R/W	SI-IF Clock Reset Resets the counter for generating master clock for the SI system. 0: Resets the counter. 1: Releases a reset.
3 to 1	—	All 0	R	Reserved
0*	SOCR	0	R/W	SO-IF Clock Reset Resets the counter for generating master clock for the SO system. 0: Resets the counter. 1: Releases a reset.

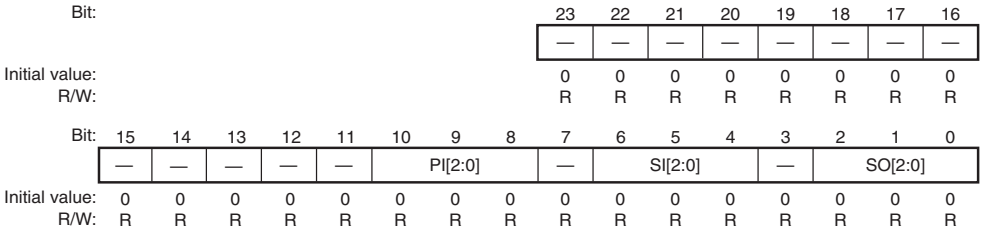
Note: This bit should be asserted longer than the audio clock period so that the counter synchronized with it is reset.

51.14.28 Software Reset Register (SOFT_RST)

SOFT__RST is a 24-bit readable/writable register that resets the internal buffers, registers and interrupt signal.

Bit:	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	SISR	—	—	—	SOSR	—	—	—	IR	—	—	—	SR
Initial value:	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1
R/W:	R	R	R	R/(W)*	R	R	R	R/(W)*	R	R	R	R/W	R	R	R	R/W



Bit	Bit Name	Initial Value	R/W	Description
23 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12*	SISR	1	R/W	Serial Input Soft Reset Resets the SI-IF module. Initializes the FFs synchronized with the bit clock in the SI-IF module. 0: Issues a reset. 1: Releases a reset.
11 to 9	—	All 0	R	Reserved
8*	SOSR	1	R/W	Serial Output Soft Reset Resets the SO-IF module. Initializes the FFs synchronized with the bit clock in the SO-IF module. 0: Issues a reset. 1: Releases a reset.
7 to 5	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
4	IR	1	R/W	Interrupt Reset Negates the interrupt signal (fmsio_int) even when the acknowledge signal (fmsii_int_ack) is not returned. 0: Issues a reset. 1: Releases a reset.
3 to 1	—	All 0	R	Reserved
0	SR	1	R/W	Software Reset Initializes all the registers. 0: Issues a reset. 1: Releases a reset.

Note: The SISR and SOSR bits should be asserted longer than the period of the bit clock applied to the SI-IF and SO-IF modules.

51.14.29 FIFO Size Register (FIFO_SZ)

FIFO_SZ is a 24-bit read-only register that indicates the capacity of the externally-connected DP-RAM.

Bit	Bit Name	Initial Value	R/W	Description
23 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	PI	000	R	Parallel Input Parallel input FIFO capacity Indicates the capacity of the connected DP-RAM. 000: 256 words These bits are always read as 000.
7	—	0	R	Reserved
6 to 4	SI	000	R	Serial Input Serial input FIFO capacity (The settings are the same as for bits 10 to 8.) These bits are always read as 000.
3	—	0	R	Reserved
2 to 0	SO	000	R	Serial Output Serial output FIFO capacity (The settings are the same as for bits 10 to 8.) These bits are always read as 000.

51.15 Interface Specifications

51.15.1 FMSI Access Specifications

(1) FMSI and DSP-IO Connection

The FMSI uses an 8-bit address space (8'h00 to 8'hFF). The FMSI registers can be read and written via the SPU2 DSP/IO bus. Figure 51.30 shows I/O space mapping viewed from the DSP side. 16-bit space from 0000 to FEFF is provided as a peripheral area. When connecting the FMSI to the DSP-IO, use an address decoder that asserts the write enable (fmsii_io_wr) and read enable (fmsii_io_rd) only for the specified upper 8-bit address. Figure 51.31 shows connection between the FMSI and DSP-IO.

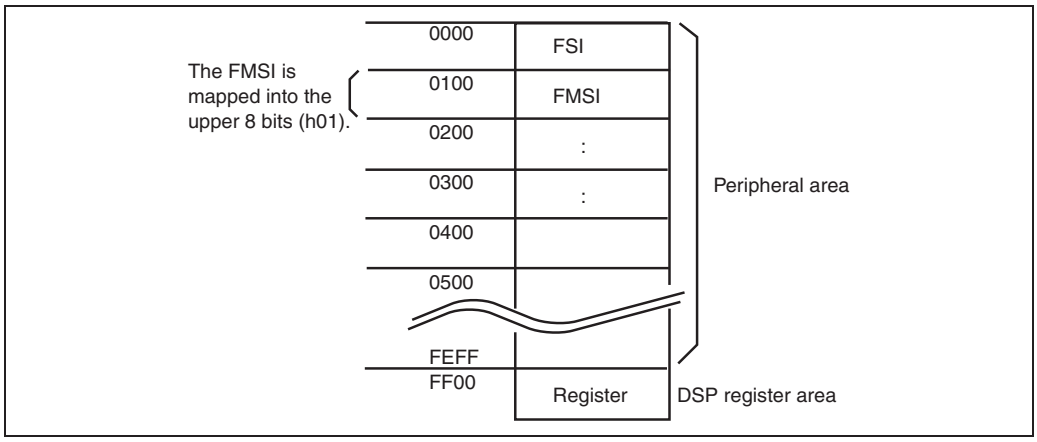


Figure 51.30 Example of DSP-IO Space Mapping

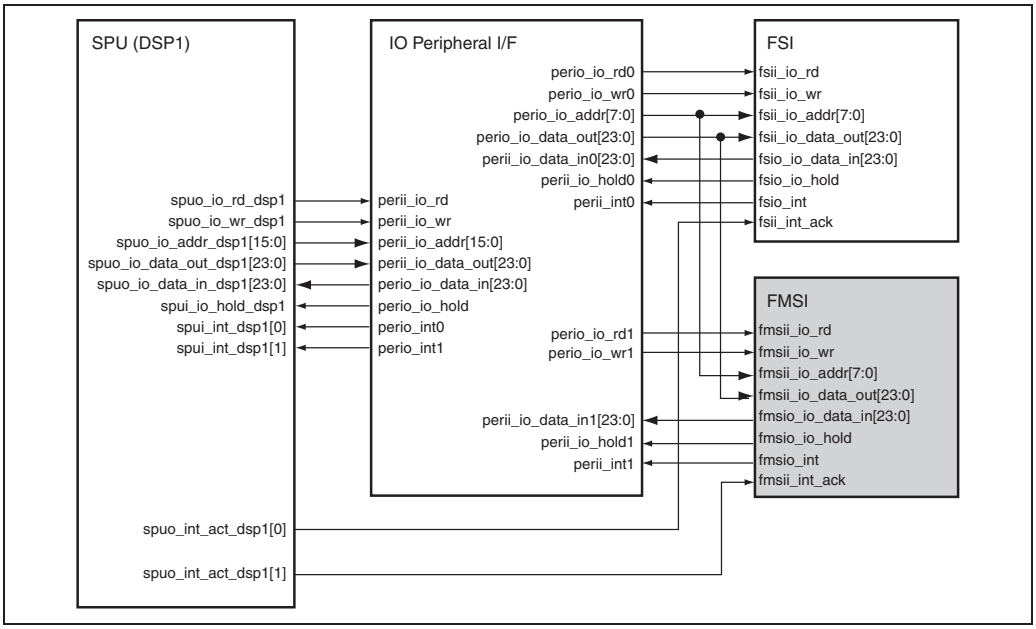

Figure 51.31 Example of Address Decoder for FMSI and DSP-IO Connection

(2) FMSI Access Timing

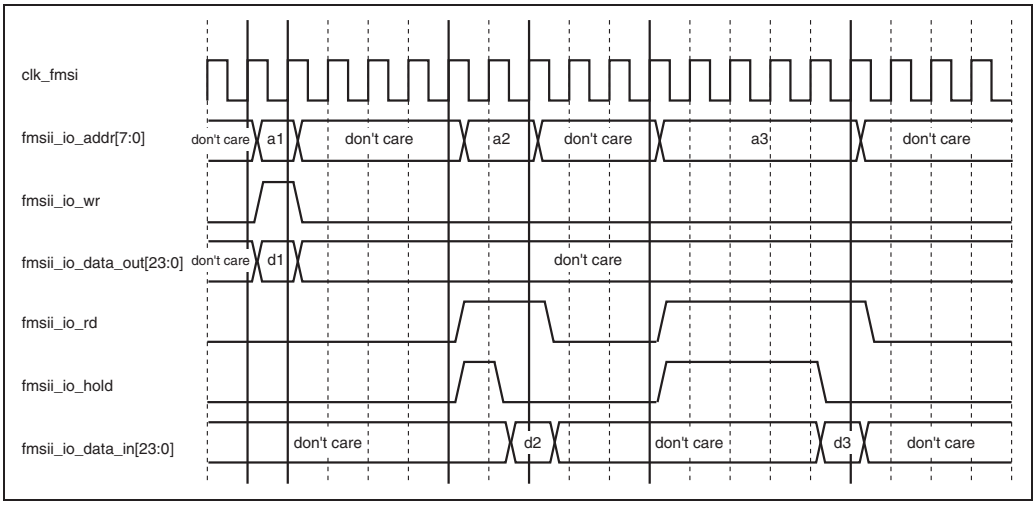

Figure 51.32 FMSI and DSP-IO Connection

Figure 51.32 shows the FMSI access timing. Write accesses are performed with no wait cycles. In read accesses, the hold signal fmsio_io_hold is asserted after the read enable signal fmsii_io_rd is output.

The number of wait cycles differs depending on the address. For the FIFO read address (S_DIDT, P_DIDT), the hold signal is kept asserted for one to four wait cycles. The other registers output an effective value, fmsio_io_data_in[23:0], after one wait cycle.

Table 51.12 summarizes the number of wait cycles for the accessible registers.

Table 51.12 Wait Cycles for FMSI Register Read/Write

Register	Read	Write
S_DIDT, P_DIDT	Initial read: 4 waits 2nd and following reads: 1 wait	Prohibited
Other registers	1 wait	No wait

51.15.2 Clock Interface Specifications

Figure 51.33 shows a block diagram of clock signals. Table 51.13 lists the FMSI clocks.

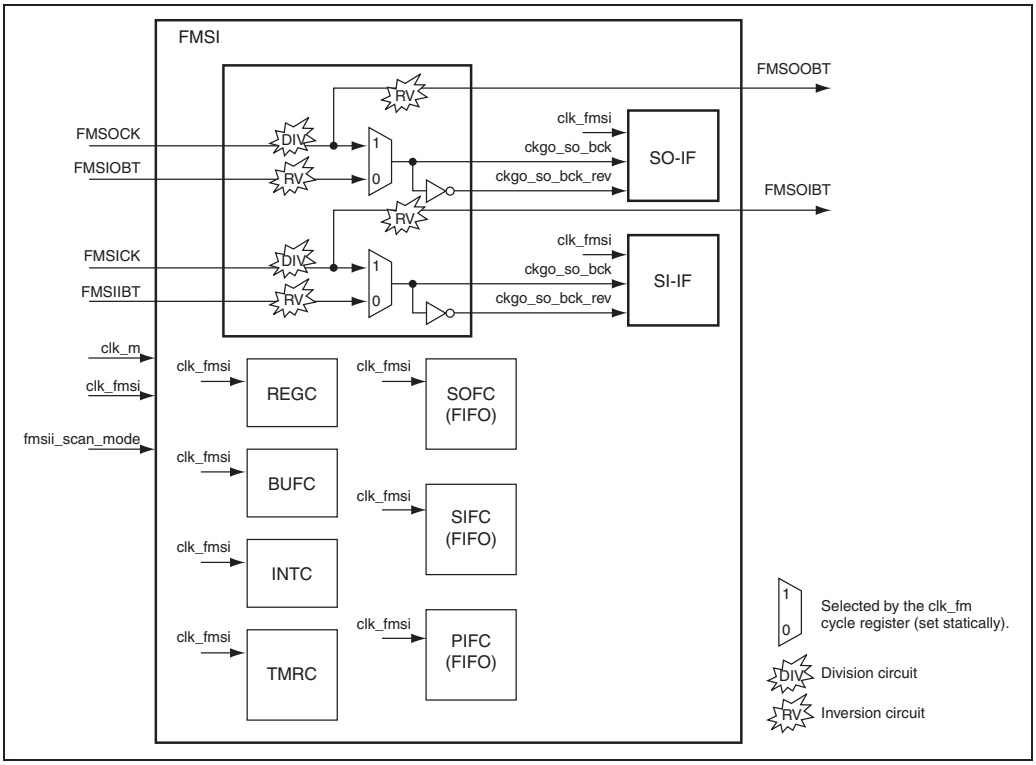

Figure 51.33 Block Diagram of FMSI Clock Inputs

The modules in the thick-line frames in figure 51.33 provide asynchronous processing.

Table 51.13 FMSI Clock Pins

Clock Name	Category	Type	Description	Synchronization (clk_fmsi basis)
clk_fmsi	Common	G4 internal	DSP operating clock	—
clk_m	Common	G4 internal	HPB bus clock	Asynchronous
FMSOCK	SO	Input	SO audio clock	Asynchronous
FMSICK	SI	Input	SI audio clock	Asynchronous
FMSIOBT	SO	Input	SO slave bit clock	Asynchronous
FMSIIBT	SI	Input	SI slave bit clock	Asynchronous
ckgo_so_bck	SO	FMSI internal	SO DOIS bit clock	Asynchronous
ckgo_so_bck_rev	SO	FMSI internal	Inverted clock of ckgo_so_bck	Asynchronous
ckgo_si_bck	SI	FMSI internal	SI DIIS bit clock	Asynchronous
ckgo_si_bck_rev	SI	FMSI internal	Inverted clock of ckgo_si_bck	Asynchronous
FMSOOBT	SO	Output	SO master bit clock	Asynchronous
FMSOIBT	SI	Output	SI master bit clock	Asynchronous

51.15.3 FIFO Access Specifications

(1) FMSI and DSP-RAM Connection

Figure 51.34 shows an example of connection between the FIFO control and DP-RAM.

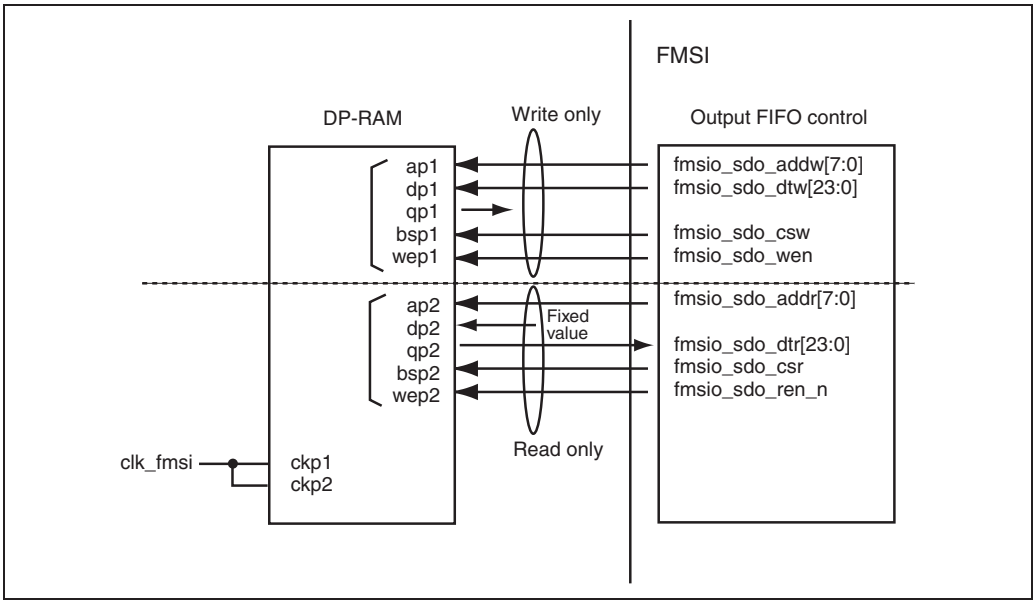

Figure 51.34 Sample Connection between Output FIFO and DP-RAM

(2) DP-RAM Access Timing

Figure 51.35 shows a timing chart of the access to the DP-RAM.

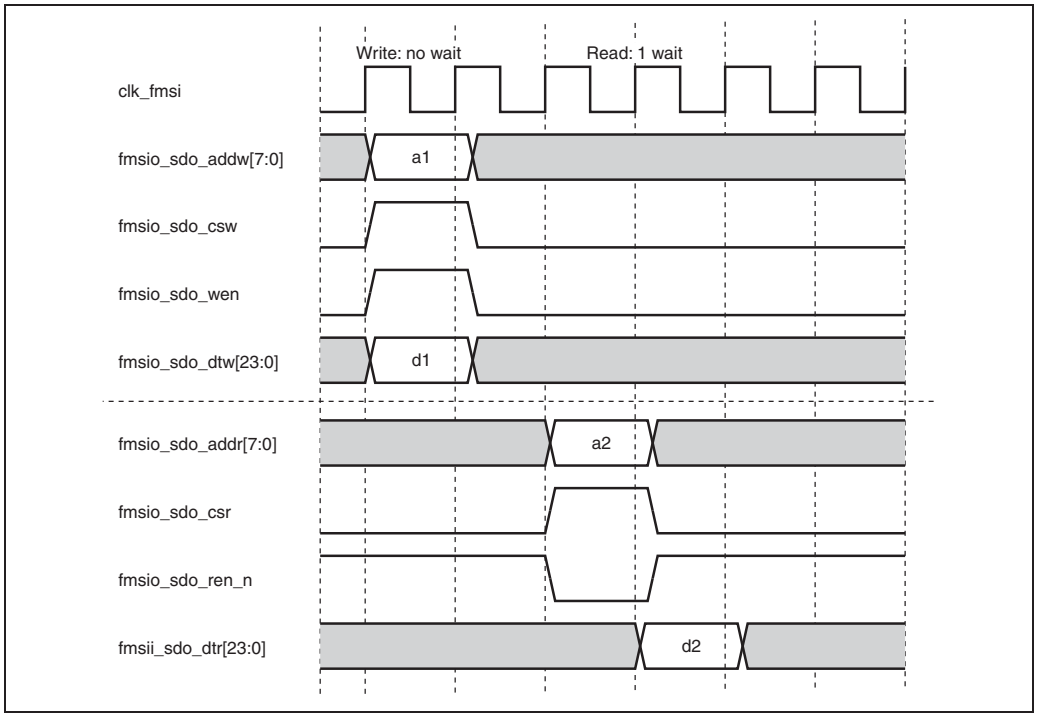

Figure 51.35 DP-RAM Access Timing

Connect a DP-RAM that can be read from or written to with the above timing. During the DP-RAM accesses, port 1 is used for write accesses only and port 2 for read accesses only. The FMSI outputs the fmsi_sdo_csw and fmsio_sdo_wen as the same signals and fmsio_sdo_csr and fmsio_sdo_ren_n as signals inverted to each other.

51.15.4 Interrupt Interface Specifications

The FMSI has one interrupt signal line. Table 51.14 shows the interrupt pin configuration.

Table51.14 Interrupt Pin Configuration

Pin Name	Input/Output	Function	Polarity
fmsio_int	Output	Interrupt requests to external modules	High
fmsii_int_ack	Input	Response to an interrupt request; the FMSI negates fmsio_int in response to fmsii_int_ack.	High

Figure 51.36 shows a register controller block for interrupt signals. Although only the int_so (serial output) is shown representatively in this figure, eight interrupt sources individually support the interrupt state and source masks and signal masks can be set independently for the sources.

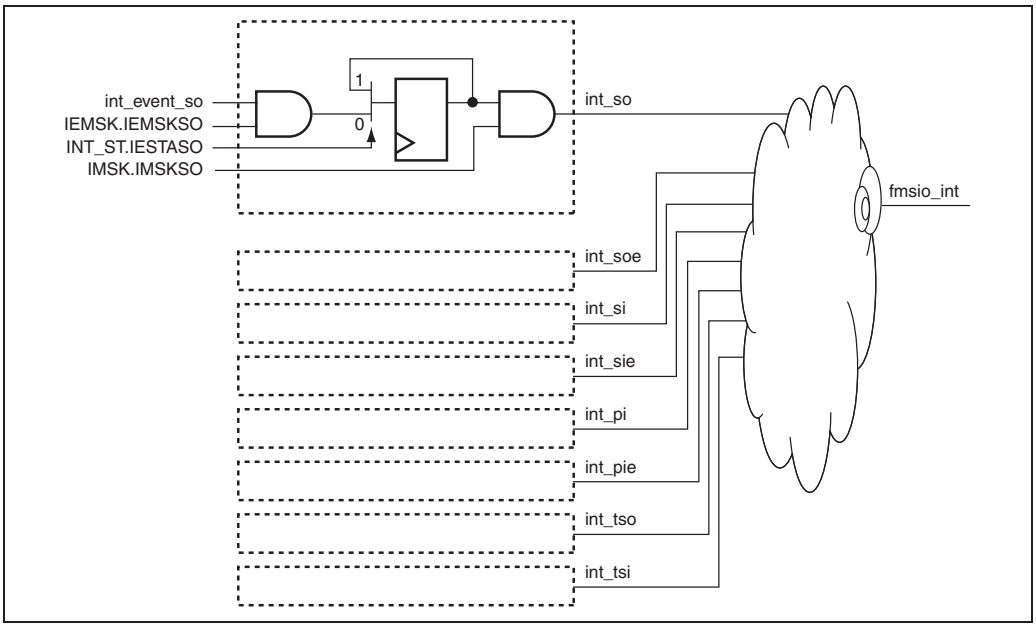

Figure 51.36 Interrupt Signals (Register Controller)

Figure 51.37 shows a timing chart of the interrupt signal. The external interrupt signal (fmsio_int) is asserted by any of eight interrupt sources. Once the interrupt signal is asserted after it is negated by fmsii_int_ack, it is never asserted again until at least one interrupt source is cleared in the status register.

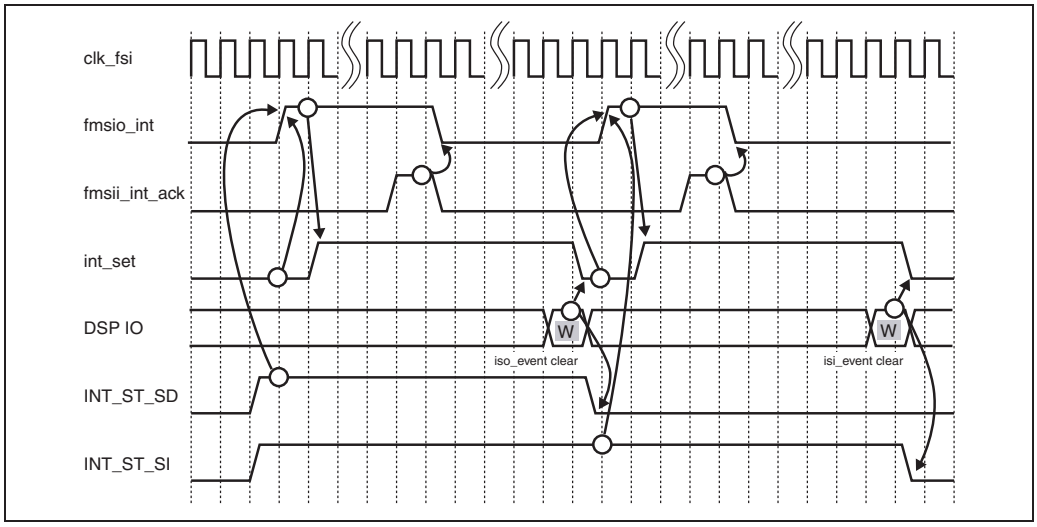

Figure 51.37 Timing Chart of Interrupt Signal

For debugging, fmsio_int can be negated without returning fmsii_int_ack by writing to the IR bit in SOFT_RST.

51.16 Reset Specifications

Table 51.15 lists the FMSI resets.

Table 51.15 FMSI Resets and Initializing Modules

Reset Name	REGC	BUFC	INTC	TMRC	CLK GEN	SOFC	SIFC	PIFC	SOIF	SIIF
Hardware reset	Reset	Reset	Reset	Reset	Reset	Reset	Reset	Reset	Reset	Reset
Software reset	Reset	Reset	Reset	Reset	Reset	Reset	Reset	Reset	Reset* 1	Reset* 1
SO-IF reset	—	—	—	—	—	—	—	—	Reset	—
SI-IF reset	—	—	—	—	—	—	—	—	—	Reset
Clock reset SOM	—	—	—	—	Reset	—	—	—	—	—
Clock reset SIMC	—	—	—	—	Reset	—	—	—	—	—
Interrupt reset	—	—	Reset* 2	—	—	—	—	—	—	—
Serial output FIFO clear	—	—	—	—	—	Reset	—	—	—	—
Serial input FIFO clear	—	Reset* 3	—	—	—	—	Reset	—	—	—
Parallel input FIFO clear	—	Reset* 3	—	—	—	—	—	Reset	—	—

—: Register retained.

Notes: 1. Except FFs synchronized with the bit clock
2. The interrupt signal is negated.
3. The buffer used for prefetching read data is initialized.

Details of the resets (initialized modules, initialized registers, and setting flows) are shown below.

1. Hardware Reset (rst_fmsi_n)
   Initializes all registers and modules by the active-low reset signal.
2. Software Reset (SOFT_RST.SR)
   Initializes all registers except the software reset register (SOFT_RST.SR) and all modules. In master operation, the bit clock that is used for asynchronous passing may be fixed due to a clock reset, perform a software reset after resetting SI-IF and SO-IF (see (9) Procedures for Initializing the FMSI).
3. SO-IF Reset, SI-IF Reset (SOFT_RST.SRSO, SOFT_RST.SRSI)

These are the reset signals to initialize the FFs that are synchronized with the bit clock.

Since the bit clock is used for asynchronous passing, this reset requires to wait for longer than 1 bit clock cycle after a register write to perform it.

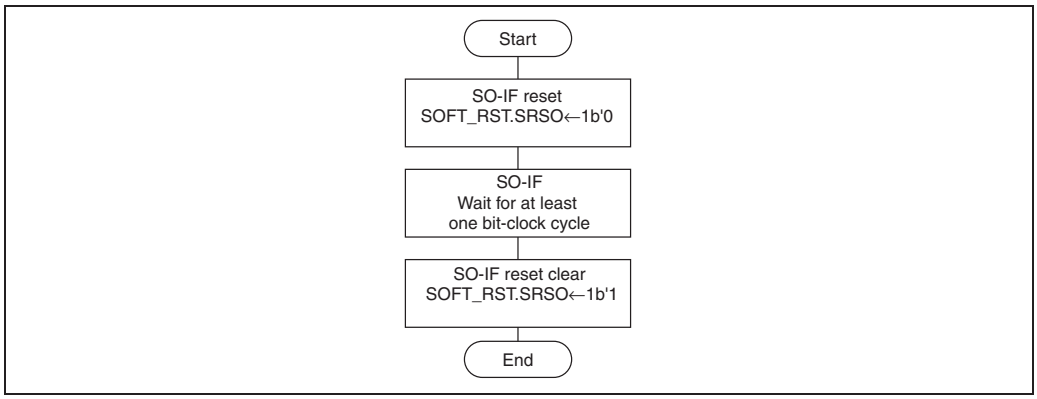

Figure 51.38 Flow of SO-IF Reset (Same for SI-IF Reset)

4. Clock Resets SOMI and SIMO (CLK_RST.CRSOMI, CLK_RST.CRSIMO)

   These are the reset signals to initialize the counters that are synchronized with the audio clock for generating the master clock.

   Since the audio clock is used for asynchronous passing, this reset requires to wait for longer than 1 audio clock cycle after a register write to perform it.

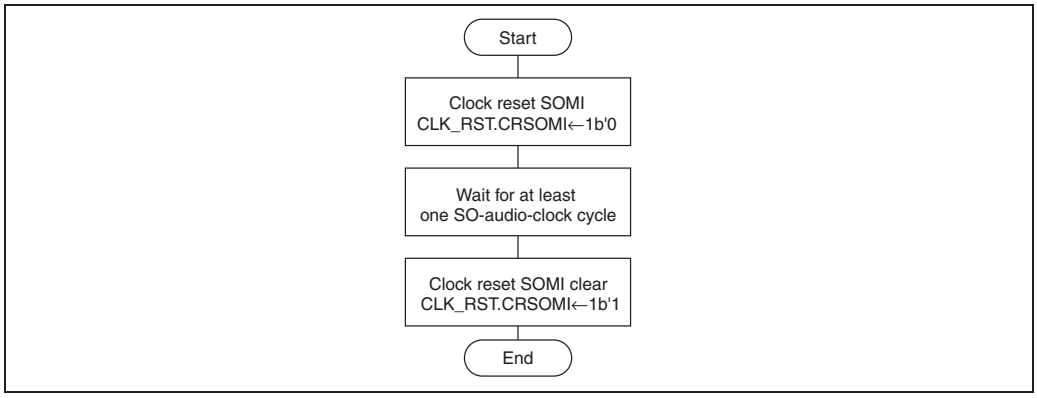

Figure 51.39 Flow of Clock Reset SOMI (Same for Clock Reset SIMO)

5. Interrupt Reset (SOFT_RST.IR)

Negates the interrupt signal (fmsio_int) when the corresponding register is written. The reset should be released after the negation.

6. Serial Output FIFO Clear (S_DOFF_CTL.CLR)

   Clears the address pointer of the serial FIFO control block (SOFC) and the error history.

7. Serial Input FIFO Clear (S_DIFF_CTL.CLR)

   Clears the address pointer of the serial FIFO control block (SIFC), the error history, and buffers for continuous 1-wait reads.

8. Parallel Input FIFO Clear (P_DIFF_CTL.CLR)

   Clears the address pointer of the parallel FIFO control block (PIFC), the error history, and buffers for continuous 1-wait reads.

9. Procedures for Initializing the FMSI

   The procedures for initializing the FMSI are shown in figure 51.40. There are two types of procedures: one by using a hardware reset and another by using a software reset. To achieve the same effect as a hardware reset, perform a software reset after SO-IF reset or SI-IF reset (initializing the FFs that are synchronized with the bit clock).

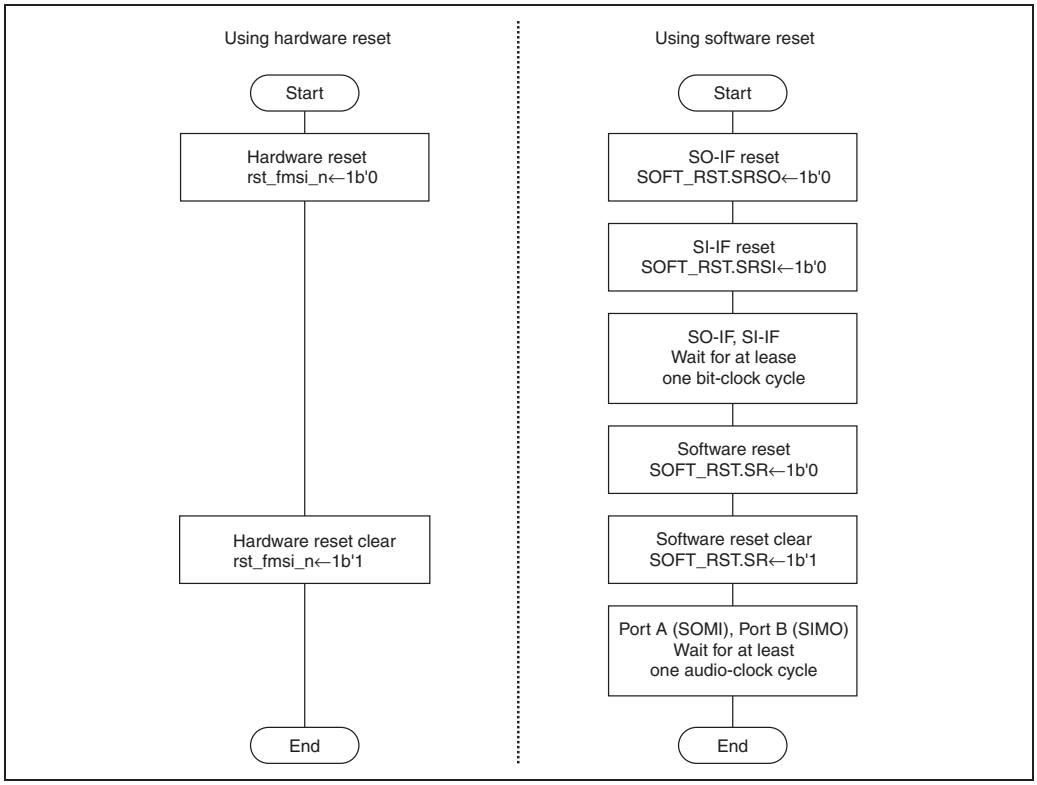

Figure 51.40 Flow of FMSI Initialization Operation

51.17 MUTE Specifications

The FMSI has normal MUTE and zero cross MUTE functions for input/output operations. The MUTE circuits are implemented for output FIFO control block (SOFC) and input FIFO control block (SIFC and PIFC).

51.17.1 Normal MUTE

The normal MUTE mutes on a per sample data basis. It is turned on (outputs 0) for channel 1 first 2 samples after it is enabled. Similarly, it is turned off for channel 1 first 2 samples after it is disabled.

Figure 51.41 shows the 2-channel audio output and the MUTE signal.

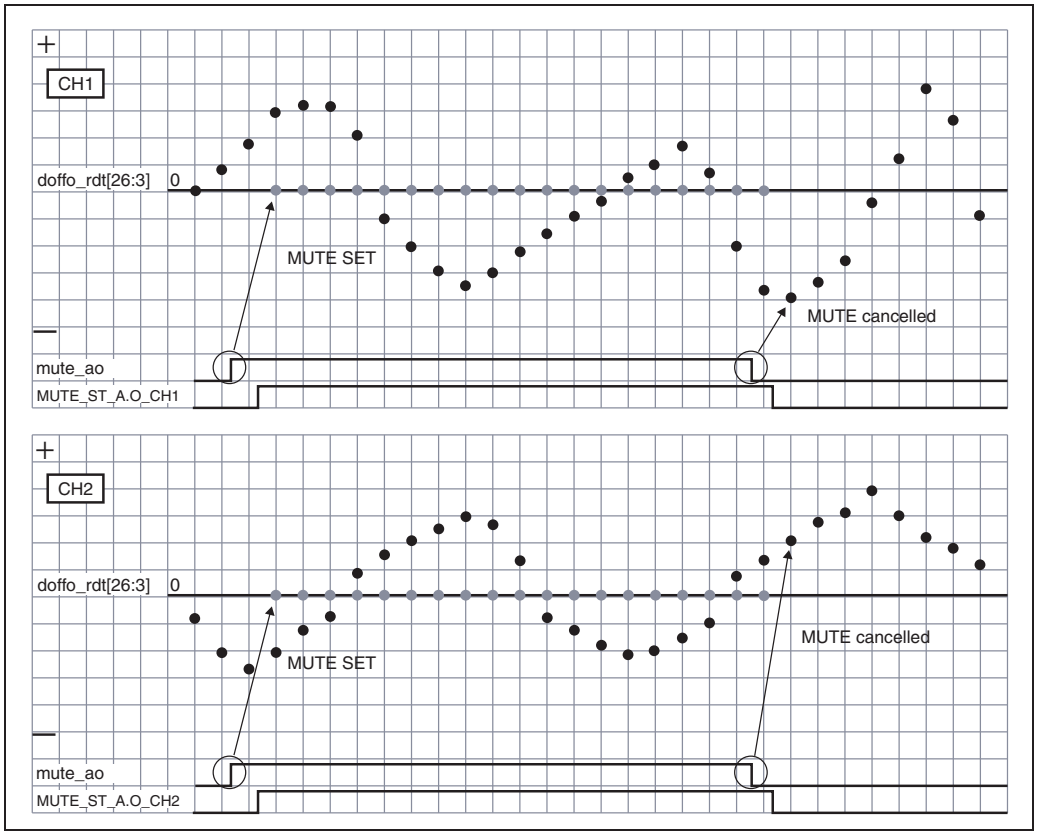

Figure 51.41 Normal MUTE Specification (Output Operation)

When the MUTE signal is asserted in input operation, the conversion module (input I2S) takes data written to input FIFOs and writes 0 to the DP-RAM.

51.17.2 Zero Cross MUTE

If the zero cross MUTE function is enabled, it compares current data to the previous one on each channel independently.

The conditions for turning on the mute are (1) the previous data is 0, (2) current data is 0, and (3) the sign of current data does not match the one of the previous data.

If any of these conditions ((1) to (3)) is satisfied, the mute is turned on (0 is output) until the zero cross MUTE function is disabled.

The mute (outputting 0) is turned off, just like it is turned on, if any of the conditions ((1) to (3)) is satisfied when current data is compared to the previous one on each channel independently.

Figure 51.42 shows the 2-channel audio output and zero cross MUTE signal.

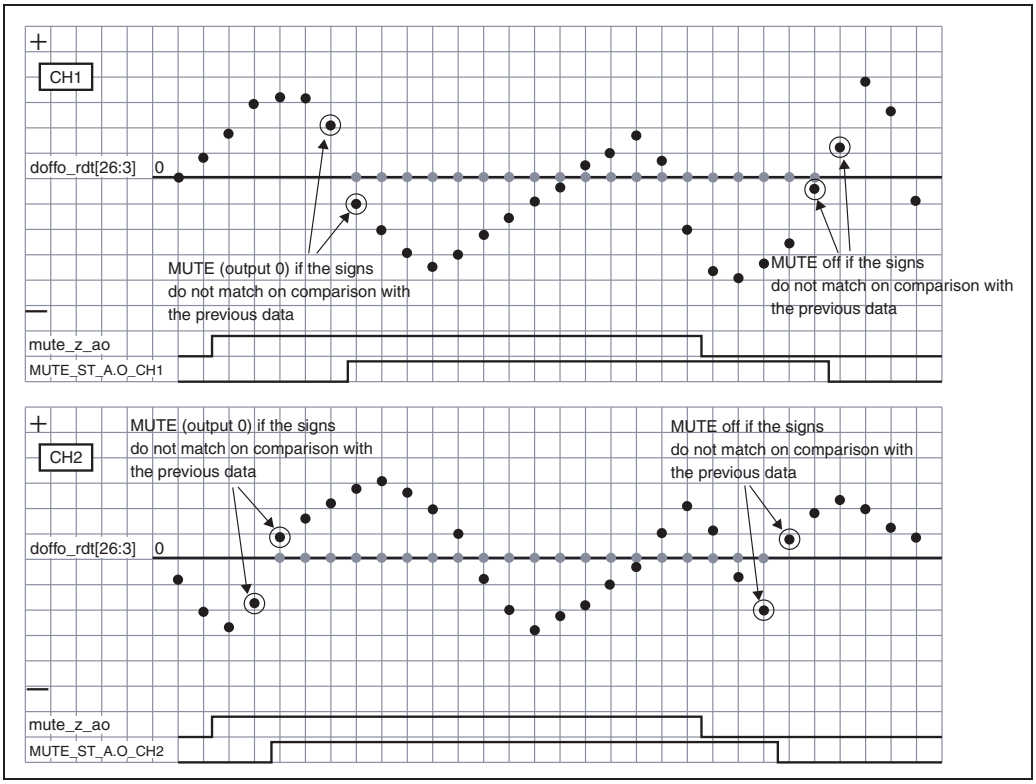

Figure 51.42 Zero Cross MUTE Specification (Output Operation)

Even if the zero cross MUTE function is enabled, the mute (outputting 0) is not turned on unless any of the conditions (1) to (3) is met.

Even if any of the conditions (1) to (3) is met, the mute (outputting 0) is not turned off unless the zero cross MUTE function is disabled.

After the zero cross MUTE function is enabled, it can be switched to the normal MUTE function to turn on/off the mute forcibly.

When the MUTE signal is asserted in input operation, the conversion module (input I2S) compares data written to input FIFOs to determine if the conditions (1) to (3) are met and writes 0 to the DP-RAM.

51.18 FIFO Overflow/Underflow

51.18.1 Specifications

When an underflow or overflow error occurs, the FIFO contains the error related information in a register. This section describes underflows and overflows in the output FIFOs and input FIFOs.

An output FIFO underflow occurs when the SO-IF requests data (req) while the FIFO is empty. When it occurs, the output FIFO outputs 24'h0 and the channel number [2:0]. An overflow occurs when the DSP tries to write more data than the FIFO capacity. Such write operations are ignored. No overflow occurs under management by the DSP.

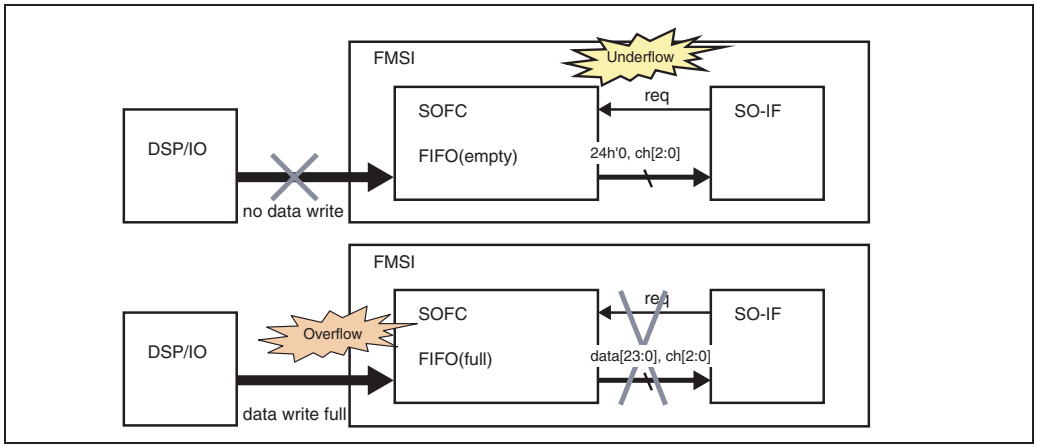

Figure 51.43 Output FIFO Underflow/Overflow

An input FIFO overflow occurs if 3-line serial data is input to the FIFO externally when it is full. The write to the input FIFO that caused an overflow is ignored. An underflow occurs when a read request is issued by the DSP while the input FIFO is empty. When it occurs, the read request returns 0. No underflow occurs under management by the DSP.

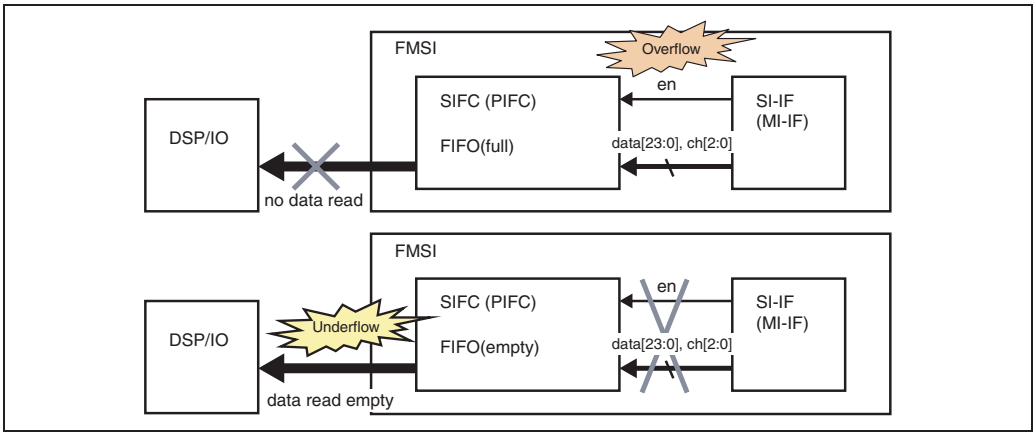

Figure 51.44 Input FIFO Overflow/Underflow

51.18.2 Error Flag Clear

Table 51.16 lists the FMSI error flags. The FMSI uses six error flags. Figures 51.45 and 51.46 show error flag clear flows for serial output and serial input, respectively.

Table 51.16 List of Error Flags

Register Name	Description	
S_DOFF_ST.OF	Serial output	Overflow error
S_DOFF_ST.UF		Underflow error
S_DIFF_ST.OF	Serial input	Overflow error
S_DIFF_ST.UF		Underflow error
P_DIFF_ST.OF	Parallel input	Overflow error
O_DIFF_ST.UF		Underflow error

(1) Clearing Serial Output Overflow Error

If an overflow occurs during serial output operation and the flag is detected, perform the processing specific to the application and clear the flag.

(2) Clearing Serial Output Underflow Error

If an underflow occurs during serial output operation and the flag is detected, perform the processing specific to the application, write the output data to S_DODT, and clear the flag.

(3) Clearing Serial Input Overflow Error

If an overflow occurs during serial input operation and the flag is detected, perform the processing specific to the application, read the input data from S_DIDT, and clear the flag.

(4) Clearing Serial Input Underflow Error

If an underflow occurs during serial input operation and the flag is detected, perform the processing specific to the application and clear the flag.

(5) Clearing Parallel Input Overflow Error

Same as (3) above.

(6) Clearing Parallel Input Underflow Error

Same as (4) above.

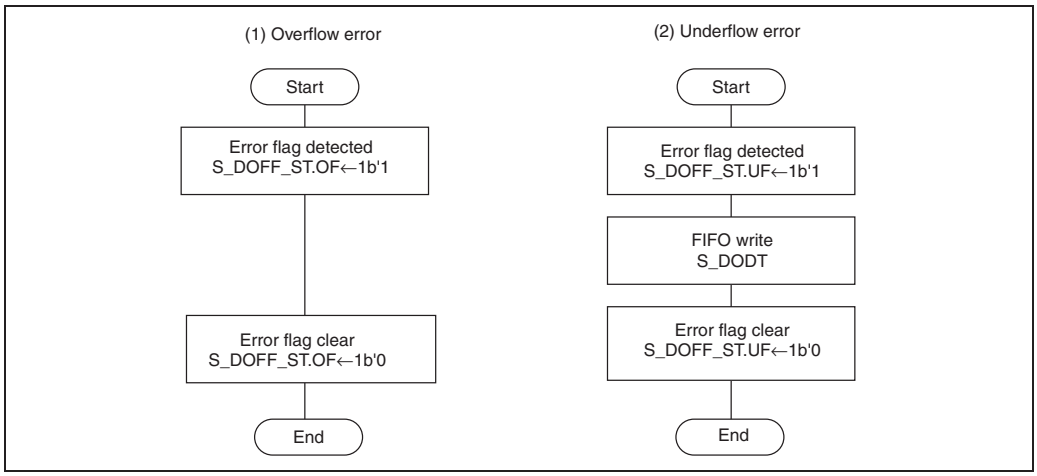

Figure 51.45 Flow for Clearing Serial Output Error Flag

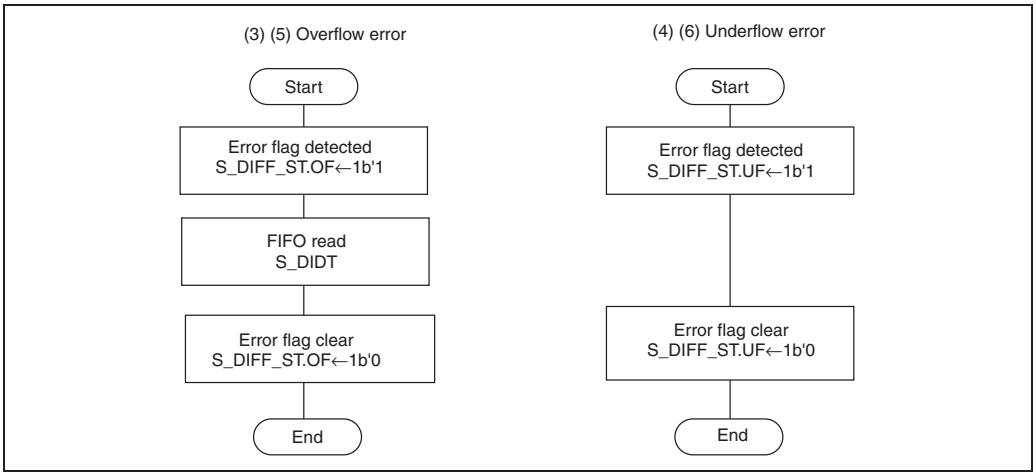

Figure 51.46 Flow for Clearing Serial Input Error Flag

51.19 FIFO Clear

Each FIFO controller has a FIFO clear function. This function performs the following:

1. Clearing the UF/OF error history
   Clears the FIFO status to 0.
2. Clearing the address pointer of the FIFO control
   Initializes the counter that controls the DP-RAM access. When a FIFO clear is performed, the address pointer returns to the start address and data prior to the clear is overwritten.
3. Clearing data prefetched by the BUFC block and the buffer pointer
   Clears data prefetched by the BUFC block for continuous reads and the buffer pointer.
4. Masking the FIFO control block
   Can be enabled for the request (CH1) corresponding to the second sample after a FIFO clear. This is because the state of the mask is determined by the request (output) and enable (input) after the format and clock settings is fixed.

51.20 Direct Transfer

The FMSI supports the following two types of direct transfers to perform serial input/output without using the DSP.

1. MI-IF → SO-IF (DRCT_SRL.SOMD = 1'b1)
2. SI-IF → MSUO-IF (DRCT_SRL.SIMD = 2'b10)

Table 51.17 shows formats and clock settings for the direct transfer.

Table 51.17 Formats and Clock Settings for Direct Transfer

Type	Input-Side Format	Output-Side Format	Bus Width
1	1 channel	MONO, MONO_Delay	24 or 16 bits only
	2 channels	PCM, I2S	↑
2	MONO, MONO_Delay	1 channel	16 bits only

In type 2 transfer above, the MSUO-IF supports only the 16-bit 1-channel transfer. Thus, there is no register to select the transfer format. Select an appropriate serial transfer format in the input-side.

51.21 Audio Format

51.21.1 Serial Format

Tables 51.18 and 51.19 show serial formats in which operation is guaranteed for the FMSI. The audio clock and format can be set independently for input and output.

Table 51.18 List of Supported Serial Formats (24-Bit Transfer)

	MONO, MONO Delay	I2S, PCM	TDM, TDM Delay
Operating Clock	**BPFMD**	**BPFMD**	**BPFMD**
Master ACKMD: 32 fs	32 bits/fs	Setting prohibited	Setting prohibited
Master ACKMD: 64 fs	64 bits/fs 32 bits/fs	64 bits/fs	Setting prohibited
Master ACKMD: 128 fs	128 bits/fs 64 bits/fs 32 bits/fs	128 bits/fs 64 bits/fs	128 bits/fs
Master ACKMD: 256 fs	256 bits/fs 128 bits/fs 64 bits/fs 32 bits/fs	256 bits/fs 128 bits/fs 64 bits/fs	256 bits/fs 128 bits/fs

	64 bits/fs	64 bits/fs	64 bits/fs
	32 bits/fs	32 bits/fs	
	16 bits/fs		
Slave	16 bits/fs or more	32 bits/fs or more	64 bits/fs or more (4 channels)
			128 bits/fs or more (8 channels)

The serial conversion section (SO-IF, SI-IF) operates based on the falling edge of the LR clock that is inverted on the rising edge of the bit clock. Although the master clock is generated according to the specification in master operation, the inversion register needs to be set properly if the external LR and bit clocks are input directly in slave operation. Along with serial data formats, the inversion settings for slave operation are shown below for reference. The LR clock and bit clock, which are output during master operation, can be inverted according to the DAC and ADC

specifications. In the MONO and MONO_Delay formats shown in figures 51.47 and 51.48, these clocks are not inverted. In the other formats, the bit clock is inverted to be output.

Register settings during master operation (address xxx indicates a serial output):

- MONO and MONO_Delay formats in figures 51.47 and 51.48:
  xxx_CKG_RV.LRM =
- PCM, I2S, TDM, and TDM_Delay formats in figures 51.49 to 51.56:
  xxx_CKG_RV.LRM =

The main formats for 3-line serial data are shown below.

In delay mode (I2S), MSB data is output one bit-clock cycle behind the LR clock.

The MONO and MONO_Delay serial data formats are shown below.

(1) MONO (1 channel), 24-bit and 16-bit

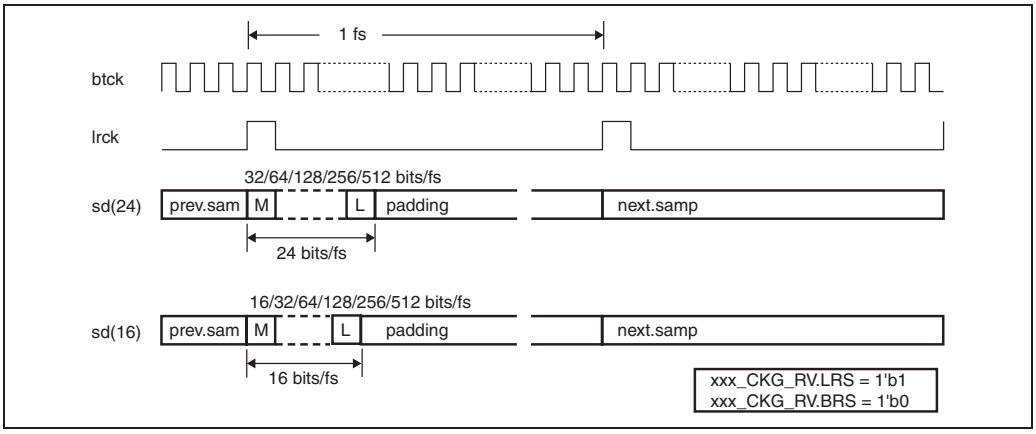

Figure 51.47 MONO Format

(2) MONO_Delay (1 channel), 24-bit and 16-bit

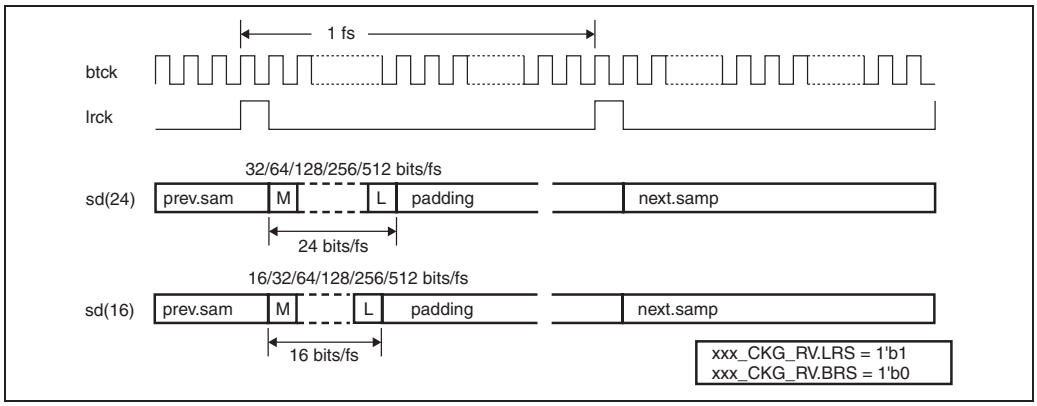

Figure 51.48 MONO_Delay Format

The PCM serial data formats are shown below.

(3) PCM (2 channels) 64 bits/fs, 24-bit and 16-bit

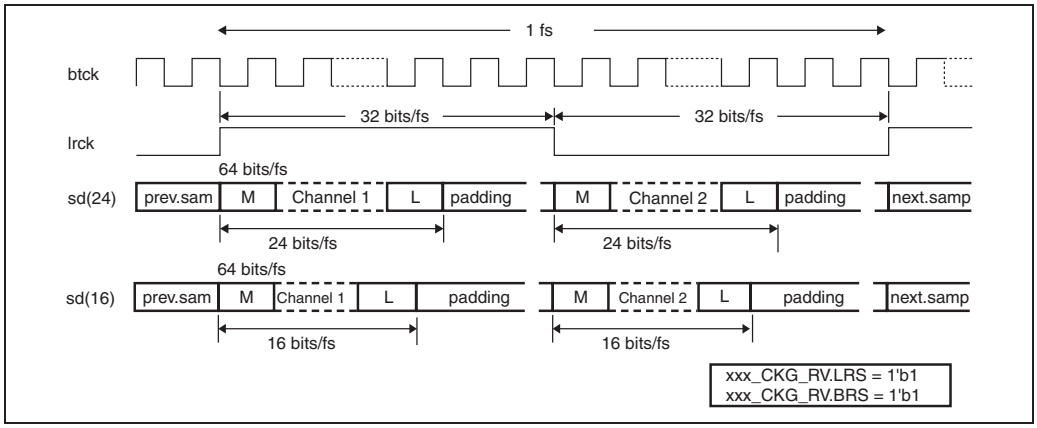

Figure 51.49 PCM Format (64 bits/fs)

(4) PCM (2 channels) 128 bits/fs, 24-bit and 16-bit

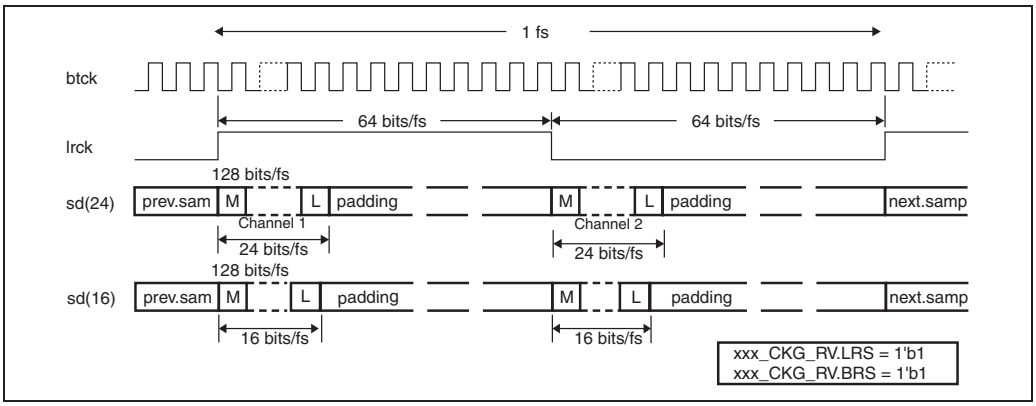

Figure 51.50 PCM Format (128 bits/fs)

The I2S serial data formats are shown below.

(5) I2S (2 channels) 64 bits/fs, 24-bit and 16-bit

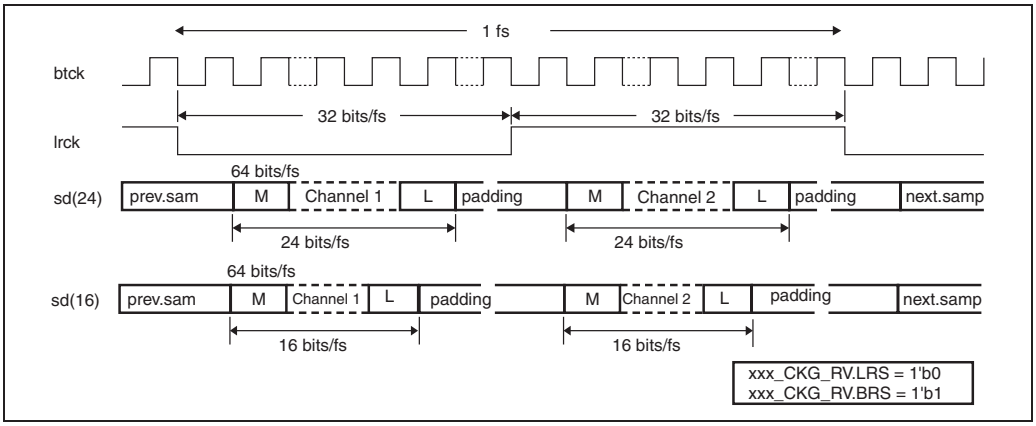

Figure 51.51 I2S Format (64 bits/fs)

(6) I2S (2 channels) 128 bits/fs, 24-bit and 16-bit

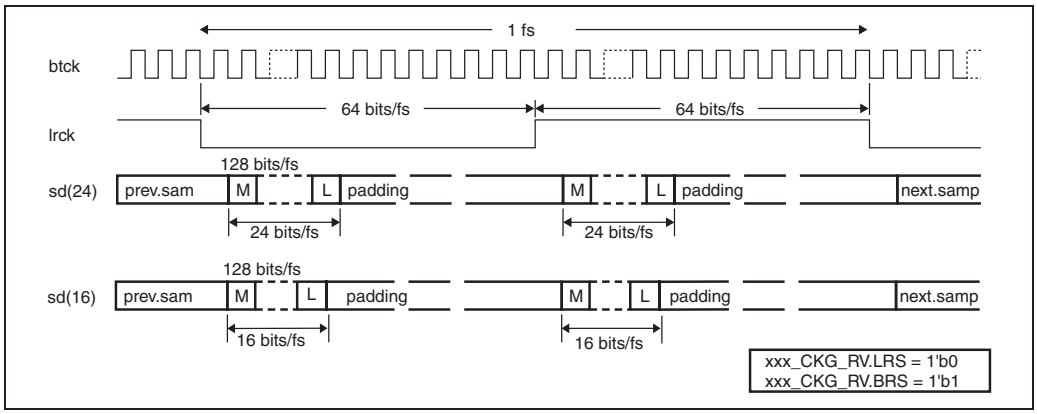

Figure 51.52 I2S Format (128 bits/fs)

The TDM and TDM_Delay serial data formats are shown below.

(7) TDM (8 channels) 256 bits/fs, 24-bit

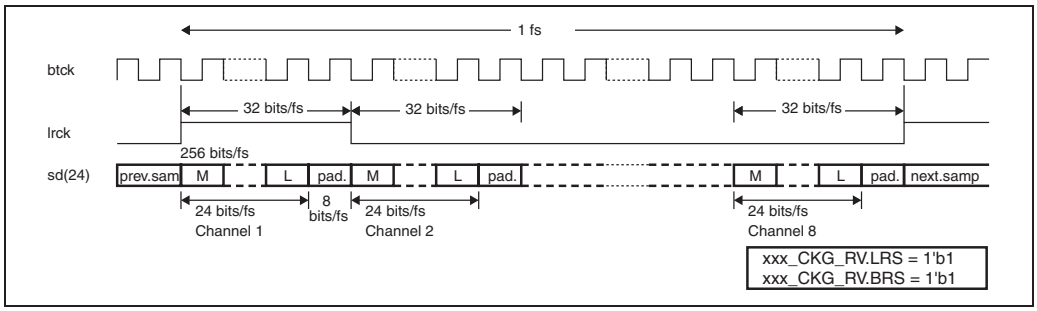

Figure 51.53 TDM Format (256 bits/fs, 24-bit)

(8) TDM (8 channels) 512 bits/fs, 24-bit

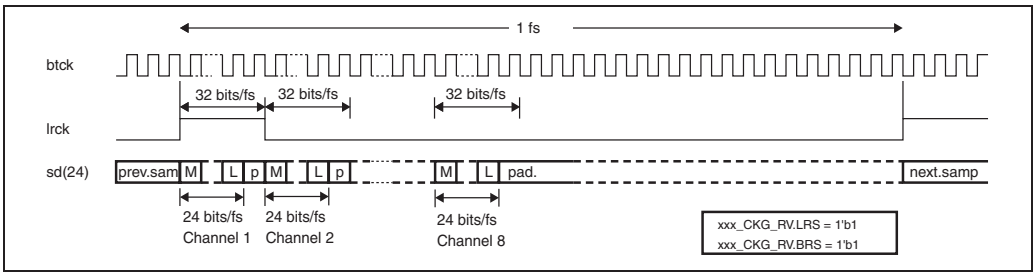

Figure 51.54 TDM Format (512 bits/fs, 24-bit)

(9) TDM_Delay (8 channels) 512 bits/fs, 24-bit

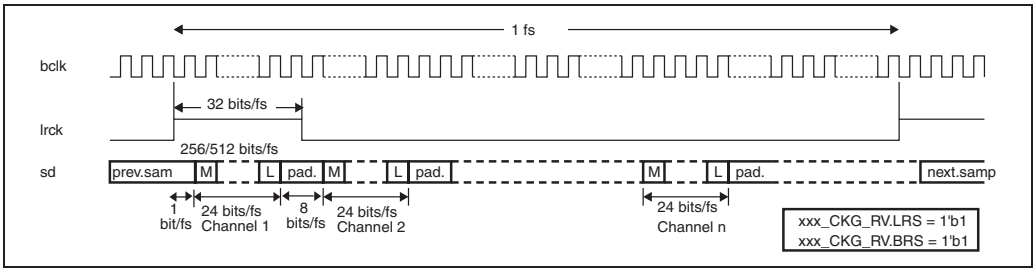

Figure 51.55 TDM_Delay Format (512 bits/fs, 24-bit)

(10) TDM (8 channels) 128 bits/fs, 16-bit

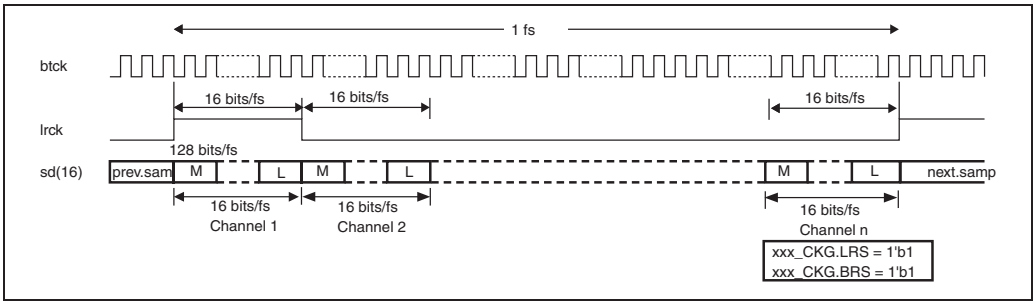

Figure 51.56 TDM Format (128 bits/fs, 16-bit)

51.21.2 Parallel Format

The FMSI supports the following parallel transfer formats.

Table 51.20 Parallel Transfer Formats (Common to 24-bit and 16-bit transfers)

Port SIMO	Port SOMI
MSUO-IF (1CH)	**MI-IF (1CH or 2CH)**
Master, ACKMD: 32 fs	Master, ACKMD: 32 fs
Master, ACKMD: 64 fs	Master, ACKMD: 64 fs
Master, ACKMD: 128 fs	Master, ACKMD: 128 fs
Master, ACKMD: 256 fs	Master, ACKMD: 256 fs
Master, ACKMD: 512 fs	Master, ACKMD: 512 fs
Slave	Slave

Figure 51.57 shows the MI-IF timing chart.

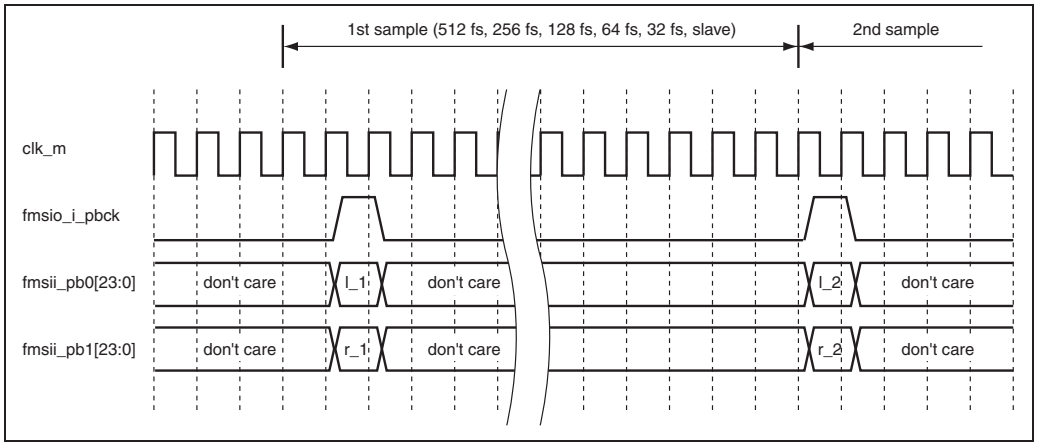

Figure 51.57 MI-IF Timing Chart

Figure 51.58 shows the MSUO-IF timing chart.

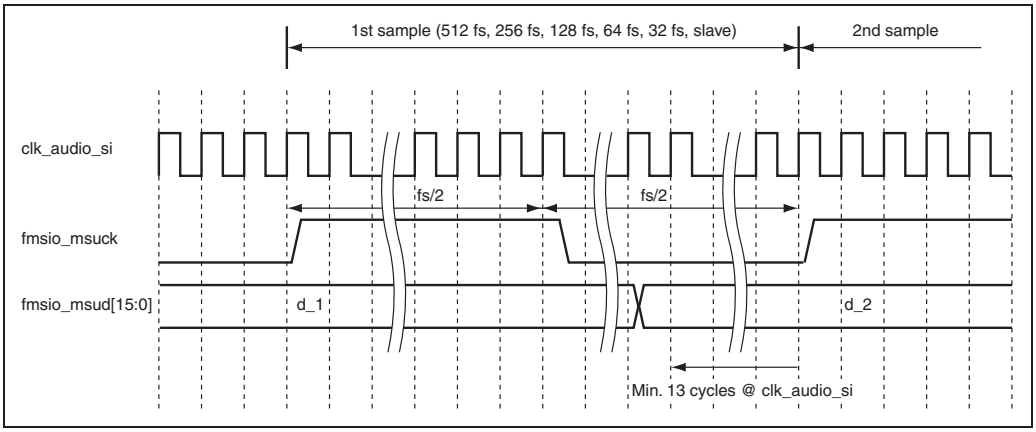

Figure 51.58 MSUO-IF Timing Chart

fmsio_msud[15:0] are received at the falling edge of fmsio_msuck and are asynchronized with clk_fmsi before being output. The output value is settled at least 13 cycles before the rising edge of fmsio_msuck.

51.22 Operation Flows

The FMSI operation flows are shown below. The FMSI can be accessed from the SPU2 DSP and CPU (via the SPU2). Before an access to the FMSI from the CPU, the clock should be supplied to the SPU2 and the SPUSRST bit in SPUSRST should be set to 1 to release the SPU2 software reset.

Figure 51.59 shows the relation between the entire FMSI operation and individual processing flows.

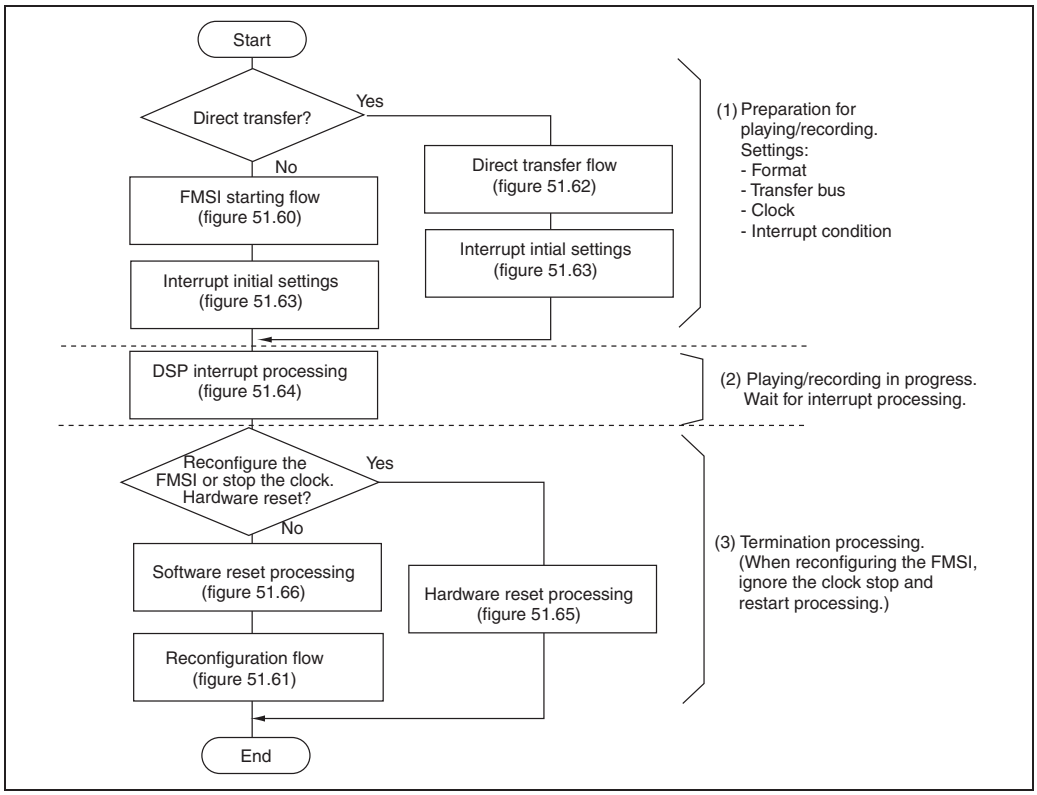

Figure 51.59 Entire FMSI Operation and Individual Processing Flows

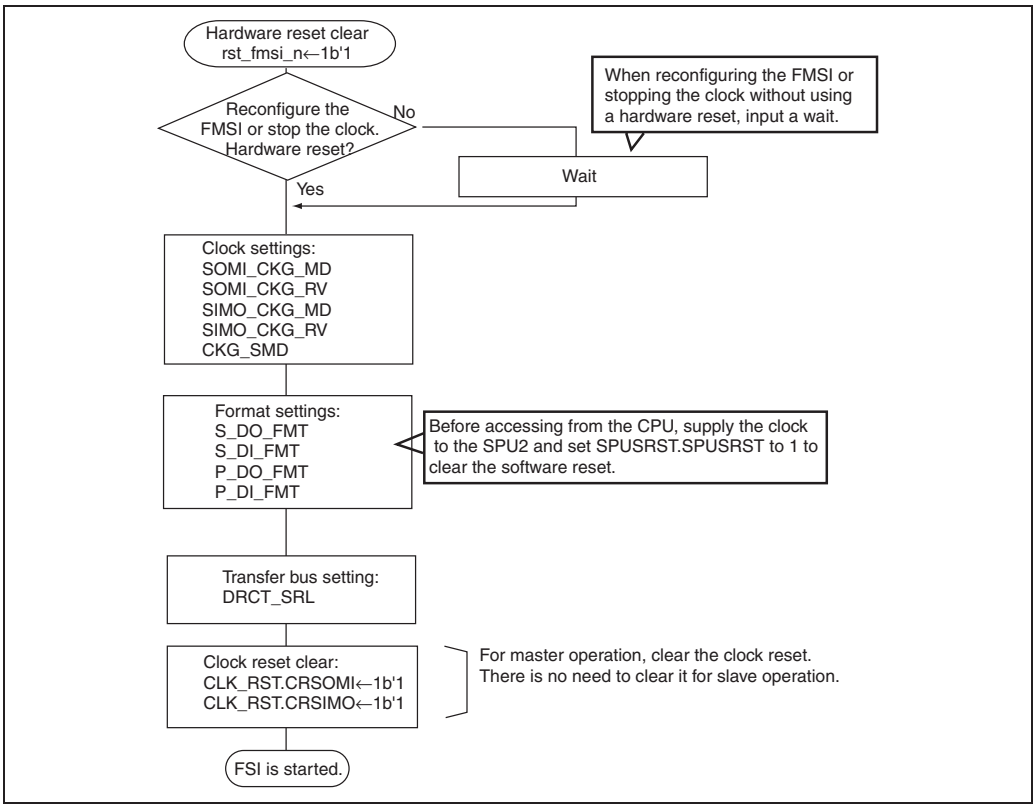
51.22.1 Procedure for Starting the FMSI

The FMSI starting procedure is shown below. In the initial settings during FMSI starting operation, the transfer path and format and operating clock are set. When modifying the transfer format after the initial settings, perform the procedure described in section 51.22.2, Procedure for Restarting the FMSI, before modifying the format. When stopping the clocks, perform the procedure described in section 51.22.6, Procedure for Stopping and Restarting Clocks, before stopping the clocks.

A flow chart for starting the FMSI is shown in figure 51.60.



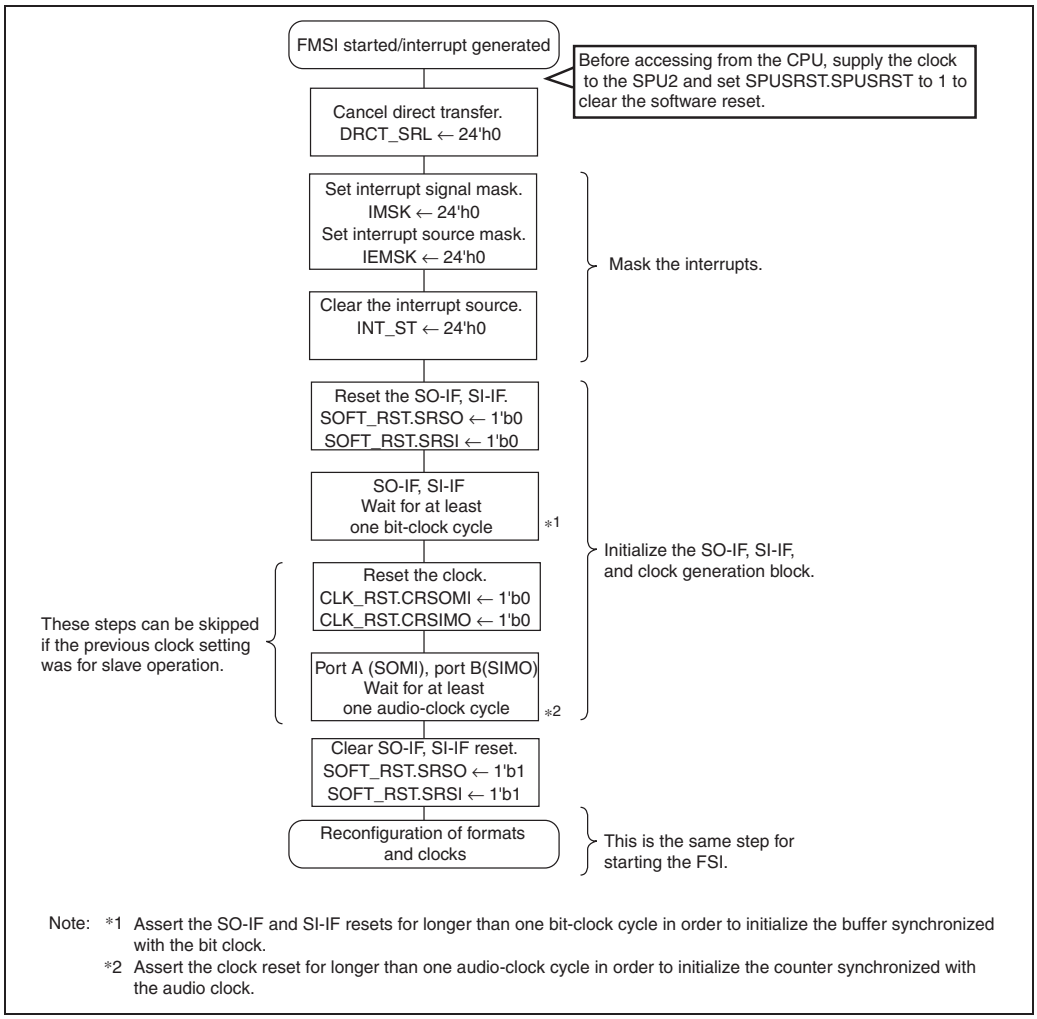


Figure 51.60 Flow for Starting FMSI

Use the steps above to start the FMSI. Paths not used for transfer should be set to the initial values. The specified audio clock is input to the serial conversion block (SO-IF, SI-IF, MI-IF, MSUO-IF).

51.22.2 Procedure for Restarting the FMSI

A flow chart for restarting the FMSI is shown below. To reconfigure transfer paths, formats, and clock setting, follow the steps in this flow. To reconfigure them using a hardware reset, this flow is not necessary. After the reset, return to the steps in section 51.22.1, Procedure for Starting the FMSI.

Note: *1 Assert the SO-IF and SI-IF resets for longer than one bit-clock cycle in order to initialize the buffer synchronized with the bit clock.
*2 Assert the clock reset for longer than one audio-clock cycle in order to initialize the counter synchronized with the audio clock.

Figure 51.61 Flow for Restarting FMSI

51.22.3 Direct Transfer Operation Flow

Figure 51.62 shows a flow for FMSI direct transfer. To prevent an underflow or overflow error from occurring in the first transfer, perform the settings in this flow.

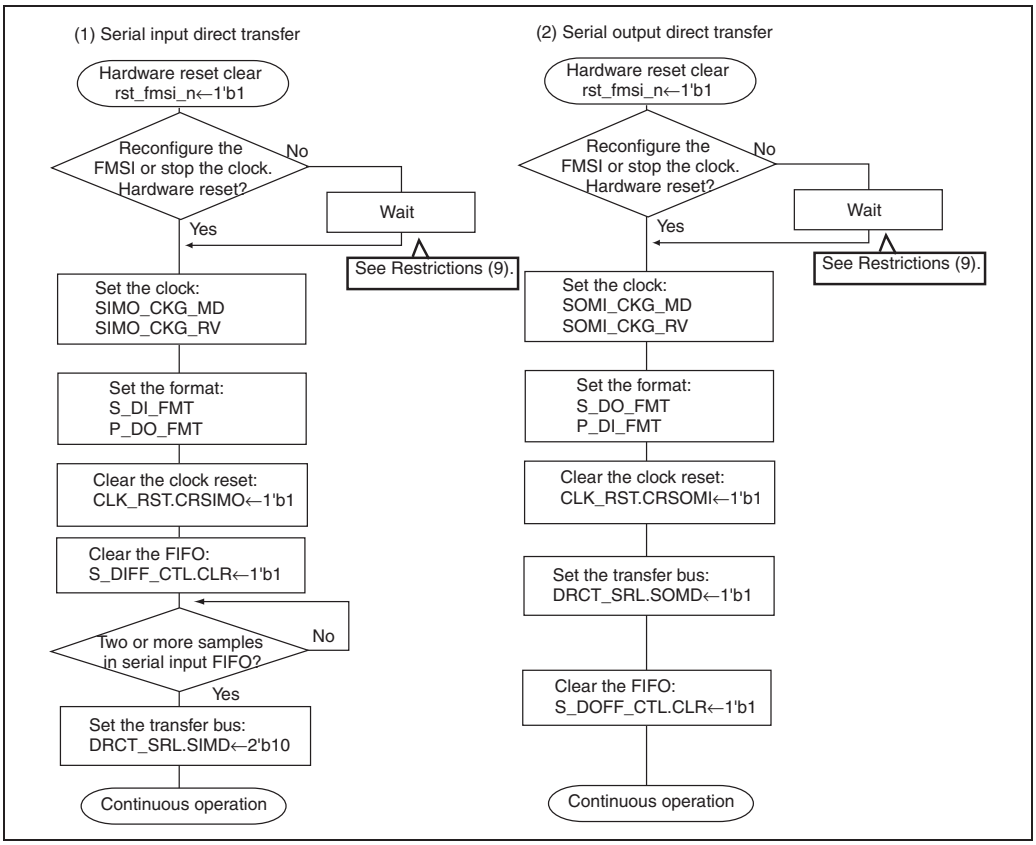

Figure 51.62 Flow for Direct Transfer

Descriptions for interrupt settings are omitted here. Add the procedure shown in section 51.22.4 before or after the FIFO clear steps. If an underflow or overflow error occurs after continuous operation, a transfer error due to unmatched sampling frequency is caused.

51.22.4 Procedure for Configuring Initial Interrupt Setting

A flow for configuring the initial interrupt setting after the FMSI starting is shown in figure 51.63.

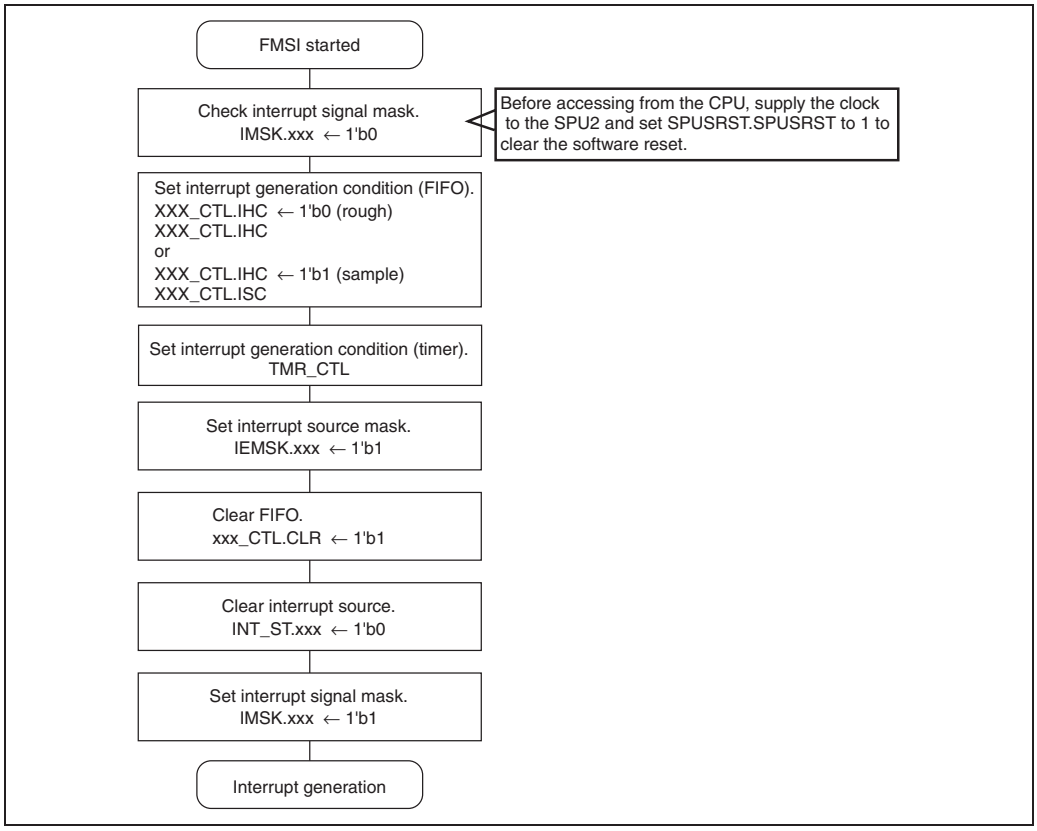

Figure 51.63 Flow for Configuring Initial Interrupt Setting

Eight interrupt conditions can be set associated with the FIFO capacity (SOFC, SIFC, and PIFC), FIFO error (SOFC, SIFC, and PIFC), and timer (TSO and TSI). "xxx" in the figure indicates any signal to be transferred.

After checking if the mask for the signal to be transferred is set, select the interrupt condition and set the interrupt source mask, then perform a FIFO clear. Clear the interrupt source that may be generated and retained before the FIFO clear, clear the signal mask.

An interrupt signal occurs based on the FIFO capacity and timer count after a FIFO clear.

51.22.5 Example of DSP Operation Flow

Figure 51.64 shows an example of the operation flow that the DSP follows to transfer audio data continuously after it accepts an interrupt.

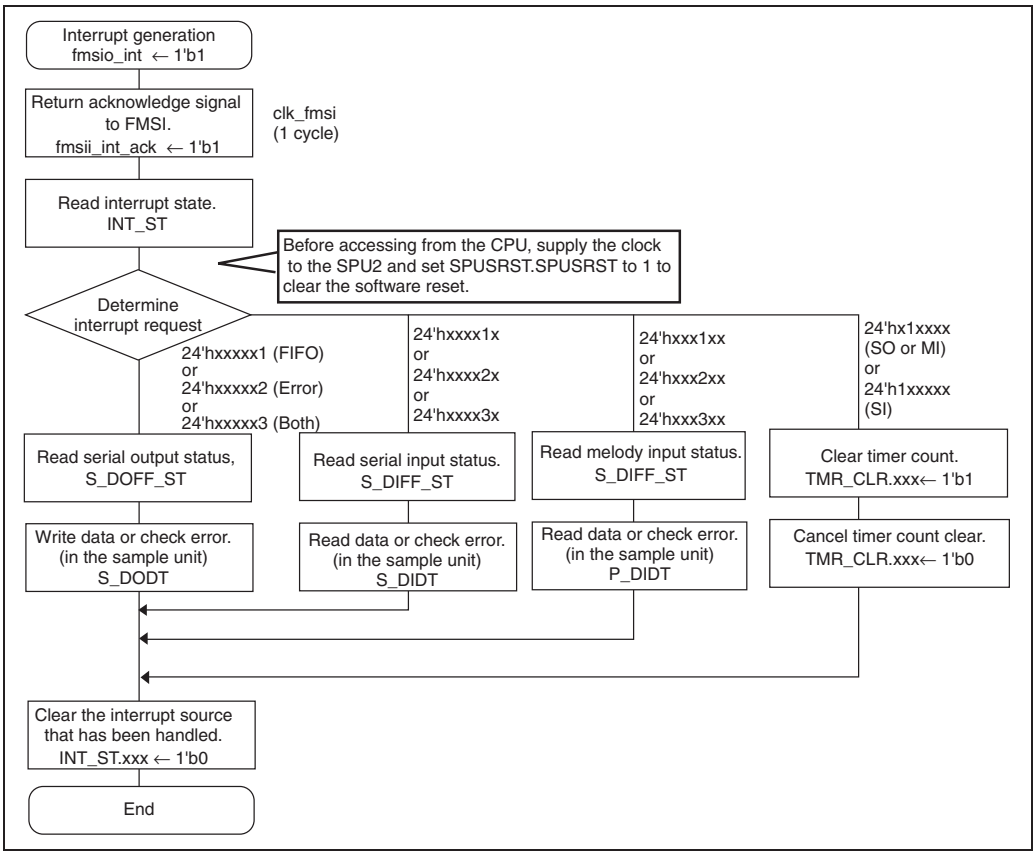

Figure 51.64 Example of DSP Operation Flow

The DSP that accepts the interrupt signal returns an acknowledge signal (fmsii_int_ack) for one cycle to the FMSI. Then, it reads the interrupt state (INT_ST) to determine which FIFO caused the interrupt and handles the interrupt adequately. When it is handled, the DSP clears the interrupt source and exits the flow. Clearing the interrupt source allows the FMSI to assert a new interrupt signal.

To handle multiple interrupt sources continuously by one interrupt, clear all the sources simultaneously at the end. After clearing the source, be sure to exit the interrupt routine and wait for fmsio_int to be set to 1.

51.22.6 Procedure for Stopping and Restarting Clocks

Figures 51.65 and 51.66 show flows for stopping and restarting clocks.

Before stopping all the FMSI clocks, input a hardware reset. After restarting the clocks, set the starting steps shown in figures 51.65 and 51.66.

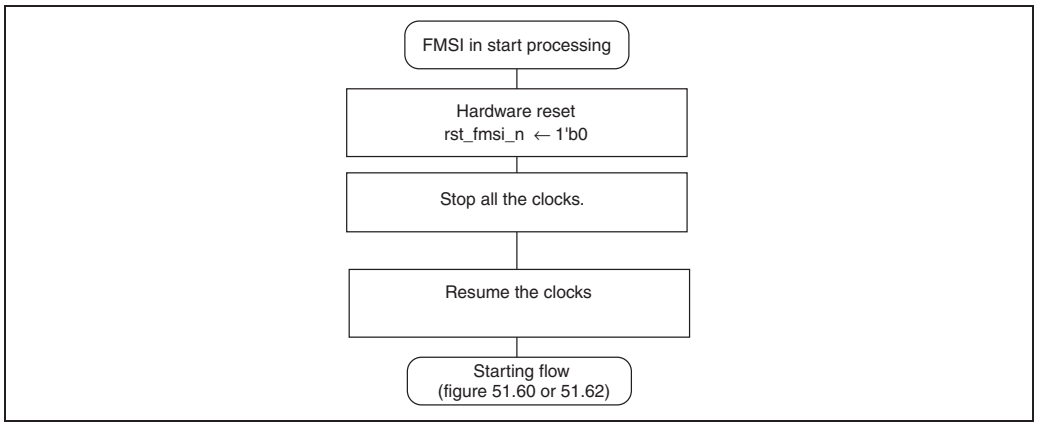

Figure 51.65 Flow for Stopping and Restarting All Clocks (Hardware Reset)

To stop specific clocks with multiple transfers in progress, perform a reset for the target transfers in the reconfiguration flow in figure 51.66 and then stop the clocks. To restart the transfer, first restart the stopped clocks and then set only the stopped transfer using the procedure in figure 51.65 or 51.66.

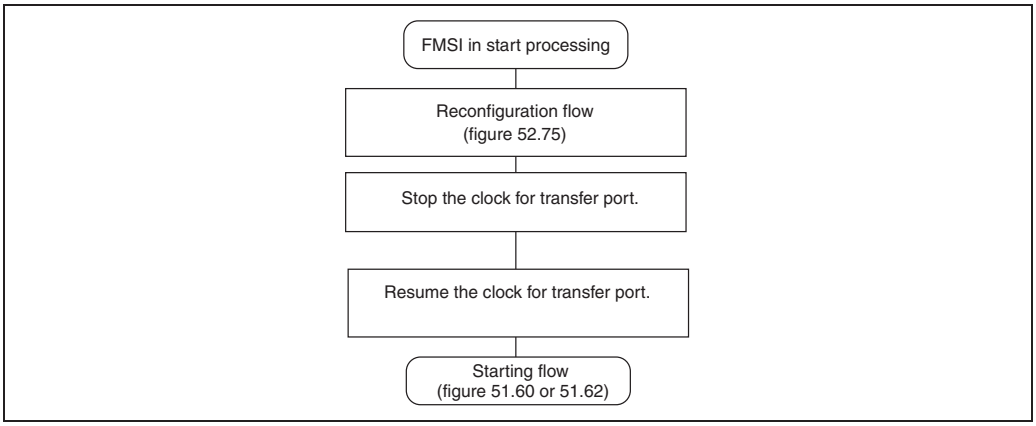

Figure 51.66 Flow for Stopping and Restarting Specific Clocks (Software Reset Only)

To stop all the clocks without using a hardware reset, perform a reset for all the ports as shown in figure 51.65.

51.23 Restrictions

Table 51.21 shows the restrictions that apply to the use of the FMSI.

Table 51.21 FMSI Usage Restrictions

	Restrictions	
No.	**Item**	**Description**
1	Direct path mode	Continuous operation can be guaranteed when the same sampling frequency is used. The same number of channels and bit width should be used between the input side and output side.
2	Port reset	When performing an internal reset of the SO-IF and SI-IF modules due to the change in formats, the reset should be longer than one cycle of the input bit-clock.
3	Clock reset	When reconfiguring the master clock, the reset should be longer than one audio-clock cycle.
4	Timer interrupt	Since one timer system is shared by the SO-IF and MI-IF, different sampling frequency operations cannot be counted at the same time.
5	Parallel IF audio clock (MI-IF)	To operate the MI-IF with an externally input audio clock (LR or MSUOsync signal for the slave), input a timing signal that has a high or low period longer than one clk_m cycle.
6	Parallel IF audio clock (MSUO-IF)	To operate the MSUO-IF with an externally input audio clock (LR signal for the slave), input a timing signal that has a high or low period longer than one clk_fmsi cycle.
7	Software reset	If FIFO is read during the entire software reset (SOFT_RST.SR) is asserted, the bus freezes. Do not perform a FIFO read (S_DIDT, P_DIDT) during a software reset.
8	Note for FMSI reconfiguration and clock stop	If the FMSI is reconfigured and clocks are stopped without using a hardware reset, the previous transfer data may be left in the MI-IF buffer. Insert a wait for 2 μs or more before performing the starting flow shown in figure 51.60.

Section 52 FSI Private Divider (FSIDIV)

The FSI Private Divider is a module that is used for generating audio clock.

52.1 Features

The functions and features are listed in table 52.1.

Table 52.1 List of FSIDIV Functions

Item	Contents	Details
Operating frequency	Source clock for master audio clock for port A	Up to 200MHz
	Source clock for master audio clock for port B	Up to 200MHz
	BUS clock	Up to 100MHz
Coverage of valid setting for divider	Frequency dividing for port A	1/2 to 1/65535
	Frequency dividing for port B	1/2 to 1/65535

Figure 52.1 shows a block diagram of the FSIDIV.

Divider for port B has the same structure and interface as divider for port A.

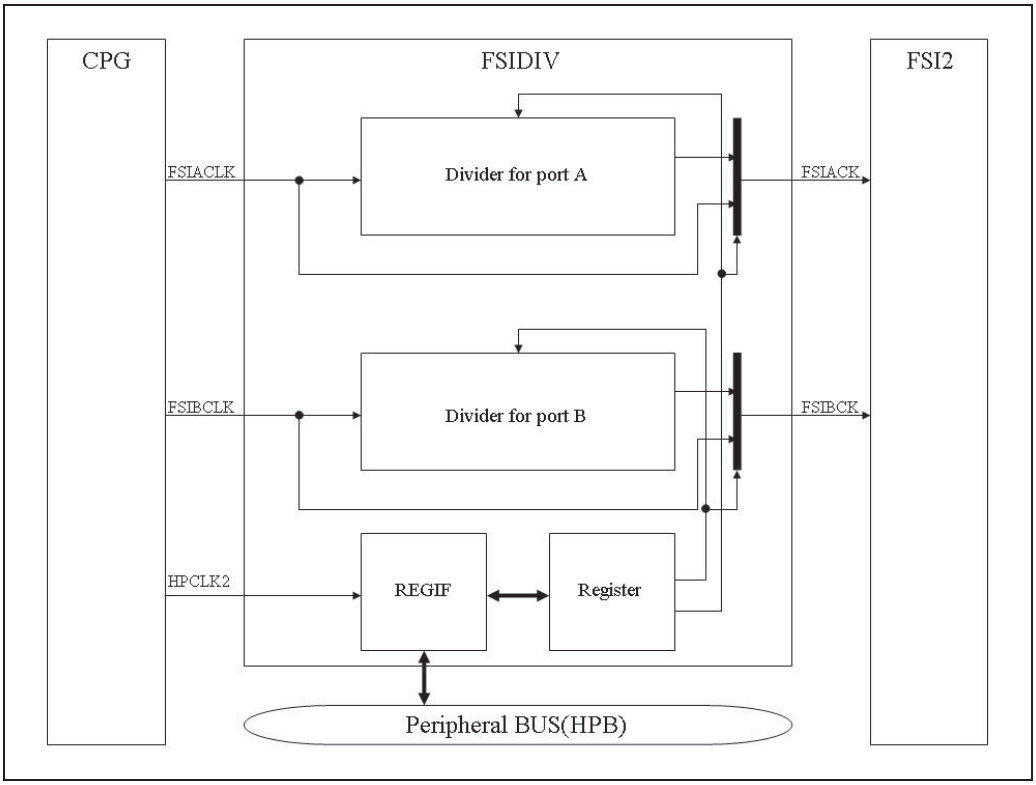

Figure 52.1 Block Diagram

52.2 Register Descriptions

Table 52.2 shows the FSIDIV register configuration.

Table 52.2 Register Configuration

Register Name	Abbreviation	R/W	initial value	Access Size	Physical Address
Port A Divider control register	FSIDIVA	R/W	H'00000000	32	H'FE1F8000
Port B Divider control register	FSIDIVB	R/W	H'00000000	32	H'FE1F8008

52.2.1 Port A Divider control register (FSIDIVA)

FSIDIVA is a 32-bit readable/writable register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

52.3 Operation explanation

Defend the following operation, using the FSIDIV module.

(1) Set “1” to SEL bit of FSIDIVA/FSIDIVB register, using the clock of dividing frequency.

(2) Set value to PARAM_A/PARAM_B bits.

(3) Set “1” to STA bit of FSIDIVA/FSIDIVB register.

(4) Waiting until changing value of EN bit to “1”.

Defend the following operation, changing the value of dividing frequency.

(1) Set “0” to STA bit of FSIDIVA/FSIDIVB register.

(2) Set value to PARAM_A/PARAM_B bits.

(3) Set “1” to STA bit of FSIDIVA/FSIDIVB register.

(4) Waiting until changing value of EN bit to “1”.

Section 53 I²C Bus Interface (IIC)

This LSI has an I²C bus interface of five channels.

Each I²C bus interface uses only one data line (SDA) and one clock line (SCL) to transfer data, saving board and connector space.

53.1 Features

The I²C bus interface has two channels (I²C0 and I²C2) in the realtime domain, three channel (I²C1 and I²C3 and I²C4) in the system domain.

- Start and stop conditions generated automatically
- Selection of acknowledge output levels when receiving
- Automatic loading of acknowledge bit when transmitting
- Data transfer conforming to the I²C format
- Wait function

  A wait can be inserted by driving the SCL pin low after data transfer, excluding acknowledgement.

  The wait can be cleared by clearing the interrupt flag.
- I²C module corresponds to single master bus only.

  This module is always in master mode. Since the slave mode is not incorporated, operation stops with bus open during loss of arbitration in data transfer.
- Four interrupt sources
  - Data transfer enable
  - Wait state
  - Non-acknowledge detection
  - Arbitration lost (operation stops with bus open when bus conflict is detected)
- Data transfer speed
  - Standard mode (100 kHz) and high-speed mode (400 kHz). I²C1 and I²C3 and I²C4 corresponds to HighSpeed (HS) transmission (2MHz or less).
  - SCL clock can be set by clock control register setting
- Clock synchronous processing of SCL line

  A hazard (spike noise) generated in the high-count period by SCL is detected as an arbitration loss.
- DMA transfer

  I²C support transmission and reception using DMA.

Figure 53.1 shows a block diagram of the I²C bus interface.

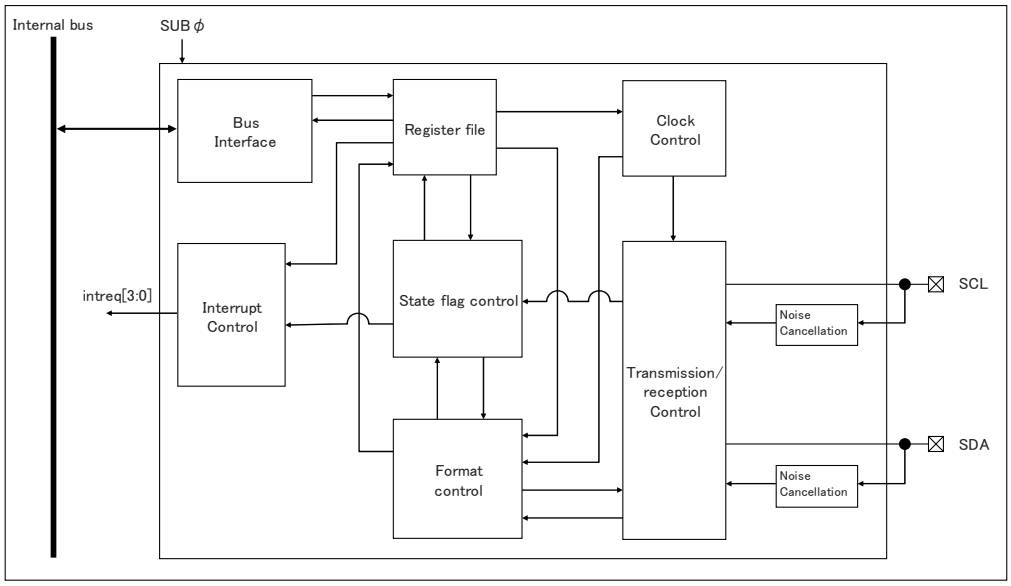

Figure 53.1 Block Diagram of I²C Bus Interface

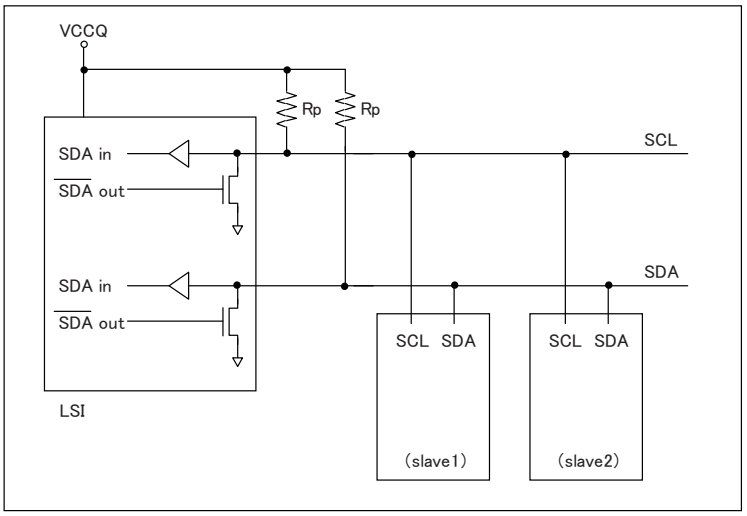

Figure 53.2 I²C Bus Interface Connections

53.2 Input/Output Pins

Table 53.1 summarizes the input/output pins used by the I²C bus interface.

Table 53.1 I²C Bus Interface Pins

Abbreviation	Function	I/O	Description
I²C_SCL0 (O/D)	I²C clock input/ output 0	I/O	I²C0 bus clock input/output pin (channel 0) Incorporates the bus drive function. The output format is the NMOS open-drain. The I/O voltage can be switched between 1.8V and 3.3V. 3.3V tolerant is supported.
I²C_SDA0 (O/D)	I²C data input/ output 0	I/O	I²C0 bus data input/output pin (channel 0) Incorporates the bus drive function. The output format is the NMOS open-drain. The I/O voltage can be switched between 1.8V and 3.3V. 3.3V tolerant is supported.
I²C_SCL1 (O/D)	I²C clock input/ output 1	I/O	I²C1 bus clock input/output pin (channel 1) Incorporates bus drive function. The output format is the NMOS open-drain. The I/O voltage can be switched between 1.8V and 3.3V. 3.3V tolerant is supported.
I²C_SDA1 (O/D)	I²C data input/ output 1	I/O	I²C1 bus data input/output pin (channel 1) Incorporates the bus drive function. The output format is the NMOS open-drain. The I/O voltage can be switched between 1.8V and 3.3V. 3.3V tolerant is supported.
I²C_SCL2 (O/D)	I²C clock input/ output 2	I/O	I²C2 bus clock input/output pin (channel 2) The output format is the NMOS open-drain or CMOS. The I/O voltage can be switched between 1.8V and 3.3V. Tolerant is non-supported.
I²C_SDA2 (O/D)	I²C data input/ output 2	I/O	I²C2 bus data input/output pin (channel 2) The output format is the NMOS open-drain or CMOS. The I/O voltage can be switched between 1.8V and 3.3V. Tolerant is non-supported.
I²C_SCL3 (O/D)	I²C clock input/ output 3	I/O	I²C3 bus clock input/output pin (channel 3) The output format is the NMOS open-drain or CMOS. The I/O voltage can be switched between 1.8V and 3.3V. Tolerant is non-supported.
I²C_SDA3 (O/D)	I²C data input/ output 3	I/O	I²C3 bus data input/output pin (channel 3) The output format is the NMOS open-drain or CMOS. The I/O voltage can be switched between 1.8V and 3.3V. Tolerant is non-supported.
I²C_SCL4 (O/D)	I²C clock input/ output 4	I/O	I²C4 bus clock input/output pin (channel 4) The output format is the NMOS open-drain or CMOS. The I/O voltage can be switched between 1.8V and 3.3V. Tolerant is non-supported.

I²C_SDA4 (O/D)	I²C data input/ output 4	I/O	I²C4 bus data input/output pin (channel 4) The output format is the NMOS open-drain or CMOS. The I/O voltage can be switched between 1.8V and 3.3V. Tolerant is non-supported.

53.3 Register Descriptions

Table 53.2 shows the register configuration of the bus interface. Table 53.3 shows the register state in each processing mode.

Table 53.2 Register Configuration of Bus Interface

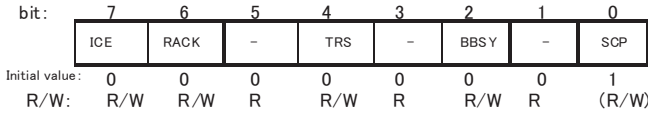
53.3.1 I²C Bus Data Registers (ICDR)

ICDR are 8-bit readable/writable registers that are used as a transmit data register when transmitting, and a receive data register when receiving.

These registers can be written to when the DTE bit in I²C bus status register ICSR is 1 in transmitting.

Receive data of ICDR is valid when the DTE bit in ICSR is 1 in receiving.

The read value of ICDR is H'FF after reset.



53.3.2 I²C Bus Control Registers (ICCR)

ICCR are 8-bit readable/writable registers that enable or disable the I²C bus interface, and transmission or reception, confirm the I²C bus interface bus status, and issue start/stop conditions.

Table 53.4 ICCR Settings

Issue Condition	When Transmitting	When Receiving
Start condition	H'94	—
Retransmission condition	H'94	H'D4 Changes from reception to transmission
Stop condition	H'90	H'C0
Changes from transmission to reception	H'81	—

bit:	7	6	5	4	3	2	1	0
	ICE	RACK	–	TRS	–	BBSY	–	SCP
Initial value:	0	0	0	0	0	0	0	1
R/W:	R/W	R/W	R	R/W	R	R/W	R	(R/W)

Bit	Bit Name	Initial Value	R/W	Description
7	ICE	0	R/W	I²C Bus Interface Enable Selects whether or not the I²C bus interface is to be used. When ICE is set to 1, transfer operations and access to each register are enabled. When ICE is cleared to 0 during data transmission, ICE releases buses and is forcibly terminated, then all registers in the I²C module are initialized. (See section 53.5, Usage Notes.) When ICE is cleared to 0 after data transmission, all registers in the I²C module are initialized. When the ICCR is updated while this module is being operated, the ICE bit must be set to 1. 0: I²C module disabled and forcibly terminated when 0 is written in data transmission. I²C module internal registers are all initialized. 1: I²C bus interface module enabled for transfer operations
6	RACK	0	R/W	Receive Acknowledge The RACK bit is for storing acknowledge data that is output to the transmission device when the I²C module is receiving data. After data is received from the transmitting device, acknowledge data that has been set to this bit is sent. 0: In receive mode, 0 is output to SDA at acknowledge output timing. 1: In receive mode, 1 is output to SDA at acknowledge output timing.
5	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	TRS	0	R/W	Transmit/Receive Select The TRS bit selects whether the I²C bus interface operates in master transmitter or master receiver mode. Although the setting of the TRS bit is modifiable during transfer, the actual change of operating mode is deferred until transfer of the frame containing the acknowledge bit is completed. On completion of this transfer, the changeover is made. 0: Master receive mode Writing of 0 to the bit (if this is done during data transfer, the operating mode is only changed after one frame has been transferred) 1: Master transmit mode Writing of 1 (at the time of a retransmission/stop condition; at this time, the operating mode is changed after a retransmission or stop condition has been generated subsequent to data transfer.)
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2	BBSY	0	R/W	Bus Busy The BBSY flag is used to issue start and stop conditions. To issue a start condition, write 1 in BBSY and 0 in SCP. A retransmit start condition is issued in the same way. To issue a stop condition, write 0 in BBSY and 0 in SCP. Since this module is always in master mode, a bus state is not detected by the BBSY bit. When a start condition is issued from other masters, it is detected that arbitration is lost and operation is stopped. 0: A stop condition is issued (the SCP bit is also used). 1: Start and retransmit conditions are issued (the SCP bit is also used).
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	SCP	1	(R/W)*	Start Condition/Stop Condition Prohibit Controls the issuing of start and stop conditions. To issue a start condition, write 1 in BBSY and 0 in SCP. A retransmit start condition is issued in the same way. To issue a stop condition, write 0 in BBSY and 0 in SCP. This bit is always read as 1. If 1 is written, the data is not stored. 0: Writing 0 issues a start or stop condition, in combination with the BBSY flag 1: Reading always returns a value of 1. Writing is ignored.

Note: * For the SCP bit, only writing 0 is valid. Always read as 1.

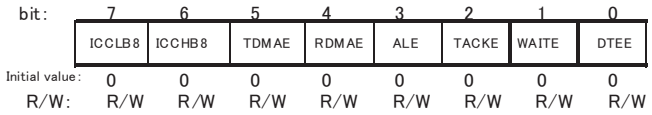
53.3.3 I²C Bus Status Registers (ICSR)

ICSR are 8-bit readable/writable registers that perform interrupt request.

bit:	7	6	5	4	3	2	1	0
	SCLM	SDAM	–	BUSY	AL	TACK	WAIT	DTE
Initial value:	1	1	0	0	0	0	0	0
R/W:	R	R	R	R	R/(W)*	R/(W)*	R/(W)*	R

Bit	Bit Name	Initial Value	R/W	Description
7	SCLM	1	R	SCL Monitor Stores data in which the SCL state is sampled at SUBϕ. 0: Indicates SCL is 0. 1: Indicates SCL is 1.
6	SDAM	1	R	SDA Monitor Stores data in which the SDA state is sampled at SUBϕ. 0: Indicates SDA is 0. 1: Indicates SDA is 1.
5	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
4	BUSY	0	R	I²C Transmit State Bit Indicates the I²C state. After the start condition is generated, I²C is in the transmit state and this bit is set to 1. After the stop condition is generated, I²C is in the non-transmit state and this bit is cleared to 0. When arbitration is lost, the SDA line is open. The SCL clock line outputs clocks until the acknowledge end of the frame and releases buses. The BUSY flag is set to 1 until acknowledge end, and is cleared to 0 at acknowledge end. 0: • In I²C non-transmit state after stop condition is generated. • At acknowledge end after arbitration is lost 1: In I²C transmit state after start condition is generated

Bit	Bit Name	Initial Value	R/W	Description
3	AL	0	R/(W)*	Arbitration Lost This flag indicates that arbitration was lost. The I²C bus interface monitors the SDA. If the I²C bus interface detects data differing from the data it sent, it sets AL to 1 to indicate that the bus has been conflicted. AL is reset by writing 0 to this bit, write access to ICDR in transmit mode, or read access to ICDR in receive mode when DTE is 1. When arbitration lost is detected in data transfer, the SDA line is open. The SCL clock line outputs clocks until the acknowledge end of the frame and releases buses. The AL bit does not depend on the ALE bit in ICIC, and is always updated. When the ALE bit in ICIC is 0, an arbitration lost interrupt request is not issued to the interrupt controller. When other masters issue the start condition, arbitration lost is detected and operation is stopped. 0: Bus arbitration won • When ICDR data is written (transmit mode) or read (receive mode) • When 0 is written in AL after reading AL = 1 1: Arbitration lost • If receive data changes when SCL clocks count at a high level in master receive mode • If the SCL line is in a low level when SCL clocks count at a high level • If a start condition is detected before this module issues a start condition • If the monitored external SDA and data output from this module disagree



Bit	Bit Name	Initial Value	R/W	Description
2	TACK	0	R/(W)*	Transmit Acknowledge Bit Stores acknowledge data issued from the receiving device in transmit mode. The non-acknowledge interrupt state can be cleared by clearing the TACK bit to 0. In transmit mode, after the receiving device receives data, it returns acknowledge data, and this data is loaded into TACK. This bit is always 0 when the TACKE bit in ICIC is 0. 0: • Transmit mode: Indicates that the receiving device has acknowledged the data (signal is 0) • When 0 is written, indicates that the receiving device has acknowledged the data (signal is 0) 1: Transmit mode: Indicates that the receiving device has not acknowledged the data (signal is 1)
1	WAIT	0	R/(W)*	Wait Indicates that a wait state follows the transmission of data other than the acknowledge bit. When the value of the WAITE bit in ICIC is 1, a data transfer that is not followed by the acknowledge bit leads to SCL being driven to the low level and the initiation of a state of waiting. At this time, the WAIT bit is automatically set to 1 and a WAIT interrupt is generated. Release from the state of waiting is accomplished by clearing the WAIT bit (to 0). WAIT is always 0 when WAITE in ICIC is 0. 0: Normal state 1: At wait

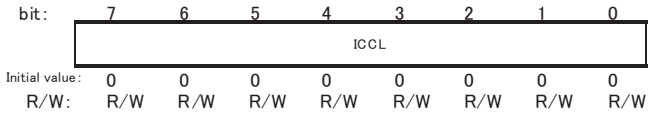
Bit	Bit Name	Initial Value	R/W	Description
0	DTE	0	R	Data Transmit Enable Indicates the transmit state between ICDR and internal transmit/receive buffer. This bit is read only, and automatically set or cleared. 0: • When reset • When data is written to ICDR in transmit mode (TRS = 1) • When data is read from ICDR in receive mode (TRS = 0) • When the TRS bit is changed • When the retransmit/stop conditions are written to the BBSY and SCP bits in ICCR 1: • When the start/retransmit conditions are generated • When transmit data is sent to the transmit buffer from ICDR in transmit mode (TRS = 1) • When receive data is sent to ICDR in receive mode (TRS = 0)

Note: * Only 0 can be written, for flag clearing.

53.3.4 I²C Interrupt Control Registers (ICIC)

ICIC are 8-bit registers that enable/disable an interrupt request.

bit:	7	6	5	4	3	2	1	0
	ICCLB8	ICCHB8	TDMAE	RDMAE	ALE	TACKE	WAITE	DTEE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W



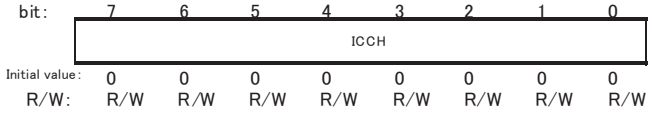
Bit	Bit Name	Initial Value	R/W	Description
7	ICCLB8	0	R/W	I²C Clock Control Low Bit 8 Sets low-level time of SCL, when the period of ICCL is set to H'100 to H'1FF in SUBϕ. Table 53.5 shows transfer rate settings.
6	ICCHB8	0	R/W	I²C Clock Control High Bit 8 Sets high-level time of SCL, when the period of ICCH is set to H'100 to H'1FF in SUBϕ. Table 53.5 shows transfer rate settings.
5	TDMAE	0	R/W1	Transmit Data DMA Transfer Request Enable1 When DTEE is 1, the TDMAE decides whether an interrupt at data transmission (TRS = 1) is used for CPU or as a DMA transfer request. When using DMA by automatic transmission, a setup of this bit is unnecessary. 0: Uses TDMAE as a CPU interrupt. 1: Uses TDMAE as a DMA transfer request to DMAC.
4	RDMAE	0	R/W1	Receive Data DMA Transfer Request Enable1 When DTEE is 1, the RDMAE decides whether an interrupt at data transmission (TRS = 0) is used for CPU or as a DMA transfer request. When using DMA by automatic transmission, a setup of this bit is unnecessary. 0: Uses RDMAE as a CPU interrupt. 1: Uses RDMAE as a DMA transfer request to DMAC

Bit	Bit Name	Initial Value	R/W	Description
3	ALE	0	R/W	Arbitration Lost Interrupt Enables/disables an arbitration lost interrupt request. An arbitration lost interrupt occurs if arbitration lost occurs when ALE is 1. At this time, the AL bit in ICSR is set to 1. With AL set to 1, do not clear ALE to 0. 0: Interrupt disabled 1: Arbitration lost interrupt
2	TACKE	0	R/W	Non-acknowledge Detection Interrupt Enables/disables a non-acknowledge detection interrupt request. A non-acknowledge interrupt occurs if non-acknowledge is received when TACKE is 1. At this time, the TACK bit in ICSR is set to 1. With TACK set to 1, do not clear TACKE to 0. 0: Interrupt disabled 1: Non-acknowledge detection interrupt
1	WAITE	0	R/W	Wait Interrupt Enables/disables a wait interrupt request. Indicates that a wait state follows the transmission of data other than the acknowledge bit by driving SCL to the low level when WAITE is 1. At this time, a WAIT interrupt occurs, and the WAIT bit in ICSR is set to 1. With WAIT in ICSR set to 1, do not clear WAITE to 0. 0: Interrupt disabled 1: Wait interrupt
0	DTEE	0	R/W	Data Transmit Enable Interrupt Enables/disables a data transmit enable interrupt request. An interrupt request is issued if the DTE bit in ICSR is set to 1 when DTEE is 1. 0: Interrupt disabled 1: Data transmit enable interrupt

53.3.5 I²C Clock Control Registers Low (ICCL)

ICCL are 8-bit readable/writable registers that can set low-level time of SCL.

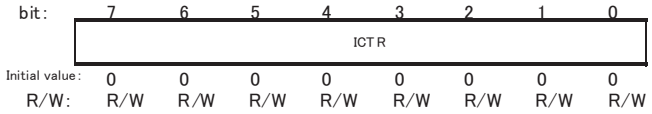
ICCL is initialized to H'00 by a reset.



Note: Settings of H'01 to H'09 are prohibited.
No SCL clock is generated for ICIC[7]=B'0 and ICCL= H'00 and H'FF or ICCH = H'00 and H'FF.

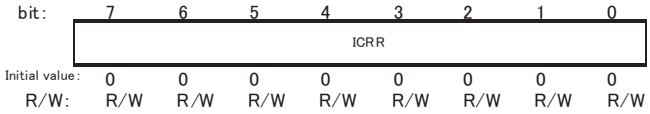
53.3.6 I²C Clock Control Registers High (ICCH)

ICCH are 8-bit readable/writable registers that can set high-level-time of SCL.



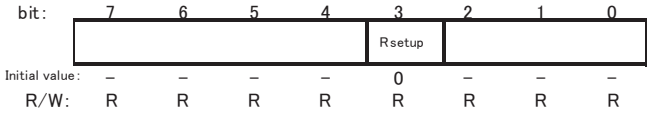
ICCH is initialized to H'00 by a reset.

Note: Settings of H'01 to H'09 are prohibited.
No SCL clock is generated for ICIC[7]=B'0 and ICCL= H'00 and H'FF or ICCH = H'00 and H'FF.



53.3.7 I²C Transmit Registers (ICTR)

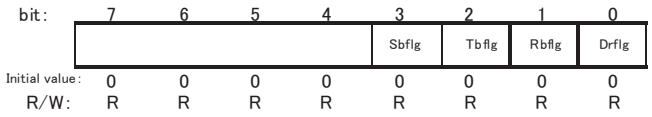
ICTR are 8-bit registers that monitor transmit data of the I²C bus interface.



53.3.8 I²C Receive Registers (ICRR)

ICRR are 8-bit registers that monitor receive data for the I²C bus interface.

53.3.9 I²C Transmit Monitor Registers (ICTA)



ICTA are 8-bit registers that monitor the retransmission condition setting status of the I²C bus interface.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	—	R	Reserved Writing to this bit is prohibited.
3	Rsetup	0	R	Retransmission Condition Setup Monitor The value of 1 remains to be set in this bit for the period from the setting of a retransmission condition (ICCR = H'94) during communication until the generation of the retransmission condition.
2 to 0	—	—	R	Reserved Writing to this bit is prohibited.

53.3.10 I²CTransmit Buffer Monitor Registers (ICTB)

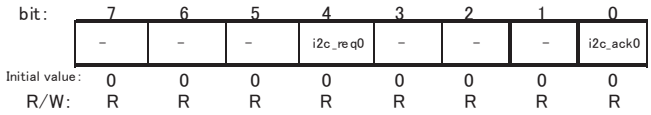
ICTB are 8-bit registers that monitor the communication status of the I²C bus interface.

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	—	R	Reserved
3	Sbflg	0	R	ICSF Buffer Flag 0: ICSF has no transmit data. 1: ICSF has transmit data.
2	Tbflg	0	R	ICTR Buffer Flag 0: ICTR has no transmit data. 1: ICTR has transmit data.
1	Rbflg	0	R	ICRR Buffer Flag 0: ICRR has no transmit data. 1: ICRR has transmit data.
0	Drflg	0	R	ICDR Buffer Flag 0: ICDR has no transmit data. 1: ICDR has transmit data.

53.3.11 I²C Transmit Control Registers (ICTC)

ICTC are 8-bit registers that select pins to be used for I²C communication with the functions of SDA delay adjustment, SCL synchronization, and pin selection.

ICTC is initialized to H'00 by a reset.

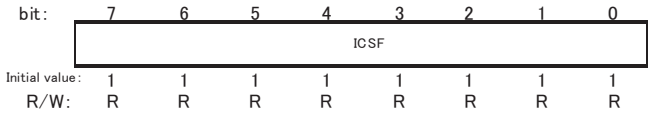


bit:	7	6	5	4	3	2	1	0
	sda_dly4	sda_dly3	sda_dly2	sda_dly1	sda_dly0	sync_en	–	–
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	sda_dly[4:0]	00000	R/W	SDA Data Delay Select These bits set the SDA data output delay from the SCL. 00000: No SDA data delay (recommended) 00001: SDA data is delayed by one SUBϕ cycle. 00010: SDA data is delayed by two SUBϕ cycles. . . . . 11110: SDA data is delayed by 30 SUBϕ cycles. 11111: SDA data is delayed by 31 SUBϕ cycles. When the SDA data output is delayed, the AC specifications of the I²C bus interface may not be satisfied. Therefore, setting these bits to 00000 is recommended.
2	sync_en	0	R/W	SCL Synchronization Select Sets whether the SCL line synchronizing function is provided or not. 0: SCL line synchronization is provided (recommended). 1: SCL line synchronization is not provided. When this bit is set to 1, the AC specifications of the I²C bus interface may not be satisfied. Therefore, setting this bit to 0 is recommended.

Bit	Bit Name	Initial Value	R/W	Description
1 to 0	—	—	R	Reserved

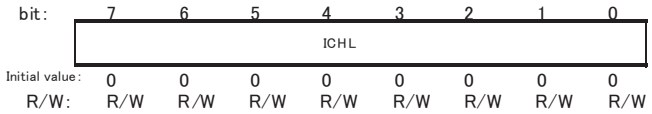
53.3.12 I²C Transmit Control Status Monitor Registers (ICTD)



ICTD are 8-bit registers that monitor communication status of the I²C bus interface.

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	0	R	Reserved
• 4	• I²C_req0	• 0	R/W	I²C Communication Request 0 • Communication request to channel-0 pins in ICTD0 • Communication request to channel-1 pins in ICTD1 0: No communication request 1: Communication request underway
3 to 1	—	0	R	Reserved
0	I²C_ack0	0	R/W	I²C Communication Status 0 Communication acknowledge to channel-0 pins in ICTD0 Communication acknowledge to channel-1 pins in ICTD1 0: No communication 1: Communication acknowledge underway

53.3.13 I²C Shift Registers (ICSF)

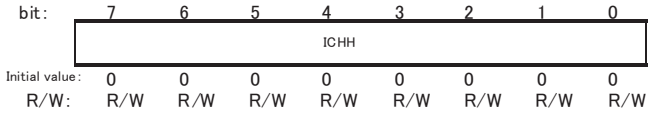


ICSF are 8-bit registers that monitor data being transmitted for the I²C bus interface.

53.3.14 I²C HighSpeed SCL register low (ICHL)

ICHL are 8-bit readable/writable registers that can set low-level time of SCL at the time of HS transmission.

ICHL is initialized by H'00 at the time of reset.

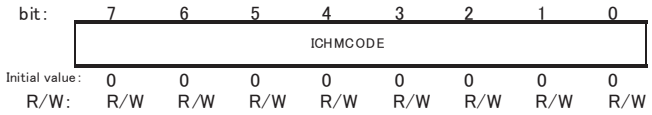


[Note] A setup of H'01 to H'03 is prohibition.

53.3.15 I²C HighSpeed SCL register high (ICHH)

ICHH is an 8-bit register and can set up the high-level time of SCL at the time of HS transmission.

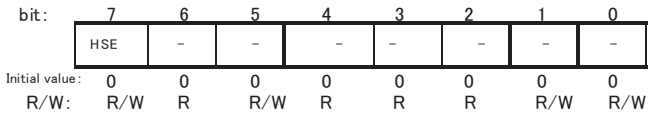
ICHH is initialized by H'00 at the time of reset.



[Note] A setup of H'01 to H'02 is prohibition.

53.3.16 I²C HighSpeed Master code register (ICHMCODE)

ICHMCODE is an 8-bit register and is a register which stores a master code required at the time of HS transmission.



ICHMCODE is initialized by H'00 at the time of reset.

53.3.17 I²C option enabling register (ICVCON)

ICVCON sets up ON/OFF of the optional feature of I²C by an 8-bit register.

Not change this register value during I²C communication.

Bit	Bit Name	Initial Value	R/W	Description
7	HSE*1	0	R/W	Hs enable bit *1 In order to use HS transmission, a setup of automatic transmission is also required. 0: HS transmission is not used. 1: HS transmission is used.
6:0	-	0	R	Reserve bit Always give the value to write in as 0.

*1 Only I²C2 and I²C3 and I²C4 are effective. Please do not access in I²C0 and I²C1.
.The automatic transmission assumes the end of communication by interruption, and error detection, please do not perform
principle polling during automatic transmission.

53.3.18 I²C automatic transmission interruption mask register (ICIMSK)

ICIMSK is an 8-bit register and chooses prohibition/permission of the interrupt request output of automatic transmission.

Interruption is outputted to AL interruption event code. Generated interruption can be checked by ICINT.

bit:	7	6	5	4	3	2	1	0
	AENDM	TMC2M	TMC1M	TMOUTM	ALM	TACKM	-	-
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	AENDM	0	R/W	End interruption mask bit of I²C automatic transmission 0: Interruption is not outputted to INTC at the time of the end of automatic transmission. 1: Interruption is outputted to INTC at the time of the end of automatic transmission.
6	TMC2M	0	R/W	End interruption mask bit of I²C automatic transmission timer count 2 0: Interruption is not outputted to INTC at the time of the end of timer count 2. 1: Interruption is outputted to INTC at the time of the end of timer count 2.
5	TMC1M	0	R/W	End interruption mask bit of I²C automatic transmission timer count 1 0: Interruption is not outputted to INTC at the time of the end of timer count 1. 1: Interruption is outputted to INTC at the time of the end of timer count 1.
4	TMOUTM	0	R/W	I²C automatic transmission timeout error interruption mask bit 0: Interruption is not outputted to INTC at the time of a timeout error. 1: Interruption is outputted to INTC at the time of a timeout error.
3	ALM	0	R/W	I²C automatic transmission AL interruption mask bit 0: Interruption is not outputted to INTC at the time of the automatic transmission AL. 1: Interruption is outputted to INTC at the time of the automatic transmission AL.
2	TACKM	0	R/W	I²C automatic transmission TACK interruption mask bit 0: Interruption is not outputted to INTC at the time of the automatic transmission TACK. 1: Interruption is outputted to INTC at the time of the automatic transmission TACK.
1	-	0	R/W	Reserve bit Always give the value to write in as 0.
0	-	0	R/W	Reserve bit Always give the value to write in as 0.

53.3.19 I²C automatic transmission interruption flag register (ICINT1, ICINT2)

ICINT is an 8-bit register and displays the interruption state at the time of automatic transmission.

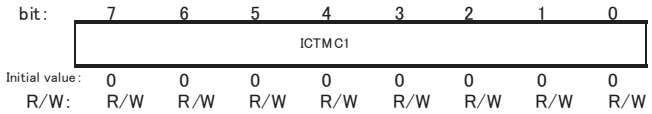
The interrupt bit can be cleared with ICASTART[7]=1 at beginning automatic operation ,or ICCR[7]=0.

bit:	7	6	5	4	3	2	1	0
	AEND	TMC2	TMC1	TMOUT	AAL	ATACK	AWAIT	ADTE
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	AEND	0	R	End flag bit of I²C automatic transmission 0: Under Automatic Transmission 1: End of Automatic Transmission
6	TMC2	0	R	End flag bit of I²C automatic transmission timer count 2 0: Timer Count 2 Un-Ending. 1: Timer Count 2 End
5	TMC1	0	R	End flag bit of I²C automatic transmission timer count 1 0: Timer Count 1 Un-Ending. 1: Timer Count 1 End
4	TMOUT	0	R	I²C automatic transmission timeout error flag bit 0: With No Timeout Error 1: Timeout Error Generating
3	AAL	0	R	I²C automatic transmission AL flag bit 0: With No AL 1: AL Generating
2	ATACK	0	R	I²C automatic transmission TACK flag bit 0: With No TACK 1: TACK Generating
1	AWAIT	0	R	I²C automatic transmission WAIT flag bit 0: With No WAIT 1: WAIT Generating
0	ADTE	0	R	I²C automatic transmission DTE flag bit 0: With No DTE 1: DTE Generating

53.3.20 I²C automatic transmission processing enabling register (ICACE1, ICACE2)

ICACE is an 8-bit register and chooses the use existence of each function under automatic transmission.



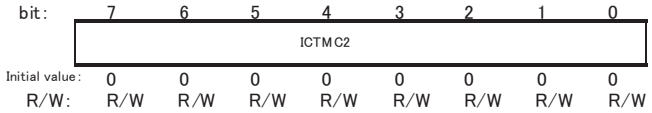
bit:	7	6	5	4	3	2	1	0
	AENDE	TMC2E	TMC1E	TMOUTE	ALE	TACKE	WAITE	–
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	AENDE	0	R/W	End detection enabling bit of automatic transmission 0: End of Automatic Transmission is not Detected. 1: Detect End of Automatic Transmission and it Outputs to ICINT.
6	TMC2E	0	R/W	A timer 1, a timer 2 enabling bit It is chosen whether end interruption of automatic transmission and timeout error detection timing are outputted after the setup time of TMC1 or TMC2. Refer to Fig. 53.3 for the wait timing of TMC1 and TMC2. ICACE[6:5] = 00:TMC1 and TMC2 are not used. It outputs after ICACE[6:5] = 01:TMC1. It outputs after ICACE[6:5] = 11:TMC1+TMC2. ICACE[6:5] = 10: Prohibition of a setup
5	TMC1E	0	R/W	
4	TMOUTE	0	R/W	Timeout error enabling bit After condition precedent generation can be detected as a timeout error to the timing set up by TMC1/TMC2, when the Low drive of SCL and the SDA continues being carried out. 0: Timeout Error is not Detected. 1: Detect Timeout Error and it Outputs to ICINT.
3	ALE	0	R/W	I²C transmission automatic AL error-handling enabling bit It is chosen whether processing to AL error generated during automatic transmission (a retry or stop processing) is performed. 0: With No Automatic AL Processing (AL is not Detected) 1: Those with automatic AL processing (opening and SCL are outputted for a SDA bus by 1 byte +ACK, and retry or stop processing is performed.)
2	TACKE	0	R/W	I²C transmission automatic ACK error-handling enabling bit It is chosen whether processing to the ACK error generated during automatic transmission (a retry or stop processing) is performed. 0: With no automatic ACK error handling. 1: Those with automatic ACK error handling. (Retry or stop processing is performed.)

1	WAITE	0	R/W	I²C transmission automatic WAIT processing enabling bit Only the time set up by ICTMCW during automatic transmission chooses whether automatic WAIT processing is performed. 0: With no automatic WAIT processing. 1: Those with automatic WAIT processing. (it set up by the ICTMCW register -- period WAIT is carried out)
0	-	0	R/W	Reserve bit Always give the value to write in as 0.

53.3.21 I²C automatic transmission timer control register 1 (ICTMC1)

ICTMC1 sets up the delay time of the detection timing of the end of automatic transmission, and a timeout error by an 8-bit register.



The delay time which can be set up by ICTMC1 becomes below. Delay time $= {}_{10}$(ICTMC1) x100xt_{SUBCK} which can be set up by ICTMC1

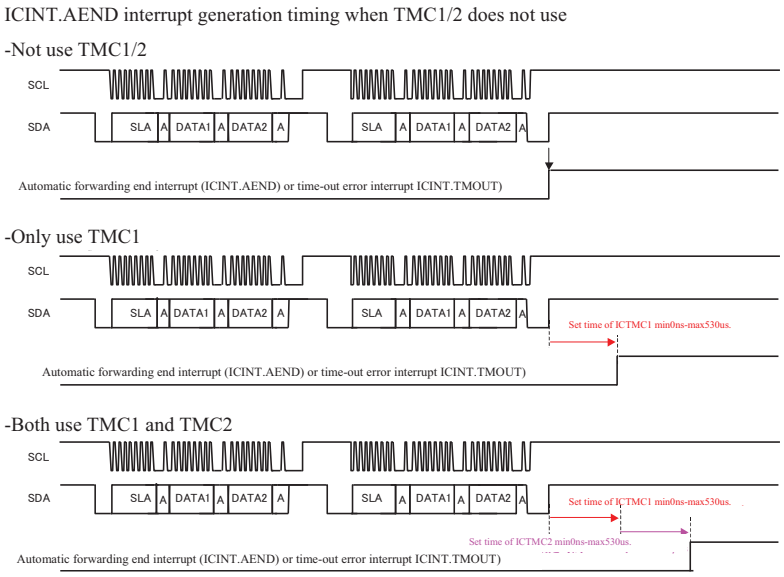
(the case of SUBCK=48MHz, it can set up from min 0us to max 530us by 2us unit.)

53.3.22 I²C automatic transmission timer control register 2 (ICTMC2)

ICTMC2 sets up the delay time of the detection timing of the end of automatic transmission, and a timeout error by an 8-bit register.

The delay time which can be set up by ICTMC2 becomes below. Delay time $= {}_{10}$(ICTMC2) x100xt_{SUBCK} which can be set up by ICTMC2

(SUBCK = in the case of 48MHz, it can set up from min 0us to max 530us by 2us unit.)



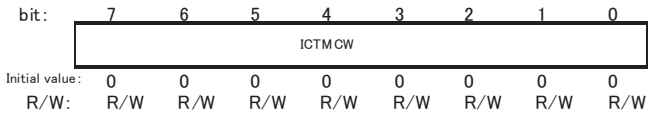


Fig. 53.3 Wait timing chart of TMC1, TMC2

53.3.23 I²C automatic transmission wait control register (ICTMCW1, ICTMCW2)

ICTMCW sets up the wait time under automatic transmission by an 8-bit register. When you carry out one set of ICACE(s) [1] and you use a wait function, please be sure to change into a set point (values other than H'00).

The wait time which can be set up by ICTMCW becomes below.

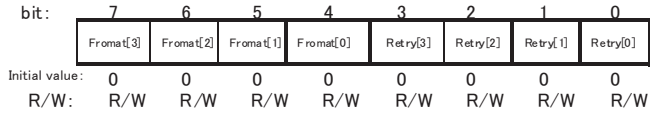
Delay time $= {}_{10}(\text{ICTMCW}) \times 10 \times t_{SUBCK}$ by ICTMCW

(SUBCK = in the case of 48MHz, it can set up by min 0ns and max53microsecond 0.2us unit.)

Although wait time can be set up this register, it is delayed by a SCL cycle unit.
For this reason , a SCL bus may not wait even if it changes this register.

Moreover, it wait for 1 SCL cycle before ACK even if it is not concerned with a setup of a wait control register during automatic transmission.

53.3.24 I²C automatic transmission transformer start register (ICSTART)



ICSTART is an 8-bit register and sets up end processing in the middle of the start of automatic transmission, and reset.

bit:	7	6	5	4	3	2	1	0
	AutoStart	AutoTrans Reset	AutoStop	–	–	–	ATDMA	ARDMA
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	AutoStart	0	R/W	I²C automatic transmission start bit When you start automatic transmission of I²C, carry out one set of these bits. Don't clear this bit zero during automatic transmission.
6	AutoTransReset	0	R/W	I²C automatic transmission processing reset bit When you reset the internal processing about automatic transmission, set this bit to 1. When you perform automatic transmission processing again, clear zero. In addition, a register is not initialized in reset by this bit. Use ICE reset, when you initialize a register.
5	AutoStop	0	R/W	It is a stop bit in the middle of I²C automatic transmission. A condition precedent is generated for under automatic transmission per 1 byte +ACK bit by carrying out one set of these bits, and communication is ended. following the communication format which will have been set up if this function is used -- an end -- things may not be made. 0: Normal Operation 1: Publish a condition precedent in the middle of automatic transmission, and communication is ended.
4:2	-	0	R/W	Reserve bit Always give the value to write in as 0.
1	AutoTDMAenable	0	R/W	At the time of automatic transmission DMA transmitting specification bit 0: DMA is not Used. 1: All Transmission is Performed by DMA.
0	AutoRDMAenable	0	R/W	At the time of automatic transmission DMA reception specification bit 0: DMA is not Used. 1: All Reception is Performed by DMA.

53.3.25 I²C automatic transmission transformer control register (ICATFR)

ICATFR is an 8-bit register and sets the number of times of a retry to an automatic transmission format.

Bit	Bit Name	Initial Value	R/W	Description
7:4	Transformat [3:0]	0000	R/W	I²C automatic transmission format selection The format of automatic transmission is specified. Refer to Fig. 53.7 for a communication format. S= start conditions, Sr= resending conditions, P= condition precedent 0000: S-> Transmitting 1->P 0001: S-> Transmitting 1 -> Receiving 1->P 0010: S-> Transmitting 1 ->Sr-> Transmitting 2->P 0011: S-> Transmitting 1 ->Sr-> Transmitting 2 -> Receiving 1->P 0100: S-> Transmitting 1 -> Receiving 1 ->Sr-> Transmitting 2->P 0101: S-> Transmitting 1 -> Receiving 1 ->Sr-> Transmitting 2 -> Receiving 2->P Others: Prohibition of a setup
3:0	ReTry[3:0]	0000	R/W	Number-of-times selection of I²C automatic transmission retry * The number of times which communicates again automatically during automatic transmission at the time of AL error or non-ACK error generating is specified. If one of the number of times of a retry turns into the number of times set as this bit, interruption of AL and non-ACK will be outputted. ReTry [3:0] =H'0: With no retry It retries to ReTry[3:0] =H'1:1 time. - It retries to ReTry[3:0] =H'E:14 time. ReTry[3:0] =H'F: Prohibition of a setup

[Note] Retry processing cannot be performed when using * DMA transfer.

53.3.26 I²C automatic transmission transformer time register 1 (ICATSET1)

ICATSET1 is an 8-bit register and it specifies the number of data of the transmission 1 of the format set up by ICATFR [7:4].

When using registers ICATD00-ICATD09, in [256 bytes of] a maximum of 10 bytes and DMA transmission, it can transmit.
A slave address is also contained in transmitting data.

ICATD00-ICATD09 are used. :
1 byte (ICATSET1 [7:0] =8'h00) - 10 bytes (ICATSET1[7:0] = 8'h09)
DMA is used. :
256 bytes (ICATSET1[7:0] =8'hFF) of MAX

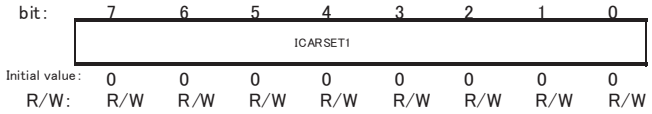
bit:	7	6	5	4	3	2	1	0
	ICATSET1							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

53.3.27 I²C automatic transmission transformer time register 2 (ICATSET2)

ICATSET2 is an 8-bit register and it specifies the number of data of the transmission 2 of the format set up by ICATFR [7:3].

When using registers ICATD10-ICATD19, in [256 bytes of] a maximum of 10 bytes and DMA transmission, it can transmit. Slave address data is also contained in transmitting data.

ICATD10-ICATD19 are used. :
1 byte (ICATSET2 [7:0] =8'h00) - 10 bytes (ICATSET2 [7:0] =8'h09)
DMA is used. :
256 bytes (ICATSET2[7:0] =8'hFF) of MAX



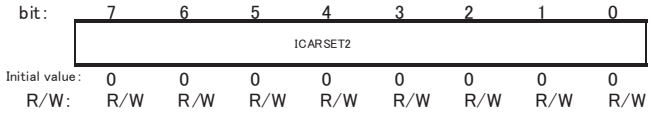
bit:	7	6	5	4	3	2	1	0
	ICATSET2							
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

53.3.28 I²C automatic transmission receipt time register 1 (ICARSET1)

ICARSET1 is an 8-bit register and it specifies the number of data of the reception 1 of the format set up by ICATFR [7:3].

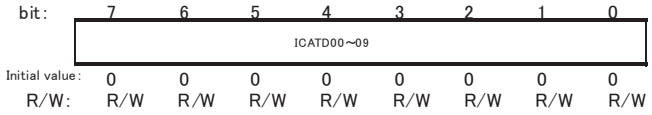
When using registers ICARD00-ICARD09, in [256 bytes of] a maximum of 10 bytes and DMA reception, it can receive.

ICARD00-ICARD09 are used. :
1 byte (ICARSET1 [7:0] =8'h00) - 10 bytes (ICARSET1 [7:0] =8'h09)
DMA is used. :
256 bytes (ICARSET1[7:0] =8'hFF) of MAX



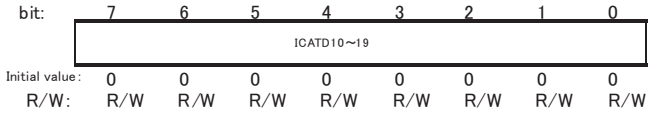
53.3.29 I²C automatic transmission receipt time register 2 (ICARSET2)

ICARSET2 is an 8-bit register and it specifies the number of data of the reception 2 of the format set up by ICATFR [7:3].



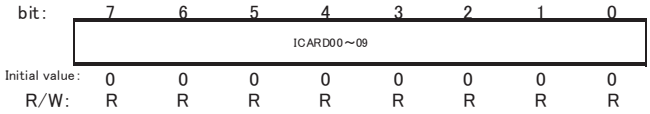
When using registers ICARD10-ICARTD19, in [256 bytes of] a maximum of 10 bytes and DMA reception, it can receive.

ICARD10-ICARD19 are used. :
1 byte (ICARSET2 [7:0] =8'h00) - 10 bytes (ICARSET2[7:0] = 8'h09)
DMA is used. :
256 bytes (ICARSET2[7:0] =8'hFF) of MAX



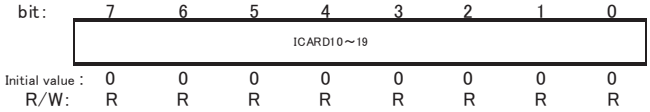
53.3.30 I²C automatic transmission transformer data 00-09 (ICATD00-ICATD09)

ICATD 00-09 is an 8-bit register, and stores the data of transmission 1.



53.3.31 I²C automatic transmission transformer data 10-19 (ICATD10-ICATD19)

ICATD 10-19 is an 8-bit register, and stores the data of transmission 2.



53.3.32 I²C automatic transmission receipt data 00-09 (ICARD00-ICARD09)

ICARD 00-09 is an 8-bit register, and stores the receiving data of reception 1.

53.3.33 I²C automatic transmission receipt data 10-19 (ICARD10-ICARD19)

ICARD 10-19 is an 8-bit register, and stores the receiving data of reception 2.

53.3.14 Transfer Rate

An I²C transfer rate can be set by ICCL, ICCH, ICIC7 and ICIC6, and SUBϕ. Table 53.5 lists transfer rate settings, and Figure 53.4 shows SCL waveforms.

Table 53.5 Transfer Rate Settings

	SUBϕ	ICIC[7] + ICCL	ICIC[6] + ICCH	Transfer Rate*2
Standard	12 MHz	H'042	H'036	100 kHz
	13.5 MHz	H'04A	H'03D	100 kHz
	24 MHz	H'082	H'06E	100 kHz
	27 MHz	H'096	H'078	100 kHz
	33 MHz	H'0AF	H'09B	100 kHz
	48 MHz	H'10B	H'0D5	100 kHz
Fast Speed*1	12 MHz	H'012	H'00C	400 kHz
	13.5 MHz	H'016	H'00C	397.1 kHz
	24 MHz	H'026	H'016	400 kHz
	27 MHz	H'02C	H'018	397.1 kHz
	33 MHz	H'033	H'020	397.6 kHz
	48 MHz	H'043	H'035	400 kHz
High Speed*3	48MHz	H'0F	H'08	2MHz

Notes: 1. When the set value of ICCL/ICCH is H'00A (minimum), 8 MHz is required for SUBϕ if a transfer rate is 400 kHz. If SUBϕ is less than 8 MHz, a transfer rate of 400 kHz is not ensured.

2. The transfer rates in above settings are theoretical values. The actual transfer rates are generally smaller than those theoretical values due to the pull-up resistor (Rp) and the capacitance (Cp). However, there is no harm in communication because the actual transfer rates satisfy the I²C bus specifications. (Smaller ICCL and ICCH can increase the actual transfer rates. In this case, though, set ICCL and ICCH to ensure that t_{LOW} and t_{HIGH} are within the specifications.)

3. In three actual measurements, a transmission rate may become low with the pull-up resistor (Rp) of a board, and electrostatic capacity (Cp). In order to improve transmission performance, please change the value of ICHL and ICHH in the range which SCL becomes in I^2C-bus standard.

(1) Notes on the transfer rate

The transfer rates in above settings are theoretical values. The actual transfer rates are generally smaller than the theoretical values due to the pull-up resistor (Rp) and the capacitance (Cp). However, there is no harm in communication because the actual transfer rates satisfy the I²C bus

specifications. (Smaller ICCL and ICCH can increase the actual transfer rates. In this case, though, set ICCL and ICCH to ensure that t_{LOW} and t_{HIGH} are within the specifications.)

A calculation example of ICCL and ICCH:*[1]

- Conditions
  - SUBϕ: 48 MHz
  - I²C transfer rate: 100 kHz
  - L/H ratio in SCL*[2]: L/H = 5/4
- Result
  - ICIC[7] + ICCL = (SUBϕ ÷ I²C transfer rate) × (L ÷ (L + H))
  - = $((48 \times 10^6) \div (100 \times 10^3)) \times (5 \div (5 + 4) = 267 = (10B)_{16}$
  - ICIC[6] + ICCH = (SUBϕ ÷ I²C transfer rate) × (H ÷ (L + H))
  - = $((48 \times 10^6) \div (100 \times 10^3)) \times (4 \div (5 + 4) = 213 = (0D5)_{16}$

Notes: 1. If the result is indivisible, some modifications are introduced to make the total count number closer to the desirable transfer rate.
2. SCL L/H ratio is arbitrary as long as it satisfies t_{LOW} and t_{HIGH}. In above case, L/H is set as 5/4.

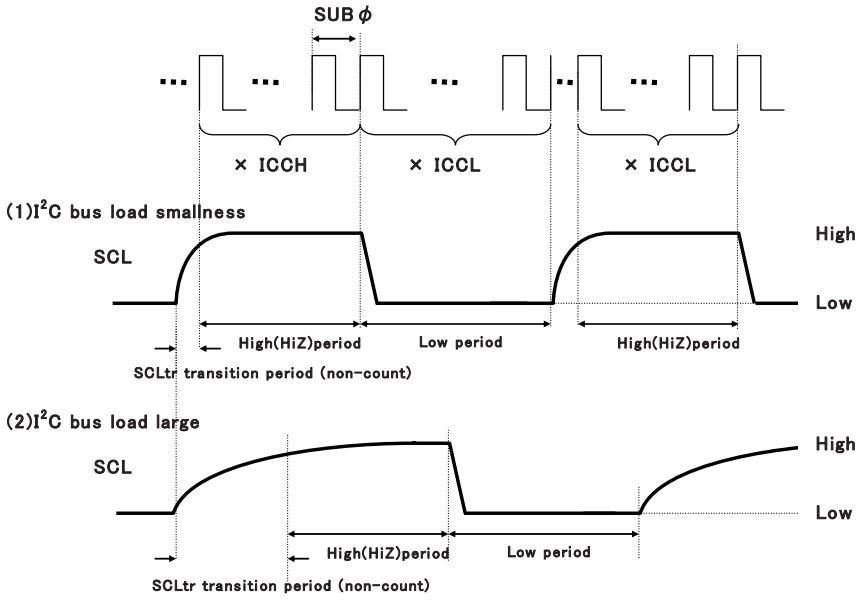


Figure 53.4 SCL Waveforms

53.4 Operation

53.4.1 I²C Bus Data Format

The I²C bus formats are addressing formats with an acknowledge bit. These are shown in figures 53.5 and 53.6. The first frame following a start condition always consists of 8 bits. the format at the time of HS mode which can be used is shown in Fig. 53.7

The symbols used in figures 53.5 and 53.6 are explained in Table 53.6.

Table 53.6 I²C Bus Data Format Symbols

Symbol	Description
S	Start condition. The master device drives SDA from high to low while SCL is high.
Sr	Retransmit condition. The master device drives SDA from high to low while SCL is high.
SLA	Slave address, by which the master device selects a slave device.
R/W	Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.
A	Acknowledge. The receiving device (the receiving device in master transmit mode, or the master in master receive mode) drives SDA low to acknowledge a transfer.
DATA	Transmitted or received data. The bit length is 8 bits.
P	Stop condition. The master device drives SDA from low to high while SCL is high.

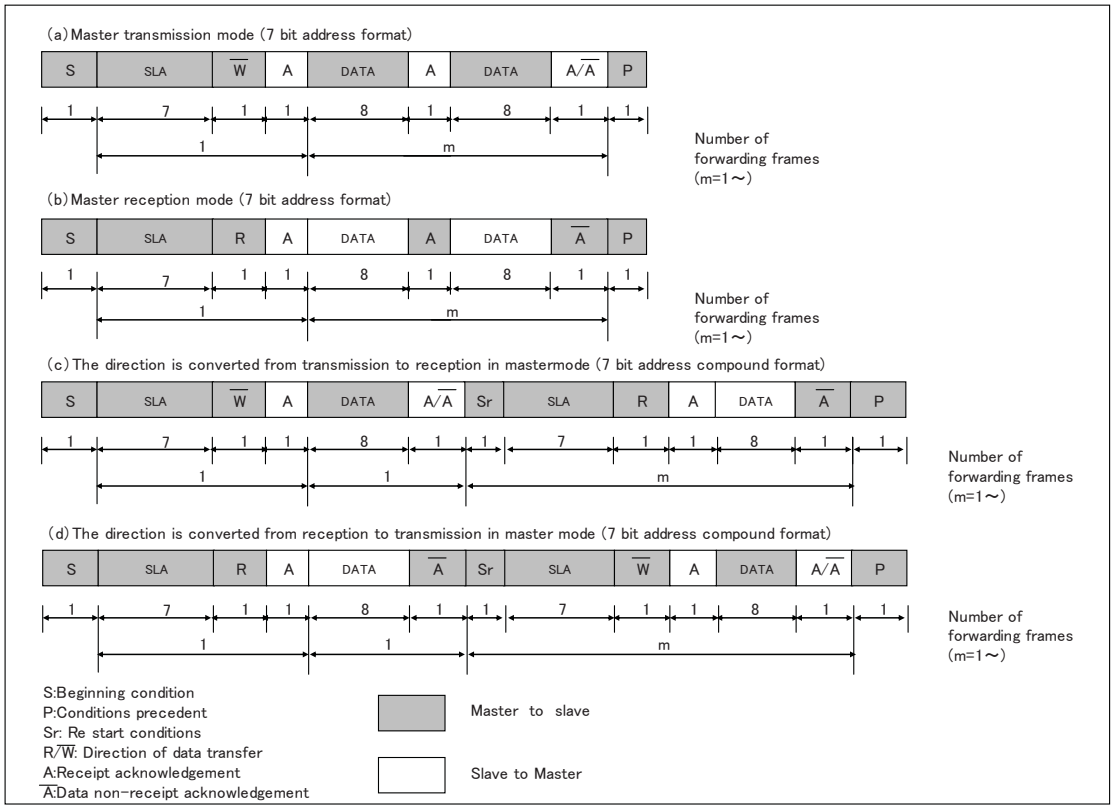

Figure 53.5 I²C Bus Data Formats (7-Bit Address Format)

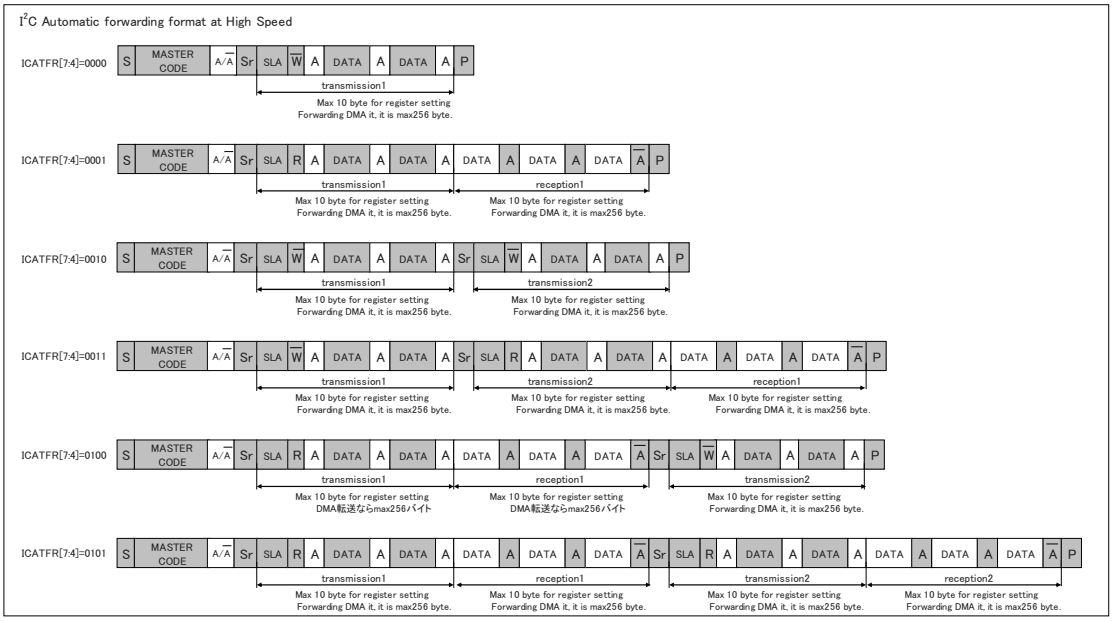

Figure 53.7. The bus data format which can be I²C HS automatic transmission used

53.4.2 Master Transmit Operation

In master transmit mode, the master device outputs the transmit clock and transmit data, and after the receiving device receives data, it returns an acknowledge signal. The transmission procedure and operations are described below.

1. Set bits in ICCL, ICCH, and ICIC according to the operating mode.
2. Write H'94 in ICCR to issue the start condition. The DTE bit in ICSR is then set to 1.
3. To transmit data, write data to ICDR. The DTE bit is then automatically cleared.
   Data transmission starts when data is sent to the internal transmit buffer. The DTE bit in ICSR is then set to 1 again.
4. To issue and generate the stop condition, write the final data to ICDR, then write H'90 to ICCR.
   DTE is not set to 1 from issuing the stop condition to generating the stop condition. After the final data is transmitted, the stop condition is generated and operation is stopped.
5. To issue and generate the retransmit condition, write the final data to ICDR, then write H'94 to ICCR.
   DTE is not set to 1 from issuing the retransmit condition to generating the retransmit condition. After the final data is transmitted, the retransmit condition is generated.
6. To change from transmission to reception, write the final data to ICDR, then write H'81 to ICCR. After transmitting the final data, transmission is automatically changed to reception and receiving operation is started.

By repeating step 3, data can be consequently transmitted. A non-acknowledge interrupt occurs if the received acknowledge bit is 1 (TACK = 1) when non-acknowledge is detected. To continuously transmit data without detecting non-acknowledge, set the TACKE bit in ICIC to 0, and perform steps 3 and 4 to 6. At this time, since non-acknowledge is not detected, data can be continuously transmitted.

To change transmission to reception, write H'81 to ICCR until the completion of transmission of the final data. At this time, if writing to ICCR is delayed, use a WAIT interrupt to write to ICCR until the completion of transmission of the final data.

To generate a retransmit condition during transmission, the final data is written to ICDR and H'94 is written to ICCR. If, due to a delay in ICDR or ICCR writing, processing is performed continuously before and after generating the ACK bit, a DTE interrupt is generated before the retransmit condition is generated, which disables the software control for normal communication. For this reason, modify ICDR and ICCR before generating the ACK bit.

ICDR and ICCR can be written before the ACK bit is generated by modifying them from the occurrence of a WAIT interrupt until the WAIT interrupt source is cleared.

To generate a stop condition during transmission, the final data is written to ICDR and H'90 is written to ICCR. If, due to a delay in ICDR or ICCR writing, processing is performed continuously before and after generating the ACK bit, a DTE interrupt is generated before the stop condition is generated. For this reason, modify ICDR and ICCR before generating the ACK bit.

ICDR and ICCR can be written before the ACK bit is generated by modifying them from the occurrence of a WAIT interrupt until the WAIT interrupt source is cleared.

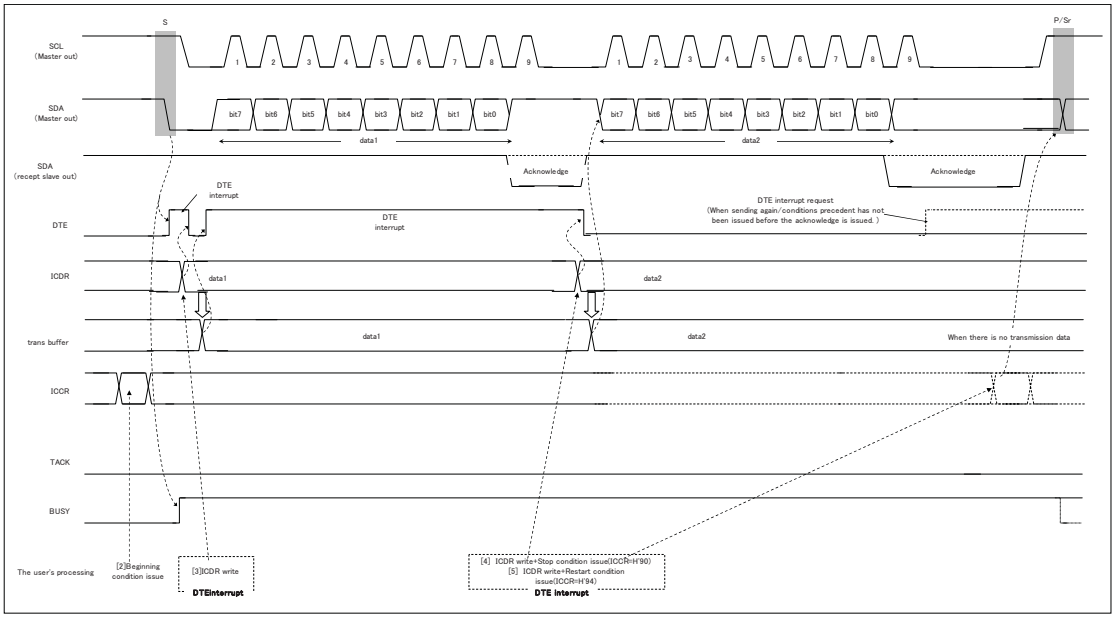

Figure 53.8 Example of Master Transmit Mode Operation Timing (WAIT = 0)

53.4.3 Master Receive Operation

In master receive mode, the master device outputs the receive clock, and returns an acknowledge signal after the transmit device transmits data. The reception procedure and operations in master receive mode are described below.

(1) When Two or More Bytes of Data are Received Continuously

1. Switch from transmit mode to receive mode automatically to start reception.
2. After data is received to the receive buffer, data is transmitted to ICDR and the DTE bit is set to 1. At this time, the next data reception starts.
3. To continuously receive data, read data from ICDR. When data is read from ICDR, the DTE bit is automatically cleared.
4. To issue/generate the stop condition, read data from ICDR, then write H'C0 to ICCR. After the stop condition is issued, the final data is received. After data is read from ICDR, the stop condition is generated to stop the operation.
5. To issue/generate the retransmit condition, read data from ICDR, then write H'D4 to ICCR. After the retransmit condition is issued, the final data is received. After data is read from ICDR, the retransmit condition is generated. Then, reception is automatically switched to transmission, and transmission starts.

Two or more bytes of data can be received continuously by repeating steps 2 and 3.

The following problem can arise if the stop or retransmission condition is to be issued during the continuous reception of two or more bytes of data. If the byte immediately before the final byte is read from ICDR and H'D4 or H'C0 (to generate the retransmission or stop condition) is written to ICCR, but writing to ICCR is delayed and processing to overwrite this register cannot be completed by the time the NACK bit should be generated on reception of the last byte (reading of ICDR), an ACK bit will be generated on reception of the last byte. This operation is not in accord with the I²C communications protocol.

Accordingly, ensure that the change to the ICCR setting is complete in time for the NACK bit to be generated in response to reading of ICDR for reception of the final byte.

Furthermore, after generation of the WAIT interrupt, reading of ICDR for the last byte but one and writing to ICCR by the time the WAIT interrupt source has been cleared ensures that the NACK bit will be generated when the last byte is received.

(2) When Only One Byte of Data is Received

When only one byte data is received, use a WAIT interrupt to issue the stop/retransmit condition to ICCR.

1. Switch from transmit mode to receive mode automatically to start reception.
2. The WAIT bit is set to 1. At this time, write H'C0 to ICCR to issue/generate the stop condition. Write H'D4 to ICCR to issue/generate the retransmit condition.
3. The WAIT bit is cleared to 0.
4. After data is received to the receive buffer, data is transmitted to ICDR and the DTE bit is set to 1.
5. When the stop condition has been issued to ICCR, the stop condition is generated to stop the operation after data is read from ICDR. When the retransmit condition has been issued to ICCR, the retransmit condition is generated, reception is then automatically switched to transmission, and transmission starts.

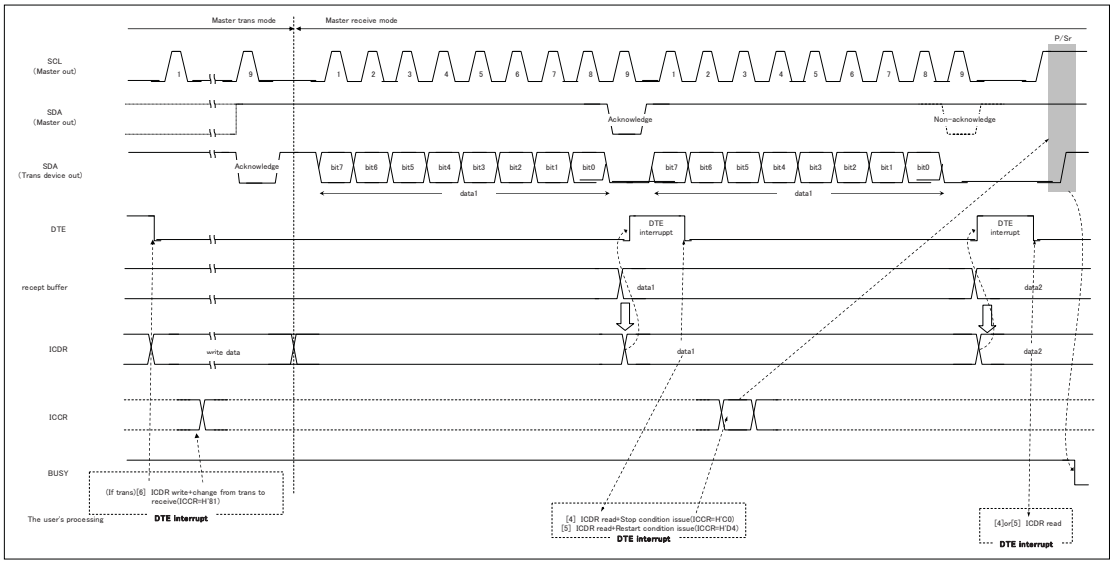

Figure 53.9 Example of Master Receive Mode Operation Timing (WAIT = 0)

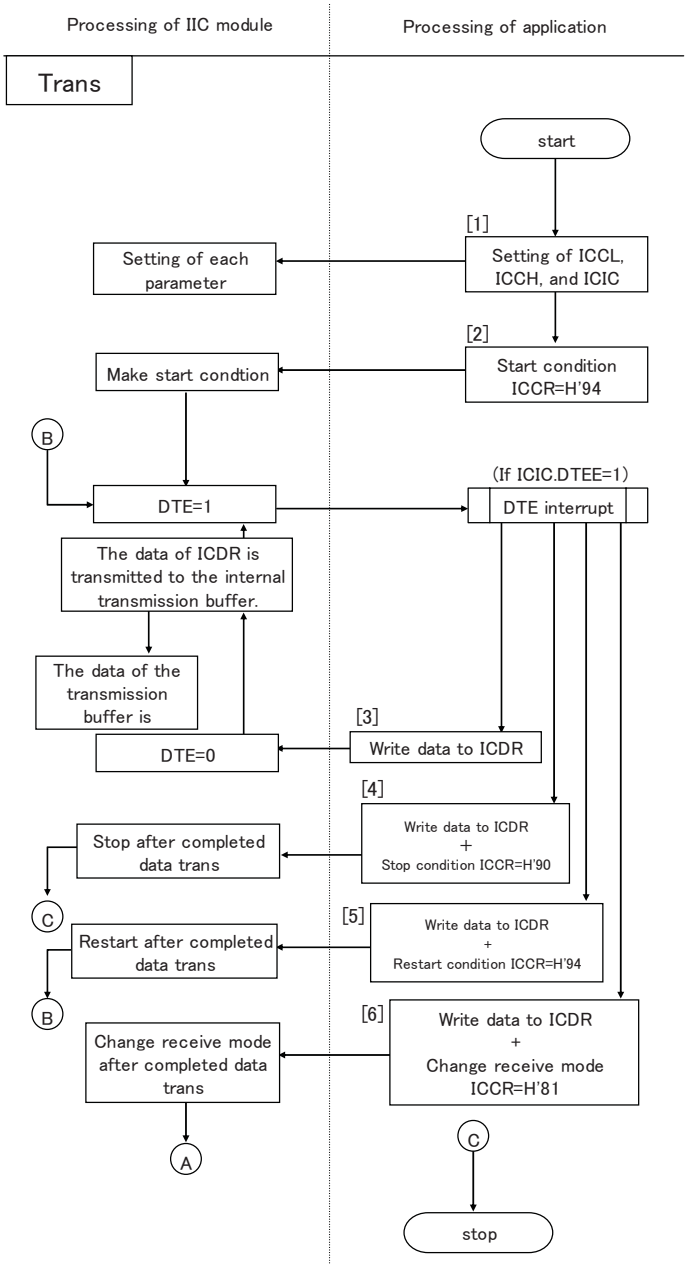

Figure 53.10 I²C Transmission Sequence (in Transmit Mode)

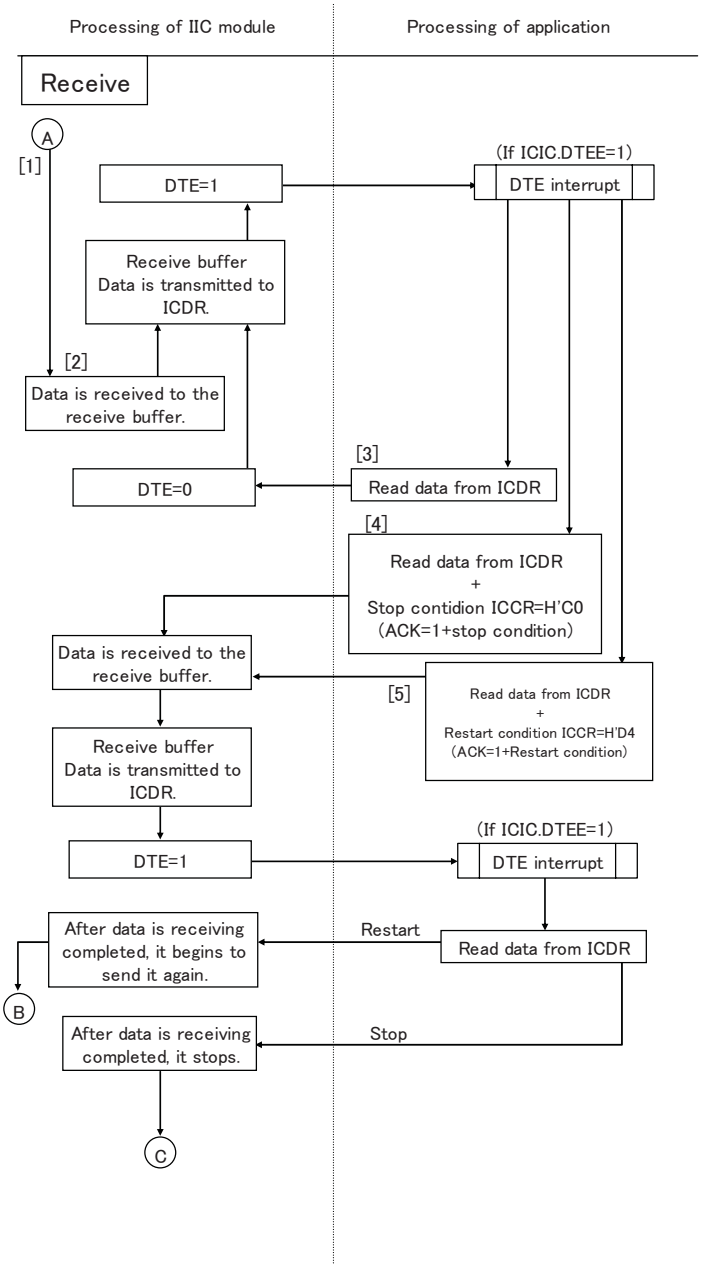

Figure 53.11 I²C Transmission Sequence (in Receive Mode of Two or More Bytes of Data)

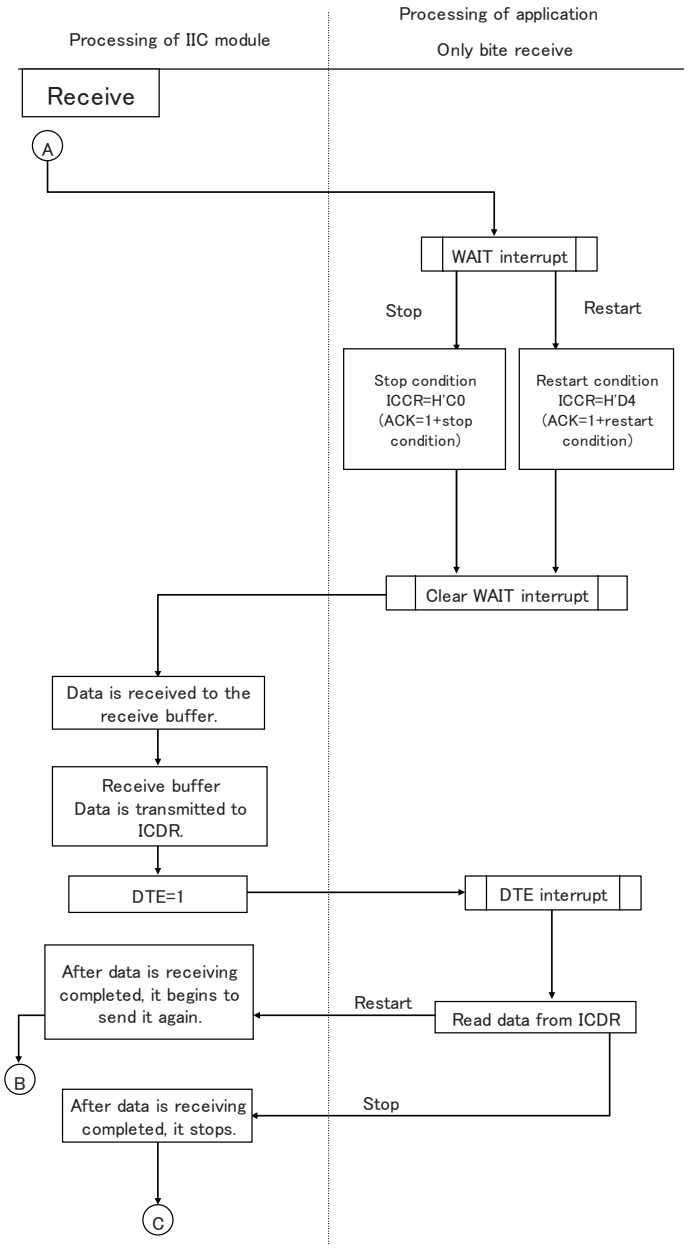

Figure 53.12 I²C Transmission Sequence (in Receive Mode of One Byte of Data)

53.4.4 I²C Continuous Transmission by DMA

In DMA transmit mode, the master device outputs a DMA request to the DMAC. The received DMAC returns ICDR data writing and DMARACK to the master device. The transmission procedure and operations are described below.

1. Set bits in ICCL, ICCH, and ICIC according to the operating mode. Set the TDMAE and WAITE bits in ICIC to 1. Then, set the DMAC. For the setting methods of the DMAC, refer to section 8, Direct Memory Access Controller (DMAC).
2. Write H'94 to ICCR to set the start condition. A DMA request is then output.
3. When the DMAC receives a DMA request, data is written to ICDR. Transmission is then started. When transmission is performed the number of times specified by DMAC, a DEI interrupt in DMAC is set.
4. To set or generate the stop condition, clear the RDMAE bit of ICIC to 0 and set the DTEE bit to 1. After setting of ICIC, the DTE bit is set to 1. At this time, when H'90 is written to ICCR, the stop condition is generated, and operation is stopped.

By repeating step 3, data can be consequently transmitted. A non-acknowledge interrupt occurs when non-acknowledge is detected. To continuously transmit data without detecting non-acknowledge, set the TACKE bit in ICIC to 0, and perform steps 3 and 4. At this time, since non-acknowledge is not detected, data can be continuously transmitted.

53.4.5 I²C Continuous Receive by DMA

In DMA receive mode, the master device outputs a DMA request to the DMAC. The DMAC that received the request returns ICDR data reading and DMARACK to the master device. When I²C continuous receive is performed by DMA, receive data of 4 bytes or more is needed. The reception procedure and operations are described below.

1. For transmission, set bits in ICCL, ICCH, and ICIC according to operating mode. Set the RDMAE and WAITE bits in ICIC to 1. Then, set the DMAC. For the setting methods of the DMAC, refer to section 8, Direct Memory Access Controller (DMAC).
2. Switch from transmit mode to receive mode automatically to start reception.
3. After data is received at the receive buffer, a DMA request is output. At this time, the next data reception starts.
4. To continuously receive data, read data from ICDR in each DMA request. When reception is performed the number of times specified by DMAC, a DEI interrupt in DMAC is set.
5. To set or generate the stop condition, clear the RDMAE bit of ICIC to 0 and set the DTEE bit to 1. After setting of ICIC, the DTE bit is set to 1. At this time, when H'D4 is written to ICCR, data is read from ICDR.
6. Write H'D4 to ICCR and read data from ICDR. The DTE bit is then cleared automatically. The DTE bit is set to 1 again, and the stop condition is generated, and operation is stopped after data has been read from ICDR.

By repeating step 3, data of 4 bytes or more can be continuously received.

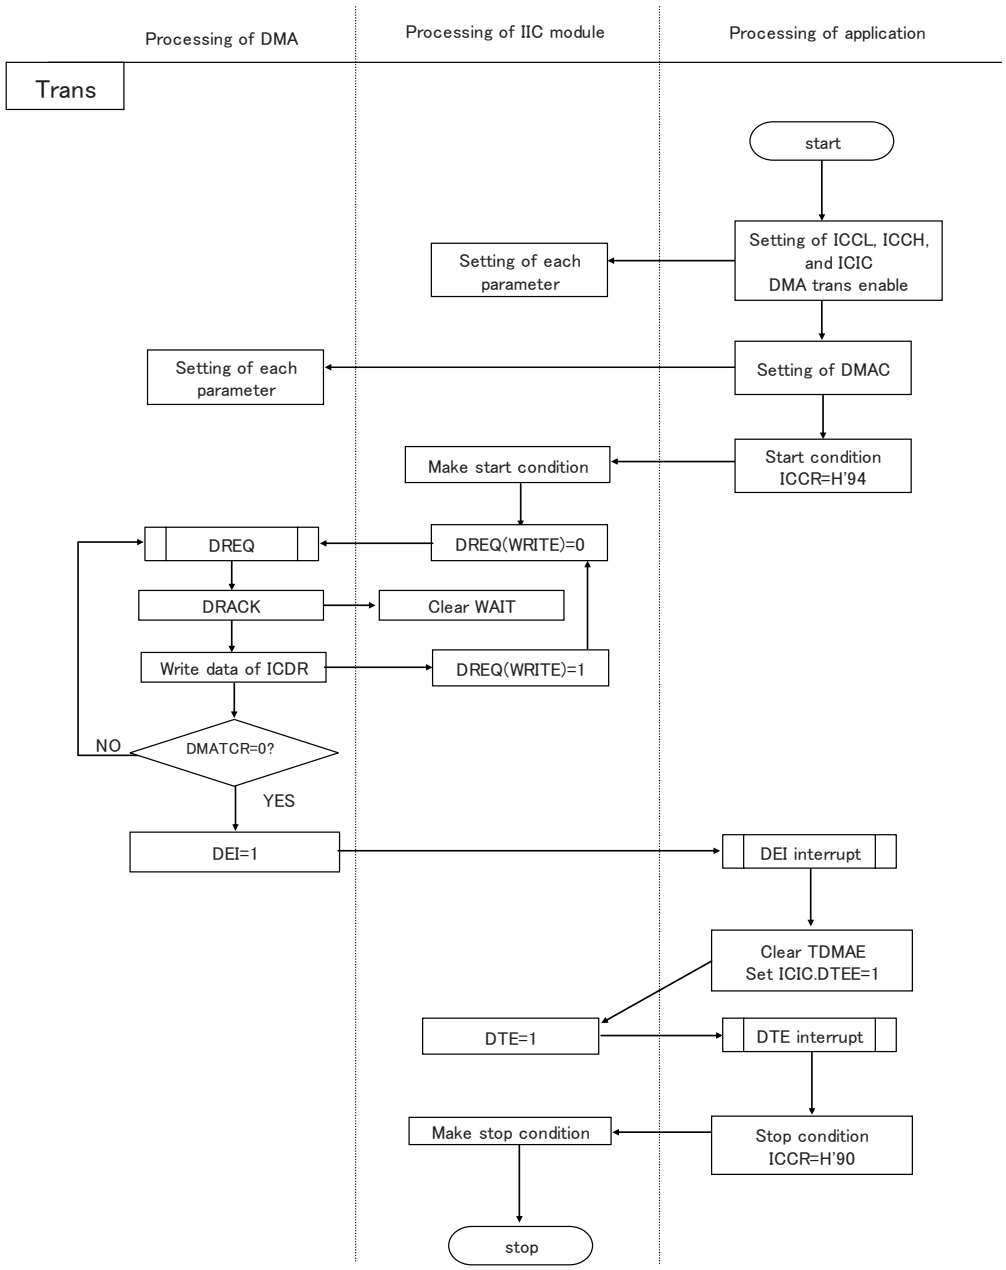

Figure 53.13 I²C Continuous Transmission Sequence by DMA

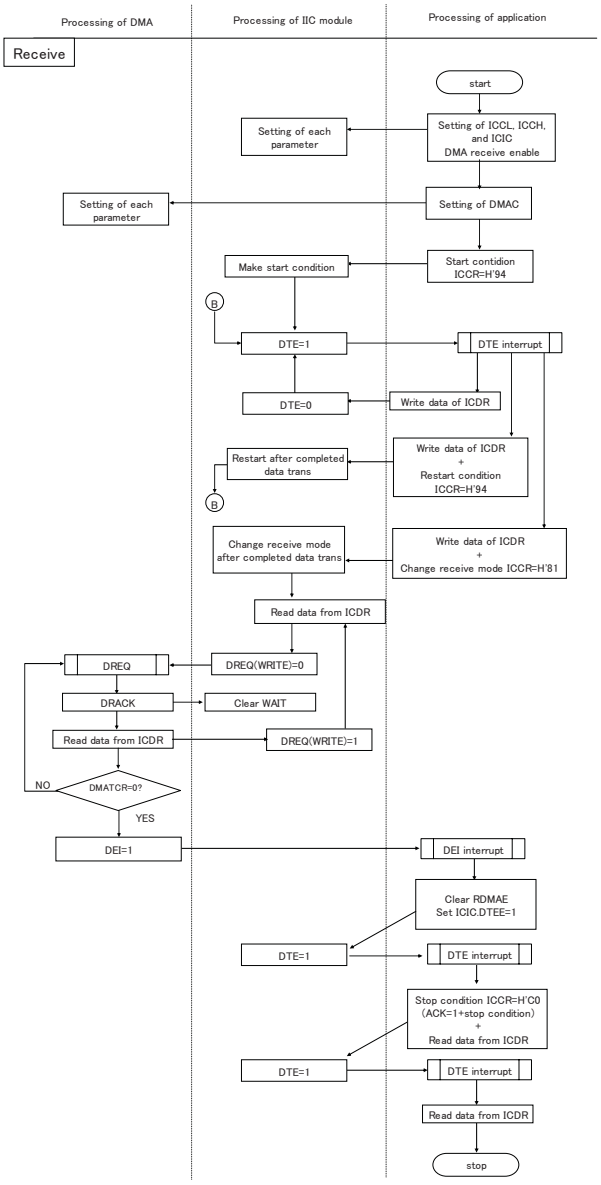

Figure 53.14 I²C Continuous Receive Sequence by DMA

53.4.6 Synchronizing SCL Line

When the SCL line state is changed from high to low, related devices start counting in the low period. When the clock of a device becomes low, the device holds the SCL line low until its clock becomes high (see Figure 53.15). However, even if the clock of the device is changed from low to high, the SCL line state does not change when clocks of other devices are in the low period. Therefore, the low period of the SCL line is determined by the device with the longest low period. At this time, a device with the short low period waits in the high state.

When all devices complete the low period, the clock line is open and in the high state. Therefore, the device clock and SCL line are in the same state, and start counting both of pulses in high level period. The SCL line enters the low state again by the device that has first completed the high period.

The low period is determined by the device with the longest low period, and the high period is determined by the device with the shortest high period. The SCL line is then synchronized.

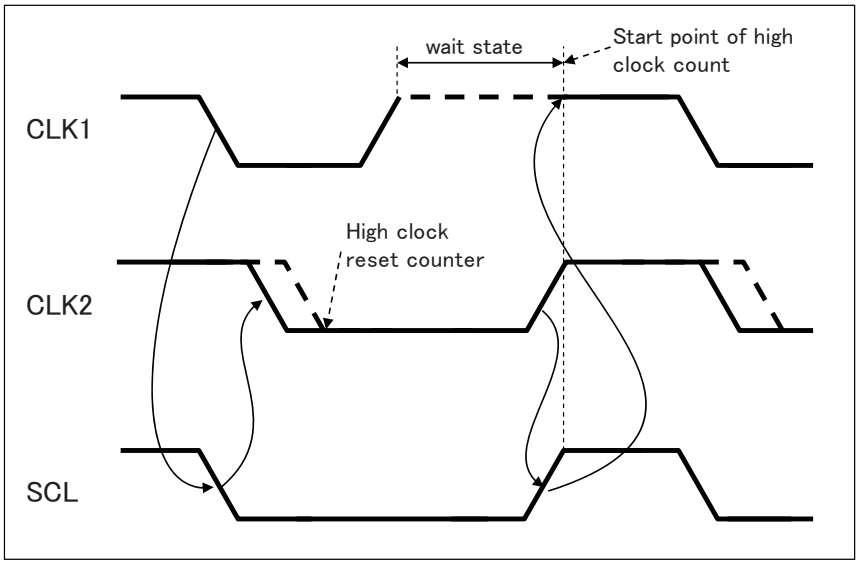

Figure 53.15 Synchronizing SCL Line

53.4.7 Noise Canceler

The logic levels at the SCL and SDA pins are routed through noise cancelers before being latched internally. Figure 53.16 shows a block diagram of the noise canceler circuit.

The noise canceler consists of three cascaded latches and a match detector. The SCL (or SDA) input signal is sampled on SUBϕ, but is not passed forward to the next circuit unless the outputs of both latches agree. If they do not agree, the previous value is held.

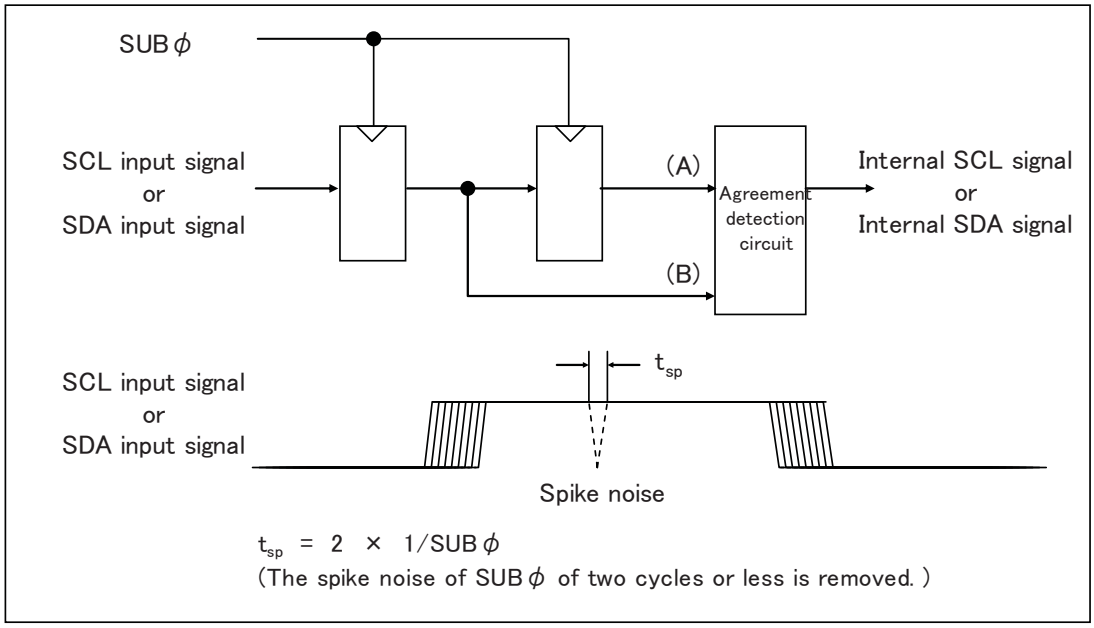

Figure 53.16 Block Diagram of Noise Canceler

53.4.8 Arbitration Lost Operation

This module can issue an arbitration lost interrupt request when bus conflict defeat occurs.

Interrupt occurrence conditions are described below.

- When received data changes while high SCL clocks are counted in master transmit/receive mode.
- When the SCL line becomes low while high SCL clocks are counted.
- When this module detects the start condition before issuing the start condition.
- When the monitored SDA (external) and data output from this module disagree.

Under the above conditions, the AL bit in ICSR is set to 1, and an arbitration lost interrupt occurs.

When arbitration lost is detected in data transmission, the SDA line is open. The SCL clock line outputs clocks until acknowledge end of the frame, then opens buses. Figure 53.17 shows an example of arbitration lost interrupt operation timing.

To cancel an interrupt, clear the AL bit in ICSR to 0. Conditions for clearing to 0 are described below.

- When data is written to ICDR (in transmission), and data is read (in reception), when DTE = 1.
- When 0 is written.

When arbitration is lost by the acknowledge bit, hold SCL and SDA at a low level.

ICE must be reset by the software to release the bus.

With the AL bit set to 1, do not clear the ALE bit to 0. Preferably, the setting of the ALE bit should be performed only before the start of communication.

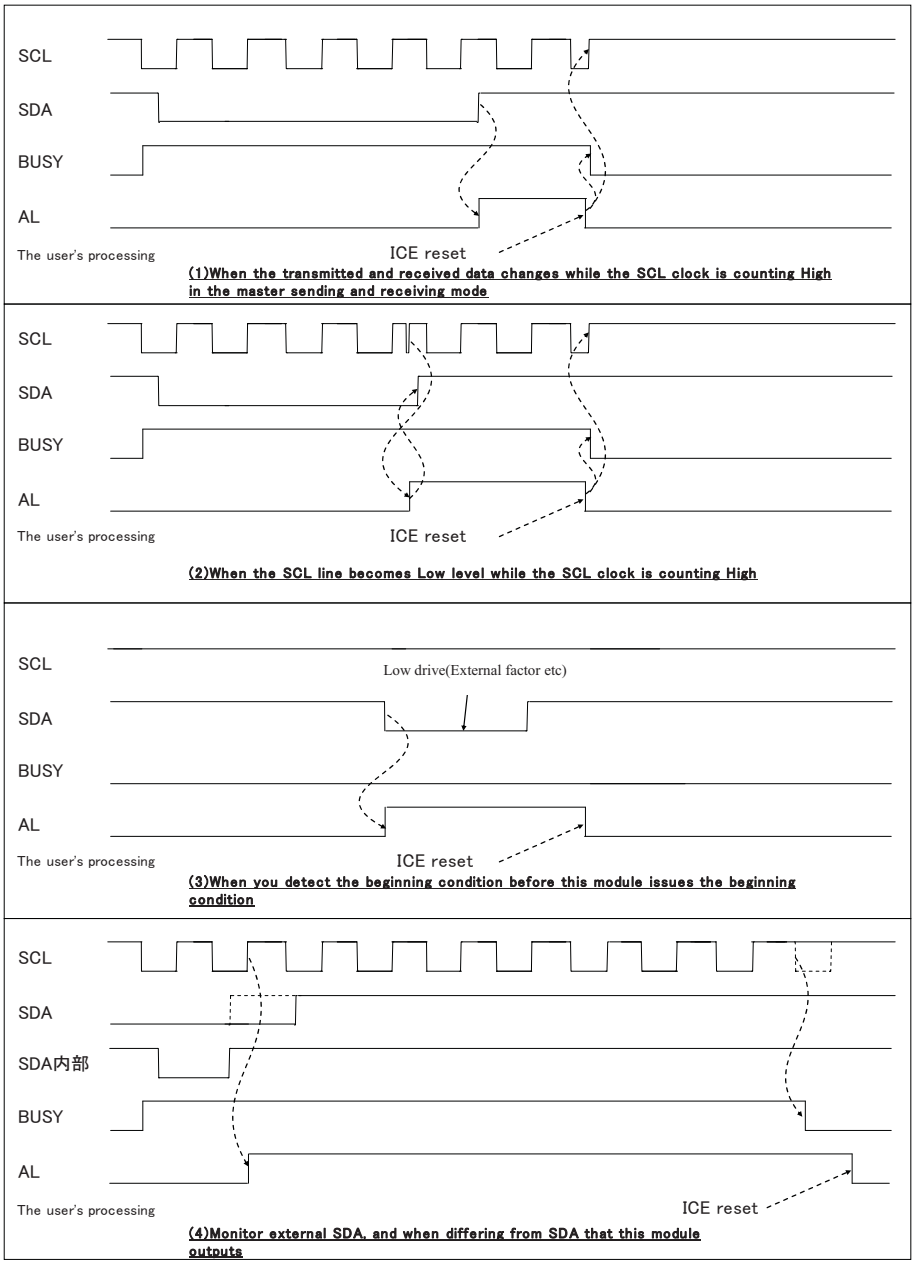

Figure 53.17 Example of Arbitration Lost Interrupt Operation Timing

53.4.9 Non-Acknowledge Operation

This module can issue a non-acknowledge interrupt when there is no acknowledge from the receiving device in transmission.

An acknowledge bit from the receiving device is stored in the TACK bit in ICSR. A non-acknowledge interrupt is issued if the TACK bit is set to 1 when TACKE in ICIC is 1.

To cancel the non-acknowledge interrupt, clear the TACK bit to 0.

With the TACK bit set to 1, do not clear the TACKE bit to 0. Preferably, the setting of the TACKE bit should be performed only before the start of communication.

Figure 53.18 shows an example of non-acknowledge operation timing.

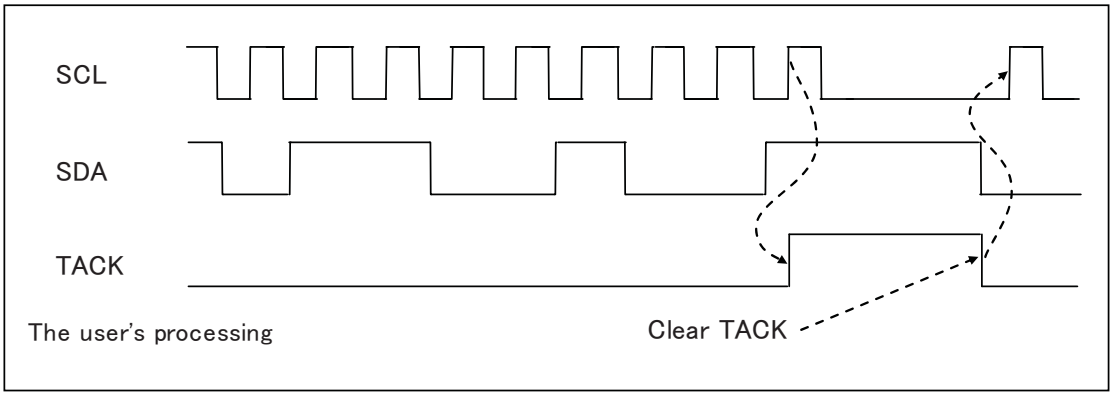

Figure 53.18 Example of Non-Acknowledge Operation Timing

53.4.10 Wait Operation

This module can make operation mode the wait state by the WAIT bit in ICSR. WAIT is set to 1 at a falling edge of the eighth transmit clock for the master device.

After that, the transmit clock is fixed to low until the WAIT bit is cleared to 0.

When the WAIT bit is cleared to 0, the ninth transmit clock is generated, and the state is returned from the wait state.

When performing the I²C communication processing using a WAIT interrupt, the I²C signals stay in the WAIT state from the time when the WAIT state is detected by the hardware until the WAIT interrupt source is cleared by the software. When the module performs communication processing only with a DTE interrupt, the I²C signals do not stay in the WAIT state. Therefore the communication is delayed by the time period where the I²C signals stay in the WAIT state.

Preferably, the setting of the WAITE bit should be performed only before the start of communication

53.4.11 I²C automatic transmission with HS transmission

This I²C is carrying out a register setup of a communication format and several transceiver data minutes beforehand at the time of HS transmission use, transmitting without passing interruption processing until it publishes interruption in the completion of communication, or a communication error henceforth it can do. The communication format and function-settings procedure which are used by automatic transmission are shown in Table 53.7.

The example of a flow of operation at the time of I²C automatic transmission is shown in Fig. 53.26.

Table 53.7 Soft processing at the time of I²C automatic transmission use

[Note] "*" in front should set up by combining with an operating condition.

"SLA and data" in front, and "receiving data" are applicable registers when performing communication which uses a data register. A write or read is required.

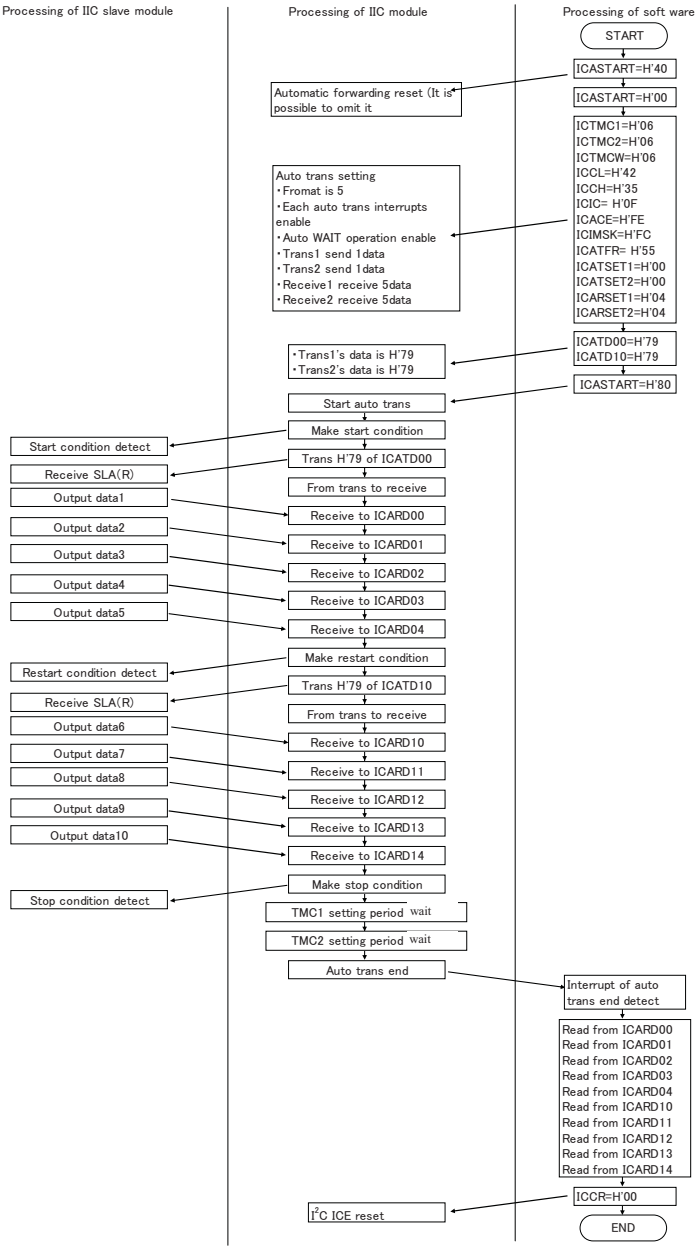

Figure 53.26 Example of an automatic transmission flow at the time of I²C Hs transmission use

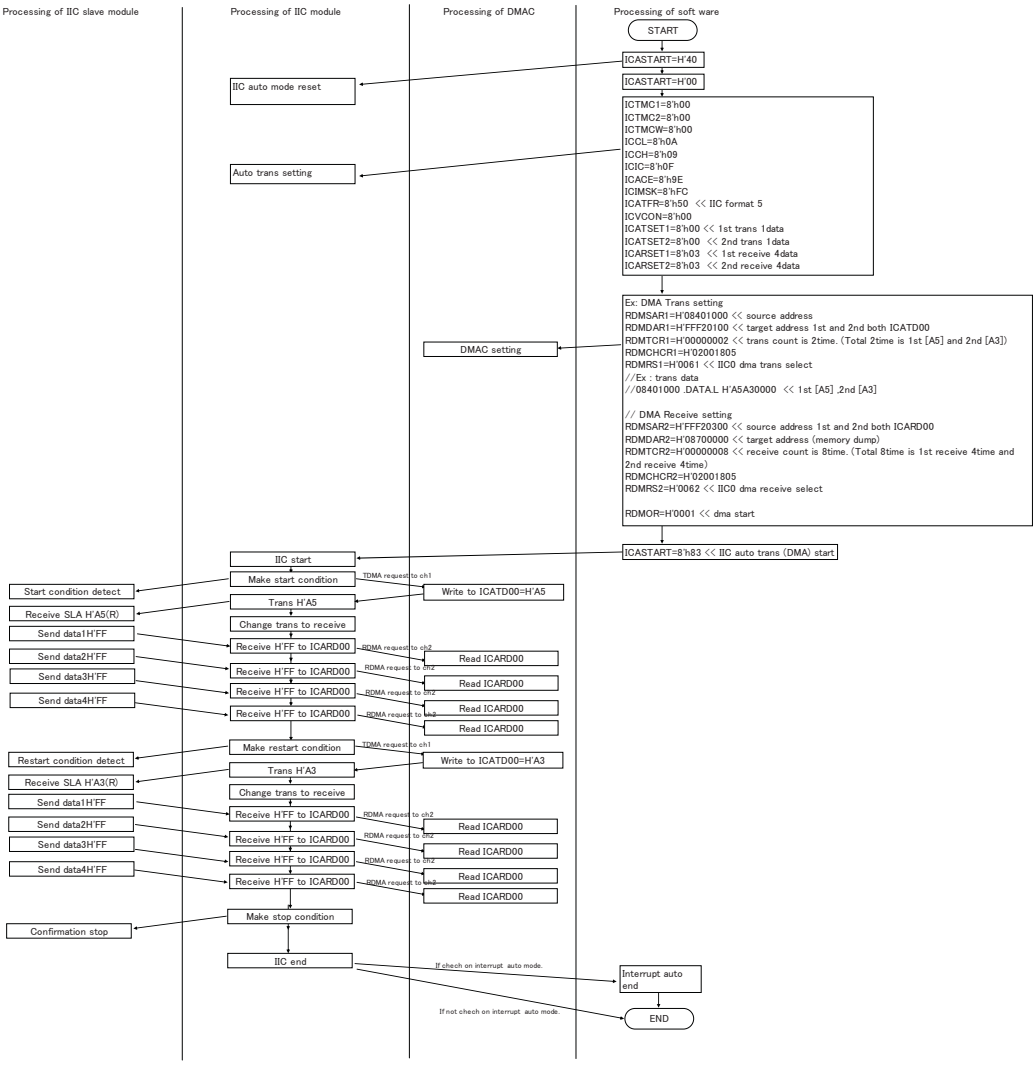

Figure 53. 27 Example of an automatic transmission flow at the time of I²C Hs transmission use (at the time of DMA use)

53.4.12 I²C HighSpeed transmission

I²C corresponds to HS transmission to less than SCL 2MHz in a HighSpeed (HS) format. (It is I^2 C2 and I^2 C3 and I^2 C4)

Automatic transmission is used in order to perform HS transmission.

The communication format which can be used by HS transmission is a figure. 53.7 Soft processing of HS transmission are shown in Table 53.7.

The flow of HS transmission of operation is explained below.

If it sets to HS transmission and an automatic transmission start is carried out, I²C will transmit 1 byte of master code (B'00001XXX) by a standard or high-speed transmission. ICCL and an ICCH register value are respectively reflected the Low period of SCL at this time, and during the High. Although one set of ACK bits after master code transmission are carried out, they do not perform TACK detection.

TACK detection is performed in the ACK bit under HS transmission.

I²C generates resending conditions and starts HS transmission. ICHL and an ICHH register value are respectively reflected the Low period of SCL at this time, and during the High.

I²C communication is performed along with the communication format set as the ICATFR register, and publish stop, end of automatic transmission, or communication error interruption after condition precedent generation henceforth.

AL detection is not performed during HS transmission. Only the period to the standup of communication of SCL of ACK bit falling to the next is possible for SCL synchronous processing. The slave device can carry out the Low drive of the SCL, and can carry out wait of the following processing to this period.

The timing chart of HS transmission and the existence of the function under transmission are shown in Fig. 53.26.

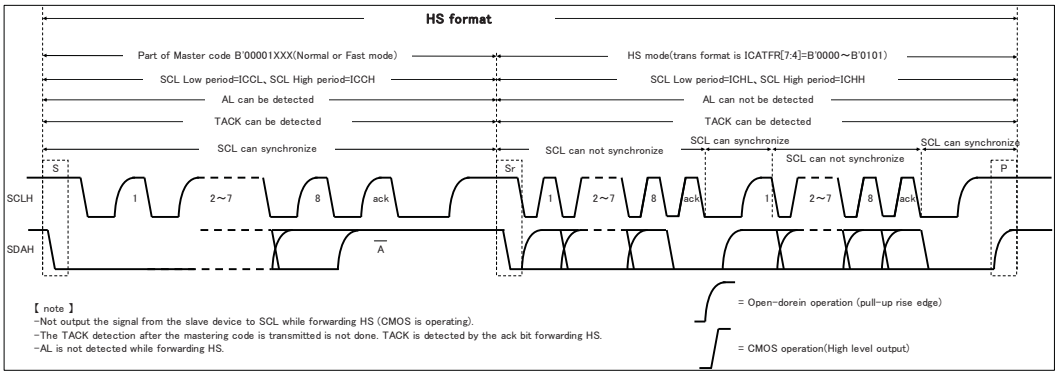

Figure 53.28 The timing chart of I²C HS transmission, and function under transmission

53.5 Usage Notes

(1) Arbitration Lost

A bus may not be released depending on the state of the slave device when arbitration lost is detected.

When resuming the communication after an arbitration lost, the initialization by the ICE bit in ICCR is required to initialize the entire internal data.

(2) ICE Reset

The SCL clock stops immediately after ICE is reset during data transmission. Therefore, a bus may not be released depending on the state of the slave device.

(3) Processing Concerning Stop Condition Generation

When data is transmitted or received after a stop condition has been issued and generated, it may not be possible to generate a stop condition hereafter. Be sure to initialize all registers in the I²C module by clearing the ICE bit in ICCR to 0 after a stop condition has been generated or before making settings to trigger data transmission or reception after a stop condition has been generated.

(4) What to do when the I²C Bus Interface is not Used

Set the ICE bit in ICCR to 0 to disable the unused channels while the I²C bus interface is not used.

(5) It is about an end by the middle about communication of I²C.

It becomes impossible to communicate in an original I²C format by end on the way. When an end is used on the way,

Please check not malfunctioning, even if the end of communication is carried out in the form where the slave side differs from a communication format.

Section 54 Key Scan Interface (KEYSC)

This LSI has a key scan interface (KEYSC) that can set the input or output bit numbers to be programmable.

54.1 Features

- Mounted in the common domain
- On-chip chattering elimination circuit (Chattering elimination time can be set to be programmable)
- Measures to deal with multiple key presses (There is a restriction.)
- Level/edge-selectable internal interrupts
- Auto key scan is controllable
- Input or output bit numbers can be set to be programmable (maximum KEYIN7 to KEYIN0 and KEYOUT7 to KEYOUT0)
- KEYSC can be set as source of power wakeup

Figure 54.1 shows a block diagram of the key scan interface and represents the form of the key pin mode 6 (KEYIN7 to KEYIN0 and KEYOUT7 to KEYOUT0).

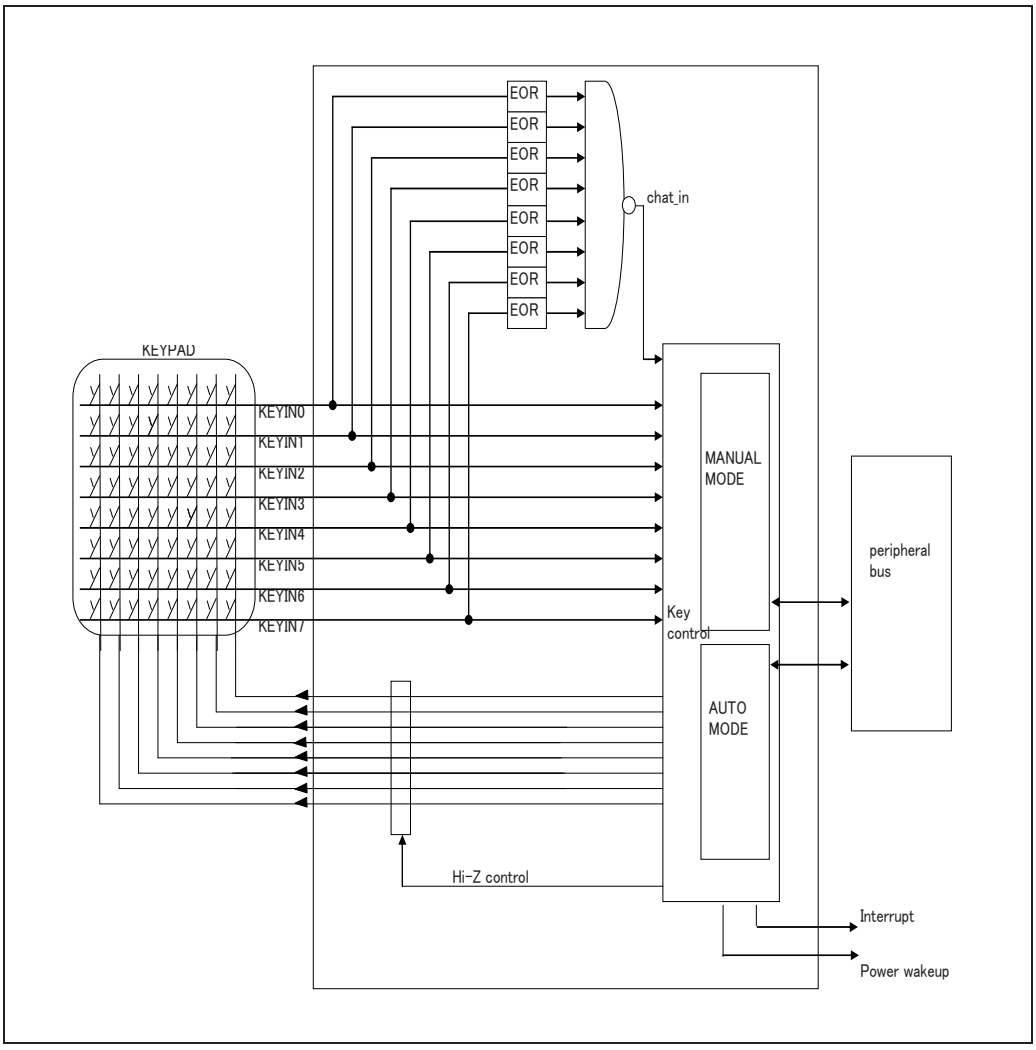

Figure 54.1 Block Diagram of Key Scan Interface (Key Pin Mode 6)

Note: The pull-up is done by GPIO setting.

54.2 Input/Output Pins

The pin configuration of the key scan interface is listed in table 54.1.

Table 54.1 Pin Configuration

Pin Name	Function	I/O	Description
KEYIN7 to KEYIN0	Input key scan interfaces 7 to 0	Input	Key scan interface for input
KEYOUT7 to KEYOUT0	Output key scan interfaces 7 to 0	Output	Key scan interface for output

54.3 Register Descriptions

Table 54.2 shows the KEYSC register configuration. Table 54.3 shows the register states in each operating mode.

Table 54.2 Register Configuration

Register Name	Abbreviation	R/W	Address*	Access Size
Manual key scan control register 1	M_KYCR1	R/W	H'E61B 0000 H'E71B 0000	16
Manual key scan control register 2	M_KYCR2	R/W	H'E61B 0004 H'E71B 0004	16
Manual key scan-in data register	M_KYINDR	R	H'E61B 0008 H'E71B 0008	16
Manual key scan-out data register	M_KYOUTDR	R/W	H'E61B 000C H'E71B 000C	16
Auto key scan control register 1	A_KYCR1	R/W	H’E61B0010 H’E71B0010	16
Auto key scan control register 2	A_KYCR2	R/W	H’E61B0014 H’E71B0014	16
Auto key scan control register 4	A_KYCR4	R/W	H’E61B001C H’E71B001C	16
Auto key scan control register 6	A_KYCR6	R/W	H’E61B0024 H’E71B0024	16
Auto key scan interrupt control register	A_KYIR	R/W	H’E61B0030 H’E71B0030	32
Auto key scan status register	A_KYSR	R/W	H’E61B0034 H’E71B0034	32
Auto key scan-in data register	A_KYINDR	R	H’E61B0038 H’E71B0038	16
Auto key scan-out data register	A_KYOUTDR	R/W	H’E61B003C H’E71B003C	16
Auto key scan data register L	A_KYSCDRL	R	H’E61B0040 H’E71B0040	32
Auto key scan data register H	A_KYSCDRH	R	H’E61B0044 H’E71B0044	32
Auto key scan data-touch register L	A_KYSCDTRL	R	H’E61B0048 H’E61B0048	32
Auto key scan data-touch register H	A_KYSCDTRH	R	H’E61B004C H’E71B004C	32

Auto key scan data-release register L	A_KYSCDRRL	R	H'E61B0050 H'E71B0050	32
Auto key scan data-release register H	A_KYSCDRRH	R	H'E61B0054 H'E71B0054	32
Auto key scan data-count register	A_KYSCDNUM	R/W	H'E61B0060 H'E71B0060	32

Note: * These registers can be accessed from both HPBC area (H'E6xx xxxx) and HPBD area (H'E7xx xxxx).

Note: *1 For details, refer to section 1-D Overview of reset.
*2 The value of bit KEYIF is undefined.

54.3.1 Manual key Scan Control Register 1 (M_KYCR1)

M_KYCR1 is a 16-bit readable/writable register that selects the functions of the key scan interface.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	KYMD[2:0]			KYOUT_IE	—	—	—	—	SCN[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	KYMD[2:0]	000	R/W	Key Pin Mode Set the KEYIN/KEYOUT pin to be used. 000: Use key pin mode 1 (KEYIN4 to KEYIN0 and KEYOUT5 to KEYOUT0 are available) 001: Use key pin mode 2 (KEYIN5 to KEYIN0 and KEYOUT4 to KEYOUT0 are available) 010: Use key pin mode 3 (KEYIN6 to KEYIN0 and KEYOUT3 to KEYOUT0 are available) 011: Use key pin mode 4 (KEYIN5 to KEYIN0 and KEYOUT5 to KEYOUT0 are available) 100: Use key pin mode 5 (KEYIN6 to KEYIN0 and KEYOUT5 to KEYOUT0 are available) 101: Use key pin mode 6 (KEYIN7 to KEYIN0 and KEYOUT7 to KEYOUT0 are available) 110: Setting prohibited 111: Setting prohibited
7	KYOUT_IE	0	R/W	Key Scan Standby Mode Cancel Enable When various standby modes are canceled by the key input, this bit should be set to 1. 0: Disables various standby modes to be canceled by the key input. 1: Enables various standby modes to be canceled by the key input.

Bit	Bit Name	Initial Value	R/W	Description
6 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	SCN[2:0]	000	R/W	Scan Timing Specify the chattering elimination time for the interrupt detection of the key scan interface. 000: RCLK/16 (0.49 ms) 001: RCLK/32 (0.98 ms) 010: RCLK/64 (1.95 ms) 011: RCLK/128 (3.91 ms) 100: RCLK/256 (7.81 ms) 101: RCLK/512 (15.63 ms) 110: RCLK/1024 (31.25 ms) 111: Chattering elimination circuit is invalid Note: To detect power wakeup operation in edge setting of KEY detect interrupt, It is necessary to do the chattering elimination setting besides 3'b111.

54.3.2 Manual key Scan Control Register 2 (M_KYCR2)

M_KYCR2 is a 16-bit readable/writable register that selects the functions of the key scan interface.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KYDIR7	KYDIR6	KYDIR5	KYDIR4	KYDIR3	KYDIR2	KYDIR1	KYDIR0	–	–	KYCPU.IE [1:0]		–	–	–	KEYIF
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	–
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	KYDIR7	0	R/W	Key Direction 7 The EOR result of the KEYIN7 pin and this bit is used to detect a KEYIN7 interrupt. Note: Values written at setting key pin modes 1 to 5 are ignored.
14	KYDIR6	0	R/W	Key Direction 6 The EOR result of the KEYIN6 pin and this bit is used to detect a KEYIN6 interrupt. Note: Values written at setting key pin modes 1, 2, and 4 are ignored.

Bit	Bit Name	Initial Value	R/W	Description
13	KYDIR5	0	R/W	Key Direction 5 The EOR result of the KEYIN5 pin and this bit is used to detect a KEYIN5 interrupt. Note: Values written at setting key pin mode 1 are ignored.
12	KYDIR4	0	R/W	Key Direction 4 The EOR result of the KEYIN4 pin and this bit is used to detect a KEYIN4 interrupt.
11	KYDIR3	0	R/W	Key Direction 3 The EOR result of the KEYIN3 pin and this bit is used to detect a KEYIN3 interrupt.
10	KYDIR2	0	R/W	Key Direction 2 The EOR result of the KEYIN2 pin and this bit is used to detect a KEYIN2 interrupt.
9	KYDIR1	0	R/W	Key Direction 1 The EOR result of the KEYIN1 pin and this bit is used to detect a KEYIN1 interrupt.
8	KYDIR0	0	R/W	Key Direction 0 The EOR result of the KEYIN0 pin and this bit is used to detect a KEYIN0 interrupt.
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	KYCPU_IE [1:0]	00	R/W	Key Internal Interrupt Enable Enable or disable internal interrupt requests to the CPU when there is key input. 00: Key interrupt requests disabled 01: Key interrupt requests enabled (level) 10: Key interrupt requests enabled (rising edge) 11: Key interrupt requests enabled (falling edge) Note: Detect point is chat_in of figure 54.1

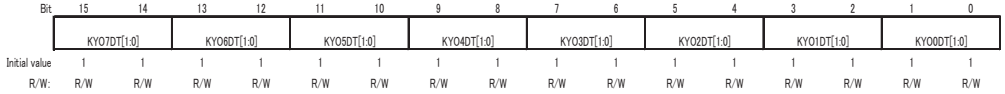
Bit	Bit Name	Initial Value	R/W	Description
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	KEYIF	Undefined (value before reset is retained)	R/W	Key Interrupt This flag is set when a key internal interrupt occurs. While this flag is 1, an internal interrupt request is sent to the CPU. (Only when M_KYCR2.KEYCPU_IE is set as rising edge and falling edge, It is held at 1 until overwritten by 0.) 0: No key interrupt occurs 1: A key interrupt occurs*

Note: * Case of level interrupts: When there is even one instance in which the result of the exclusive OR (EOR) of the KEYIN7 to KEYIN0 and the KYDIR7 to KYDIR0, respectively, is 0.

54.3.3 Manual key Scan-In Data Register (M_KYINDR)

M_KYINDR is a 16-bit read-only register that stores the data of pins KEYIN7 to KEYIN0. Bits KYI7DT to KYI0DT correspond respectively to pins KEYIN7to KEYIN0.

In order to use the key scan interface functions, the pin function controller should be used to set the pin function settings to the key scan interface pin side. Pins KEYIN7 to KEYIN0 are pulled-up in the internal LSI.



Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	KYI7DT	KYI6DT	KYI5DT	KYI4DT	KYI3DT	KYI2DT	KYI1DT	KYI0DT
Initial value	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0.
7	KYI7DT	0	R	State of Pin KEYIN7 (1 at high or 0 at low) Note: This bit is always read as 0 in key pin modes 1 to 5.
6	KYI6DT	0	R	State of Pin KEYIN6 (1 at high or 0 at low) Note: This bit is always read as 0 in key pin modes 1, 2, and 4.
5	KYI5DT	0	R	State of Pin KEYIN5 (1 at high or 0 at low) Note: This bit is always read as 0 in key pin mode 1.
4	KYI4DT	1	R	State of Pin KEYIN4 (1 at high or 0 at low)
3	KYI3DT	1	R	State of Pin KEYIN3 (1 at high or 0 at low)
2	KYI2DT	1	R	State of Pin KEYIN2 (1 at high or 0 at low)
1	KYI1DT	1	R	State of Pin KEYIN1 (1 at high or 0 at low)
0	KYI0DT	1	R	State of Pin KEYIN0 (1 at high or 0 at low)

54.3.4 Manual key Scan-Out Data Register (M_KYOUTDR)

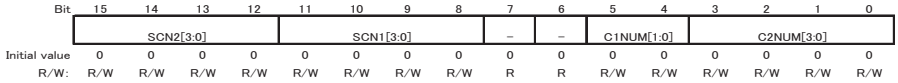
M_KYOUTDR is a 16-bit readable/writable register that stores the output data for pins KEYOUT7 to KEYOUT0. Bits KYO7DT to KYO0DT correspond respectively to pins KEYOUT7 to KEYOUT0.

In order to use the key scan interface functions, the pin function controller should be used to set the pin function settings to the key scan interface pin side.

Bit	Bit Name	Initial Value	R/W	Description
15, 14	KYO7DT[1:0]	11	R/W	KYOnDT: Control output data of pin KEYOUTn. (n = 0 to 7) 00: Low-level output 01: High-level output 10: High-impedance state 11: High-impedance state Note: KYO7DT: Values written at setting key pin mode 1 to 5 are ignored. KYO6DT: Values written at setting key pin mode 1 to 5 are ignored. KYO5DT: Values written at setting key pin mode 2 and key pin mode 3 are ignored. KYO4DT: Values written at setting key pin mode 3 are ignored.
13, 12	KYO6DT[1:0]	11	R/W	
11, 10	KYO5DT[1:0]	11	R/W	
9, 8	KYO4DT[1:0]	11	R/W	
7, 6	KYO3DT[1:0]	11	R/W	
5, 4	KYO2DT[1:0]	11	R/W	
3, 2	KYO1DT[1:0]	11	R/W	
1, 0	KYO0DT[1:0]	11	R/W	

54.3.5 Auto key Scan control register 1(A_KYCR1)

A_KYCR1 is a 16-bit readable/writable register that selects the functions of the key scan interface.



Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KEYEXT	–	–	–	–	KYMD[2:0]			–	–	–	MASK VALUE	–	SCN0[2:0]		
Initial value	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R/W	R	R	R	R	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	KEYEXT	0	R/W	KEY module operation mode can be set 0:MANUAL mode M_register-name can be used 1:AUTO mode A_register-name can be used
14 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	KYMD[2:0]	All 0	R/W	KEY pin mode Set the KEYIN/KEYOUT pin to be used. 000: Use key pin mode 1 (KEYIN4 to KEYIN0 and KEYOUT5 to KEYOUT0 are available) 001: Use key pin mode 2 (KEYIN5 to KEYIN0 and KEYOUT4 to KEYOUT0 are available) 010: Use key pin mode 3 (KEYIN6 to KEYIN0 and KEYOUT3 to KEYOUT0 are available) 011: Use key pin mode 4 (KEYIN5 to KEYIN0 and KEYOUT5 to KEYOUT0 are available) 100: Use key pin mode 5 (KEYIN6 to KEYIN0 and KEYOUT5 to KEYOUT0 are available) 101: Use key pin mode 6 (KEYIN7 to KEYIN0 and KEYOUT7 to KEYOUT0 are available)

				110: Setting prohibited 111: Setting prohibited
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	MASK VALUE	1	R/W	This bit value is used to value of Unused key pin.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2 to 0	SCN0[2:0]	000	R/W	Scan Timing 0 Specify the chattering elimination time for the the key scan interface. 000: RCLK/16 (0.49 ms) 001: RCLK/32 (0.98 ms) 010: RCLK/64 (1.95 ms) 011: RCLK/128 (3.91 ms) 100: RCLK/256 (7.81 ms) 101: RCLK/512 (15.63 ms) 110: RCLK/1024 (31.25 ms) 111: Chattering elimination circuit is invalid Note: To detect power wakeup operation in edge setting of KEY detect interrupt, It is necessary to do the chattering elimination setting besides 3'b111.

54.3.6 Auto key Scan control register 2(A_KYCR2)

A_KYCR2 is a 32-bit readable/writable register that set the each timing.

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	SCN2[3:0]	0000	R/W	Scan timing 2 Specify the wait timing at key scan. 0000: RCLK/16 (0.49ms) 0001: RCLK/32 (0.98ms) 0010: RCLK/64 (1.95ms) 0011: RCLK/128 (3.91ms) 0100: RCLK/256 (7.81ms) 0101: RCLK/512 (15.63ms) 0110: RCLK/1024 (31.25ms) 0111: RCLK/2048 (62.5ms) 1000: RCLK/4096 (125ms) 1001: RCLK/8192 (250ms) 1010: RCLK/16384 (500ms) 1011: RCLK/32768 (1s)
11 to 8	SCN1[3:0]	0000	R/W	Scan timing 1 Specify the measure timing per KEYOUT pin at AUTO KEY SCAN. It is time from setting KEYOUT to reading KEYIN. 0000: RCLK (30.5us) 0001: RCLK/2 (61.0us) ~ 1111: RCLK/16 (488us)

7 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5 to 4	C1NUM[1:0]	All 0	R/W	When key data after AUTO KEY SCAN is same as this bits value times, it is used as temporary valid key data. 00: 1 times 01: 2 times 10: 3 times 11: 4 times
3 to 0	C2NUM[3:0]	All 0	R/W	When temporary valid key data is different from last valid key data and temporary valid key data is same as this bits value times, it is used as valid key data. 0000: setting prohibited 0001: 1 times ~ 1111: 15 times

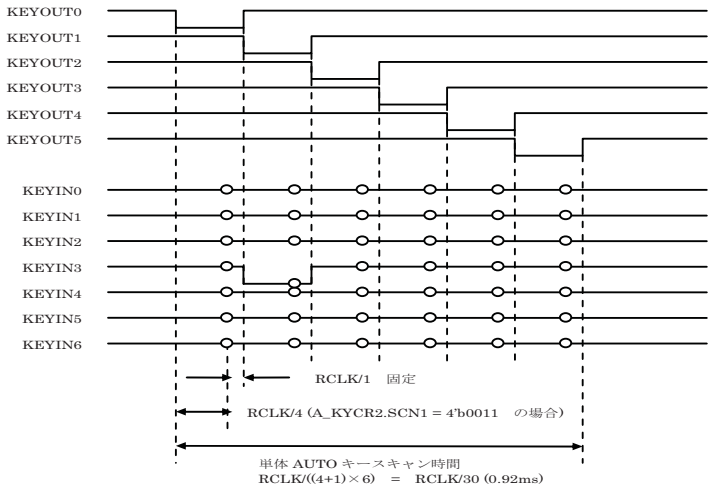


Figure 54.2 example of AUTO KEY SCAN TIMING

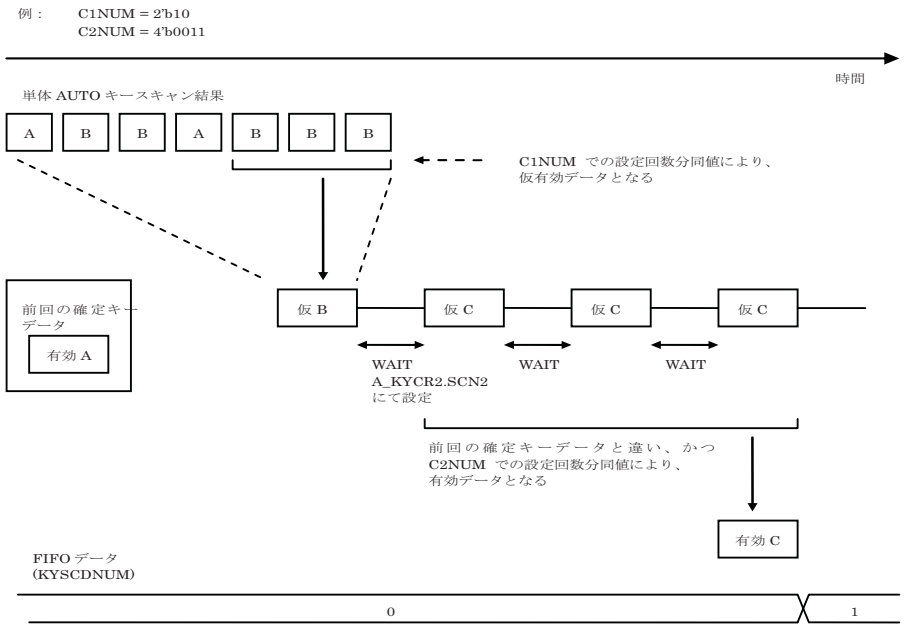

Figure 54.3 Flow until fixing valid data

54.3.7 Auto key Scan control register 4(A_KYCR4)

A_KYCR4 is a 16-bit readable/writable register that selects the functions of the key scan interface.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	–	–	–	–	–	–	–	–	–	–	–	NOFIFO	–	AUTO LPSC	–	AUTOKS
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W

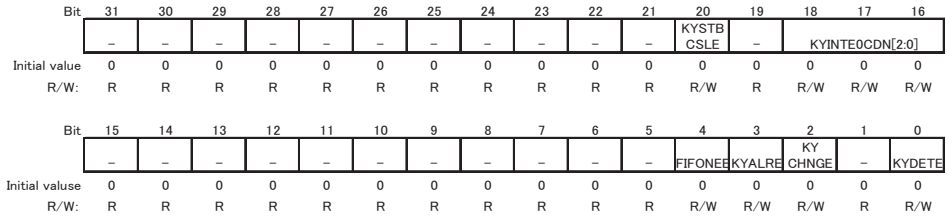
Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

4	NOFIFO	0	R/W	Disable FIFO of Key scan data 0:FIFO enable 1:FIFO disable When this bit is 1 and valid data is acquired, A_KYSCFRH/A_KYSCDRL is always updated.
3	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	AUTOLPC	0	R/W	AUTO Key scan loop enable When this bit is written 1, until key is released, valid key data is acquired after key is detected.
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	AUTOKS	0	R/W	AUTO key scan enable When this bit is written 1, valid key data is acquired only once.

Note: Don't write 1 to both AUTOLPC and AUTOKS at same time.

54.3.8 Auto key Scan control register 6(A_KYCR6)

A_KYCR6 is a 16-bit readable/writable register that selects the functions of the key scan interface.



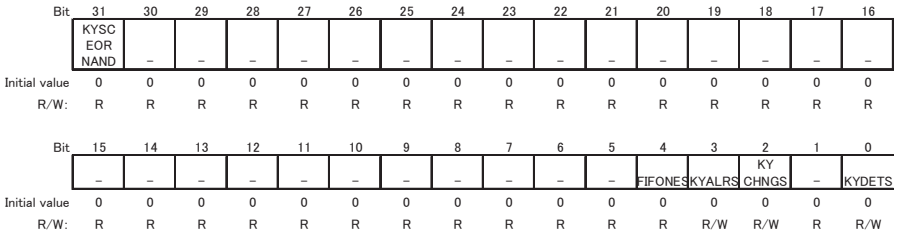
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KY DIR7	KY DIR6	KY DIR5	KY DIR4	KY DIR3	KY DIR2	KY DIR1	KY DIR0	–	–	–	–	–	–	–	–
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description

15	KYDIR7	0	R/W	KEY Direction 7 The EOR result of the KEYIN7 pin and this bit is used to detect a KEYIN7 interrupt. Note: Values written at setting key pin modes 1 to 5 are ignored.
14	KYDIR6	0	R/W	KEY Direction 6 The EOR result of the KEYIN6 pin and this bit is used to detect a KEYIN6 interrupt. Note: Values written at setting key pin modes 1, 2, and 4 are ignored.
13	KYDIR5	0	R/W	KEY Direction 5 The EOR result of the KEYIN5 pin and this bit is used to detect a KEYIN5 interrupt. Note: Values written at setting key pin modes 1 are ignored.
12	KYDIR4	0	R/W	KEY Direction 4 The EOR result of the KEYIN4 pin and this bit is used to detect a KEYIN4 interrupt.
11	KYDIR3	0	R/W	KEY Direction 3 The EOR result of the KEYIN3 pin and this bit is used to detect a KEYIN3 interrupt.
10	KYDIR2	0	R/W	KEY Direction 2 The EOR result of the KEYIN2 pin and this bit is used to detect a KEYIN2 interrupt.
9	KYDIR1	0	R/W	KEY Direction 1 The EOR result of the KEYIN1 pin and this bit is used to detect a KEYIN1 interrupt.
8	KYDIR0	0	R/W	KEY Direction 0 The EOR result of the KEYIN0 pin and this bit is used to detect a KEYIN0 interrupt.

7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

54.3.9 Auto key scan interrupt control register (A_KYIR)



A_KYIR is a 32-bit readable/writable register that selects the functions related to interrupt.

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	KYSTB CSLE	0	R/W	Power wakeup enable When power wakeup is canceled by the key input, this bit should be set to 1. 0: Disables power wakeup to be canceled by the key input. 1: Enables power wakeup to be canceled by the key input.
19	—	0	R	Reserved These bits are always read as 0. The write value

				should always be 0.
18 to 16	KYINTE 0CDN[2: 0]	000	R/W	Condition of KEY detect interrupt Indicate condition of KEY detection 000: Key detect requests disabled 001: Key detect request enabled(level) 010: Key detect request enabled(rising edge) 011:Key detect request enabled(falling edge) 100: Key detect request enabled(both edge) 101 to 111:Reserved
15 to 5	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	FIFONE E	0	R/W	FIFO NotEmpty interrupt enable 0: FIFO interrupt disabled 1: interrupt is enabled
3	KYALR E	0	R/W	KEY all-release interrupt enable 0: key definition interrupt disabled 1: key definition interrupt enabled
2	KYCHN GE	0	R/W	KEY change interrupt 0: KEY change interrupt disabled 1: KEY change interrupt enabled
1	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

0	KYDETE	0	R/W	KEY detect interrupt 0: KEY detect interrupt disabled 1: KEY detect interrupt enabled

54.3.10 Auto key scan status register (A_KYSR)

A_KYSR is a 32-bit readable/writable register that represents interrupt status.

Bit	Bit Name	Initial Value	R/W	Description
31	KYSCEORNAND	All 0	R	Indicate Key detect result The write data should be always 0.
30 to 5	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	FIFONES	0	R	FIFONotEmpty 0:There is not data in FIFO 1:There is data in FIFO Although this bit can not be written, 1 is not recommended to be written. When A_KYCR4.NOFIFO is 1, this bit Always Display 0.

3	KYALRS	0	R/W	KEY all release 0: No KEY all release has been detected 1: KEY all release has been detected This bit can be cleared by written 0. 1 can not be written.
2	KYCHANGS	0	R/W	KEY change detect interrupt 0: No KEYSCAN change detect interrupt has been detected 1: KEYSCAN change detect interrupt has been detected This bit can be cleared by written 0. 1 can not be written.
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	KYDETS	0	R/W	KEY detect interrupt 0: No KEY detect interrupt has been detected 1: KEY detect interrupt has been detected This bet should be cleared by software, as long as A_HYIR.KYINTECDN[2:0] is rising edge, falling edge and both edge. This bit can be cleared by written 0. 1 can not be written.

54.3.11 Auto key scan-in data register (A_KYINDR)

A_KYINDR is a 16-bit read-only register that stores the data of pins KEYIN7 to KEYIN0. Bits KYI7DT to KYI0DT correspond respectively to pins KEYIN7 to KEYIN0.

In order to use the key scan interface functions, the pin function controller should be used to set the pin function settings to the key scan interface pin side. Pins KEYIN7 to KEYIN0 are pulled-up in the internal LSI.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

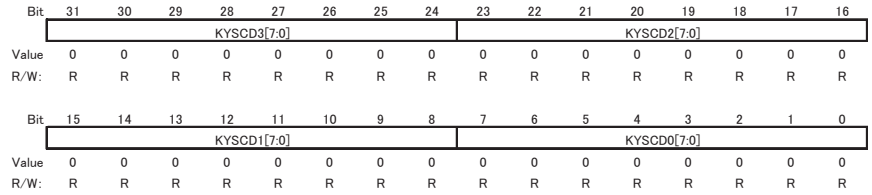
54.3.12 Auto key Scan-Out Data Register (A_KYOUTDR)

A_KYOUTDR is a 16-bit readable/writable register that stores the output data for pins KEYOUT7 to KEYOUT0. Bits KYO7DT to KYO0DT correspond respectively to pins KEYOUT7 to KEYOUT0.

In order to use the key scan interface functions, the pin function controller should be used to set the pin function settings to the key scan interface pin side.



M_KYOUTDR

Bit	Bit Name	Initial Value	R/W	Description
15,14	KYO7DT[1:0]	11	R/W	KYOnDT: Control output data of pin KEYOUTn. (n = 0 to 7) 00: Low-level output 01: High-level output 10: High-impedance state 11: High-impedance state Note: value is reflected by all key mode.
13,12	KYO6DT[1:0]	11	R/W

1, 0	KYO0DT[1:0]	11	R/W	

54.3.13 Auto key scan data register L (A_KYSCDRL)

A_KYOUTDR is a 32-bit read-only register that stores the scanned data of KEYOUT 3 to 0.

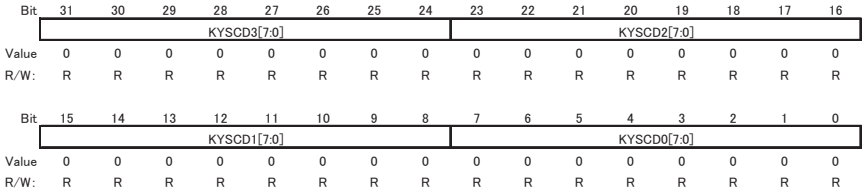
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	KYSC3[7:0]	All 0	R	KYOUT3 scan data These bits store Inverted value of KEYIN7 to KEYIN0. Only KEYOUT3 is low level, and other KEYOUT is Hi-Z. Bit corresponding to place where key was pushed becomes 1.
23 to 16	KYSC2[7:0]	All 0	R	KYOUT2 scan data These bits store Inverted value of KEYIN7 to KEYIN0. Only KEYOUT2 is low level, and other KEYOUT is Hi-Z. Bit corresponding to place where key was pushed becomes 1.
15 to 8	KYSC1[7:0]	All 0	R	KYOUT1 scan data These bits store Inverted value of KEYIN7 to KEYIN0. Only KEYOUT1 is low level, and other KEYOUT is Hi-Z. Bit corresponding to place where key was pushed becomes 1.
7 to 0	KYSC1[7:0]	All 0	R	KYOUT0 scan data These bits store Inverted value of KEYIN7 to KEYIN0. Only KEYOUT0 is low level, and other KEYOUT is Hi-Z. Bit corresponding to place where key was pushed becomes 1.

54.3.14 Auto key scan data register H (A_KYSCDRH)

A_KYOUTDR is a 32-bit read-only register that stores the scanned data of KEYOUT 3 to 0.

Number of FIFO (KYSCDNUM) is reduced by reading this register.

Note: Read this register after reading A_KYSCDRL.



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

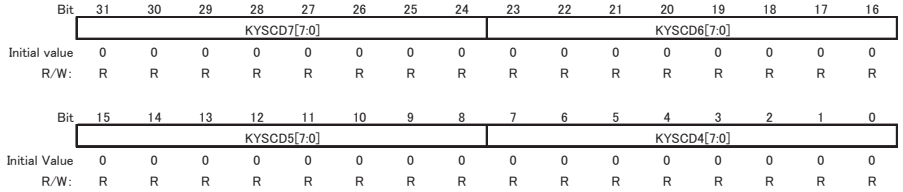
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	KYSC7[7:0]	All 0	R	KYOUT7 scan data These bits store Inverted value of KEYIN7 to KEYIN0. Only KEYOUT7 is low level, and other KEYOUT is Hi-Z. Bit corresponding to place where key was pushed becomes 1.
23 to 16	KYSC6[7:0]	All 0	R	KYOUT6 scan data These bits store Inverted value of KEYIN7 to KEYIN0. Only KEYOUT6 is low level, and other KEYOUT is Hi-Z. Bit corresponding to place where key was pushed becomes 1.
15 to 8	KYSC5[7:0]	All 0	R	KYOUT5 scan data These bits store Inverted value of KEYIN7 to KEYIN0. Only KEYOUT5 is low level, and other KEYOUT is Hi-Z. Bit corresponding to place where key was pushed becomes 1.
7 to 0	KYSC4[7:0]	All 0	R	KYOUT4 scan data These bits store Inverted value of KEYIN7 to KEYIN0. Only KEYOUT4 is low level, and other KEYOUT is Hi-Z. Bit corresponding to place where key was pushed becomes 1.

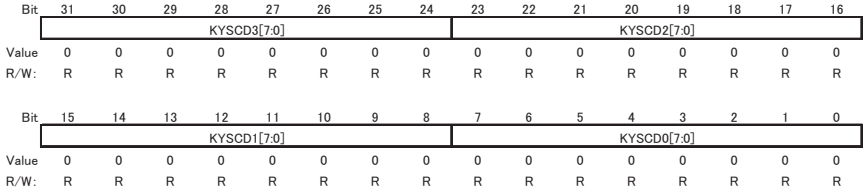
54.3.15 Auto key scan data-touch register L (A_KYSCDTRL)



A_KYSCDTRL is a 32-bit read-only register. After data acquisition of KEYSCAN, compared with the last data, the bit corresponding to the key touch stores 1. In case of A_KYCR4.NOFIFO being 1'b0, this register is valid.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	KYSCD3[7:0]	All 0	R	KYOUT3 scan data After data acquisition of KEYOUT3, compared with the last data, the bit corresponding to the key touch stores 1.
23 to 16	KYSCD2[7:0]	All 0	R	KYOUT2 scan data After data acquisition of KEYOUT2, compared with the last data, the bit corresponding to the key touch stores 1.
15 to 8	KYSCD1[7:0]	All 0	R	KYOUT1 scan data After data acquisition of KEYOUT1, compared with the last data, the bit corresponding to the key touch stores 1.
7 to 0	KYSCD0[7:0]	All 0	R	KYOUT0 scan data After data acquisition of KEYOUT0, compared with the last data, the bit corresponding to the key touch stores 1.

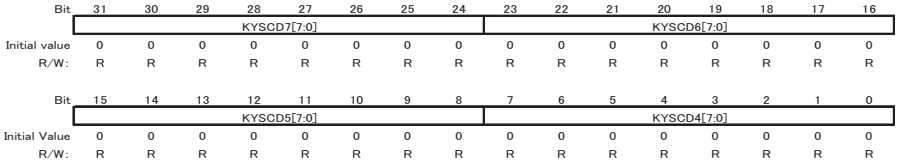
54.3.16 Auto key scan data-touch register H (A_KYSCDTRH)



A_KYSCDTRH is a 32-bit read-only register. After data acquisition of KEYSCAN, compared with the last data, the bit corresponding to the key touch stores 1. In case of A_KYCR4.NOFIFO being 1'b0, this register is valid.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	KYSC7[7:0]	All 0	R	KYOUT7 scan data After data acquisition of KEYOUT7, compared with the last data, the bit corresponding to the key touch stores 1.
23 to 16	KYSC6[7:0]	All 0	R	KYOUT6 scan data After data acquisition of KEYOUT6, compared with the last data, the bit corresponding to the key touch stores 1.
15 to 8	KYSC5[7:0]	All 0	R	KYOUT5 scan data After data acquisition of KEYOUT5, compared with the last data, the bit corresponding to the key touch stores 1.
7 to 0	KYSC4[7:0]	All 0	R	KYOUT4 scan data After data acquisition of KEYOUT4, compared with the last data, the bit corresponding to the key touch stores 1.

54.3.17 Auto key scan data-release register L (A_KYSCDRRL)

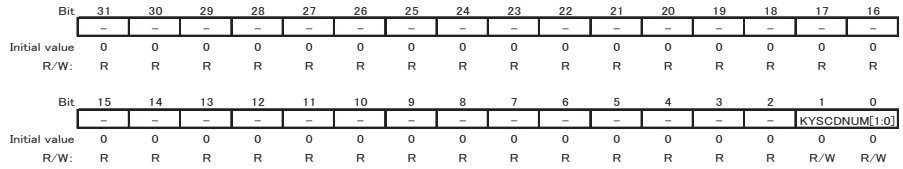


A_KYSCDRRL is a 32-bit read-only register. After data acquisition of KEYSCAN, compared with the last data, the bit corresponding to the key-release stores 1. In case of A_KYCR4.NOFIFO being 1'b0, this register is valid.

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	KYSCD3[7:0]	All 0	R	KYOUT3 scan data After data acquisition of KEYOUT3, compared with the last data, the bit corresponding to the key-release stores 1.
23 to 16	KYSCD2[7:0]	All 0	R	KYOUT2 scan data After data acquisition of KEYOUT2, compared with the last data, the bit corresponding to the key-release stores 1.
15 to 8	KYSCD1[7:0]	All 0	R	KYOUT1 scan data After data acquisition of KEYOUT1, compared with the last data, the bit corresponding to the key-release stores 1.
7 to 0	KYSCD0[7:0]	All 0	R	KYOUT0 scan data After data acquisition of KEYOUT0, compared with the last data, the bit corresponding to the key-release stores 1.

54.3.18 Auto key scan data-release register H (A_KYSCDRRH)

A_KYSCDRRH is a 32-bit read-only register. After data acquisition of KEYSCAN, compared with the last data, the bit corresponding to the key-release stores 1. In case of A_KYCR4.NOFIFO being 1'b0, this register is valid.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	KYSCD3[7:0]	All 0	R	KYOUT3 scan data After data acquisition of KEYOUT3, compared with the last data, the bit corresponding to the key-release stores 1.
23 to 16	KYSCD2[7:0]	All 0	R	KYOUT2 scan data After data acquisition of KEYOUT2, compared with the last data, the bit corresponding to the key-release stores 1.
15 to 8	KYSCD1[7:0]	All 0	R	KYOUT1 scan data After data acquisition of KEYOUT1, compared with the last data, the bit corresponding to the key-release stores 1.
7 to 0	KYSCD0[7:0]	All 0	R	KYOUT0 scan data After data acquisition of KEYOUT0, compared with the last data, the bit corresponding to the key-release stores 1.

54.3.19 Auto key scan data-count register (A_KYSCDNUM)

A_KYSCDNUM is a 32-bit readable/writable register that represents the number of data preserved in FIFO. Even if what value is written, FIFO is cleared. In case of A_KYCR4.NOFIFO being 1'b0, this register is valid.

IM

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
1 to 0	KYSCDNUM[1:0]	All 0	R/W	Scan data number 00: 0 01: 1 11: 2 These bits can be cleared by writing any value.

54.4 Operation

54.4.1 Introduction

This module KEYSC install MANUAL and AUTO mode. These modes are selected by A_KYCR1.KEYEXT.

54.4.2 AUTO MODE operation

(1) AUTO KEY SCAN operation

1. Setting example

Table 54.4 Setting example of AUTO KEY SCAN

Register	Setting value	contents
A_KYCR1	16'h8400	[15] KEYEXT = 1'b1:AUTO mode* [10:8] KYMD[2:0] = 3'b101:KEY pin mode6 [2:0] SCN0[2:0] = 3'b000:key detect chattering elimination RCLK/16(0.49ms)
A_KYCR2	16'h7201	[15:12] SCN2[3:0] = 4'b0111:WAIT per key scan RCLK/2048(62.5ms) [11:8] SCN1[3:0] = 4'b0010:WAIT per KEYOUT setting RCLK/4(122us) [3:0] C2NUM[3:0] = 4'b0001
A_KYCR4	16'h0001	[0] AUTOKS = 1'b1: Excute AUTO KEY SCAN *
A_KYCR6	16'h0000	[14:8] KYDIR[6:0] = 7'b00
A_KYOUTDR	16'h0000	[11:0] KYO<7 to 0>DT[1:0] = H'0000: All output data of KEYOUTn is low level

A_KYIR	32'h00000010	[4] FIFONEE = 1'b1:FIFO interrupt*

Note: * When AUTO MODE, must be set as shown in the above-mentioned.

Others are arbitrary.

Executing AUTO KEY SCAN (AUTOKS = 1'b1) have to be after all register setting is finish.

2. Operation flow by setting example

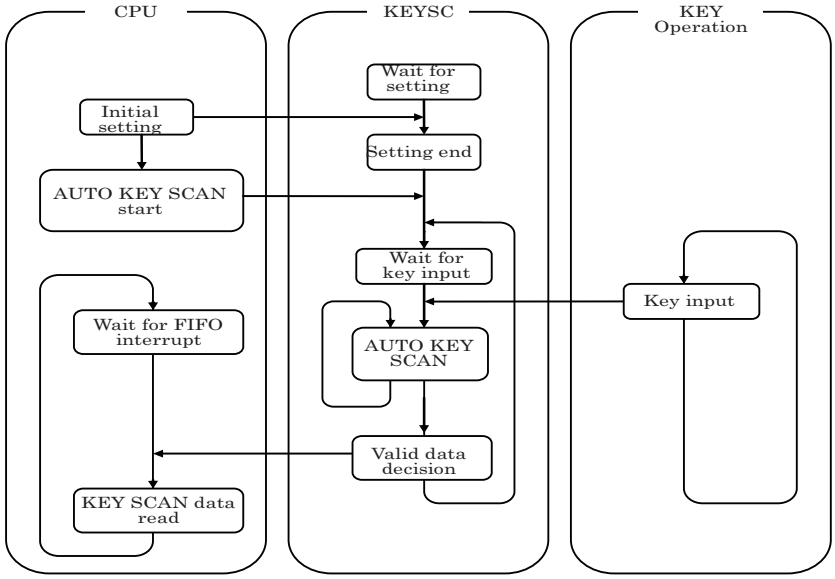


Figure 54.4 AUTO KEY SCAN operation flow

After CPU initializes KEYSC register, CPU starts AUTO KEY SCAN by A_KYCR4.AUTOKS bit and shifts to FIFO INTERRUPT WAIT state of KEY scan-in data. KEYSC module shifts to KEY INPUT WAIT state when AUTO KEY SCAN is started. If KEYSC module in KEY INPUT WAIT state detects KEY input, KEYSC module shifts to AUTO KEY SCAN state and starts KEY SCAN. When valid key data is decided, AUTO KEY SCAN returns to KEY INPUT WAIT state. KEY SCAN is continued repeatedly until all KEY is released. At this time, KEYSC module shifts AUTO KEY SCAN state again if KEY has been pushed. In order to request reading key scan-in data to CPU, KEYSC module generates FIFO interrupt after KEYSC module stores valid key data in FIFO. CPU reads KEY scan-in data until FIFO interrupt is negated. When all KEY is released, KEYSC module returns INPUT WAIT state after valid data is decided.

(2) AUTO KEY SCAN LOOP operation

1. Setting example

Register	Setting value	Contents
A_KYCR1	16'h8400	[15] KEYEXT = 1: AUTO mode* [10:8] KYMD[2:0] = 3'b101: KEY pin mode 6 [2:0] SCN0[2:0] = 3'b000: key detect chattering elimination RCLK/16(0.49ms)
A_KYCR2	16'h7201	[15:12] SCN2[3:0] = 4'b0111: WAIT per key scan [11:8] SCN1[3:0] = 4'b0010: WAIT per KEYOUT setting [3:0] C2NUM[3:0] = 4'b0001
A_KYCR4	16'h0004	[4] AUTOLPSC = 1'b1:Excute loop scan*
A_KYCR6	16'h0000	[14:8] KYDIR[7:0] = 7'h00
A_KYOUTDR	16'h0000	[11:0] KYO<7 to 0>DT[1:0]: All output data of KEYOUTn is low level
A_KYIR	32'h00000010	[4] FIFONEE = 1'b1:FIFO interrupt*

Note: * When Auto mode, must be set as shown in the above-mentioned.

Others are arbitrary.

Executing AUTO KEY SCAN LOOP (AUTOLPSC = 1'b1) have to be after all register setting is finish.

2. Operation flow by setting example

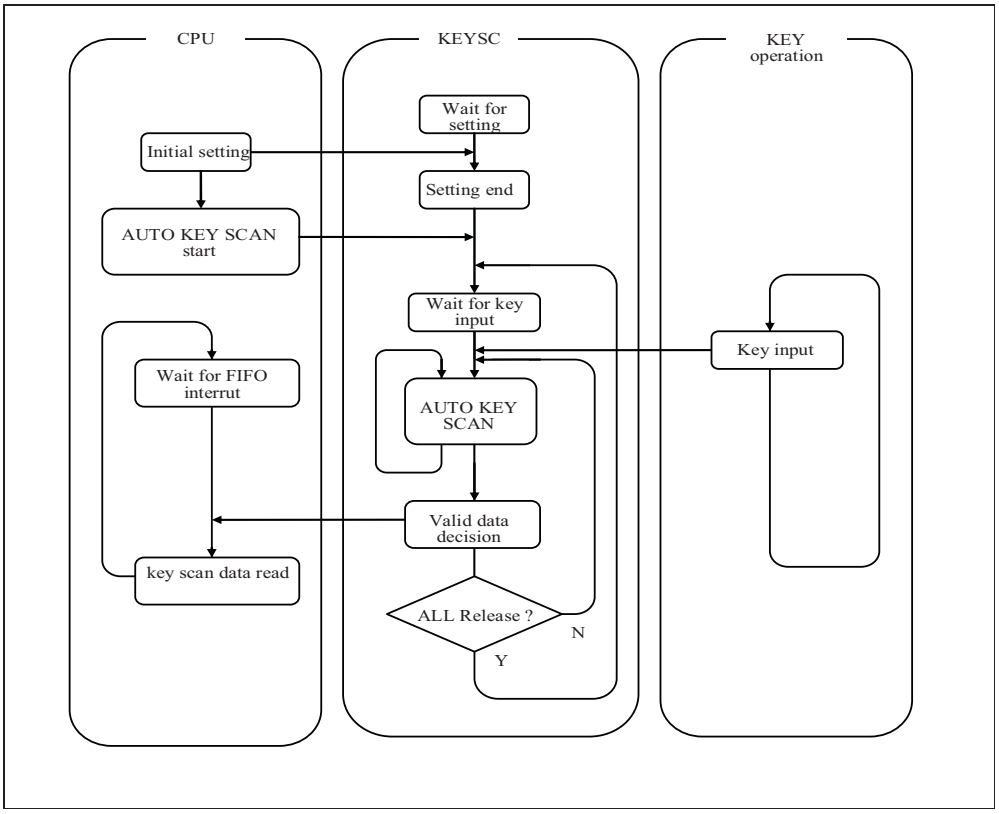

Figure 54.5 AUTO KEY SCAN LOOP operation flow

After CPU initializes KEYSC register, CPU starts AUTO KEY SCAN LOOP by A_KYCR4.AUTOLPSC bit and shifts to FIFO INTERRUPT WAIT. KEYSC module shifts to KEY INPUT WAIT state when AUTO KEY SCAN LOOP is started. If KEYSC module in KEY INPUT WAIT state detects KEY input, KEYSC module shifts to AUTO KEY SCAN LOOP state and starts KEY scan. When valid key data is decided, if its value is all-release, KEYSC module shifts to KEY INPUT WAIT state otherwise KEY SCAN is executed again. In order to request reading key scan-in data to CPU, KEYSC module generates FIFO interrupt after KEYSC module stores valid key data in FIFO. CPU reads KEY scan-in data until FIFO interrupt is negated. When all KEY is released, KEYSC module repeats KEY SCAN after valid data is decided and its value is all-release. KEYSC module returns INPUT WAIT state when valid data is all-release.

54.4.3 Interrupt and Power Wakeup at AUTO mode

Figure 54.6 shows diagrammatic illustration of interrupt and power wakeup at AUTO mode.

There is four interrupts: KEY detect interrupt, KEY change interrupt, KEY all release interrupt and FIFO interrupt.

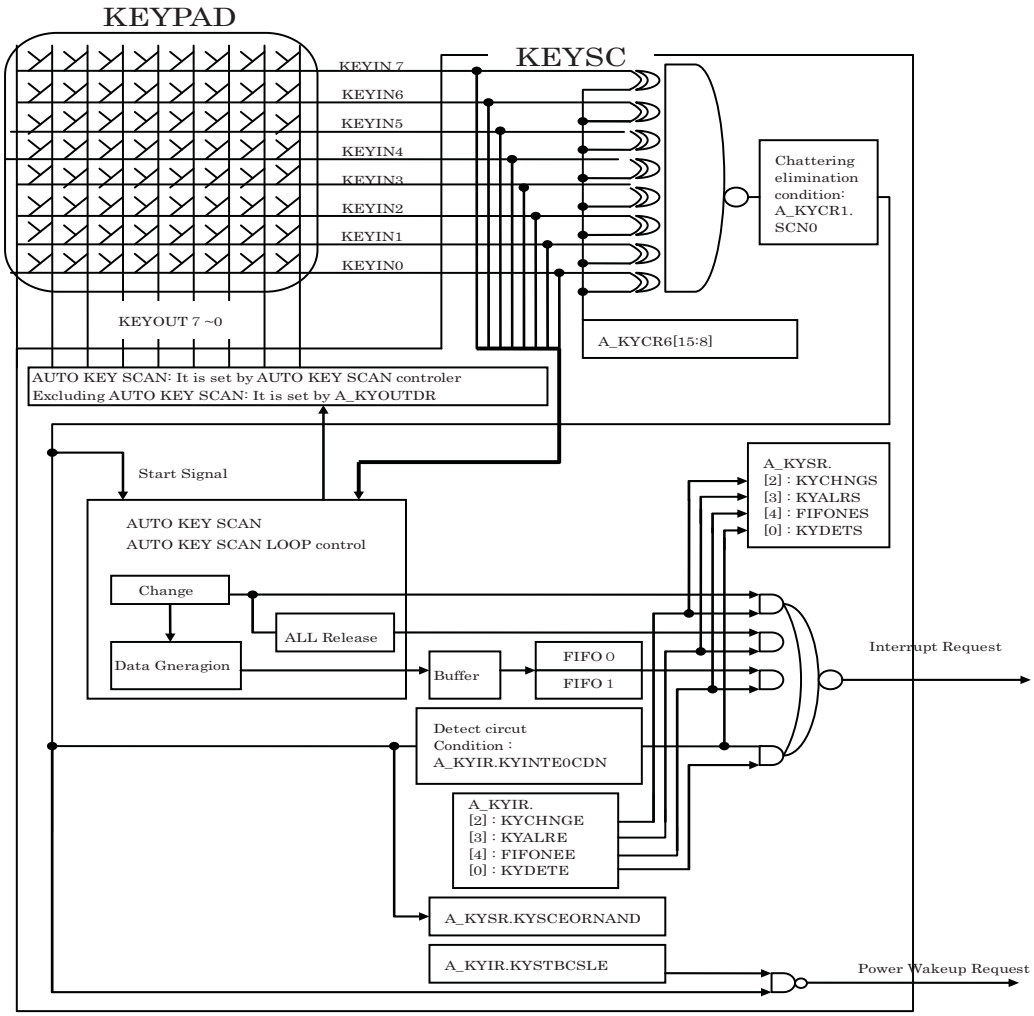

Figure 54.6 diagrammatic illustration of interrupt and power wakeup at AUTO mode

(1) Interrupt

1. KEY detect interrupt

It is used to generate interrupt when the key is pushed without using AUTO KEY SCAN mode and AUTO KEY SCAN LOOP mode. Interrupt can be generated, when key is pushed once or more (setting example: A_KYOUTDR = H'0000, A_KYCR6 = H'0000, A_KYIR = H'00010001). To clear interrupt except for level setting, writing 0 to A_KYSR.KYDETS and reading it repeatedly is needed until 0 is reflected in it.

2. KEY change interrupt

A_KYSR.KYCHNGS stores 1 at AUTO KEY SCAN mode and AUTO KEY SCAN LOOP mode, when AUTO key scan data is different from last one. AUTO key scan data is stored in A_KYSCDRL and A_KYSCDRH. Reading data is needed after WAIT until A_KYSCDNUM store figure excluding 0, because time that data is reflected in that register is slower than time that interrupt is generated. To clear interrupt, writing 0 to A_KYSR.KYCHNGES and reading it repeatedly is needed until 0 is reflected in it.

3. KEY all release interrupt

A_KYSR.KYALRS stores 1 at AUTO KEY SCAN mode and AUTO KEY SCAN LOOP mode, when AUTO key scan data is different from last data and key is all released. AUTO key scan data is stored in A_KYSCDRL and A_KYSCDRH. Reading data is needed after WAIT until A_KYSCDNUM store figure excluding 0, because time that data is reflected in that register is slower than time that interrupt is generated. To clear interrupt, writing 0 to A_KYSR.KYCHNGES and reading it repeatedly is needed until 0 is reflected in it.

4. FIFO interrupt

A_KYSR.FIFONES stores 1 at AUTO KEY SCAN mode and AUTO KEY SCAN LOOP mode, when AUTO key scan data is different from last data. AUTO key scan data is stored in A_KYSCDRL and A_KYSCDRH. Data can be read at once after interrupt has generated. When data is read and the number of data in FIFO becomes 0, A_KYSR.FIFONES becomes 0 automatically. Writing 0 in A_KYSR.FIFONES is not necessary.

(2) Power wakeup

Power wakeup and interrupt can be processed by using KEY detect interrupt. The setting example is shown below.

Register	Setting value	Contents
A_KYSR1	16'h8400	[15] KEYEXT = 1: AUTO mode *1 [10:8] KYMD[2:0] = 3'b100:KEY pin mode 5 [2:0] SCN0[2:0] = 3'b000: key detect chattering elimination RCLK/16(0.49ms) *2
A_KYCR6	16'h0000	[14:8] KYDIR[6:0] = 7'h00
A_KYOUTDR	16'h0000	[11:0]KYO<5 to 0>DT[1:0] = H'0000:all output data low level of KEYOUTn *1
A_KYIR	32'h00120004	[20] KYSTBCSLE = 1'b1:key scan power wakeup enable *1 [18:16] KYINTE0CDN[2:0] = 3'b010:rising edge *1 [0] KYDETE = 1'b1:KEY detect interrupt

*1 These values in this example are just for reference.Only set KYSTBCSLE = 1'b1 is mandatory.

*2 Set SCN0[2:0] = 3'b111 is prohibited.

When key is pushed, power wakeup and interrupt is generated. Writing 0 to A_KYSR.KYDETS and reading it repeatedly is needed until 0 is reflected in it.

54.4.4 Handling of Data at AUTO KEY SCAN MODE and AUTO KEY SCAN LOOP MODE

Detected key data is stored to the buffer once at AUTO KEY SCAN MODE and AUTO KEY SCAN LOOP MODE. The buffer is always a superscription. FIFO controller confirms (1) and (2) and takes data stored in the buffer into FIFO. Figure 54.7 shows flow of data.

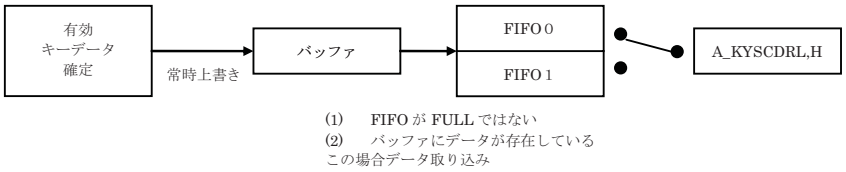

Figure 54.7 flow of data

54.4.5 About output of all key release data at AUTO KEY SCAN and AUTO KEY SCAN LOOP

(1) Data of the first time

Although the sequence is executed at AUTO KEY SCAN and AUTO KEY SCAN LOOP when key is pushed, if key is released while valid data is decided, it is likely to fix it as all data release, though it is data of the first time.

(2) After detecting all key release

Start signal of sequence at AUTO KEY SCAN and AUTO KEY SCAN LOOP is signal (KYSCEORNAND) after all key detect chattering elimination. When chattering elimination setting is done, as for KYSCEORNAND, the timing slows more than the actual key release.

Figure 54.8 shows all key release detect.

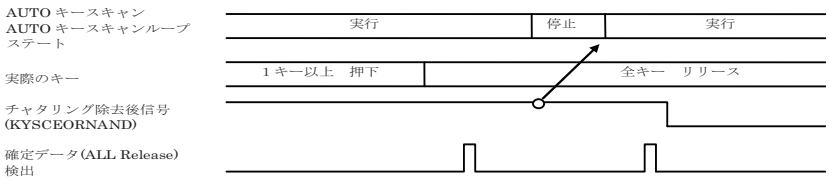

Figure 54.8 all key release detect

54.4.6 When AUTO KEY SCAN and AUTO KEY SCAN LOOP is released

To release AUTO KEY SCAN and AUTO KEY SCAN LOOP MODE, writing 0 in A_KYCR4.AUTOLPSC or A_KYCR4.AUTOKS is needed. However the limiting conditions exist as follow.

(1) Setting prohibition period until the next restarting

Wait (single AUTO KEY SCAN operation time (RCLK/(((A_KYCR2.SCN1 + 1) + 1 * 8)) is needed.

(2) Data annulment after mode is released

After AUTO KEY SCAN MODE and AUTO KEY SCAN LOOP MODE are released, data may be stored in FIFO. Therefore setting of interrupt inhibit is needed. Before restart, FIFO clear is needed by writing to A_KYSCDNUM.

54.4.7 External Pin Control

It is necessary to set the pull-up to KEYIN pins by GPIO setting. However, when the BSCMD pin is 1, KEYIN will automatically becomes pull-up

54.4.8 Chattering Elimination

By setting the M_KYCR1.SCN bit and A_KYCR1.SCN0, chattering elimination in key interrupt detection is possible. Through this chattering elimination, if a key is pressed continuously for longer than a length of time set by the SCN bits, a continuous key press is recognized. Thereafter, when a state in which a key is released continues for longer than a length of time set by the SCN bits, the key is recognized as having been released.

54.4.9 Detection of Multiple Key Presses

While the KYOUTDR setting is used to set the KEYOUT7 to KEYOUT0 pins to the low-level output in order one at a time, and with the other seven pins at high impedance, multiple key presses can be detected by reading KYINDR.

54.4.10 Interrupt generation not anticipated after initial setting of KEYSC

Only once immediately after beginning of KEYSC operation, though the key is not pushed, interrupt might be generated mis-recognizing the key push. To avoid it, by using CPGA software reset register, KEYSC reset is needed before KEYSC initial setting.

54.4.11 Examples of Use of MANUAL MODE

(1) Level Interrupt (KYCPU_IE1 and KYCPU_IE0 = B'01)

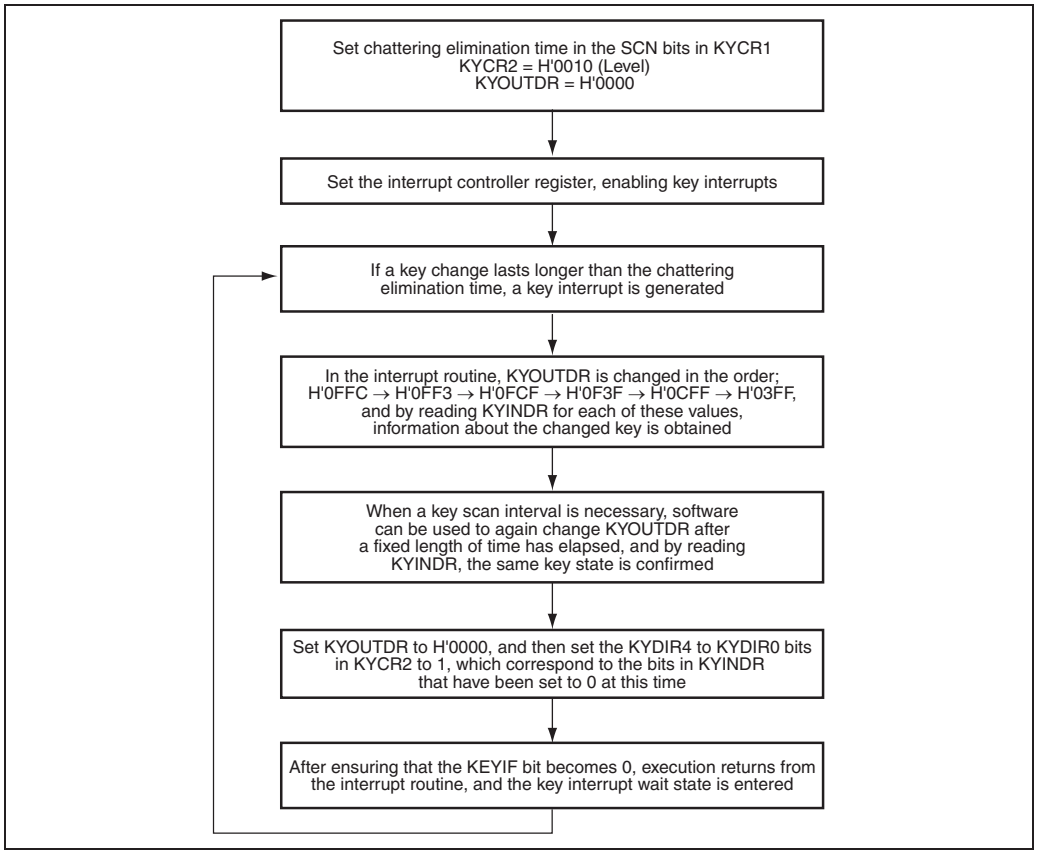

Figure 54.9 Example of Key Scan Using Level Interrupt (Key Pin Mode 1)

(2) Edge Interrupt (KYCPU_IE1 and KYCPU_IE0 = B'1x)

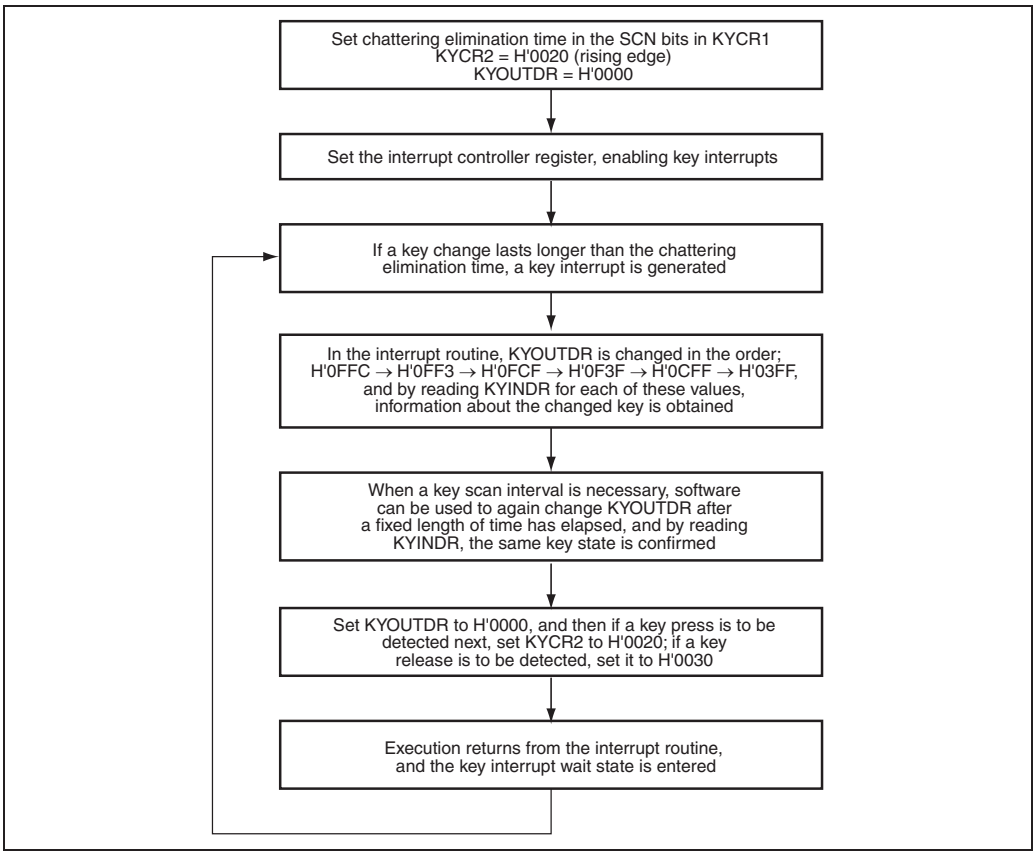

Figure 54.10 Example of Key Scan Using Edge Interrupt (Key Pin Mode 1)

Section 55 IrDA Controller (IrDA)

The IrDA controller (IrDA) controls infrared data communication conforming to IrDA PHY standard 1.1/1.3 in three different speed modes: serial infrared (SIR)-UART (2,400 bits to 115.2 kbits/s) mode, medium infrared (MIR) (0.576 Mbits/s or 1.152 Mbits/s) mode, and fast infrared (FIR) (4.0 Mbits/s) mode.

The IrDA incorporates modules such as an SIR-UART engine, an MIR&FIR engine, a cyclic redundancy check (CRC) engine, a buffer RAM, and an interrupt controller. The SIR-UART engine controls communication in SIR-UART mode and the MIR&FIR engine controls communication in MIR and FIR modes.

The buffer RAM holds one frame of transmit data or up to 16 frames of received data.

In transmission, when one frame of data stored in the buffer RAM has been completely transmitted, transmission is disabled, notifying the end of transmission by issuing an interrupt.

There are two modes for reception; non-FIFO mode where the buffer RAM is treated as a single RAM and FIFO mode where the buffer RAM is treated as a 16-stage FIFO. In the non-FIFO mode, when one frame of data has been completely received and stored in the buffer RAM, reception is disabled, notifying the end of reception by issuing an interrupt. In the FIFO mode, continuous reception of up to 16 frames, DMA auto-request, and interrupt notices are available without software intervention.

In SIR-UART, MIR, and FIR modes, auto-receive mode is available, in which reception is automatically enabled after transmission is completed.

It is possible to set the appropriate SIR transmit pulse width according to the characteristics of the infrared light receiving and emitting module used. The serial interaction pulse (SIP) output and abort output functions are also available. A 48-MHz clock signal is used for communication.

55.1 Features

Table 55.1 IrDA Features

Item	Description
Standard	IrDA PHY1.1/1.3
Communication mode	SIR-UART mode: 2400 bits, 9600 bits, 19.2 kbits, 38.4 kbits, 57.6 kbits, or 115.2 kbits/s MIR mode: 0.576 Mbits/s or 1.152 Mbits/s FIR mode: 4.0 Mbits/s
Data transfer	Transmission: 1 frame unit (The end of transmission is notified by issuing an interrupt.) Reception: Selectable between the frame by frame non-FIFO mode and 16-stage FIFO mode FIFO mode: automatic continuous frame reception, DMA request
Interrupt	• SIR-UART mode Transmission: Frame transmit end Reception: Frame receive end (sources: normal end, transfer area overflow, framing error, and timeout) • MIR mode and FIR mode Transmission: Frame transmit end Reception: Frame receive end (sources: normal end, transfer area overflow, CRC error, and abort detection) • FIFO mode Transmission: None Reception: FIFO interrupts (sources: FIFO write, FIFO area overflow, DMA transfer end)
Pulse modulation/demodulation	SIR-UART mode transmission: Pulse width setting function
Infrared light receiving and emitting module interface	Transmission: IRDA_OUT (SIP output function, abort output function, level inversion function) Reception: IRDA_IN (level inversion function)
Test mode	Internal loop back function for transmit/receive signals

Figure 55.1 shows an internal block diagram of the IrDA.

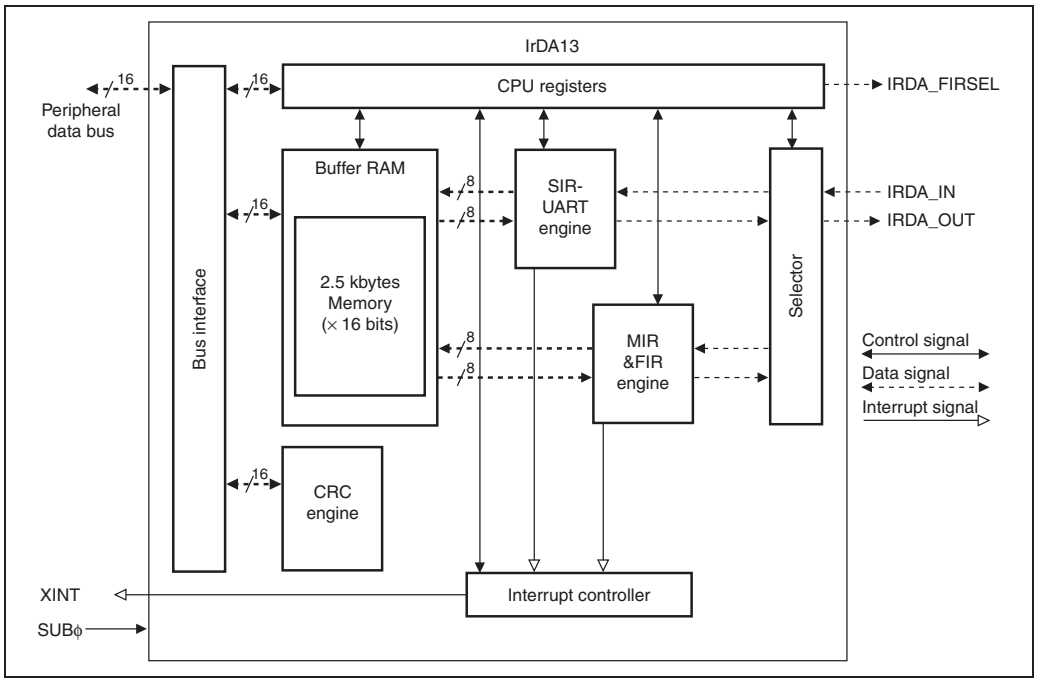

Figure 55.1 Internal Block Diagram of IrDA

55.2 Input/Output Pins

The IrDA has the input/output pins listed in Table 55.2.

Table 55.2 IrDA Pin Configuration

Pin Name	Function	I/O	Description
IRDA_IN	Receive data input	Input	Inputs the received data.
IRDA_OUT	Transmit data output	Output	Outputs the data to be transmitted.
IRDA_FIRSEL	FIR select	Output	Switches between SIR, MIR, and FIR modes.

55.3 Register Descriptions

Table 55.3 shows the IrDA register configuration. Table 55.4 shows the register states in each operating mode.

Table 55.3 IrDA Register Configuration

Register	Abbreviation	R/W	Address	Access Size
Transfer mode register	IRTMR	R/W	H'E6D0 1F00	8/16
Configuration register	IRCFR	R/W	H'E6D0 1F02	8/16
IR control register	IRCTR	R/W	H'E6D0 1F04	8/16
Transmit frame length register	IRTFLR	R/W	H'E6D0 1F20	8/16
Transmit control register	IRTCTR	R/W	H'E6D0 1F22	8/16

55.3.1 Transfer Mode Register (IRTMR)

IRTMR, shared by SIR-UART, MIR, and FIR modes, is a register that selects a transfer mode and simultaneously masks all the interrupts in each transfer mode.

Before switching the transfer modes or transmit and receive modes through this register, transmission and reception must be disabled.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TMD[1:0]		FIRMD		—	—	—	FIFO RIM	—	—	—	MIM	—	—	—	SIM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	TMD[1:0]	00	R/W	Transfer Mode These bits select the transfer mode. When the mode setting has been completed, either the SIR-UART engine or the MIR&FIR engine corresponding to the selected mode starts operating. 0X: SIR-UART mode 10: FIR mode 11: MIR mode Note: X: Don't care.
13, 12	FIRMD[1:0]	00	R/W	FIR Modulation/Demodulation Pulse Distinction Mode These bits select distinction mode for single pulses or double pulses in the FIR modulation/demodulation pulse reception. In Auto mode, the single-pulse and double-pulse widths are automatically defined based on the interval between STA and PA for distinction. In Manual mode, the single-pulse and double-pulse widths are defined by a register setting for distinction. 0X: Auto mode 10: Manual mode 1 (Single pulse: SUBϕ $\times$ 8 cycles or less, Double pulse: SUBϕ $\times$ 9 cycles or more) 11: Manual mode 2 (Single pulse: SUBϕ $\times$ 9 cycles or less, Double pulse: SUBϕ $\times$ 10 cycles or more) Note: X: Don't care

Bit	Bit Name	Initial Value	R/W	Description
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	FIFORIM	0	R/W	FIFO receive interrupt mask This is a mask register that is located above FIFORSMSK. It masks all the interrupt sources of FIFORS. 0: Masks no interrupts. 1: Masks all the interrupts.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	MIM	0	R/W	MIR/FIR Interrupt Mask Masks all the interrupts generated in MIR and FIR modes. 0: Masks no interrupts. 1: Masks all the interrupts.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SIM	0	R/W	SIR Interrupt Mask Masks all the interrupts generated in SIR-UART mode. 0: Masks no interrupts. 1: Masks all the interrupts.

55.3.2 Configuration Register (IRCFR)

IRCFR, shared by SIR-UART, MIR, and FIR modes, is a register that controls the receive timeout time and the transmit signals.

Before setting this register, transmission and reception must be disabled.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TPW	—	—	—	—	—	RTO[1:0]		MBR	—	—	STAC	—	—	ABT	SIP
Initial value:	0	—	—	—	—	—	0	0	0	—	—	0	—	—	0	0
R/W:	R/W	R	R	R	R	R	R/W	R/W	R/W	R	R	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	TPW	0	R/W	Transmit Pulse Width (in SIR-UART mode only) Specifies the transmit pulse width in SIR-UART mode. 0: 1.63 μs 1: 3/16T of one-bit duration.
14 to 10	—	Undefined	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	RTO[1:0]	00	R/W	Receive Timeout (in SIR-UART mode only) These bits specify the receive timeout time in SIR-UART mode. Setting these bits allows a timeout interrupt to be generated when the interval between the bytes in the same frame exceeds the specified timeout time. The actual interval between the bytes is defined as the interval between the stop bits. 00: A timeout interrupt is not generated. 01: A timeout interrupt is generated when the interval between the bytes exceeds 1 ms. 11: A timeout interrupt is generated when the interval between the bytes exceeds 10 ms. 11: Setting prohibited.

Bit	Bit Name	Initial Value	R/W	Description
7	MBR	0	R/W	MIR Baud Rate Specifies the baud rate in MIR mode. 0: 0.576 Mbits/s 1: 1.152 Mbits/s
6, 5	—	Undefined	R	Reserved These bits are always read as 0. The write value should always be 0.
4	STAC	0	R/W	Start Flag (STA) Count (in MIR and FIR modes only) Specifies the number of STA in a transmit frame in MIR and FIR modes. 0: One STA in FIR mode and two STA in MIR mode. 1: Two STA in FIR mode and three STA in MIR mode.
3, 2	—	Undefined	R	Reserved These bits are always read as 0. The write value should always be 0.
1	ABT	0	R/W	Abort Output (in MIR and FIR modes only) Aborts transmission in MIR and FIR modes. While this bit is 1, the abort state continues to be output from the transmit data output pin. This bit is not used in SIR-UART mode; the abort state is output by writing a character sequence indicating the abort state to the buffer RAM. 0: Normal transmission 1: Abort output
0	SIP	0	R/W	SIP Output (in MIR and FIR modes only) In MIR and FIR modes, SIP is output to notify a device with a communication speed of 115.2 kbits/s or slower that communication is currently being performed in MIR or FIR mode. When this bit is modified to 1, a 1.6-μs-wide SIP pulse is output within 8.7 μs. The 500-ms interval between SIPs should be measured using software. 0: Normal transmission 1: SIP output

55.3.3 IR Control Register (IRCTR)

IRCTR, shared by SIR-UART, MIR, and FIR modes, is a register that controls the infrared light module interface signals.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RSI	—	—	—	—	—	—	IRIN	TSI	—	TSS[1:0]		—	—	—	FIRS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	RSI	0	R/W	Inverted Receive Signal Input Inverts the received signal before pulse modulation. The logic level of the received signal input is usually negative; however, if the receive signal pin of the infrared light receiving and emitting module used employs the positive logic level, the input signal can be inverted using this bit. 0: Does not invert the received signal. 1: Inverts the received signal.
14 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	IRIN	0	R/W	IRDA_IN Monitor Indicates the status of the IRDA_IN pin. 0: Low level 1: High level
7	TSI	0	R/W	Inverted Transmit Signal Output Inverts the pulse-modulated transmit signal before outputting. 0: Does not invert the transmit signal. 1: Inverts the transmit signal.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	TSS[1:0]	00	R/W	Transmit Signal Select Selects the transmit signal output; specifically, selects whether to transmit the signal normally or to control the signal directly through these bits. 00: Normal output 01: Setting prohibited 10: 0 output 11: 1 output
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	FIRS	0	R/W	FIR_SELECT Specifies the FIR_SELECT output for controlling the infrared light receiving and emitting module. 0: 0 output 1: 1 output

55.3.4 Transmit Frame Length Register (IRTFLR)

IRTFLR, shared by SIR-UART, MIR, and FIR modes, is a register that specifies the transmit frame length.

When this register is read, the specified number of data bytes is always read out. If transmission is enabled with this register set to the initial value, no data is transmitted. Here, the TE bit is cleared to 0 and a transmit end interrupt is generated simultaneously, completing transmission.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	TFL[12:0]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	TFL[12:0]	H'000	R/W	Transmit Frame Length These bits specify the number of data bytes in a frame to be transmitted. In SIR-UART mode, the number of data bytes should include framewrapping. In MIR and FIR modes, the number of data bytes excludes framewrapping; only the IrLAP payload part is considered.

55.3.5 Transmit Control Register (IRTCTR)

IRTCTR, shared by SIR-UART, MIR, and FIR modes, is a register that specifies auto-receive mode and enables/disables transmission.

If transmission is disabled during SIR-UART mode transmission, the SIR-UART engine discards the currently transmitting data byte**,** terminating transmission. In this case, the transmit data is regarded as illegal frame data, and thus does not bring about the reception state even if auto-receive mode is enabled.

If transmission is disabled during MIR or FIR mode transmission, the MIR&FIR engine immediately stops transmission, thus terminating transmission. In this case, the transmit data is regarded as illegal frame data, and thus does not bring about the reception state even if auto-receive mode is enabled.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ARMOD	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	ARMOD	0	R/W	Auto-Receive Mode Specifies auto-receive mode after transmission, in which the end of transmission automatically causes the reception state. 0: No auto-receive mode 1: Auto-receive mode
14 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	TE	0	R/W	Transmit Enable Enables/disables transmission. This bit is automatically cleared to 0 after transmission. 0: Disables transmission. 1: Enables transmission.

55.3.6 Receive Frame Length Register (IRRFLR)

IRRFLR, shared by SIR-UART, MIR, and FIR modes, is a register in which the length of the received frame is stored after reception.

When this register is read during reception, the number of data bytes that have been received so far is read out. This register is initialized if the receive-disabled state is switched to receive-enabled state.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	RFL[12:0]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	RFL[12:0]	H'000	R	Receive Frame Length These bits indicate the number of data bytes received in the frame. In SIR-UART mode, the indicated number of data bytes includes framewrapping. In MIR and FIR modes, the indicated number of data bytes excludes framewrapping; only the IrLAP payload part is considered.

55.3.7 Receive Control Register (IRRCTR)

IRRCTR, shared by SIR-UART, MIR, and FIR modes, is a register that enables/disables reception.

If reception is disabled during SIR-UART mode reception, the SIR-UART engine discards the currently receiving data byte, thus terminating reception. If reception is disabled during MIR and FIR mode reception, the MIR&FIR engine immediately stops reception**,** terminating reception.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	REPRE	—	—	—	RE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	REPRE	0	R/W	Repeated receive enable Controls whether RE is automatically cleared after reception. REPRE must be set to 1 only when FIFOEN is 1 to prevent the next received data from being overwritten. 0: RE is automatically cleared after reception. 1: RE is not automatically cleared after reception.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	RE	0	R/W	Receive Enable Enables/disables reception. This bit is automatically cleared to 0 after reception. 0: Disables reception. 1: Enables reception.

55.3.8 SIR-UART Mode Interrupt Source Register (SIRISR)

SIRISR, used in SIR-UART mode, is a register that indicates the sources of the interrupts generated in SIR-UART mode. Writing 1 to the bits in SIRICR clears the corresponding bits in this register to 0.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FRE	—	—	—	TROV	—	TOT	FER	FTE	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	FRE	0	R	Frame Receive End Indicates that one frame has been received. 0: One frame has not been received. 1: One frame has been received.
14 to 12	—	All 0	R	Reserved These bits are always read as 0.
11	TROV	0	R	Transfer Area Overflow Indicates that the quantity of the received data bytes has exceeded the buffer RAM area, causing a transfer area overflow. 0: A transfer area overflow has not occurred. 1: A transfer area overflow has occurred.
10	—	0	R	Reserved This bit is always read as 0.
9	TOT	0	R	Timeout Indicates that the interval between the received data bytes in the same frame exceeds the timeout time (1 ms or 10 ms) specified in IRCFR, causing a timeout. 0: A timeout has not occurred. 1: A timeout has occurred.

Bit	Bit Name	Initial Value	R/W	Description
8	FER	0	R	Framing Error Indicates that no stop bit is appended to the received data, causing a framing error. 0: A framing error has not occurred. 1: A framing error has occurred.
7	FTE	0	R	Frame Transmit End Indicates that one frame has been transmitted. 0: One frame has not been transmitted. 1: One frame has been transmitted.
6 to 0	—	All 0	R	Reserved These bits are always read as 0.

55.3.9 SIR-UART Mode Interrupt Mask Register (SIRIMR)

SIRIMR, used in SIR-UART mode, is a register that masks the interrupts generated in SIR-UART mode.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FREIM	—	—	—	TROVIM	—	TOTIM	FERIM	FTEIM	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
15	FREIM	0	W	Frame Receive End Interrupt Mask Masks the frame receive end interrupt. 0: Does not mask the frame receive end interrupt. 1: Masks the frame receive end interrupt.
14 to 12	—	All 0	W	Reserved The write value should always be 0.
11	TROVIM	0	W	Transfer Area Overflow Interrupt Mask Masks the transfer area overflow interrupt. 0: Does not mask the transfer area overflow. 1: Masks the transfer area overflow.

Bit	Bit Name	Initial Value	R/W	Description
10	—	0	W	Reserved The write value should always be 0.
9	TOTIM	0	W	Timeout Interrupt Mask Masks the timeout interrupt. 0: Does not mask the timeout interrupt. 1: Masks the timeout interrupt.
8	FERIM	0	W	Framing Error Interrupt Mask Masks the framing error interrupt. 0: Does not mask the framing error interrupt. 1: Masks the framing error interrupt.
7	FTEIM	0	W	Frame Transmit End Interrupt Mask Masks the frame transmit end interrupt. 0: Does not mask the frame transmit end interrupt. 1: Masks the frame transmit end interrupt.
6 to 0	—	All 0	W	Reserved The write value should always be 0.

55.3.10 SIR-UART Mode Interrupt Clear Register (SIRICR)

SIRICR, used in SIR-UART mode, is a register that clears the interrupts generated in SIR-UART mode. After 1 is written to the bits in this register thus clearing the corresponding interrupts, the bits automatically return to 0.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FREIC	—	—	—	FROVIC	—	TOTIC	FERIC	FTEIC	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
15	FREIC	0	W	Frame Receive End Interrupt Clear Clears the frame receive end interrupt. 0: Does not clear the frame receive end interrupt. 1: Clears the frame receive end interrupt.

Bit	Bit Name	Initial Value	R/W	Description
14 to 12	—	All 0	W	Reserved The write value should always be 0.
11	FROVIC	0	W	Transfer Area Overflow Interrupt Clear Clears the transfer area overflow interrupt. 0: Does not clear the transfer area overflow. 1: Clears the transfer area overflow.
10	—	0	W	Reserved The write value should always be 0.
9	TOTIC	0	W	Timeout Interrupt Clear Clears the timeout interrupt. 0: Does not clear the timeout interrupt. 1: Clears the timeout interrupt.
8	FERIC	0	W	Framing Error Interrupt Clear Clears the framing error interrupt. 0: Does not clear the framing error interrupt. 1: Clears the framing error interrupt.
7	FTEIC	0	W	Frame Transmit End Interrupt Clear Clears the frame transmit end interrupt. 0: Does not clear the frame transmit end interrupt. 1: Clears the frame transmit end interrupt.
6 to 0	—	All 0	W	Reserved The write value should always be 0.

55.3.11 SIR-UART Mode Baud Rate Count Register (SIRBCR)

SIRBCR, used in SIR-UART mode, is a register that specifies the baud rate used for both transmission and reception.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	BRC[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 6	—	All 0	R	Reserved The write value should always be 0.
5 to 0	BRC[5:0]	000000	R/W	Baud Rate Count These bits specify the frequency division ratio (baud rate counter value) to produce the desired baud rate from the externally input clock signal. Since the frequency of the externally input 48-MHz clock signal is divided by 26 prior to generating the communication clock signal, the baud rate calculation equation and the baud rate counter values given below are used. The resultant frequency error is +0.16%, which falls within the tolerance prescribed in the IrDA standard. The baud rate counter value must be modified after disabling transmission and reception. Baud rate (bits/s) = 1.8432 MHz/{(baud rate counter value + 1) × 16} Baud rate (bits/s) Baud rate counter value (Hex) 2400 47 (H'2F) 9600 11 (H'B) 19.2 k 5 (H'5) 38.4 k 2 (H'2) 57.6 k 1 (H'1) 115.2 k 0 (H'0)

55.3.12 MIR/FIR Mode Interrupt Source Register (MFIRISR)

MFIRISR, used in MIR and FIR modes, is a register that indicates the sources of the interrupts generated in MIR and FIR modes. Writing 1 to the bits in MFIRICR clears the corresponding bits in this register to 0.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FRE	—	—	—	TROV	—	ABTD	CRC ER	FTE	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	FRE	0	R	Frame Receive End Indicates that one frame has been received. 0: One frame has not been received. 1: One frame has been received.
14 to 12	—	All 0	R	Reserved These bits are always read as 0.
11	TROV	0	R	Transfer Area Overflow Indicates that the quantity of the received data bytes has exceeded the buffer RAM area, causing a transfer area overflow. 0: A transfer area overflow has not occurred. 1: A transfer area overflow has occurred.
10	—	0	R	Reserved This bit is always read as 0.
9	ABTD	0	R	Abort Detection Indicates that an illegal pulse code has been detected in the received data (= abort detection). 0: No illegal pulse codes have been detected. 1: An abort has been detected.

Bit	Bit Name	Initial Value	R/W	Description
8	CRCER	0	R	CRC error Indicates that a CRC error has occurred in the received data. 0: A CRC error has not occurred. 1: A CRC error has occurred.
7	FTE	0	R	Frame Transmit End Indicates that one frame has been transmitted. 0: One frame has not been transmitted. 1: One frame has been transmitted.
6 to 0	—	All 0	R	Reserved These bits are always read as 0.

55.3.13 MIR/FIR Mode Interrupt Mask Register (MFIRIMR)

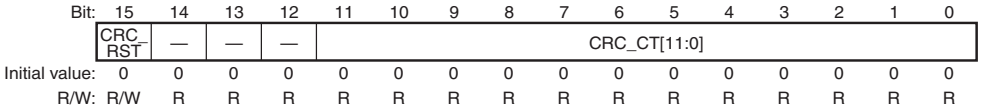
MFIRIMR, used in MIR and FIR modes, is a register that masks the interrupts generated in MIR and FIR modes.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FREIM	—	—	—	TROVIM	—	ABTDIM	CRCERIM	FTEIM	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
15	FREIM	0	W	Frame Receive End Interrupt Mask Masks the frame receive end interrupt. 0: Does not mask the frame receive end interrupt. 1: Masks the frame receive end interrupt.
14 to 12	—	All 0	W	Reserved The write value should always be 0.
11	TROVIM	0	W	Transfer Area Overflow Interrupt Mask Masks the transfer area overflow interrupt. 0: Does not mask the transfer area overflow. 1: Masks the transfer area overflow.

Bit	Bit Name	Initial Value	R/W	Description
10	—	0	W	Reserved The write value should always be 0.
9	ABTDIM	0	W	Abort Detection Interrupt Mask Masks the abort detection interrupt. 0: Does not mask the abort detection interrupt. 1: Masks the abort detection interrupt.
8	CRCERIM	0	W	CRC Error Interrupt Mask Masks the CRC error interrupt. 0: Does not mask the CRC error interrupt. 1: Masks the CRC error interrupt.
7	FTEIM	0	W	Frame Transmit End Interrupt Masks the frame transmit end interrupt. 0: Does not mask the frame transmit end interrupt. 1: Masks the frame transmit end interrupt.
6 to 0	—	All 0	W	Reserved The write value should always be 0.

55.3.14 MIR/FIR Mode Interrupt Clear Register (MFIRICR)



MFIRICR, used in MIR and FIR modes, is a register that clears the interrupts generated in MIR and FIR modes. After 1 is written to the bits in this register thus clearing the corresponding interrupts, the bits automatically return to 0.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FREIC	—	—	—	TEOVIC	—	ABTDIC	CRCERIC	FTEIC	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
15	FREIC	0	W	Frame Receive End Interrupt Clear Clears the frame receive end interrupt. 0: Does not clear the frame receive end interrupt. 1: Clears the frame receive end interrupt.

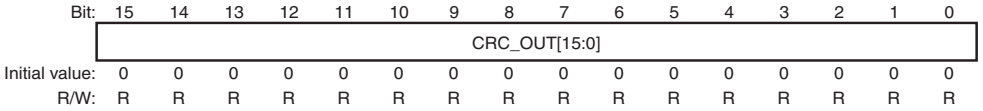
Bit	Bit Name	Initial Value	R/W	Description
14 to 12	—	All 0	W	Reserved The write value should always be 0.
11	TEOVIC	0	W	Transfer Area Overflow Interrupt Clear Clears the transfer area overflow interrupt. 0: Does not clear the transfer area overflow. 1: Clears the transfer area overflow.
10	—	0	W	Reserved The write value should always be 0.
9	ABTDIC	0	W	Abort Detection Interrupt Clear Clears the abort detection interrupt. 0: Does not clear the abort detection interrupt. 1: Clears the abort detection interrupt
8	CRCERIC	0	W	CRC Error Interrupt Clear Clears the CRC error interrupt. 0: Does not clear the CRC error interrupt 1: Clears the CRC error interrupt
7	FTEIC	0	W	Frame Transmit End Interrupt Clear Clears the frame transmit end interrupt. 0: Does not clear the frame transmit end interrupt. 1: Clears the frame transmit end interrupt.
6 to 0	—	All 0	W	Reserved The write value should always be 0.

55.3.15 CRC Engine Control Register (CRCCTR)

Bit	Bit Name	Initial Value	R/W	Description
15	CRC_RST	0	R/W	CRC Engine Reset Clears all registers related to CRC calculation. After reset, this bit automatically returns to 0. 0: Normal CRC calculation 1: CRC engine reset
14 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 0	CRC_CT [11:0]	H'000	R	CRC Engine Input Data Count The number of data items that have been input to the CRC engine can be read. After the data count reaches 4096, it will wrap around to H'000.

55.3.16 CRC Engine Input Data Register (CRCIR)

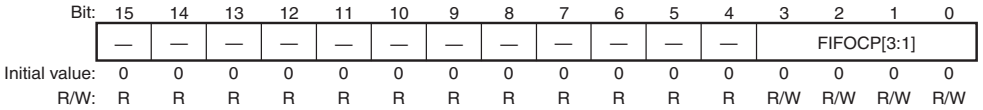
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CRC_IN[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W



Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	W	Reserved These bits are always read as 0. The write value should always be 0.
11 to 0	CRC_IN [11:0]	H'00	W	CRC Engine Input Data The data to be input to the CRC engine should be specified here. The specified data is shifted into the CRC engine calculation register, starting with the LSB (CRC_IN0) of the data into the MSB (CRC_REG15) side of the calculation register.

55.3.17 CRC Engine Calculation Register (CRCCR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CRC_REG[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	CRC_REG [15:0]	H'0000	W	CRC Engine Calculation Data This is a writable register used for diagnosis. Typically, there is no need to access this register.

55.3.18 CRC Engine Output Data Register (CRCOR)

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	CRC_OUT [15:0]	H'0000	R	CRC Engine Output Data The result of calculation in the CRC engine can be read. The result of calculation is shifted into CRC_OUT[15].

55.3.19 FIFO Current Pointer (FIFOCP)

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	FIFOCP[3:0]	H'0	R/W	These bits indicate the number of a FIFO where received data and status from the serial engine are stored. These are incremented by one after reception and wrap from H'F to H'0. These are valid when FIFOEN is 1. These are initialized when FIFOCLR is 1.

55.3.20 FIFO Follow Pointer (FIFOFP)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	FIFOFP[3:1]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	FIFOFP[3:0]	H'0	R/W	These bits indicate the number of the FIFO that is waiting for DMA transfer. These are incremented by one after transmission and wrap from H'F to H'0. These are valid when FIFOEN is 1 and the DMAONE bit triggers the DMA transfer. These are initialized when FIFOCLR is 1.

55.3.21 Receive Status FIFO Interrupt Mask (FIFORSMSK)

ビット:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	FREM	0	R/W	Masks the RS[15] bit interrupts of all the 16 FIFORS register planes. 1: Masks all the interrupts. 0: Masks no interrupts.
14 to 12	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11	TROVM	0	R/W	Masks the TROV bit interrupts of all of the 16 FIFORS register planes. 1: Masks all the interrupts. 0: Masks no interrupts.
10	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
9	RSM[9]	0	R/W	Masks the RS[9] bit interrupts of all of the 16 FIFORS register planes. 1: Masks all the interrupts. 0: Masks no interrupts.
8	RSM[8]	0	R/W	Masks the RS[8] bit interrupts of all of the 16 FIFORS register planes. 1: Masks all the interrupts. 0: Masks no interrupts.
7 to 5	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	FPOVM	0	R/W	Masks the FPOV bit interrupts of all of the 16 FIFORS register planes. 1: Masks all the interrupts.. 0: Masks no interrupts.
3 to 2	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	DMATEM	0	R/W	Masks the DMATE bit interrupts of all of the 16 FIFORS register planes. 1: Masks all the interrupts. 0: Masks no interrupts.
0	VALIDM	0	R/W	Masks the VALID bit interrupts of all of the 16 FIFORS register planes. 1: Masks all the interrupts. 0: Masks no interrupts.

55.3.22 Receive Status FIFO Interrupt Source OR (FIFORSOR)

FIFORSOR shows the ORed value of each interrupt source of all the 16 FIFORS register planes.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FREO	—	—	—	TROVO	—	RSO[9]	RSO[8]	—	—	—	FPOVO	—	—	DMATE	VALID
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	FREO	0	R	Shows the ORed value of the RS[15] bits of all the 16 FIFORS register planes.
14 to 12	—	0	R	Reserved
11	TROVO	0	R	Shows the ORed value of the TROV bits of all the 16 FIFORS register planes.
10	—	0	R	Reserved
9	RSO[9]	0	R	Shows the ORed value of the TROV bits of all the 16 FIFORS register planes.
8	RSO[8]	0	R	Shows the ORed value of the TROV bits of all the 16 FIFORS register planes.
7 to 5	—	0	R	Reserved
4	FPOVO	0	R	Shows the ORed value of the FPOV bits of all the 16 FIFORS register planes.
3 to 2	—	0	R	Reserved
1	DMATEO	0	R	Shows the ORed value of the DMATE bits of all the 16 FIFORS register planes.
0	VALIDO	0	R	Shows the ORed value of the VALID bits of all the 16 FIFORS register planes.

55.3.23 FIFO Select (FIFOSEL)

FIFOSEL specifies the number of the FIFORS register to be accessed.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	FIFOSEL[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	FIFOSEL[3:0]	H'0	R/W	Specifies the number of FIFORS and FIFORFL to be accessed in hexadecimal value.

55.3.24 Receive Status FIFO (FIFORS)

There are 16 planes of FIFORS numbered from 0 to 15. Each of them is used sequentially beginning with plane 0 to store an interrupt source corresponding to each received frame.

This register is common to SIR/MIR/FIR modes. However, the RS[9] and RS[8] bit specifications differ between SIR and MIR/FIR modes. For details, see each bit description.

Set the desired plane number in the FIFOSEL register before making read/write access to it.

To avoid overrun, erase the specified FIFORS register by writing all 0s to it as soon as possible after the FIFORS register and the buffer RAM data are read.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FRE	—	—	—	TROV	—	RS[9]	RS[8]	—	—	—	FPOV	—	—	DMATE	VALID
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R/W	R	R/W	R/W	R	R	R	R/W	R	R	R/W	R/W

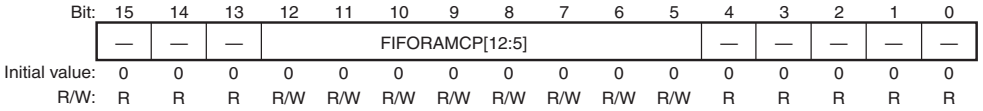
Bit	Bit Name	Initial Value	R/W	Description
15	FRE	0	R/W	Frame Receive End Indicates that one frame has been received. This bit is common to SIR/MIR/FIR modes. 0: One frame has not been received. 1: One frame has been received.
14 to 12	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	TROV	0	R/W	Transfer Area Overflow Indicates that the quantity of the received data bytes has exceeded the buffer RAM area, causing a transfer area overflow. This bit is common to SIR/MIR/FIR modes. When a transfer area overflow occurs, the buffer RAM data may be overwritten before being read out. 0: A transfer area overflow has not occurred. 1: A transfer area overflow has occurred.
10	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
9	RS[9]	0	R/W	This bit specification differ between SIR and MIR/FIR modes. In SIR mode: Timeout Indicates that the interval between the received data bytes in the same frame exceeds the timeout time (1 ms or 10 ms) specified in IRCFR, causing a timeout. 0: A timeout has not occurred. 1: A timeout has occurred. In MIR/FIR modes: Abort Detection Indicates that an illegal pulse code has been detected in the received data (= abort detection). 0: No illegal pulse codes have been detected. 1: An abort has been detected.

Bit	Bit Name	Initial Value	R/W	Description
8	RS[8]	0	R/W	This bit specification differ between SIR and MIR/FIR modes. In SIR mode: Framing Error Indicates that no stop bit is appended to the received data, causing a framing error. 0: A framing error has not occurred. 1: A framing error has occurred. In MIR/FIR modes: CRC Error Indicates that a CRC error has occurred in the received data. 0: A CRC error has not occurred. 1: A CRC error has occurred.
7 to 5	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	FPOV	0	R/W	FIFO Pointer Overrun This bit is turned on when the serial engine block writes the next frame receive status if the VALID bit is 1. All other bits than FPOV in the FIFORS register are unchanged. 0: No FIFO pointer overrun has occurred. 1: A FIFO pointer overrun has occurred.
3 to 2	—	0	—	Reserved These bits are always read as 0. The write value should always be 0.
1	DMATE	0	R/W	DMA Transfer End This bit is turned on when one frame DMA transfer has completed. 0: A DMA transfer has not completed. 1: A DMA transfer has completed.

Bit	Bit Name	Initial Value	R/W	Description
0	VALID	0	R/W	FIFORS Valid This bit is turned on when the status information on a newly received frame is stored in the FIFORS register. 0: There is no valid status information. 1: There is valid status information.

55.3.25 Receive Frame Length FIFO (FIFORFL)

There are 16 planes of FIFORFL numbered from 0 to 15. Each of them is used sequentially beginning with plane 0 to store a received frame length.

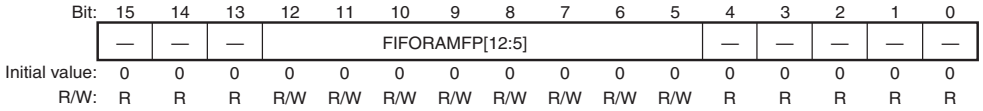


This register is common to SIR/MIR/FIR modes.

Set the desired plane number in the FIFOSEL register before making read/write access to it.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	FIFORFL[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	FIFORFL[3:0]	H'0	RW	Received Frame Length These bits indicate the number of data bytes received in the frame. In SIR-UART mode, the indicated number of data bytes includes framewrapping. In MIR and FIR modes, the indicated number of data bytes excludes framewrapping; only the IrLAP payload part is considered.



55.3.26 FIFORAM Current Pointer (FIFORAMCP)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	FIFORAMCP[12:5]								—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 5	FIFORAMCP [12:5]	H'0	RW	FIFORAM Current Pointer These bits represent the pointer to the buffer RAM that is used as FIFO by the serial engine, where the data to be received in the next one frame will be written. The pointer is updated when the data received in one frame is written. The pointer value always starts on a 32-bit boundary. The current FIFORAMCP indicates the value that is obtained by adding the previous FIFORFL (received data length) to the previous FIFORAMCP and then rounding up to the next 32-bit boundary.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

55.3.27 FIFORAM Follow Pointer (FIFORAMFP)

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 5	FIFORAMFP [12:5]	H'0	RW	FIFORAM Follow Pointer These bits provide the offset address when the received data in the buffer RAM that is used as FIFO is to be read. Set a value that is obtained by adding the FIFORFL (the previously received frame length) to the previous FIFORAMFP and then rounding up to the next 32-bit boundary. For DMA transfer, the value is calculated and set automatically. When reading the received data from the buffer RAM that is used as FIFO, read it sequentially from the start address of the buffer RAM with incrementing addresses.
4 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

55.3.28 Bus Interface Control (BIFCTL)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FIFO CLR	—	FIF OEN	—	—	—	—	BIG	DMA CLR	—	—	—	—	—	—	DMA ONE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R/W	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	FIFOCLR	0	R/W	FIFO Clear Write 1 then 0 to this bit to initialize the FIFO control block registers at a time. 0: Does not initialize the FIFO control block. 1: Initializes the FIFO control block. Registers to be affected: FIFOSEL, FIFOCP, FIFOFP, FIFORS[0-F], FIFORAMCP, FIFORAMFP, FIFO_RFL[0-F]
14	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
13	FIFOEN	0	R/W	FIFO Enable 0: Uses the receive buffer RAM as a single continuous area. 1: Uses the receive buffer RAM as 16 planes of FIFO.
12 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	BIG	0	R/W	Endian Switch 0: Little endian 1: Big endian
7	DMACLR	0	R/W	DMA Clear Write 1 then 0 to this bit to initialize the DMA control block registers at a time. 0: Does not initialize the DMA control block. 1: Initializes the DMA control block. Register to be affected: DMAONE

Bit	Bit Name	Initial Value	R/W	Description
6 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DMAONE	0	R/W	DMA Single Request This bit initiates a DMA transfer request for one frame. This bit is cleared at the end of the DMA transfer automatically. The request must be initiated when there is a frame waiting for DMA transfer. 0: Does not request DMA transfer. 1: Requests DMA transfer for one frame.

55.4 Operation

55.4.1 Frame Format

The IrDA performs communication in the frame format shown in Figure 55.2. In SIR-UART mode, framewrapping through software is required, in which the XBOF, BOF, FCS, and EOF codes are appended before and after the payload data (shaded in the figure). In MIR and FIR modes, the hardware automatically performs framewrapping for the IrLAP payload.

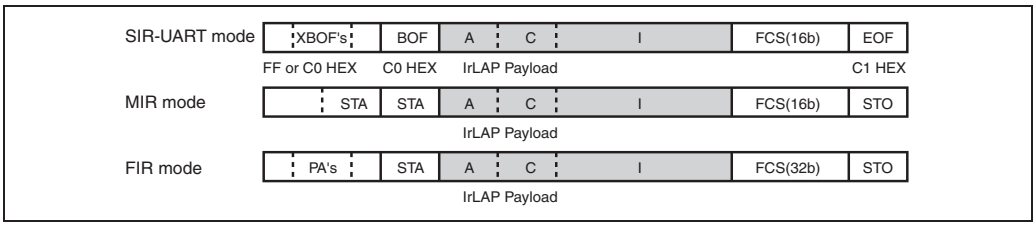


Figure 55.2 Frame Format

55.4.2 Buffer RAM

The IrDA incorporates a 5120-kbyte buffer RAM. In reception, the FIFOEN bit in the BIFCTL register can be used to switch between the non-FIFO and FIFO modes.

(1) Non-FIFO mode

In SIR-UART mode, one frame of framewrapped data is stored in this RAM, whereas in MIR and FIR modes, only the IrLAP payload part in one frame is stored.

Since the buffer RAM is allocated to the linear address space in terms of the CPU, the CPU can access data at any address in the buffer RAM area. When transmission is started, the SIR-UART or the MIR&FIR engine reads data sequentially, starting at H'000, the start address of the buffer RAM. Similarly, when reception is started, the SIR-UART or the MIR&FIR engine writes data sequentially, starting at H'000, the start address of the buffer RAM.

(2) FIFO mode

In transmission, the buffer RAM cannot be used in the FIFO mode, so the FIFOEN bit must be written to 0.

The buffer RAM can be used as up to 16 planes of FIFO only in reception by writing 1 to the FIFOEN bit.

The size of one FIFO plane varies from 0 to 5120 bytes depending on the number of received data bytes in one frame.

Receive operations are described in details below with examples.

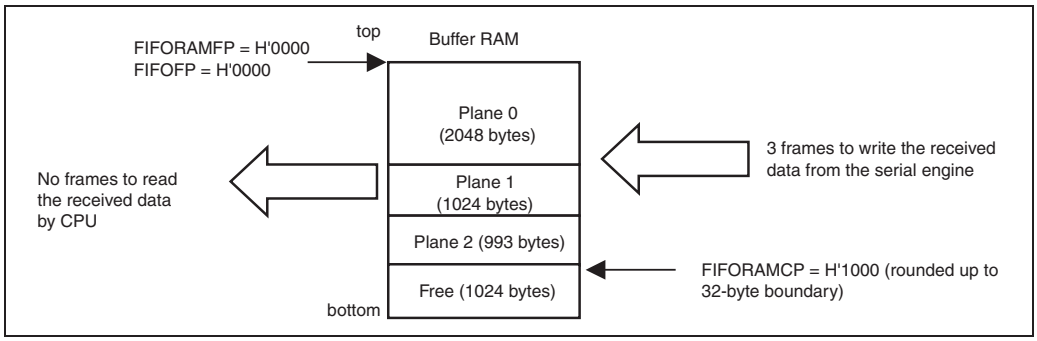

Figure 55.3 Buffer RAM FIFO Operation Example 1

In Example 1, 3 received frames are written from the serial engine to the buffer RAM and no received frames are read from the buffer RAM by the CPU. After these operations, FIFORAMCP points at H'1000 as 933 bytes of plane 2 is rounded up to 32-byte boundary. This leaves a free area with a size of 1024 bytes.

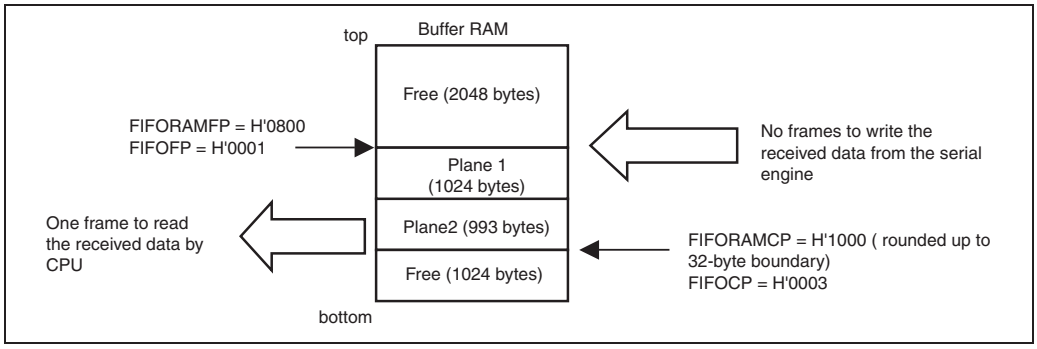

Figure 55.4 Buffer RAM FIFO Operation Example 2

Example 2 shows the buffer RAM after one frame of reading the received data by CPU. In this example, the size of free area is increased to 3072 bytes. FIFORAMFP points at H'0800. This pointer value is updated automatically at the end of a DMA transfer as long as it is initiated by the DAMONE register.

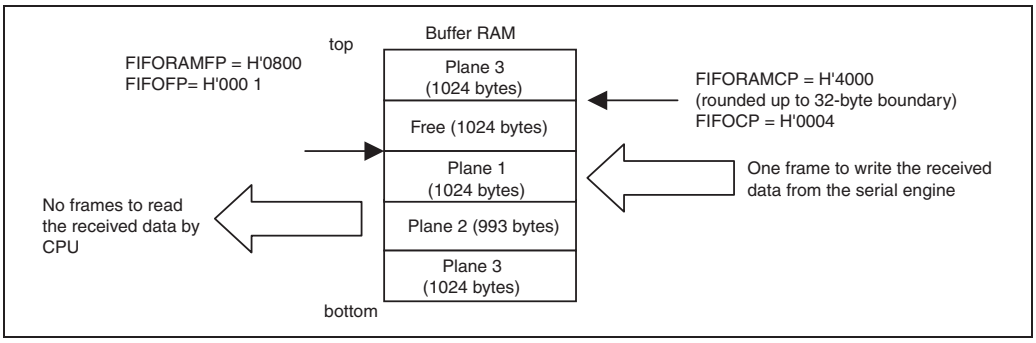

Figure 55.5 Buffer RAM FIFO Operation Example 3

Example 3 shows the buffer RAM after one frame (2048 bytes) of writing the received data from the serial engine to 3 planes. The size of free area is decreased to 1024 bytes. FIFORAMCP is wrapped around to H'0400.

55.4.3 DMA Transfer

The IrDA can generate DMA transfer requests in frame units to read the received data stored in the buffer RAM.

The DMA transfer control flow is shown below.

1) Initiate a serial reception with the FIFOEN bit set to 1.
2) Wait for the reception to complete (FRE=1, bit 15 in FIFORS).
3) Set up the DMAC module.
   (1) Set the value that is obtained by rounding up the FIFORFL register value pointed by the FIFOFP register to 32-byte boundary in DMATCR.

   To transfer more than one frame at a time, set the value that is obtained by rounding up the FIFORFL register values for all frames on frame-by-frame basis and summing up all the resulting values in DMATCR.
   (2) Set the DMA transfer size to 32 bytes (TS[3:0]=0100).
   (3) Set the destination address mode to increment (DM[1:0]=01).
   (4) Set the source address mode to increment (SM[1:0]=01).

(5) Set the resource selection to select DMA extended resource selector (RS[3:0]=1000).
(6) Set the DMA source address register to the start address of the IrDA buffer RAM (DMASAR=H'E6D00000).
(7) Set the DMA destination address register to the destination memory address.
(8) Select the IrDA module in the DMA extended resource selector (DMARS).
(9) Set the DMA enable (DE=1 in the DMACHCR register and DME=1 in the DMAOR register).

4) Start one frame transfer (DMAONE=1).
5) Wait for the read from the IrDA memory to complete (check if DMATE=1 in FIFO_RS).
Repeat from step 4) as required if more than one frame length is set in DMATCR during the DMAC module set-up.
6) Wait for the store to the destination memory to complete (check if TE=1 in DMACHCR).

55.4.4 Data Transfer

The IrDA is in SIR-UART mode after reset; it can be placed in MIR or FIR mode by modifying IRTMR.

(1) Transmission in SIR-UART Mode

In SIR-UART mode transmission, after transmit data with frame wrapping is written to the buffer RAM by the CPU or the DMAC, writing the number of data bytes to be transmitted to IRTFLR and then writing 1 to the TE bit in IRTCTR actually starts transmitting the data.

Once transmission is enabled, the SIR-UART engine reads one byte of data at a time from the buffer RAM to perform transmission. The SIR-UART engine continues reading data from the buffer RAM until it has read the EOF code or the quantity of data bytes equal to the number specified in IRTFLR. When the EOF code has been transmitted, the TE bit is cleared to 0 and a transmit end interrupt is generated simultaneously. This switches the mode to SIR-UART reception mode if auto-receive mode is set.

Notes: 1. If the ARMOD bit in IRTCTR is 1 when transmission has completed, the hardware automatically writes 1 to the RE bit in IRRCTR thus enabling SIR-UART mode reception.
In auto-receive mode, the received data overwrites the transmit data in the buffer RAM.
2. Set the correct transmit frame length to IRTFLR and set the correct EOF code (H'C1) to the buffer RAM. If the EOF code is not found within the byte position specified by

IRTFLR, a transmit end interrupt is not generated. If the incorrect EOF code is set, clear the TE bit to 0 and then set the bit to 1 to enable transmission again.

(2) Reception in SIR-UART Mode

In SIR-UART mode reception, writing 1 to the RE bit in IRRCTR enables reception. Once reception is enabled, the SIR-UART engine waits for the data to be received, and on receiving data, the SIR-UART engine writes one byte of data at a time to the buffer RAM. In this case, the SIR-UART engine writes the entire framewrapped data. Reading IRRFLR gives the number of bytes written to the buffer RAM.

When the EOF code has been successfully received and written to the buffer RAM, a receive end interrupt is generated and the RE bit in IRRCTR is cleared to 0 simultaneously.

If the quantity of the received data bytes with framewrapping exceeds the buffer RAM area, a transfer area overflow interrupt is generated. If the received data has some faults which subsequently lead to a missing stop bit, a framing error interrupt is generated.

If the receive pulses are interrupted during reception of a frame of data, thus disabling data reception for a specified time, a timeout interrupt is generated. The timeout time (no timeout, 1 ms, or 10 ms) can be specified in IRCFR.

Note: A receive end interrupt is not generated if either a transfer area overflow interrupt, a framing error interrupt, or a timeout interrupt is generated.

(3) Transmission in MIR and FIR Modes

In MIR and FIR mode transmission, after transmit data without framewrapping is written to the buffer RAM by the CPU or the DMAC, writing the number of data bytes to be transmitted to IRTFLR and then writing 1 to the TE bit in IRTCTR actually starts transmitting the data.

Once transmission is enabled, the MIR&FIR engine reads one byte of data at a time from the buffer RAM to perform transmission. In this case, the MIR&FIR engine appends the codes such as preamble (PA), start flag (STA), frame check sequence (FCS), and/or stop flag (STO) before and after the IrLAP payload data depending on the mode. The MIR&FIR engine reads the quantity of data bytes equal to the number specified in IRTFLR from the buffer RAM. When STO has been transmitted, the TE bit is cleared to 0 and a transmit end interrupt is generated simultaneously.

Note: If the ARMOD bit in IRTCTR is 1 when transmission has completed, the hardware automatically writes 1 to the RE bit in IRRCTR thus enabling MIR or FIR mode reception. In auto-receive mode, the received data overwrites the transmit data in the buffer RAM.

(4) Reception in MIR and FIR Modes

In MIR and FIR mode reception, writing 1 to the RE bit in IRRCTR enables reception. Once reception is enabled, the MIR&FIR engine waits for PA or STA depending on the mode. On confirming the appropriate STA sequence, the MIR&FIR engine regards the following received data as the IrLAP payload data, thus writing one byte of the data at a time to the buffer RAM.

When the STO flag has been received, a receive end interrupt is generated and the RE bit in IRRCTR is cleared to 0 simultaneously to complete reception.

After receiving the STO flag, the hardware performs a CRC check. If a CRC error is detected, a CRC error interrupt is generated. When reception has been successfully ended without a CRC error, only the IrLAP payload data is written to the buffer RAM; no CRC data is written. Reading IRRFLR indicates the number of bytes having been written to the buffer RAM.

If the quantity of the received data bytes without framewrapping exceeds the buffer RAM area, a transfer area overflow interrupt is generated. If an illegal code has been detected in the received data, an abort detection interrupt is generated.

Note: A receive end interrupt is not generated if either a transfer area overflow interrupt or an abort detection interrupt is generated.

55.4.5 Interrupts

It is possible to generate the SIR-UART mode interrupts, the MIR/FIR mode interrupts, or the FIFO mode interrupts that are selected by IRTMR.

The output of the SIR-UART mode interrupts and the MIR/FIR mode interrupts can be masked as required through the corresponding interrupt mask registers. The output of the FIFO mode interrupts can be masked on the basis of interrupt sources that are ORed between all of 16 planes of FIFO interrupt statuses. The sources of the generated interrupts can be determined through the corresponding interrupt source registers. The interrupt output pin continues outputting a low level signal until all the interrupt sources have been cleared or masked.

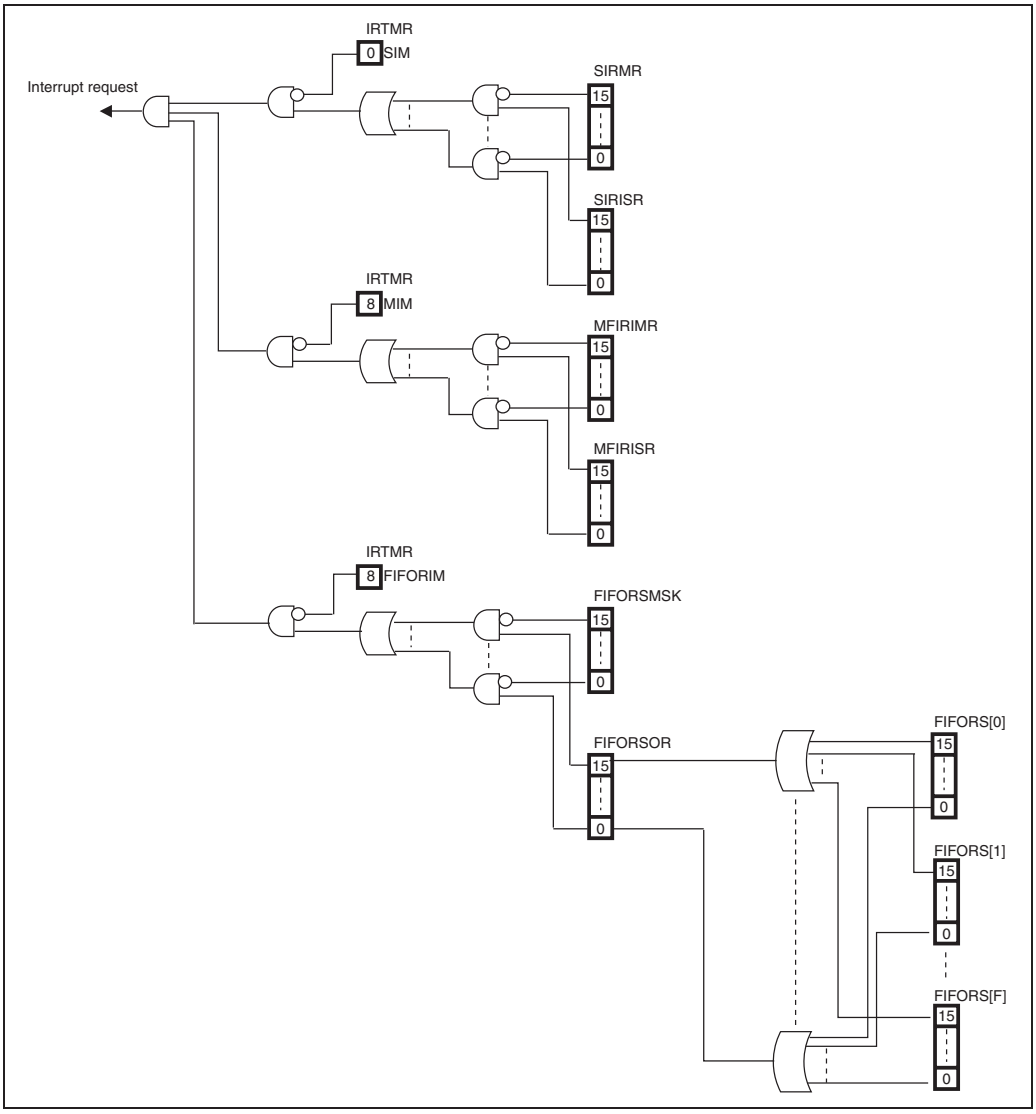

Figure 55.6 Interrupt Related Diagram

55.4.6 SIP Output and Abort

(1) SIP Output

In MIR and FIR modes, SIP is output to notify a device with a communication speed of 115.2 kbits/s or slower that communication is currently being performed in MIR or FIR mode. When 1 is written to the SIP bit in IRCFR, a 1.6-µs-wide SIP pulse is output within 8.7 µs. SIP must be output while transmission is disabled. In MIR and FIR modes, if transmission is enabled immediately after SIP has started to be output, the start of data transmission is suspended while SIP is output; transmission starts after the 8.7-µs duration. The 500-ms interval between SIPs should be measured using software.

(2) Abort

In MIR and FIR modes, the abort output function and abort detection function are available.

The abort output is started or terminated by setting the ABT bit in IRCFR to 1 or 0, respectively. Specifically, the abort state continues after PA and STA are transmitted depending on the mode. Abort output is different from normal data transmission in that it must be output while transmission is disabled.

In reception, if an illegal code has been detected between the STA flag and the following STO flag received, it is regarded as the abort state.

In SIR-UART mode, abort output and abort detection should be implemented through software. In transmission, the abort state is output by writing a character sequence indicating the abort state in the frame. In reception, the received frame is checked through software to see if it contains a character sequence indicating the abort state.

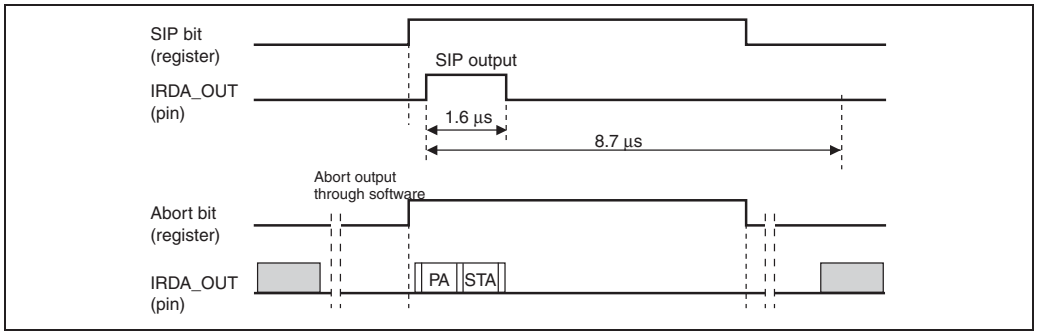

Figure 55.7 SIP Output and Abort Output

55.4.7 Pulse Modulation and Demodulation

Pulse modulation and demodulation of transmit and receive data are shown in Figure 55.4. In SIR-UART mode, either 3/16T or 1.63 μs can be selected through programming as the width of the pulse to be transmitted. In MIR and FIR modes, the pulse width is controlled through the hardware.

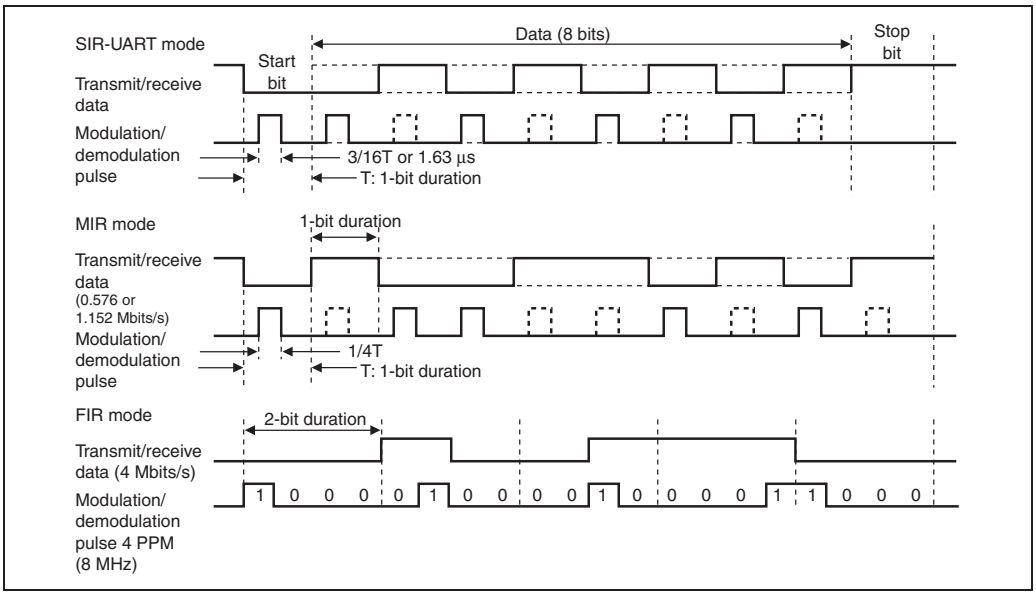

Figure 55.8 Pulse Modulation and Demodulation

55.4.8 Communication Clock

(1) Communication Clock in FIR Mode

In FIR mode, the 48-MHz input clock is used without modification for pulse modulation and demodulation.

(2) Communication Clock in MIR Mode

In MIR mode, the 48-MHz clock is used without modification as the communication clock.

In MIR mode, data is generated at a rate of 1.152 or 0.576 Mbits/s based on the 48-MHz clock; therefore, the variation point (leading edge) of each data bit may have a maximum of ±6.95-ns jitter compared to the case in which data is generated based on the communication clock given by 16 times the 1.152 Mbits/s rate (18.432 MHz). This results in a maximum of ±13.9-ns jitter between two arbitrary data variation points. This value is ±1.6% and ±0.8% for the transfer rates of 1.152 Mbits/s and 0.576 Mbits/s, respectively.

The IrDA standard allows ±0.1% rate tolerance in MIR mode.

If the input clock signal contains some error, the error accumulates between a certain pulse to the next pulse. The maximum error (±0.1% × 7) is produced when STA code B'01111110 is sent based on the clock with a tolerance of ±0.1%.

Therefore, the maximum IrDA jitter in MIR mode transmission is calculated as follows:

For 1.152 Mbits/s: ±1.6% + (±0.1%) × 7 = ±2.3%

For 0.576 Mbits/s: ±0.8% + (±0.1%) × 7 = ±1.5%

The above values fall within the ±2.9% range prescribed in the IrDA standard. The margin for each rate is as follows:

For 1.152 Mbits/s: 868 ns × (±0.6%) = ±5.2 ns

For 0.576 Mbits/s: 1,736 ns × (±1.4%) = ±24.3 ns

(3) Communication Clock in SIR-UART Mode

In SIR-UART mode, the communication clock frequency must be 16 times 115.2 kHz, that is, 1.8432 MHz. The frequency tolerance is ±0.87%. To satisfy this condition, the IrDA divides the frequency of the 48-MHz input clock signal by 26 to generate a 1.846-MHz internal communication clock signal. The resultant frequency error is +0.16%.

55.4.9 IrDA Operation Example

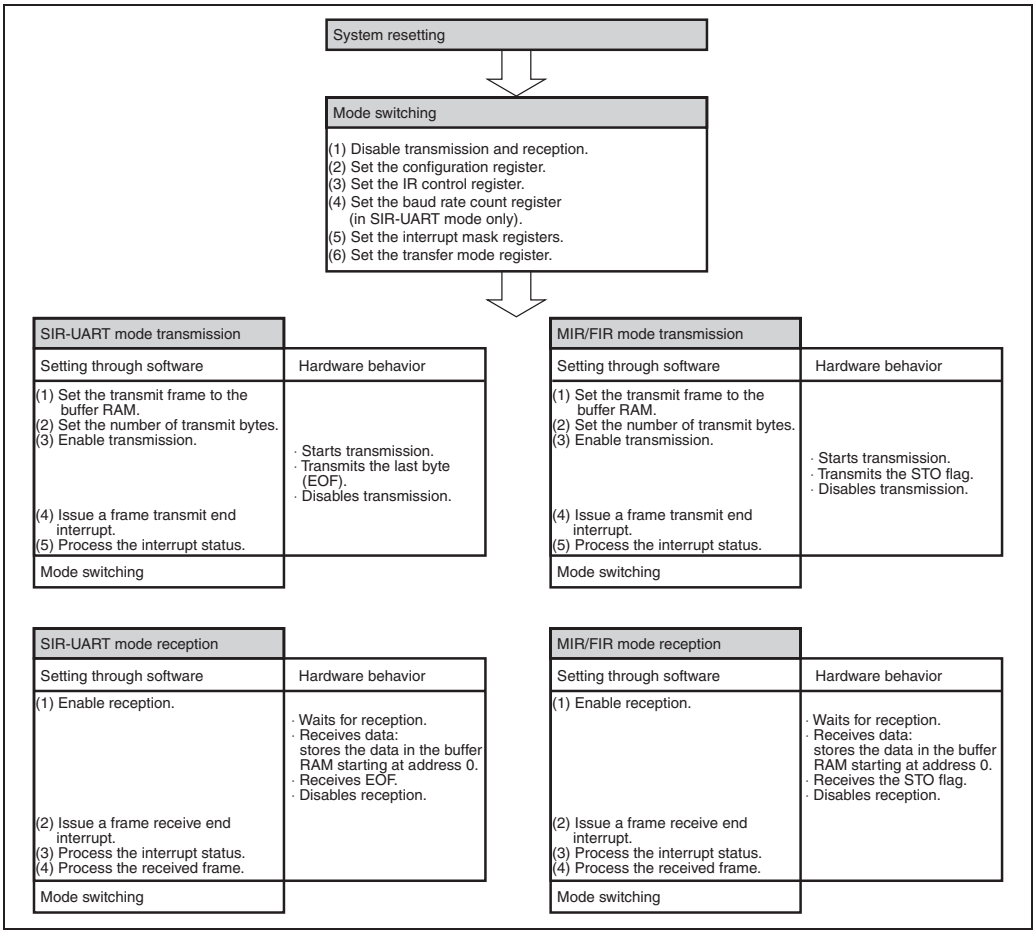

Figure 55.9 IrDA Operation Example

55.4.10 CRC Engine (16-Bit CRC)

(1) CRC Engine (16-Bit CRC) Configuration

The CRC engine consists of an input data register, a byte counter, a CRC engine calculation register (CRCCR), and a CRC engine output register (CRCOR). Table 55.5 summarizes the CRC engine functions. Figure 55.6 shows a configuration of the CRC engine.

Table 55.5 Summary of CRC Engine Functions

Item	Function
Generator polynomial	X16 + X12 + X5 + 1
Data input	Byte write
	CRC calculation in 8-bit units beginning with the lower bits
CRC output	16-bit CRC generator output
	The result of CRC calculation is shifted into the upper bits in order.
Maximum data length	4096 bytes

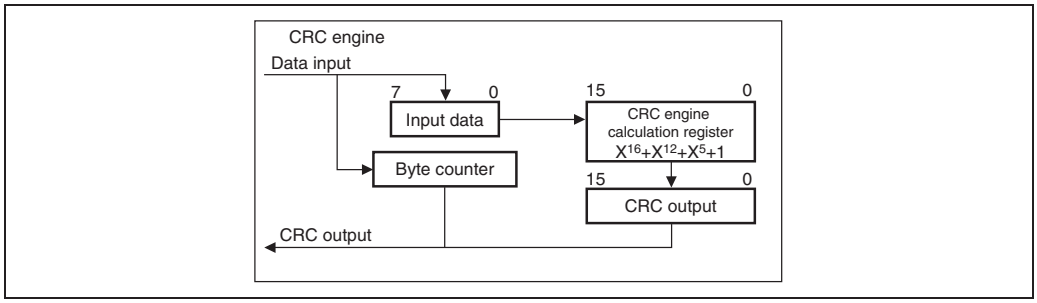

Figure 55.10 CRC Engine Configuration

(2) CRC Engine Operation

Writing 8-bit input data to the CRC engine starts CRC calculation in 8-bit units beginning with the lower bits to output a 16-bit calculation result. Figure 55.7 gives an overview of the CRC engine calculation.

An example of CRC calculation is shown here. After resetting the registers, write H'CC, H'F5, H'F1, and H'A7 as input data in that order. The resultant byte count will be H'4 and H'51DF will be output as the CRC calculation result.

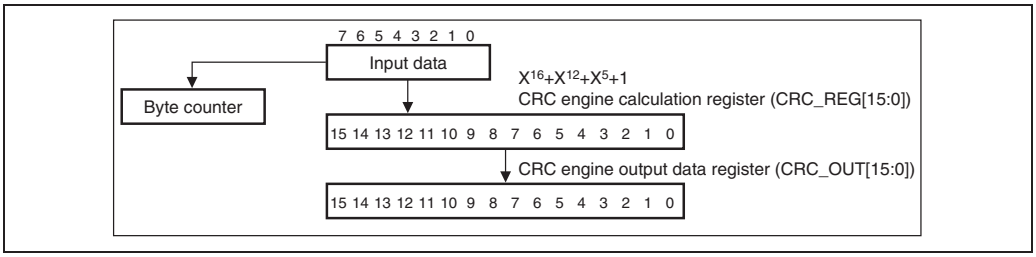

Figure 55.11 CRC Engine Operation

57. IO Port(GPIO)

57.2 Overview

IO Port(GPIO) consists of control registers to select functions and input or output direction of the multiplexed pins and general input/output port registers. Pin functions and input/output directions can be selected for each pin irrespective of operating mode of the LSI.

Table 57.1 List of Multiplexed Pins

[Notes] *1 When the value of the BSCMD pin is 1, general port(PORT*) are unconditionally selected.

*2 At the time of MFI boot, ACMFI-related pins(MEMC_*) are unconditionally selected.

*3 When using the pins for the trace or debug function, set up the debug function select register. They are switched to the trace or debug function regardless of the PORTxxCR setting. For details, see section 60, Debugging Specifications.

*4 Don’t use function 0 of CEC pin.

57.2 Register Description

The following registers are used in the GPIO.

Table57.2 Register Configuration

Side	Register name	Abbreviated name	R/W	Address	Initial value	Access size
D	PORT0 Port control register	PORT0CR	R/W	H'E6051000	H'A0	8,32
D	PORT1 Port control register	PORT1CR	R/W	H'E6051001	H'A0	8,32
D	PORT2 Port control register	PORT2CR	R/W	H'E6051002	H'10	8,32
D	PORT3 Port control register	PORT3CR	R/W	H'E6051003	H'A0	8,32
D	PORT4 Port control register	PORT4CR	R/W	H'E6051004	H'A0	8,32
D	PORT5 Port control register	PORT5CR	R/W	H'E6051005	H'A0	8,32
D	PORT6 Port control register	PORT6CR	R/W	H'E6051006	H'A0	8,32
D	PORT7 Port control register	PORT7CR	R/W	H'E6051007	H'A0	8,32
D	PORT8 Port control register	PORT8CR	R/W	H'E6051008	H'A0	8,32
D	PORT9 Port control register	PORT9CR	R/W	H'E6051009	H'10	8,32
D	PORT10 Port control register	PORT10CR	R/W	H'E605100A	H'10	8,32
D	PORT11 Port control register	PORT11CR	R/W	H'E605100B	H'10	8,32
D	PORT12 Port control register	PORT12CR	R/W	H'E605100C	H'A0	8,32
D	PORT13 Port control register	PORT13CR	R/W	H'E605100D	H'A0	8,32
D	PORT14 Port control register	PORT14CR	R/W	H'E605100E	H'A0	8,32
D	PORT15 Port control register	PORT15CR	R/W	H'E605100F	H'10	8,32
D	PORT16 Port control register	PORT16CR	R/W	H'E6051010	H'A0	8,32
D	PORT17 Port control register	PORT17CR	R/W	H'E6051011	H'A0	8,32
D	PORT18 Port control register	PORT18CR	R/W	H'E6051012	H'A0	8,32
D	PORT19 Port control register	PORT19CR	R/W	H'E6051013	H'12	8,32
D	PORT20 Port control register	PORT20CR	R/W	H'E6051014	H'11	8,32
D	PORT21 Port control register	PORT21CR	R/W	H'E6051015	H'11	8,32
D	PORT22 Port control register	PORT22CR	R/W	H'E6051016	H'11	8,32
D	PORT23 Port control register	PORT23CR	R/W	H'E6051017	H'11	8,32
D	PORT24 Port control register	PORT24CR	R/W	H'E6051018	H'11	8,32
D	PORT25 Port control register	PORT25CR	R/W	H'E6051019	H'11	8,32
D	PORT26 Port control register	PORT26CR	R/W	H'E605101A	H'11	8,32
D	PORT27 Port control register	PORT27CR	R/W	H'E605101B	H'11	8,32
D	PORT28 Port control register	PORT28CR	R/W	H'E605101C	H'11	8,32
D	PORT29 Port control register	PORT29CR	R/W	H'E605101D	H'11	8,32
D	PORT30 Port control register	PORT30CR	R/W	H'E605101E	H'11	8,32
D	PORT31 Port control register	PORT31CR	R/W	H'E605101F	H'11	8,32
D	PORT32 Port control register	PORT32CR	R/W	H'E6051020	H'11	8,32
D	PORT33 Port control register	PORT33CR	R/W	H'E6051021	H'11	8,32
D	PORT34 Port control register	PORT34CR	R/W	H'E6051022	H'11	8,32

[Notes] *1 For details, see section 5.6, LSI Internal Communication Interrupt/Power Reset (Request to the AP Block) and section 5.7, LSI Internal Communication Interrupt/Power Reset (Request to SYS from RT), section 5.8, LSI Internal Communication Interrupt/Power Reset (Request to RT from SYS).

*2 Accessing Address H'E605XXXX, It is controlled by the GPIO semaphore of HPB.

Accessing Address H'E607XXXX, It is not controlled by the GPIO semaphore of HPB.

*3 When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read.

57.2.1 PORTn Control registerPORTnCR)

ビット：	7	6	5	4	3	2	1	0
	PULMD[1:0]		IE	OE	—	PTMD[2:0]		
初期値：								
R/W：	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit name	Initial value	R/W	Description
7, 6	PULMD[1:0]	Please refer Table59.1	R/W	Specify pull-up or pull-down of the port. 0x: Pull-up/pull-down OFF 10: Pull-down 11: Pull-up When a pull-up function is chosen in the case of a pin without a pull-up Operation and a write-in value cannot be guaranteed. When a pull-down function is chosen in the case of a pin without a pull-down Operation and a write-in value cannot be guaranteed.
5	IE	Please refer Table59.1	R/W	Enables or disables the input of the port. 0 : Input is disabled. 1 : Input is enabled. In the case of the pin only for an output, please always write in an initial value at the time of this register writing.
4	OE	Please refer Table59.1	R/W	Enables or disables the output of the port. 0 : Output is disabled. 1 : Output is enabled. In the case of the pin only for an input, please always write in an initial value at the time of this register writing.
3	-	0	R	Reserve bit This bit is always read as 0. The write value should always be 0.

Bit	Bit name	Initial value	R/W	Description
2 to 0	PTMD[2:0]	Please refer Table58.1	R/W	Pin Function Select. 000 : Select Function0. 001 : Select Function1. 010 : Select Function2. 011 : Select Function3. 100 : Select Function4. 101 : Select Function5. 110 : Select Function6. 111 : Select Function7. At the time of setting up the function in which a definition is not given, an operation and a write-in value are not guaranteed.

[Notes] To drive external pins specified as output Hi-Z, select function 0 (port function) and set the OE bit to 0.

PULMD is always effective, but IE and OE are effective only at the time of a selection of function 0.

57.2.2 Module function select register1 (MSEL1CR)

MSEL1CR is a 32-bit readable/writable register that selects module functions from multiplexed pin functions.

ビット:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W

Bit	Bit name	Initial value	R/W	Description
31	MSEL31	0	R/W	IRQ31 Pin Setting 0 : The input of SDHICMD1 Pin(PORT184) is effective. 1 : The input of LCDD17 Pin(PORT138) is effective.
30	MSEL30	0	R/W	IRQ30 Pin Setting 0 : The input of SDHID1_3 Pin(PORT183) is effective. 1 : The input of LCDD9 Pin(PORT130) is effective.
29	MSEL29	0	R/W	IRQ29 Pin Setting 0 : The input of SDHID1_2 Pin(PORT182) is effective. 1 : The input of LCDD8 Pin(PORT129) is effective.
29	MSEL28	0	R/W	IRQ28 Pin Setting 0 : The input of SDHID1_1 Pin(PORT181) is effective. 1 : The input of LCDD2 Pin(PORT123) is effective.

Bit	Bit name	Initial value	R/W	Description
27	MSEL27	0	R/W	IRQ27 Pin Setting 0 : The input of SDHID1_0 Pin(PORT180) is effective. 1 : The input of LCDD1 Pin(PORT122) is effective.
26	MSEL26	0	R/W	IRQ26 Pin Setting 0 : The input of SDHICD0 Pin(PORT172) is effective. 1 : The input of LCDD0 Pin(PORT121) is effective.
25 to 17	-	All0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	MSEL16	0	R/W	IRQ16 Pin Setting 0 : The input of MEMC_AD8 Pin(PORT84) is effective. 1 : The input of CEC Pin(PORT170) is effective.
15	MSEL15	0	R/W	IRQ15 Pin Setting 0 : The input of MEMC_AD7 Pin(PORT83) is effective. 1 : The input of LCDDCK Pin(PORT147) is effective.
14	MSEL14	0	R/W	IRQ14 Pin Setting 0 : The input of MEMC_AD6 Pin(PORT82) is effective. 1 : The input of LCDVSYN Pin(PORT146) is effective.
13	MSEL13	0	R/W	IRQ13 Pin Setting 0 : The input of MEMC_AD5 Pin(PORT81) is effective. 1 : The input of LCDHSYN Pin(PORT145) is effective.
12	MSEL12	0	R/W	IRQ12 Pin Setting 0 : The input of MEMC_AD4 Pin(PORT80) is effective. 1 : The input of LCDD16 Pin(PORT137) is effective.
11, 10	-	All0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	MSEL9	0	R/W	IRQ9 Pin Setting 0 : The input of A23 Pin(PORT42) is effective. 1 : The input of HPD Pin(PORT169) is effective.
8	MSEL8	0	R/W	IRQ8 Pin Setting 0 : The input of VBUS0_1 Pin(PORT168) is effective. 1 : The input of A22 Pin(PORT41) is effective.
7	MSEL7	0	R/W	IRQ7 Pin Setting 0 : The input of VBUS0_0 Pin(PORT167) is effective. 1 : The input of A21 Pin(PORT40) is effective.
6	MSEL6	0	R/W	IRQ6 Pin Setting 0 : The input of A20 Pin(PORT39) is effective. 1 : The input of SCIFB_CTS_N Pin(PORT164) is effective.

Bit	Bit name	Initial value	R/W	Description
5	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	MSEL4	0	R/W	IRQ4 Pin Setting 0 : The input of FMSOIBT Pin(PORT17) is effective. 1 : The input of SCIFB_RTS_N Pin(PORT163) is effective.
3	MSEL3	0	R/W	IRQ3 Pin Setting 0 : The input of FSIAOMC Pin(PORT8) is effective. 1 : The input of FMSOILR Pin(PORT16) is effective.
2	MSEL2	0	R/W	IRQ2 Pin Setting 0 : The input of FSIACK Pin(PORT4) is effective. 1 : The input of FSIAILR Pin(PORT5) is effective.
1	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	MSEL0	0	R/W	IRQ0 Pin Setting 0 : The input of FSIAIBT Pin(PORT6) is effective. 1 : The input of SCIFB_SCK Pin(PORT162) is effective.

57.2.3 Module function selection register3 (MSEL3CR)

MSEL3CR is a 32-bit readable/writable register that selects module functions from multiplexed pin functions.

Bit	Bit name	Initial value	R/W	Description
13 to 11	-	All0	R	Reserved These bits are always read as 0. The write value should always be 0.
10	MSEL10	0	R/W	MSIOF1 Pin Setting 0 :Select BSC Pin.(Function3 of PORT39-44) 1 :Select MFI Pin.(Function2 of PORT88-93)
9 to 7	-	All0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	MSEL6	0	R/W	MFI Pin function settings(Function1 of PORT93-96) 0 :Select ACMFI2. (MEMC_BUSCLK, MEMC_CS1, MEMC_ADV, MEMC_WAIT) 1 :Select ACMFI1. (MEMC_A0, MEMC_A1, MEMC_DREQ0, MEMC_DREQ1)
5	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	MSEL4	0	R/W	RESETA Pin pullup Setting. 0 :pullup enable 1 :pullup disable
3, 2	-	All0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	MSEL1	0	R/W	EDEBGREQ Pin pull-up/down Setting. 0 : Pull-down 1 : Pull-up
0	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.

57.2.5 USB Control register2 (USBCR2)

ビット：	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	USB_START	—	—	USB_COR[4:0]					USB_OFF	—	—	USB_CNT[4:0]				
初期値：	0	0	0	0	1	0	1	0	—	0	0	0	1	0	1	0
R/W：	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit name	Initial value	R/W	Description
15	USB_START	0	R/W	Start Bit 1: Writing 1 to this bit starts a countdown of the RCLK period. Set this bit to enable the USB-PHY0 after VBUS0_0 is detected. This bit is always read as 0. After setting the USB_COR bit, write 1 to this bit. [Note] Even if USB-PHY0 is put into Power ON state(USB_OFF=0), after it becomes Power OFF state(USB_OFF=1) it is reactivated when it starts up by writing in this bit 1. This transition of USB_OFF bit is reflected in USB_PHY_ON and USB_PHY_OFF bits of USB PHY0 Interruption control registerAP. Please issue software reset of USB module, after USB-PHY valid.
14, 13	-	All0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 8	USB_COR [4:0]	01010	R/W	Countdown Setting Specifies the countdown value till start. Note: The countdown starts with "this bit +1" : Valid value range: 0 to h'1E
7	USB_OFF	-	R	USB-PHY0 Power Shutoff Status This bit is read-only. 0: USB-PHY0 isolation cell* disabled, power ON This bit is cleared 0 when the counter value is all 0. The USB-PHY0 power is ON and USB communications are available. 1: USB-PHY0 isolation cell* enabled, power OFF This bit is set to 1 at reset or when VBUS0_0 is detected as low level. The USB-PHY0 power is OFF and USB communications are not available. This causes the VBUS signal supplied to USBHS to be low and the VBUS signal is disconnected even if the VBUS0_0 pin is high level.
6, 5	-	All0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit name	Initial value	R/W	Description
4 to 0	USB_CNT [4:0]	01010	R	Count Value When the count value is all 0, it means the USB-PHY0 isolation cell* is disabled and the power is ON. When VBUS0_0 is detected as low level, the USB_COR value is set.

[Notes]* The isolation cell prevents unknown value propagation by mask signal.

57.2.6 USB Control register4 (USBCR4)

ビット：	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit name	Initial value	R/W	Description
15, 14	VIF_MODE [1:0]	00	R/W	SPU2 outside interrupt/net synchronous signal input bit This register permit interrupt signal from the outside pin to SPU2 and the input of a net synchronous signal. 00: The interrupt signal to SPU2 is not permitted. A net synchronous signal is not input. 01: The interrupt signal to SPU2 is not permitted. The input from the VINT_I pin is input as a net synchronous signal. 10: The input from the VINT_I pin is considered as SPU2 outside interrupt. A net synchronous signal is not input. 11: The input from the IRQ pin is considered as SPU2 outside interrupt. The USCCR2 register is used for the select of IRQ pin. The input from the VINT_I pin is input as a net synchronous signal.
13	VOINT_CLR	0	R/W	VOSYNC interrupt clear bit 0: Interrupt from the VOSYNC module can be set. 1: Interrupt from the VOSYNC module is cleared. Please set 0 in this bit after it clears.
12	VOINT_MASK	0	R/W	VOSYNC interrupt mask bit 0: Interrupt from the VOSYNC module is masked. 1: Interrupt from the VOSYNC module is permitted.
11, 10	VOCLK_SEL [1:0]	00	R/W	The source clock of VOSYNC module selection bit The source clock that generates 8KHz is selected. 00: EXTAL1(26MHz) is a source clock of 8KHz. 01: EXTAL2(48MHz) is a source clock of 8KHz. 10: EXTAL1(27MHz) is a source clock of 8KHz. 11: Reserved.
9	VORESET	0	R/W	Reset is issued to the VOSYNC module. 0: The VOSYNC module usually operates. 1: Reset is issued to the VOSYNC module.
8	VOSYNCEN	0	R/W	Net synchronous signal effective bit 0: Even if a net synchronous signal is supplied, 8KHz is not generated. 1: 8KHz is generated based on a net synchronous signal.

Bit	Bit name	Initial value	R/W	Description
7	VOMASTER	0	R/W	VOSYNC master bit 0: 8KHz is generated based on a net synchronous signal. 1: A net synchronous signal is not used, and 8KHz is generated only from the source clock selected by the VOCLK_SEL bit.
6	SPDIFSEL	0	R/W	SPDIF port selection bit Either of two SPDIF ports that exist in FSI is selected. 0: SPDIF of port B is used. 1: SPDIF of port A is used.
5 to 3	-	All0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	USC_SEL [2:0]	000	R/W	FSI/BBIF2 pins selection bit 000: General mode (BBIF2/FSI is connected with each external pin). 001: Through mode (FSI pins are connected with BBIF2 pins internally). 010: FSI-BBIF connection mode (BBIF module is connected with the FSI port internally). 011: Reserved. 100: FSI-VOSYNC master (SCLK/SYNC of FSI is supplied by VOSYNC). 101: Reserved. 110: FSI-BBIF connection mode (BBIF module is connected with the FSI port internally. SCLK/SYNC is supplied by VOSYNC). 111: Reserved.

R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit name	Initial value	R/W	Description
15	-	1	R	Reserved These bits are always read as 1. The write value should always be 1.
14 to 8	-	All0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	IIC0_CONTA	0	R/W	IIC0 tf Characteristics switching signal
6	IIC0_CONTB	0		CONTA CONTB tf Value VIH/VIL Value 0 0 Default Default 1 0 8ns or Smaller Default 0 1 Default VIH=20mV Decrease VIL=20mV increase 1 1 8ns or Smaller VIH=20mV Decrease VIL=20mV increase
5	IIC1_CONTA	0	R/W	IIC1tf Characteristics switching signal
4	IIC1_CONTB	0	R/W	CONTA CONTB tf Value VIH/VIL Value 0 0 Default Default 1 0 8ns or Smaller Default 0 1 Default VIH=20mV Decrease VIL=20mV increase 1 1 8ns or Smaller VIH=20mV Decrease VIL=20mV increase
3	-	0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	HDMIIIC_STBY	0	R/W	Controls the standby of the HDMI-IIC interface buffer (HDMI_SCL and HDMI_SDA pins). 0: Normal use 1: Standby The time from when this bit is cleared to 0 until the I2C buffer is powered up and operates stably is specified 600ns at a maximum.
1	IIC0_PS33E	0	R/W	Controls the Schmitt input of the IIC0_SCL and IIC0_SDA pins. If IO Voltage(VccQ) of IIC0_SCL and IIC0_SDA pins is 1.8V, and External pull-up voltage is 2.8V, please select “for 1.8V”. 0: For 1.8V 1: For 2.8V

Bit	Bit name	Initial value	R/W	Description
0	IIC1_PS33E	0	R/W	Controls the Schmitt input of the IIC1_SCL and IIC1_SDA pins(1.8V use/2.8V use). If IO Voltage(VccQ) of IIC1_SCL and IIC1_SDA pins is 1.8V, and External pull-up voltage is 2.8V, please select “for 1.8V”. 0: For 1.8V 1: For 2.8V

57. 2. 26 PORTL095_064 Data register (PORTL095_064DR)

Bit	Bit name	Description
31 to 0	PORTL095 to PORTL064	A Port Data Register for Function Numbers 095 to 064 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57. 2. 27 PORTL127_096 Data register (PORTL127_096DR)

Bit	Bit name	Description
31 to 0	PORTL127 to PORTL096	A Port Data Register for Function Numbers 127 to 096 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57. 2. 28 PORTL159_128 Data register (PORTL159_128DR)

Bit	Bit name	Description
31 to 0	PORTL159 to PORTL128	A Port Data Register for Function Numbers 159 to 128 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57.2.29 PORTL191_160 Data register (PORTL191_160DR)

Bit	Bit name	Description
31 to 0	PORTL191 to PORTL160	A Port Data Register for Function Numbers 191 to 160 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57.2.30 PORTD031_000 Data register (PORTD031_000DR)

Bit	Bit name	Description
31 to 0	PORTD031 to PORTD000	A Port Data Register for Function Numbers 031 to 000 in side D When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57.2.31 PORTD063_032 Data register (PORTD063_032DR)

Bit	Bit name	Description
31 to 0	PORTD063 to PORTD032	A Port Data Register for Function Numbers 063 to 032 in side D When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57. 2. 32 PORTR063_032 Data register (PORTR063_032DR)

Bit	Bit name	Description
31 to 0	PORTR063 to PORTR032	A Port Data Register for Function Numbers 063 to 032 in side R When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57.2.33 PORTR095_064 Data register (PORTR095_064DR)

Bit	Bit name	Description
31 to 0	PORTR095 to PORTR064	A Port Data Register for Function Numbers 095 to 064 in side R When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57.2.34 PORTR191_160 Data register (PORTR191_160DR)

Bit	Bit name	Description
31 to 0	PORTR191 to PORTR160	A Port Data Register for Function Numbers 191 to 160 in side R When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57.2.35 PORTU127_096 Data register (PORTU127_096DR)

Bit	Bit name	Description
31 to 0	PORTU127 to PORTU096	A Port Data Register for Function Numbers 127 to 096 in side U When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57.2.36 PORTU159_128 Data register (PORTU159_128DR)

Bit	Bit name	Description
31 to 0	PORTU159 to PORTU128	A Port Data Register for Function Numbers 159 to 128 in side U When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the write value is output from the pin.

57.2.37 PORTL095_064 Data set register (PORTL095_064DSR)

Bit	Bit name	Description
31 to 0	PORTL095 to PORTL064	A Data Set Register for Port Data Register PORTL095_064DR for Function Numbers 095 to 064 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTL095_064DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57.2.38 PORTL127_096 Data set register (PORTL127_096DSR)

Bit	Bit name	Description
31 to 0	PORTL127 to PORTL096	A Data Set Register for Port Data Register PORTL127_096DR for Function Numbers 127 to 096 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTL127_096DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57.2.39 PORTL159_128 Data set register (PORTL159_128DSR)

Bit	Bit name	Description
31 to 0	PORTL159 to PORTL128	A Data Set Register for Port Data Register PORTL159_128DR for Function Numbers 159 to 128 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTL159_128DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57.2.40 PORTL191_160 Data set register (PORTL191_160DSR)

Bit	Bit name	Description
31 to 0	PORTL191 to PORTL160	A Data Set Register for Port Data Register PORTL191_160DR for Function Numbers 191 to 160 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTL191_160DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57. 2. 41 PORTD031_000 Data set register (PORTD031_000DSR)

Bit	Bit name	Description
31 to 0	PORTD031 to PORTD000	A Data Set Register for Port Data Register PORTD031_000DR for Function Numbers 031 to 000 in side D When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTD031_000DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57. 2. 42 PORTD063_032 Data set register (PORTD063_032DSR)

Bit	Bit name	Description
31 to 0	PORTD063 to PORTD032	A Data Set Register for Port Data Register PORTD063_032DR for Function Numbers 063 to 032 in side D When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTD063_032DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57. 2. 43 PORTR063_032 Data set register (PORTR063_032DSR)

Bit	Bit name	Description
31 to 0	PORTR063 to PORTR032	A Data Set Register for Port Data Register PORTR063_032DR for Function Numbers 063 to 032 in side R When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTR063_032DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57. 2. 44 PORTR095_064 Data set register (PORTR095_064DSR)

Bit	Bit name	Description
31 to 0	PORTR095 to PORTR064	A Data Set Register for Port Data Register PORTR095_064DR for Function Numbers 095 to 064 in side R When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTR095_064DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57. 2. 45 PORTR191_160 Data set register (PORTR191_160DSR)

Bit	Bit name	Description
31 to 0	PORTR191 to PORTR160	A Data Set Register for Port Data Register PORTR191_160DR for Function Numbers 191 to 160 in side R When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTR191_160DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57. 2. 46 PORTU127_096 Data set register (PORTU127_096DSR)

Bit	Bit name	Description
31 to 0	PORTU127 to PORTU096	A Data Set Register for Port Data Register PORTU127_096DR for Function Numbers 127 to 096 in side U When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTU127_096DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57. 2. 47 PORTU159_128 Data set register (PORTU159_128DSR)

Bit	Bit name	Description
31 to 0	PORTU159 to PORTU128	A Data Set Register for Port Data Register PORTU159_128DR for Function Numbers 159 to 128 in side U When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTU159_128DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 1 by writing 1 to it and the corresponding pin outputs high. 0: Retains the state. 1: Sets to 1.

57. 2. 48 PORTL095_064 Data clear register (PORTL095_064DCR)

Bit	Bit name	Description
31 to 0	PORTL095 to PORTL064	A Data Clear Register for Port Data Register PORTL095_064DR for Function Numbers 095 to 064 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTL095_064DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57.2.49 PORTL127_096 Data clear register (PORTL127_096DCR)

Bit	Bit name	Description
31 to 0	PORTL127 to PORTL096	A Data Clear Register for Port Data Register PORTL127_096DR for Function Numbers 127 to 096 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTL127_096DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57.2.50 PORTL159_128 Data clear register (PORTL159_128DCR)

Bit	Bit name	Description
31 to 0	PORTL159 to PORTL128	A Data Clear Register for Port Data Register PORTL159_128DR for Function Numbers 159 to 128 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTL159_128DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57.2.51 PORTL191_160 Data clear register (PORTL191_160DCR)

Bit	Bit name	Description
31 to 0	PORTL191 to PORTL160	A Data Clear Register for Port Data Register PORTL191_160DR for Function Numbers 191 to 160 in side L When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTL191_160DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57.2.52 PORTD031_000 Data clear register (PORTD031_000DCR)

Bit	Bit name	Description
31 to 0	PORTD031 to PORTD000	A Data Clear Register for Port Data Register PORTD031_000DR for Function Numbers 031 to 000 in side D When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTD031_000DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57.2.53 PORTD063_032 Data clear register (PORTD063_032DCR)

Bit	Bit name	Description
31 to 0	PORTD063 to PORTD032	A Data Clear Register for Port Data Register PORTD063_032DR for Function Numbers 063 to 032 in side D When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTD063_032DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57.2.54 PORTR063_032 Data clear register (PORTR063_032DCR)

Bit	Bit name	Description
31 to 0	PORTR063 to PORTR032	A Data Clear Register for Port Data Register PORTR063_032DR for Function Numbers 063 to 032 in side R When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTR063_032DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57.2.55 PORTR095_064 Data clear register (PORTR095_064DCR)

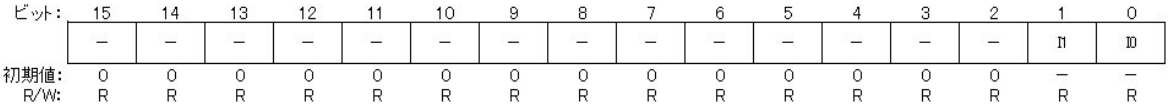
Bit	Bit name	Description
31 to 0	PORTR095 to PORTR064	A Data Clear Register for Port Data Register PORTR095_064DR for Function Numbers 095 to 064 in side R When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTR095_064DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57. 2. 56 PORTR191_160 Data clear register (PORTR191_160DCR)

Bit	Bit name	Description
31 to 0	PORTR191 to PORTR160	A Data Clear Register for Port Data Register PORTR191_160DR for Function Numbers 191 to 160 in side R When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTR191_160DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57.2.57 PORTU127_096 Data clear register (PORTU127_096DCR)

Bit	Bit name	Description
31 to 0	PORTU127 to PORTU096	A Data Clear Register for Port Data Register PORTU127_096DR for Function Numbers 127 to 096 in side U When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTU127_096DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.



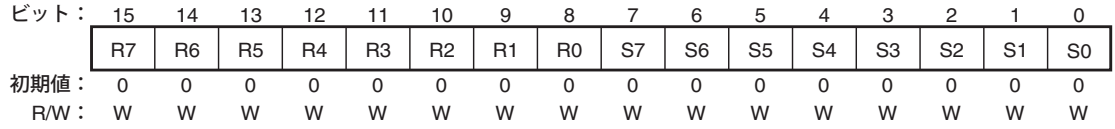
57.2.58 PORTU159_128 Data clear register (PORTU159_128DCR)

Bit	Bit name	Description
31 to 0	PORTU159 to PORTU128	A Data Clear Register for Port Data Register PORTU159_128DR for Function Numbers 159 to 128 in side U When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read. When the IE bit of PORTnCR is set to 0, the PORTU159_128DR register value is read. If no corresponding port exists for the function number, 0 is read. When the OE bit of PORTnCR is set to 1, the desired bit is written to 0 by writing 1 to it and the corresponding pin outputs low. 0: Retains the state. 1: Clears to 0.

57.2.59 CPORT GPI Register (CGPI)

CGPI is a 16-bit read-only register and the corresponding GPI pin level is read.

This register is contained in the AP block.



Bit	Bit name	Initial value	R/W	Description
15 -2	-	0	R	Reserved These bits are always read as 0.
1	I1	-	R	The level of the pin corresponding to GPI1 is read.
0	I0	-	R	The level of the pin corresponding to GPI0 is read.

57.2.60 CPORT GPO Set reset register (CGPOSR)

CGPOSR is a 16-bit write-only register that sets the output data of the general output ports in the AP block. This register shares addresses with CGPOR.

This register is contained in the AP block.

Bit	Bit name	Initial value	R/W	Description
15	R7	0	W	When this bit is set to 1, GPO7 outputs 0 (reset).
14	R6	0	W	When this bit is set to 1, GPO6 outputs 0 (reset).
13	R5	0	W	When this bit is set to 1, GPO5 outputs 0 (reset).
12	R4	0	W	When this bit is set to 1, GPO4 outputs 0 (reset).
11	R3	0	W	When this bit is set to 1, GPO3 outputs 0 (reset).
10	R2	0	W	When this bit is set to 1, GPO2 outputs 0 (reset).
9	R1	0	W	When this bit is set to 1, GPO1 outputs 0 (reset).
8	R0	0	W	When this bit is set to 1, GPO0 outputs 0 (reset).
7	S7	0	W	When this bit is set to 1, GPO7 outputs 1 (set).
6	S6	0	W	When this bit is set to 1, GPO6 outputs 1 (set).
5	S5	0	W	When this bit is set to 1, GPO5 outputs 1 (set).
4	S4	0	W	When this bit is set to 1, GPO4 outputs 1 (set).
3	S3	0	W	When this bit is set to 1, GPO3 outputs 1 (set).
2	S2	0	W	When this bit is set to 1, GPO2 outputs 1 (set).

Bit	Bit name	Initial value	R/W	Description
1	S1	0	W	When this bit is set to 1, GPO1 outputs 1 (set).
0	S0	0	W	When this bit is set to 1, GPO0 outputs 1 (set).

57.2.61 CPORT GPO Read register (CGPOR)

CGPOR is a 16-bit read-only register that reads the output data of the general output ports in the AP block. This register shares addresses with CGPOSR.

This register is contained in the AP block.

57.2.62 CPORT GPOR2S Set reset register (CGPOR2SSR)

CGPOR2SSR is a 16-bit write-only register that sets the output data notifying the WakeUp factor from RT to SYS domain. This register shares addresses with CGPOR2SR.

This register is contained in the AP block.

0	S0	0	W	When this bit is set to 1, GPOR2S0 outputs 1 (set).

57.2.63 CPORT GPOR2S Read register (CGPOR2SR)

CGPOR2SR is a 16-bit read-only register that reads the output data notifying the WakeUp factor from RT to SYS domain. This register shares addresses with CGPOR2SSR.

This register is contained in the AP block.

ビット：	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

14	R6	0	W	When this bit is set to 1, GPOS2R6 outputs 0 (reset).
13	R5	0	W	When this bit is set to 1, GPOS2R5 outputs 0 (reset).
12	R4	0	W	When this bit is set to 1, GPOS2R4 outputs 0 (reset).
11	R3	0	W	When this bit is set to 1, GPOS2R3 outputs 0 (reset).
10	R2	0	W	When this bit is set to 1, GPOS2R2 outputs 0 (reset).
9	R1	0	W	When this bit is set to 1, GPOS2R1 outputs 0 (reset).
8	R0	0	W	When this bit is set to 1, GPOS2R0 outputs 0 (reset).
7	S7	0	W	When this bit is set to 1, GPOS2R7 outputs 1 (set).
6	S6	0	W	When this bit is set to 1, GPOS2R6 outputs 1 (set).
5	S5	0	W	When this bit is set to 1, GPOS2R5 outputs 1 (set).
4	S4	0	W	When this bit is set to 1, GPOS2R4 outputs 1 (set).
3	S3	0	W	When this bit is set to 1, GPOS2R3 outputs 1 (set).
2	S2	0	W	When this bit is set to 1, GPOS2R2 outputs 1 (set).
1	S1	0	W	When this bit is set to 1, GPOS2R1 outputs 1 (set).
0	S0	0	W	When this bit is set to 1, GPOS2R0 outputs 1 (set).

57.2.65 CPORT GPOS2R Lead registerCGPOS2RR)

CGPOS2RR is a 16-bit read-only register that reads the output data notifying the WakeUp factor from SYS to RT domain. This register shares addresses with CGPOS2RSR.

This register is contained in the AP block.

57.3 USB Hardware Configuration

The figure below shows the USB hardware configuration in this LSI.

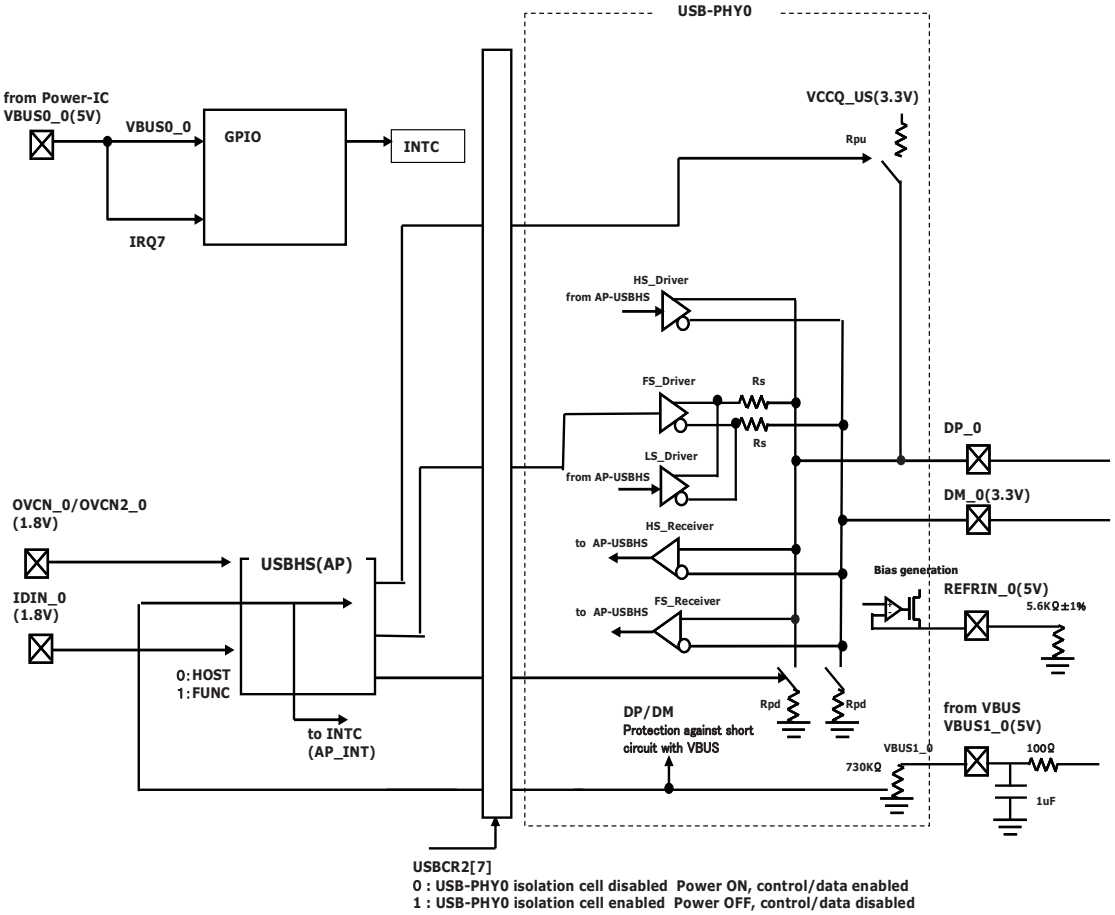

Figure57.1 Schematic Diagram of USB Hardware Configuration

57.4 USB PHY Hardware Configuration of interruption

The figure below shows the USB PHY hardware configuration of interruption in this LSI.

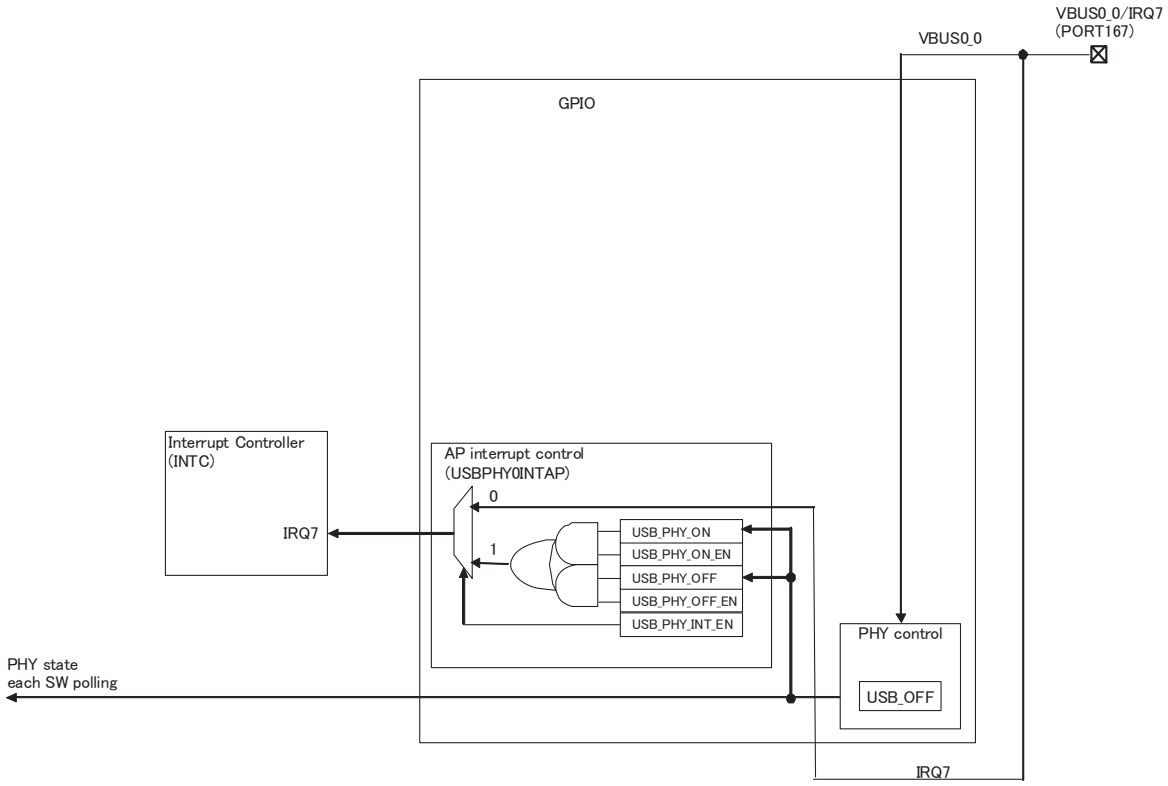

Figure57.2 USB PHY Hardware Configuration of interruption

57.5 PORT Control system

The figure below shows the PORT control configuration in this LSI.

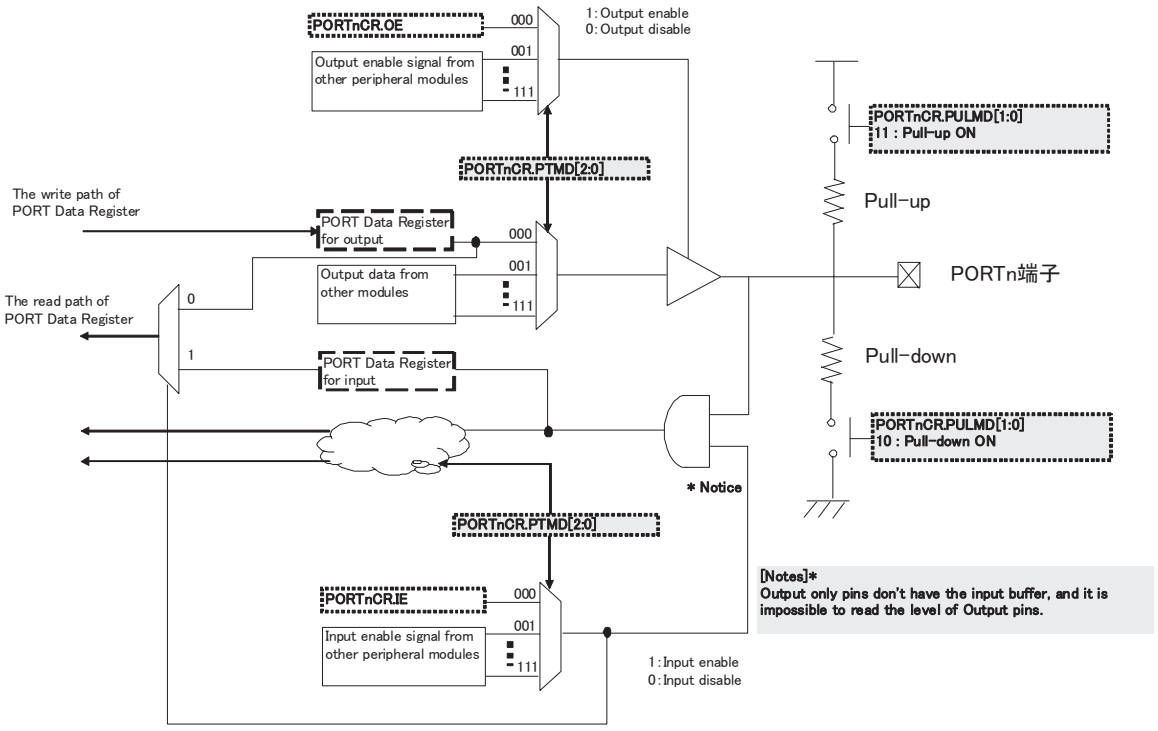

Figure57.3 Schematic view of PORT Control system

Section 58 User Debugging Interface (H-UDI)

The H-UDI is a serial interface, which conforms to the JTAG (IEEE 1149.4: IEEE Standard Test Access Port and Boundary-Scan Architecture) standard. The H-UDI is also used for emulator connection to the AP-RT core.

58.1 Features

The H-UDI is a serial interface that conforms to the JTAG standard. The H-UDI is also used for emulator connection to the AP-RT core. When using an emulator, H-UDI functions should not be used. Refer to the appropriate emulator users manual for the method of connecting the emulator.

The H-UDI has six pins: TCK, TMS, TDI, TDO, TRST_N, and ASEBRK_N/BRKACK. The pin functions except ASEBRK_N/BRKACK and serial communications protocol conform to the JTAG standard. This LSI has additional six pins for emulator connection (AUDSYNC, AUDCK, and AUDATA3 to AUDATA0). Whether these pins are allocated as external pins of this LSI depends on the settings of DBGMD21, DBGMD20, and DBGMDT pins. For details, see section 60, Debugging Specifications (DBG).

Figure 58.1 shows a block diagram of the H-UDI.

The H-UDI circuit includes the TAP (Test Access Port) controller and five registers (SDBPR, SDIR, SDDRH, SDDRL, and SDINT). SDBPR supports the JTAG bypass mode, SDIR is used for commands, SDDR is used for data, and SDINT is used for H-UDI interrupts. SDIR is directly accessed from the TDI and TDO pins.

The TAP controller and control registers are initialized by driving the TRST_N pin low or by applying the TCK signal for five or more clock cycles with the TMS pin set to 1. This initialization sequence is independent of the reset pin for this LSI. Other circuits are initialized by a normal reset.

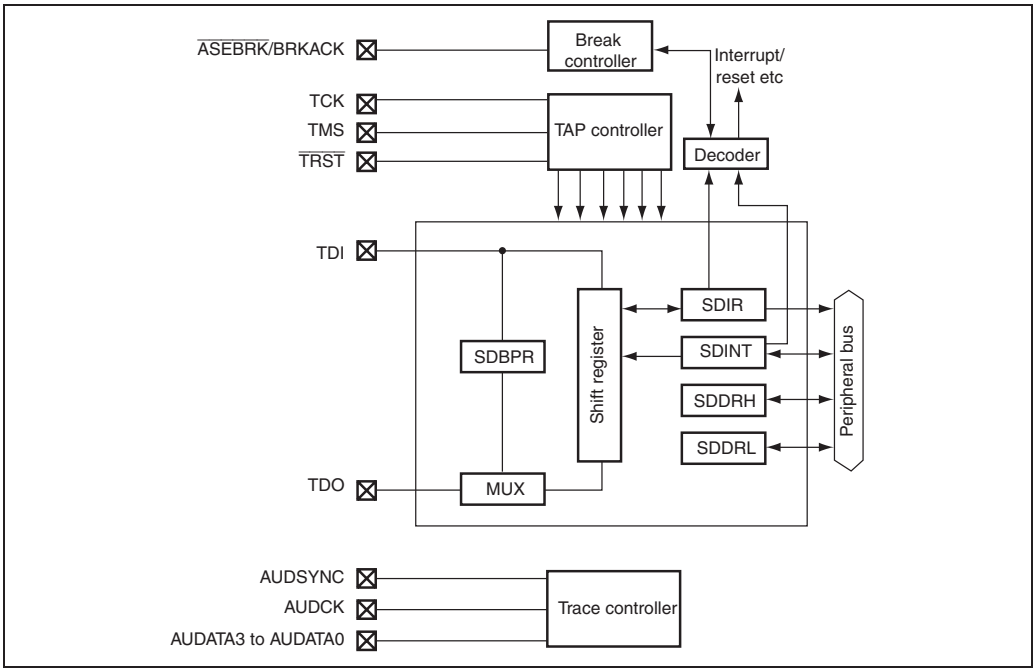

Figure 58.1 H-UDI Block Diagram

58.2 Input/Output Pins

Table 58.1 shows the pin configuration for the H-UDI.

Table 58.1 Pin Configuration

Name	Abbreviation	I/O	Function	When Not in Use
Clock	TCK	Input	Functions as the serial clock input pin stipulated in the JTAG standard. Data input to the H-UDI via the TDI pin or data output via the TDO pin is performed in synchronization with this signal.	Open*[1]
Mode	TMS	Input	Mode Select Input Changing this signal in synchronization with the TCK signal determines the significance of data input via the TDI pin. Its protocol conforms to the JTAG standard (IEEE standard 1149.1).	Open*[1]
Reset	TRST_N*[2]	Input	H-UDI Reset Input This signal is received asynchronously with a TCK signal. Asserting this signal resets the JTAG interface circuit. When a power is supplied, the TRST_N pin should be asserted for a given period regardless of whether or not the JTAG function is used, which differs from the JTAG standard.	Fixed to ground or $\overline{\text{RESET}}$ connection*[3]
Data input	TDI	Input	Data Input Data is sent to the H-UDI by changing this signal in synchronization with the TCK signal.	Open*[1]
Data output	TDO	Output	Data Output Data is read from the H-UDI in synchronization with the TCK signal.	Open
Emulator	ASEBRK_N/ BRKACK	I/O	Pins for an emulator	Open*[1]
Emulator	AUDSYNC, AUDCK, AUDATA3 to AUDATA0	Output	Pins for an emulator	Open

Notes: 1. This pin is pulled up in this LSI. When using interrupts or resets via the H-UDI or emulator, the use of external pull-up resistors will not cause any problem.
2. When using interrupts or resets via the H-UDI or emulator, the TRST_N pin should be designed so that it can be controlled independently and can be controlled to retain low level while the $\overline{\text{RESET}}$ pin is asserted at a power-on reset.

3. This pin should be connected to ground or $\overline{\text{RESET}}$ (or another signal with the same behavior). When this pin is fixed to ground, however, there is one problem. Since the TRST_N pin is pulled up within this LSI, a weak current flows when the pin is externally connected to a ground pin. The value of the current is determined by a resistance of the pull-up MOS for the port pin. Although this current does not affect the operation of this LSI, it consumes unnecessary power.

The TCK clock and the CPG of this LSI should be set to ensure that the frequency of the TCK clock is equal to or less than the frequency of HP ϕ in this LSI.

58.3 Register Descriptions

The H-UDI has the following registers.

Table 58.2 Register Configuration (1)

		CPU Side				
Register Name	**Abbreviation**	**R/W**	**Logical Address**	**Physical Address**	**Size**	**Initial Value*1**
Instruction register	SDIR	R	H'FC11 0000	H'FC11 0000	16	H'0EFF
Data register H	SDDR/SDDRH	R/W	H'FC11 0008	H'FC11 0008	32/16	Undefined
Data register L	SDDRL	R/W	H'FC11 000A	H'FC11 000A	16	Undefined
Interrupt source register	SDINT	R/W	H'FC11 0018	H'FC11 0018	16	H'0000
Bypass register	SDBPR*2	—	—	—	—	Undefined

Note: 1. The low level of the TRST_N pin or the Test-Logic-Reset state of the TAP controller initializes to these values.
2. SDBPR cannot be accessed from the CPU.

Table 58.3 Register Configuration (2)

		H-UDI Side		
Register Name	**Abbreviation**	**R/W**	**Size**	**Initial Value*1**
Instruction register	SDIR	R/W	32	H'FFFF FFFD (fixed value*2)
Data register H	SDDR/SDDRH*4	—	—	—
Data register L	SDDRL*4	—	—	—
Interrupt source register	SDINT	W*3	32	H'0000 0000
Bypass register	SDBPR	R/W	1	Undefined

Notes: 1. The low level of the TRST_N pin or the Test-Logic-Reset state of the TAP controller initializes to these values.
2. When reading via the H-UDI, the value is always H'FFFF FFFD.
3. Only 1 can be written to the LSB by the H-UDI interrupt command.
4. SDDR(SDDRH, SDDRL) cannot be accessed via the H-UDI.

Table 58.4 Register States in Each Operating Mode

Register Name	Abbreviation	Reset
Instruction register	SDIR	H'0EFF
Data register H	SDDR/SDDRH	Undefined
Data register L	SDDRL	Undefined
Interrupt source register	SDINT	H'0000

58.3.1 Instruction Register (SDIR)

SDIR is a 16-bit read-only register that can be read from the CPU. Commands are set via the serial input (TDI). SDIR is initialized by TRST_N or in the Test-Logic-Reset state and can be written by the H-UDI irrespective of the CPU mode. Operation is not guaranteed when a reserved command is set to this register.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TI								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	1	1	1	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	TI	B'00001110	R	Test Instruction Bits 7 to 0 11111111: Bypass 0110xxxx: H-UDI reset negate 0111xxxx: H-UDI reset assert 101xxxxx: H-UDI interrupt 00001110: Initial state Other than above: Setting prohibited
7 to 0	—	All 1	R	Reserved These bits are always read as 1.

58.3.2 Data Register H and L (SDDRH and SDDRL)

SDDR is a 32-bit register that comprises two registers: SDDRH and SDDRL. SDDRH and SDDRL are also 16-bit registers that can be read from or written to by the CPU. SDDR as a 32-bit register can be read from or written to by the CPU. The register value is not initialized by a reset for the CPU but is initialized by TRST_N.

- SDDRH

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

58.3.3 Interrupt Source Register (SDINT)

SDINT is a 16-bit register that can be read from or written to by the CPU. Specifying an H-UDI interrupt command in SDIR via H-UDI pin (Update-IR) sets the INTREQ bit to 1. While an H-UDI interrupt command is set in SDIR, SDINT which is connected between the TDI and TDO pins can be read as a 32-bit register. In this case, the upper 16 bits will be 0 and the lower 16 bits represent the SDINT value.

Only 0 can be written to the INTREQ bit by the CPU. While this bit is set to 1, an interrupt request will continue to be generated. This bit, therefore, should be cleared by the interrupt handling routine. It is initialized by TRST_N or in the Test-Logic-Reset state.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INTREQ
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 1	—	All 0	R	Reserved For reading from or writing to these bits, see General Precautions on Handling of Product.
0	INTREQ	0	R/W	Interrupt Request Indicates whether or not an interrupt by an H-UDI interrupt command has occurred. Clearing this bit to 0 by the CPU cancels an interrupt request. When writing 1 to this bit, the previous value is maintained.

58.4 Operation

58.4.1 TAP Control

Figure 58.2 shows the internal states of the TAP controller. The state transitions basically conform to the JTAG standard.

- State transitions occur according to the TMS value at the rising edge of the TCK signal.
- The TDI value is sampled at the rising edge of the TCK signal and shifted at the falling edge of the TCK signal.
- The TDO value is changed at the falling edge of the TCK signal. The TDO signal is in a Hi-Z state other than in the Shift-DR or Shift-IR state.
- A transition to the Test-Logic-Reset by clearing TRST_N to 0 is performed asynchronously with the TCK signal.

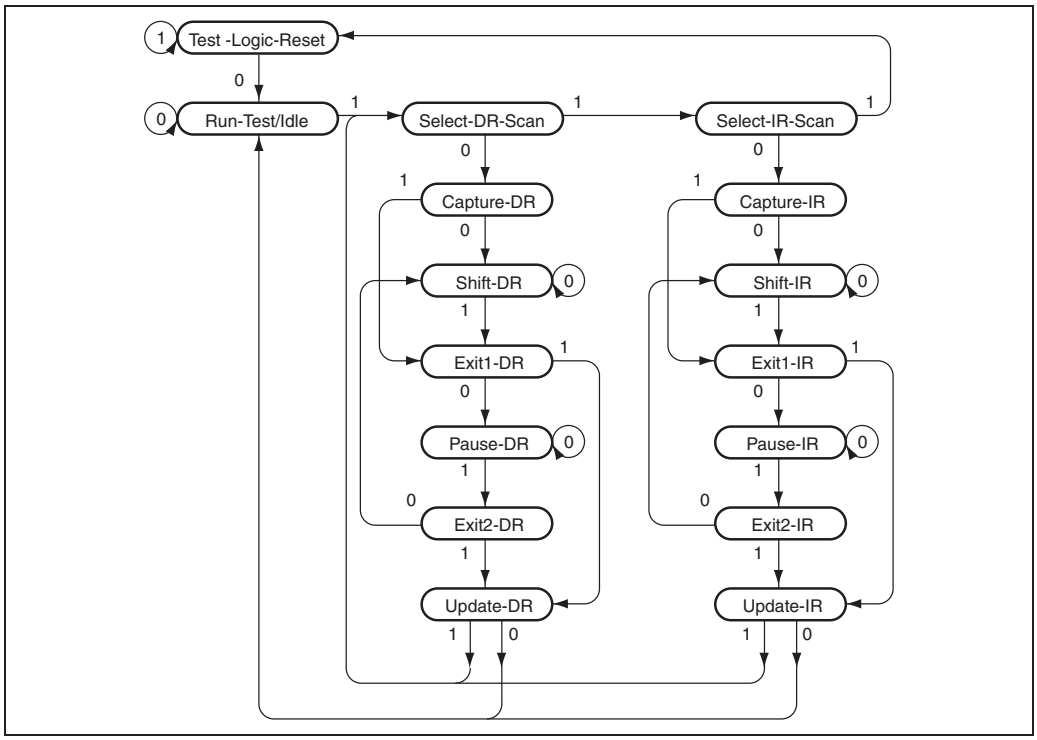

Figure 58.2 TAP Controller State Transitions

58.4.2 H-UDI Reset

The SDIR command can be used to reset the A3RI, A3RV, and A4R areas that include the AP-RT core. After the H-UDI reset assert command has been sent from the H-UDI pin, sending the H-UDI reset negate command resets the CPU (see figure 58.3). The required time between the H-UDI reset assert and H-UDI reset negate commands is the same as the time for holding the reset pin low in order to reset this LSI by a power-on reset.

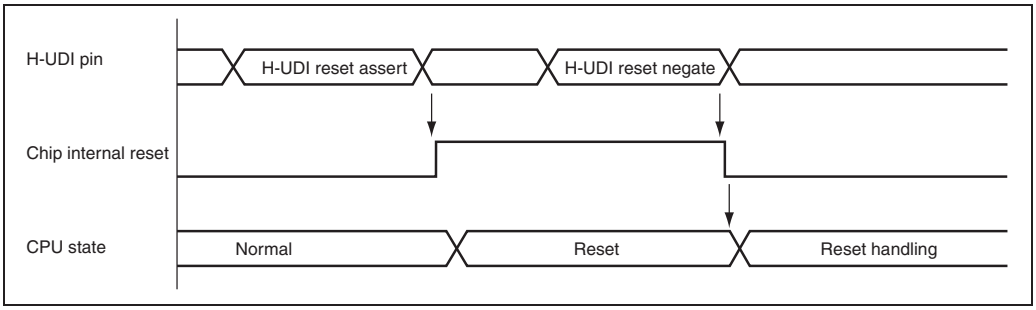

Figure 58.3 H-UDI Reset

58.4.3 H-UDI Interrupt

The H-UDI interrupt function generates an interrupt by setting the appropriate command in SDIR from the H-UDI. An H-UDI interrupt request signal is asserted when the INTREQ bit in SDINT is set to 1 by setting the appropriate command. Since the interrupt request signal is not negated until the INTREQ bit is cleared to 0 by software, it is not possible to lose the interrupt request. While an H-UDI interrupt command is set in SDIR, SDINT is connected between the TDI and TDO pins.

58.5 Usage Notes

- Once an SDIR command is set, it will be changed only by an assertion of the TRST_N signal, making the TAP controller Test-Logic-Reset state, or writing other commands from the H-UDI.
- The H-UDI is used for emulator connection to the AP-RT core. Therefore, H-UDI functions cannot be used when using an emulator.

Section 59 User Break Controller (UBC)

The user break controller (UBC) provides versatile functions to facilitate program debugging of the AP-RT core (SH4AL-DSP). The term "CPU" in this section refers to the AP-RT core. These functions help to ease creation of a self-monitor/debugger, which allows easy program debugging using this LSI alone, without using the in-circuit emulator. Various break conditions can be set in the UBC: instruction fetch or read/write access of an operand, operand size, data contents, address value, and program stop timing for instruction fetch.

59.1 Features

1. The following break conditions can be set.

   Break channels: Two (channels 0 and 1)

   User break conditions can be set independently for channels 0 and 1, and can also be set as a single sequential condition for the two channels, that is, a sequential break. (Sequential break involves two cases such that the channel 0 break condition is satisfied in a certain bus cycle and then the channel 1 break condition is satisfied in a different bus cycle, and vice versa.)

- Address

  When 40 bits containing ASID and 32-bit address are compared with the specified value, all the ASID bits can be compared or masked.

  32-bit address can be masked bit by bit, allowing the user to mask the address in desired page sizes such as lower 12 bits (4-Kbyte page) and lower 10 bits (1-Kbyte page).

  One address bus can be selected among three operand buses: operand address bus (SAB), X memory address bus (XAB), and Y memory address bus (YAB)

- Data

  32 bits can be masked only for channel 1.

  One data bus can be selected among three data buses: operand data bus (SDB), X memory data bus (XDB), and Y memory data bus (YDB)

- Bus cycle

  The program can break either for instruction fetch (PC break) or operand access.

- Read or write access

- Operand sizes

  Byte, word, and longword are supported.

2. The user-designated exception handling routine for the user break condition can be executed.
3. Pre-instruction-execution or post-instruction-execution can be selected as the PC break timing.
4. A maximum of $2^{12} - 1$ repetition counts can be specified as the break condition (available only for channel 1).

Figure 59.1 shows the UBC block diagram.

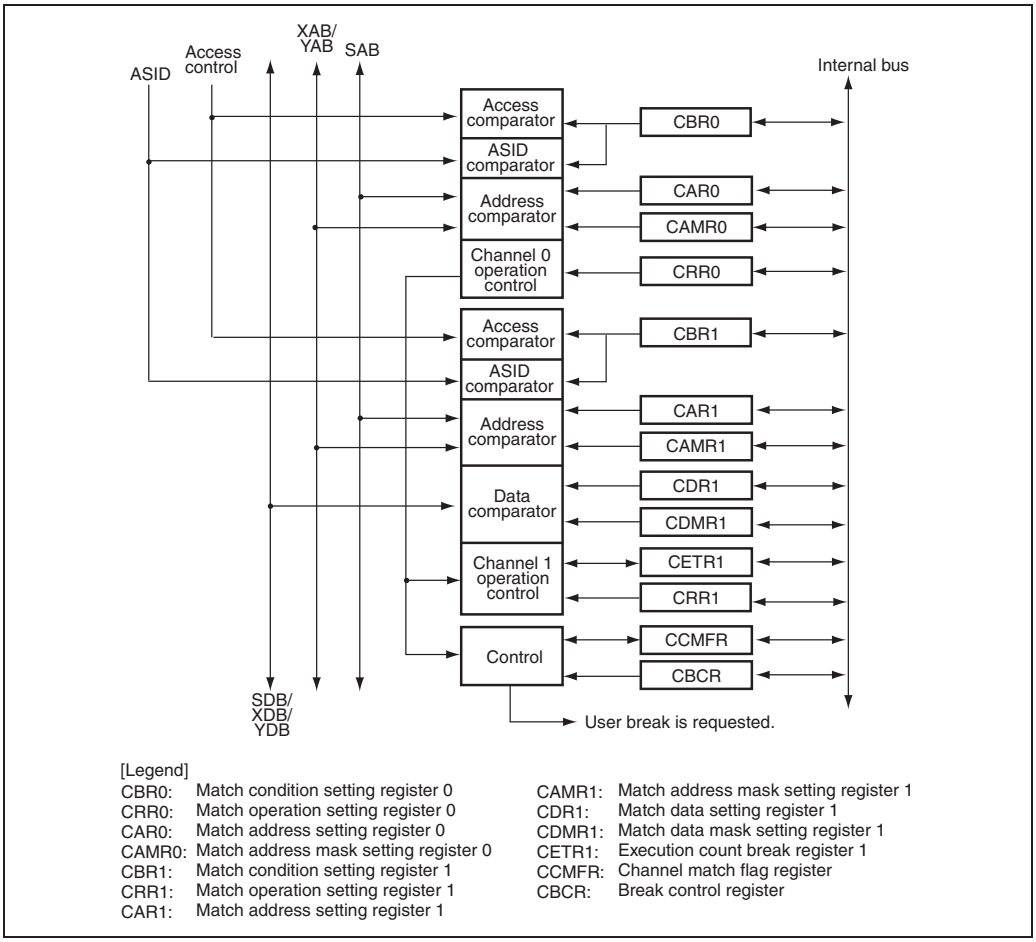

Figure 59.1 Block Diagram of UBC

59.2 Register Descriptions

The UBC has the following registers.

Table 59.1 Register Configuration

Register Name	Abbreviation	R/W	P4 Address	Area 7 Address	Access Size
Match condition setting register 0	CBR0	R/W	H'FF20 0000	H'FF20 0000	32

Execution count break register 1	CETR1	Undefined	Retained	Retained
Channel match flag register	CCMFR	H'0000 0000	Retained	Retained
Break control register	CBCR	H'0000 0000	Retained	Retained

The access size must be the same as the control register size. If the size is different, the register is not written to if attempted, and reading the register returns the undefined value. A desired break may not occur between the time when the instruction for rewriting the control register is executed and the time when the written value is actually reflected on the register. In order to confirm the exact timing when the control register is updated, read the data, which has been written most recently. The subsequent instructions are valid for the most recently written register value.

59.2.1 Match Condition Setting Registers 0 and 1 (CBR0 and CBR1)

CBR0 and CBR1 are readable/writable 32-bit registers which specify the break conditions for channels 0 and 1, respectively. The following break conditions can be set in the CBR0 and CBR1: (1) whether or not to include the match flag in the conditions, (2) whether or not to include the ASID, and the ASID value when included, (3) whether or not to include the data value, (4) operand size, (5) whether or not to include the execution count, (6) bus type, (7) instruction fetch cycle or operand access cycle, and (8) read or write access cycle.

- CBR0

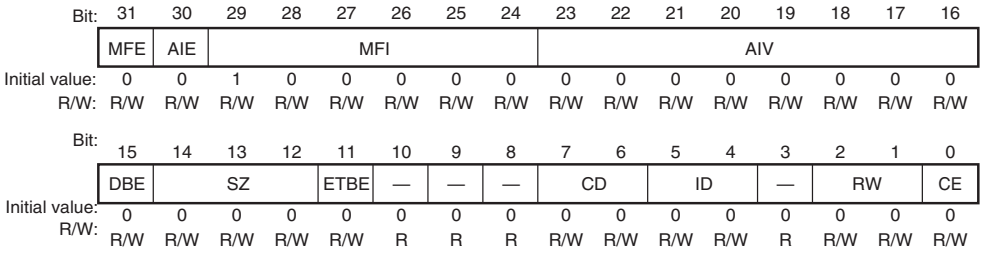
R/W:	R	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W



Bit	Bit Name	Initial Value	R/W	Description
31	MFE	0	R/W	Match Flag Enable Specifies whether or not to include the match flag value specified by the MFI bit of this register in the match conditions. When the specified match flag value is 1, the condition is determined to be satisfied. 0: The match flag is not included in the match conditions; thus, not checked. 1: The match flag is included in the match conditions.
30	AIE	0	R/W	ASID Enable Specifies whether or not to include the ASID specified by the AIV bit of this register in the match conditions. 0: The ASID is not included in the match conditions; thus, not checked. 1: The ASID is included in the match conditions.

Bit	Bit Name	Initial Value	R/W	Description
29 to 24	MFI	100000	R/W	Match Flag Specify Specify the match flag to be included in the match conditions. 000000: MF0 bit of the CCMFR register 000001: MF1 bit of the CCMFR register Others: Reserved (setting prohibited) Note: The initial value is the reserved value, but when 1 is written into CBR0[0], MFI must be set to 000000 or 000001. And note that the channel 0 is not hit when MFE bit of this register is 1 and MFI bits are 000000 in the condition of CCRMF.MF0 = 0.
23 to 16	AIV	All 0	R/W	ASID Specify Specify the ASID value to be included in the match conditions.
15	—	0	R	Reserved For read/write in this bit, refer to General Precautions on Handling of Product.
14 to 12	SZ	All 0	R/W	Operand Size Select Specify the operand size to be included in the match conditions. This bit is valid only when the operand access cycle is specified as a match condition. 000: The operand size is not included in the match conditions; thus, not checked (any operand size specifies the match condition).* 001: Byte access 010: Word access 011: Longword access Others: Reserved (setting prohibited)
11 to 8	—	All 0	R	Reserved For read/write in these bits, refer to General Precautions on Handling of Product.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	CD	All 0	R/W	Bus Select Specify the bus to be included in the match conditions. This bit is valid only when the operand access cycle is specified as a match condition. 00: Operand bus for operand access 01: X bus for operand access 10: Y bus for operand access 11: Reserved (setting prohibited)
5, 4	ID	All 0	R/W	Instruction Fetch/Operand Access Select Specify the instruction fetch cycle or operand access cycle as the match condition. 00: Instruction fetch cycle or operand access cycle 01: Instruction fetch cycle 10: Operand access cycle 11: Instruction fetch cycle or operand access cycle
3	—	0	R	Reserved For read/write in this bit, refer to General Precautions on Handling of Product.
2, 1	RW	All 0	R/W	Bus Command Select Specify the read/write cycle as the match condition. This bit is valid only when the operand access cycle is specified as a match condition. 00: Read cycle or write cycle 01: Read cycle 10: Write cycle 11: Read cycle or write cycle
0	CE	0	R/W	Channel Enable Validates/invalidates the channel. If this bit is 0, all the other bits of this register are invalid. 0: Invalidates the channel. 1: Validates the channel.

Note: * If the data value is included in the match conditions, be sure to specify the operand size.

- CBR1

Bit	Bit Name	Initial Value	R/W	Description
31	MFE	0	R/W	Match Flag Enable Specifies whether or not to include the match flag value specified by the MFI bit of this register in the match conditions. When the specified match flag value is 1, the condition is determined to be satisfied. 0: The match flag is not included in the match conditions; thus, not checked. 1: The match flag is included in the match conditions.
30	AIE	0	R/W	ASID Enable Specifies whether or not to include the ASID specified by the AIV bit of this register in the match conditions. 0: The ASID is not included in the match conditions; thus, not checked. 1: The ASID is included in the match conditions.
29 to 24	MFI	100000	R/W	Match Flag Specify Specify the match flag to be included in the match conditions. 000000: The MF0 bit of the CCMFR register 000001: The MF1 bit of the CCMFR register Others: Reserved (setting prohibited) Note: The initial value is the reserved value, but when 1 is written into CBR1[0], MFI must be set to 000000 or 000001. And note that the channel 1 is not hit when MFE bit of this register is 1 and MFI bits are 000001 in the condition of CCRMF.MF1 = 0.

Bit	Bit Name	Initial Value	R/W	Description
23 to 16	AIV	All 0	R/W	ASID Specify Specify the ASID value to be included in the match conditions.
15	DBE	0	R/W	Data Value Enable*2 Specifies whether or not to include the data value in the match condition. This bit is valid only when the operand access cycle is specified as a match condition. 0: The data value is not included in the match conditions; thus, not checked. 1: The data value is included in the match conditions.
14 to 12	SZ	All 0	R/W	Operand Size Select Specify the operand size to be included in the match conditions. This bit is valid only when the operand access cycle is specified as a match condition. 000: The operand size is not included in the match condition; thus, not checked (any operand size specifies the match condition).*1 001: Byte access 010: Word access 011: Longword access Others: Reserved (setting prohibited)
11	ETBE	0	R/W	Execution Count Value Enable Specifies whether or not to include the execution count value in the match conditions. If this bit is 1 and the match condition satisfaction count matches the value specified by the CETR1 register, the operation specified by the CRR1 register is performed. 0: The execution count value is not included in the match conditions; thus, not checked. 1: The execution count value is included in the match conditions.
10 to 8	—	All 0	R	Reserved For read/write in these bits, refer to General Precautions on Handling of Product.

Bit	Bit Name	Initial Value	R/W	Description
7, 6	CD	All 0	R/W	Bus Select Specify the bus to be included in the match conditions. This bit is valid only when the operand access cycle is specified as a match condition. 00: Operand bus for operand access 01: X bus for operand access 10: Y bus for operand access 11: Reserved (setting prohibited)
5, 4	ID	All 0	R/W	Instruction Fetch/Operand Access Select Specify the instruction fetch cycle or operand access cycle as the match condition. 00: Instruction fetch cycle or operand access cycle 01: Instruction fetch cycle 10: Operand access cycle 11: Instruction fetch cycle or operand access cycle
3	—	0	R	Reserved For read/write in this bit, refer to General Precautions on Handling of Product.
2, 1	RW	All 0	R/W	Bus Command Select Specify the read/write cycle as the match condition. This bit is valid only when the operand access cycle is specified as a match condition. 00: Read cycle or write cycle 01: Read cycle 10: Write cycle 11: Read cycle or write cycle
0	CE	0	R/W	Channel Enable Validates/invalidates the channel. If this bit is 0, all the other bits in this register are invalid. 0: Invalidates the channel. 1: Validates the channel.

Notes: 1. If the data value is included in the match conditions, be sure to specify the operand size.

2. The OCBI instruction is handled as longword write access without the data value, and the PREF, OCBP, and OCBWB instructions are handled as longword read access without the data value. Therefore, do not include the data value in the match conditions for these instructions.

59.2.2 Match Operation Setting Registers 0 and 1 (CRR0 and CRR1)

CRR0 and CRR1 are readable/writable 32-bit registers which specify the operation to be executed when channels 0 and 1 satisfy the match condition, respectively. The following operations can be set in the CRR0 and CRR1 registers: (1) breaking at a desired timing for the instruction fetch cycle and (2) requesting a break.

- CRR0

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved For read/write in these bits, refer to General Precautions on Handling of Product.
13	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
12 to 2	—	All 0	R	Reserved For read/write in these bits, refer to General Precautions on Handling of Product.
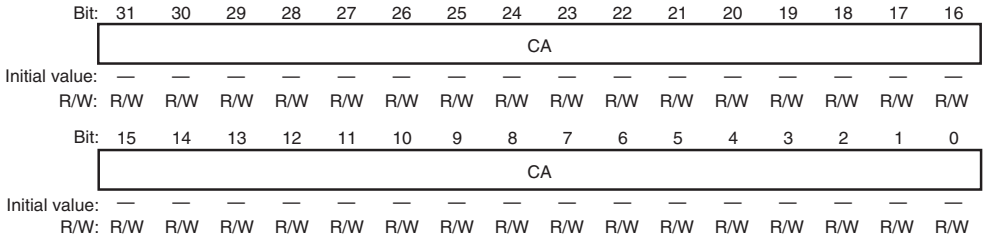
1	PCB	0	R/W	PC Break Select Specifies either before or after instruction execution as the break timing for the instruction fetch cycle. This bit is invalid for breaks other than ones for the instruction fetch cycle. 0: Sets the PC break before instruction execution. 1: Sets the PC break after instruction execution.
0	BIE	0	R/W	Break Enable Specifies whether or not to request a break when the match condition is satisfied for the channel. 0: Does not request a break. 1: Requests a break.

59.2.3 Match Address Setting Registers 0 and 1 (CAR0 and CAR1)



CAR0 and CAR1 are readable/writable 32-bit registers specifying the virtual address to be included in the break conditions for channels 0 and 1, respectively. One of three address buses to be included in the break condition is selected by the CD bit of the match condition setting registers (CBR0 and CBR1).

- CAR0

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CA	Undefined	R/W	Compare Address Specify the address to be included in the break conditions. When the operand bus has been specified using the CBR0 register, specify the SAB address in CA[31:0]. When the X bus has been specified using the CBR0 register, specify the values of XAB15 to XAB1 in CA[31:17]. In this case, any values are specified in CA[16:0]. When the Y bus has been specified using the CBR0 register, specify the values of YAB15 to YAB1 in CA[15:1]. In this case, any values are specified in CA[31:16] and CA[0].

- CAR1

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CA	Undefined	R/W	Compare Address Specify the address to be included in the break conditions. When the operand bus has been specified using the CBR1 register, specify the SAB address in CA[31:0]. When the X bus has been specified using the CBR1 register, specify the values of XAB15 to XAB1 in CA[31:17]. In this case, any values are specified in CA[16:0]. When the Y bus has been specified using the CBR1 register, specify the values of YAB15 to YAB1 in CA[15:1]. In this case, any values are specified in CA[31:16] and CA[0].

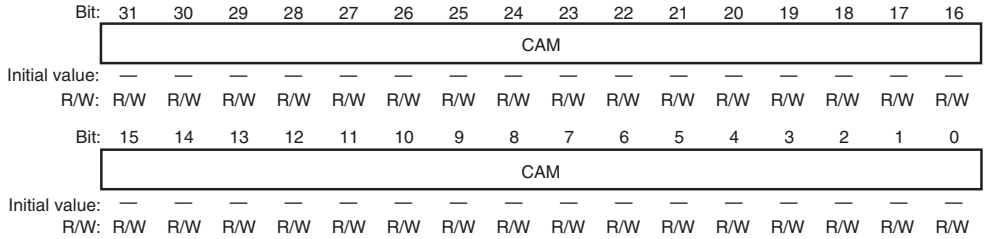


Table 59.3 Settings for Match Address Setting Register

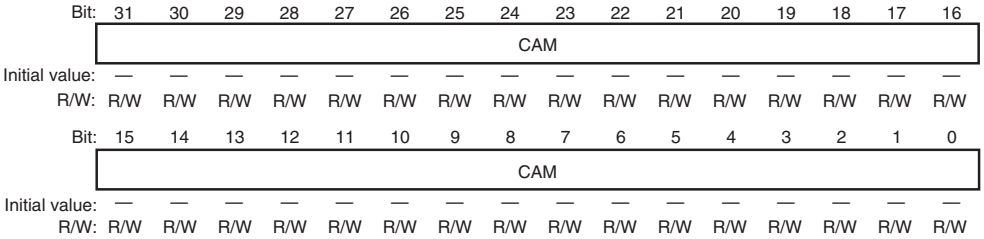
Bus Selected Using CBR0, CBR1	CA[31:17]	CA[16]	CA[15:1]	CA[0]
Operand bus	SAB31 to SAB17	SAB16	SAB15 to SAB1	SAB0
X bus	XAB15 to XAB1	Don't care	Don't care	Don't care
Y bus	Don't care	Don't care	YAB15 to YAB1	Don't care

59.2.4 Match Address Mask Setting Registers 0 and 1 (CAMR0 and CAMR1)



CMAR0 and CMAR1 are readable/writable 32-bit registers which specify the bits to be masked among the address bits specified by using the match address setting register of the corresponding channel. (Set the bits to be masked to 1.)

- CAMR0

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CAM	Undefined	R/W	Compare Address Mask Specify the bits to be masked among the address bits, which are specified using the CAR0 register. (Set the bits to be masked to 1.) 0: Address bits CA[n] are included in the break condition. 1: Address bits CA[n] are masked and not included in the break condition. [n] = any values from 31 to 0

- CAMR1

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CAM	Undefined	R/W	Compare Address Mask Specify the bits to be masked among the address bits, which are specified using the CAR1 register. (Set the bits to be masked to 1.) 0: Address bits CA[n] are included in the break condition. 1: Address bits CA[n] are masked and not included in the break condition. [n] = any values from 31 to 0

59.2.5 Match Data Setting Register 1 (CDR1)

CDR1 is a readable/writable 32-bit register which specifies the data value to be included in the break conditions for channel 1. One of three address buses to be included in the break condition is selected by the CD bit of the match condition setting register (CBR1).

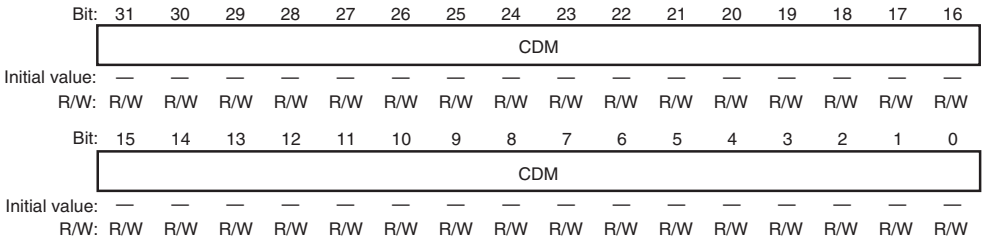
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CD															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CD															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CD	Undefined	R/W	Compare Data Value Specify the data value to be included in the break conditions. When the operand bus has been specified using the CBR1 register, specify the SDB data value in CD[31:0]. When the X bus has been specified using the CBR1 register, specify the values of XDB15 to XDB0 in CD[31:16]. In this case, any values are specified in CD[15:0]. When the Y bus has been specified using the CBR1 register, specify the values of YDB15 to YDB0 in CD[15:0]. In this case, any values are specified in CD[31:16].

Table 59.4 Settings for Match Data Setting Register

Bus and Size Selected Using CBR1	CD[31:24]	CD[23:16]	CD[15:8]	CD[7:0]
Operand bus (byte)	Don't care	Don't care	Don't care	SDB7 to SDB0
Operand bus (word)	Don't care	Don't care	SDB15 to SDB8	SDB7 to SDB0
Operand bus (longword)	SDB31 to SDB24	SDB23 to SDB16	SDB15 to SDB8	SDB7 to SDB0
X bus (word)	XDB15 to XDB8	XDB7 to XDB0	Don't care	Don't care
X bus (longword)	XDB31 to XDB24	XDB23 to XDB16	XDB15 to XDB8	XDB7 to XDB0
Y bus (word)	Don't care	Don't care	YDB15 to YDB8	YDB7 to YDB0
Y bus (longword)	YDB31 to YDB24	YDB23 to YDB16	YDB15 to YDB8	YDB7 to YDB0



Notes: 1. If the data value is included in the match conditions, be sure to specify the operand size.

2. The OCBI instruction is handled as longword write access without the data value, and the PREF, OCBP, and OCBWB instructions are handled as longword read access without the data value. Therefore, do not include the data value in the match conditions for these instructions.

3. When the data value is included as the match condition on the operand bus for instructions MOVS.W @-As,Ds, MOVS.W @As,Ds, MOVS.W @As+,Ds, and MOVS.W @As+Ix,Ds, be sure to set the data in CD[15:0].

59.2.6 Match Data Mask Setting Register 1 (CDMR1)

CDMR1 is a readable/writable 32-bit register which specifies the bits to be masked among the data value bits specified using the match data setting register. (Set the bits to be masked to 1.)

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CDM	Undefined	R/W	Compare Data Value Mask Specify the bits to be masked among the data value bits specified using the CDR1 register. (Set the bits to be masked to 1.) 0: Data value bits CD[n] are included in the break condition. 1: Data value bits CD[n] are masked and not included in the break condition. [n] = any values from 31 to 0

59.2.7 Execution Count Break Register 1 (CETR1)

CETR1 is a readable/writable 32-bit register which specifies the number of the channel hits before a break occurs. A maximum value of $2^{12} - 1$ can be specified. When the execution count value is included in the match conditions by using the match condition setting register, the value of this register is decremented by one every time the channel is hit. When the channel is hit after the register value reaches H'001, a break occurs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CET											
Initial value:	0	0	0	0	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved For read/write in these bits, refer to General Precautions on Handling of Product.
11 to 0	CET	Undefined	R/W	Execution Count Specify the execution count to be included in the break conditions.

59.2.8 Channel Match Flag Register (CCMFR)

CCMFR is a readable/writable 32-bit register, which indicates whether or not the match conditions have been satisfied for each channel. When a channel match condition has been satisfied, the corresponding flag bit is set to 1. To clear the flags, write the data containing value 0 for the bits to be cleared and value 1 for the other bits to this register. (The logical AND between the value which has been written and the current register value is actually written to the register.) Sequential operation using multiple channels is available by using these match flags.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MF1	MF0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved For read/write in these bits, refer to General Precautions on Handling of Product.
1	MF1	0	R/W	Channel 1 Condition Match Flag This flag is set to 1 when the channel 1 match condition has been satisfied. To clear the flag, write 0 to this bit. 0: Channel 1 match condition has not been satisfied. 1: Channel 1 match condition has been satisfied.
0	MF0	0	R/W	Channel 0 Condition Match Flag This flag is set to 1 when the channel 0 match condition has been satisfied. To clear the flag, write 0 to this bit. 0: Channel 0 match condition has not been satisfied. 1: Channel 0 match condition has been satisfied.

59.2.9 Break Control Register (CBCR)

CBCR is a readable/writable 32-bit register, which specifies whether or not to use the user break debugging support function. For details on the user break debugging support function, refer to section 59.4, User Break Debugging Support Function.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UBDE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved For read/write in these bits, refer to General Precautions on Handling of Product.
0	UBDE	0	R/W	User Break Debugging Support Function Enable Specifies whether or not to use the user break debugging support function. 0: Does not use the user break debugging support function. 1: Uses the user break debugging support function.

59.3 Operation Description

59.3.1 Definition of Words Related to Accesses

"Instruction fetch" refers to an access in which an instruction is fetched. For example, fetching the instruction located at the branch destination after executing a branch instruction is an instruction access. "Operand access" refers to any memory access accompanying execution of an instruction. For example, accessing an address (PC + disp × 2 + 4) in the instruction MOV.W@(disp,PC),Rn is an operand access. "Data" is used in contrast to "address".

All types of operand access are classified into read or write access. Special care must be taken in using the following instructions.

- PREF, OCBP, and OCBWB: Instructions for a read access
- MOVCA.L and OCBI: Instructions for a write access
- TAS.B: Instruction for a single read access or a single write access

The operand access accompanying the PREF, OCBP, OCBWB, and OCBI instructions is access without the data value; therefore, do not include the data value in the match conditions for these instructions.

The operand size should be defined for all types of operand access. Available operand sizes are byte, word, and longword. For operand access accompanying the PREF, OCBP, OCBWB, MOVCA.L, and OCBI instructions, the operand size is defined as longword.

59.3.2 User Break Operation Sequence

The following describes the sequence from when the break condition is set until the user break exception handling is initiated.

1. Specify the operand size, bus, instruction fetch/operand access, and read/write as the match conditions using the match condition setting register (CBR0 or CBR1). Specify the break address using the match address setting register (CAR0 or CAR1), and specify the address mask condition using the match address mask setting register (CAMR0 or CAMR1). To include the ASID in the match conditions, set the AIE bit in the match condition setting register and specify the ASID value by the AIV bit in the same register. To include the data value in the match conditions, set the DBE bit in the match condition setting register; specify the break data using the match data setting register (CDR1); and specify the data mask condition using the match data mask setting register (CDMR1). To include the execution count in the match conditions, set the ETBE bit of the match condition setting register; and specify the execution count using the execution count break register (CETR1). To use the sequential break, set the MFE bit of the match condition setting register; and specify the number of the first channel using the MFI bit.
2. Specify whether or not to request a break when the match condition is satisfied and the break timing when the match condition is satisfied as a result of fetching the instruction using the match operation setting register (CRR0 or CRR1). After having set all the bits in the match condition setting register except the CE bit and the other necessary registers, set the CE bit and read the match condition setting register again. This ensures that the set values in the control registers are valid for the subsequent instructions immediately after reading the register. Setting the CE bit of the match condition setting register in the initial state after reset via the control registers may cause an undesired break.
3. When the match condition has been satisfied, the corresponding condition match flag (MF1 or MF0) in the channel match flag register (CCMFR) is set. A break is also requested to the CPU according to the set values in the match operation setting register (CRR0 or CRR1). The CPU operates differently according to the BL bit value of the SR register: when the BL bit is 0, the CPU accepts the break request and executes the specified exception handling; and when the BL bit is 1, the CPU does not execute the exception handling.
4. The match flags (MF1 and MF0) can be used to confirm whether or not the corresponding match condition has been satisfied. Although the flag is set when the condition is satisfied, it is not cleared automatically; therefore, write 0 to the flag bit by issuing a memory store instruction to the channel match flag register (CCMFR) in order to use the flag again.
5. Breaks may occur virtually at the same time for channels 0 and 1. In this case, only one break request is sent to the CPU; however, the two condition match flags corresponding to these breaks may be set.

6. While the BL bit in the SR register is 1, no break requests are accepted. However, whether or not the condition has been satisfied is determined. When the condition is determined to be satisfied, the corresponding condition match flag is set.
7. If the sequential break conditions are set, the condition match flag is set every time the match conditions are satisfied for each channel. When the conditions have been satisfied for the first channel in the sequence but not for the second channel in the sequence, clear the condition match flag for the first channel in the sequence in order to release the first channel in the sequence from the match state.

59.3.3 Instruction Fetch Cycle Break

1. If the instruction fetch cycle is set in the match condition setting register (CBR0 or CBR1), the instruction fetch cycle is handled as a match condition. To request a break upon satisfying the match condition, set the BIE bit in the match operation setting register (CRR0 or CRR1) of the corresponding channel. Either before or after executing the instruction can be selected as the break timing according to the PCB bit value. If the instruction fetch cycle is specified as a match condition, be sure to clear the LSB to 0 in the match address setting register (CAR0 or CAR1); otherwise, no break occurs.
2. If pre-instruction-execution break is specified for the instruction fetch cycle, the break is requested when the instruction is fetched and determined to be executed. Therefore, this function cannot be used for the instructions, which are fetched through overrun (i.e., the instructions fetched during branching or making transition to the interrupt routine but not executed). For priorities of pre-instruction-execution break and the other exceptions, refer to the SH4AL-DSP Software Manual. If pre-instruction-execution break is specified for the delayed slot of the delayed branch instruction, the break is requested before the delayed branch instruction is executed. However, do not specify pre-instruction-execution break for the delayed slot of the RTE instruction.
3. If post-instruction-execution break is specified for the instruction fetch cycle, the break is requested after the instruction which satisfied the match condition has been executed and before the next instruction is executed. Similar to pre-instruction-execution break, this function cannot be used for the instructions, which are fetched through overrun. For priorities of post-instruction-execution break and the other exceptions, refer to the SH4AL-DSP Software Manual. If post-instruction-execution break is specified for the delayed branch instruction and its delayed slot, the break does not occur until the first instruction at the branch destination.
4. If the instruction fetch cycle is specified as the channel 1 match condition, the DBE bit of match condition setting register CBR1 becomes invalid, the settings of match data setting register CDR1 and match data mask setting register CDMR1 are ignored. Therefore, the data value cannot be specified for the instruction fetch cycle break.

59.3.4 Operand Access Cycle Break

1. Table 59.5 shows the relation between the operand sizes specified using the match condition setting register (CBR0 or CBR1) and the address bits to be compared for the operand access cycle break.

Table 59.5 Relation between Operand Sizes and Address Bits to be Compared

Selected Operand Size	Address Bits to be Compared
Longword	Address bits A31 to A2
Word	Address bits A31 to A1
Byte	Address bits A31 to A0
Operand size is not included in the match conditions	Address bits A31 to A2 for longword access Address bits A31 to A1 for word access Address bits A31 to A0 for byte access

The above table means that if address H'0000 1003 is set in the match address setting register (CAR0 or CAR1), for example, the match condition is satisfied for the following access cycles (assuming that all the other conditions are satisfied):

— Longword access to address H'0000 1000
— Word access to address H'0000 1002
— Byte access to address H'0000 1003

2. When the data value is included in the channel 1 match conditions:
   If the data value is included in the match conditions, be sure to select the longword, word, or byte as the operand size using the operand size select bit (SZ) of the match condition setting register (CBR1), and also set the match data setting register (CDR1) and the match data mask setting register (CDMR1). With these settings, the match condition is satisfied when both of the address and data conditions are satisfied. The data value and mask control for byte access, word access, and longword access should be set in bits 7 to 0, 15 to 0, and 31 to 0 in the bits CDR1 and CDMR1, respectively. When the data value is included as the break condition for instructions MOVS.W @-As,Ds, MOVS.W @As,Ds, MOVS.W @As+,Ds, and MOVS.W @As+lx,Ds, be sure to set the data value and mask in the bits 15 to 0 of CDR1 and CDMR1.
3. The operand access accompanying the PREF, OCBP, OCBWB, and OCBI instructions are access without the data value; therefore, if the data value is included in the match conditions for these instructions, the match conditions will never be satisfied.

4. If the operand bus is selected, a break occurs after executing the instruction which has satisfied the conditions and immediately before executing the next instruction. However, if the data value is included in the match conditions, a break may occur after executing several instructions after the instruction which has satisfied the conditions; therefore, it is impossible to identify the instruction causing the break. If such a break has occurred for the delayed branch instruction or its delayed slot, the break does not occur until the first instruction at the branch destination.

   However, do not specify the operand break for the delayed slot of the RTE instruction. And if the data value is included in the match conditions, it is not allowed to set the break for the preceding the RTE instruction by one to six instructions.

59.3.5 X Memory or Y Memory Bus Cycle Break

1. The X memory or Y memory can be selected by using the bus select bit (CD bit) of the match condition setting register (CBR0 or CBR1). Both X memory and Y memory cannot be included at the same time in one channel much condition. When the X bus or Y bus/ operand access/read or write/word or longword are set in the match condition, the memory access of X bus or Y bus is treated as the match condition.
2. To specify the X memory address as the match condition, set the X memory address and mask in the upper 16-bit of the match address setting register (CAR0 or CAR1) and the match address mask setting register (CAMR0 or CAMR1). To specify the Y memory address as the match condition, set the Y memory address and mask in the lower 16-bit of the match address setting register (CAR0 or CAR1) and the match address mask setting register (CAMR0 or CAMR1). When the data value is included as the channel 1 match condition, the data value of the X bus is set in the upper 16-bit of the match data setting register (CDR1) and match data mask setting register (CDMR1); and the data value of Y bus is set in the lower 16-bit of those registers for word access. For longword access, 32-bit data value of the X or Y bus and mask are set in CDR1 and CDMR1.
3. The operand access break of the X or Y memory bus is occurred at the same timing as that of the operand bus. For details, see section 59.3.4, Operand Access Cycle Break.

59.3.6 Sequential Break

1. Sequential break conditions can be specified by setting the MFE and MFI bits in the match condition setting registers (CBR0 and CBR1). (Sequential break involves two cases such that channel 0 break condition is satisfied then channel 1 break condition is satisfied, and vice versa.) To use the sequential break function, clear the MFE bit of the match condition setting register and the BIE bit of the match operation setting register of the first channel in the sequence, and set the MFE bit and specify the number of the second channel in the sequence using the MFI bit in the match condition setting register of the second channel in the sequence. If the sequential break condition is set, the condition match flag is set every time the match condition is satisfied for each channel. When the condition has been satisfied for the first channel in the sequence but not for the second channel in the sequence, clear the condition match flag for the first channel in the sequence in order to release the first channel in the sequence from the match state.
2. As the sequential break conditions, the operand bus, X bus, or Y bus can be specified for the first and second channels in the sequence; the execution count break condition can also be specified for channel 1.
3. If the match conditions for the first and second channels in the sequence are satisfied within a significantly short time, sequential operation may not be guaranteed in some cases, as shown below.

- When the Match Condition is Satisfied at the Instruction Fetch Cycle for Both the First and Second Channels in the Sequence:

Instruction B is 0 instruction after instruction A	Equivalent to setting the same addresses; do not use this setting.
Instruction B is one instruction after instruction A	Sequential operation is not guaranteed.
Instruction B is two or more instructions after instruction A	Sequential operation is guaranteed.

- When the match condition is satisfied at the instruction fetch cycle for the first channel in the sequence whereas the match condition is satisfied at the operand access cycle for the second channel in the sequence:

Instruction B is 0 or one instruction after instruction A	Sequential operation is not guaranteed.
Instruction B is two or more instructions after instruction A	Sequential operation is guaranteed.

- When the match condition is satisfied at the operand access cycle for the first channel in the sequence whereas the match condition is satisfied at the instruction fetch cycle for the second channel in the sequence:

Instruction B is 0 to five instructions after instruction A	Sequential operation is not guaranteed.
Instruction B is six or more instructions after instruction A	Sequential operation is guaranteed.

- When the match condition is satisfied at the operand access cycle for both the first and second channels in the sequence:

Instruction B is 0 to five instructions after instruction A	Sequential operation is not guaranteed.
Instruction B is six or more instructions after instruction A	Sequential operation is guaranteed.

59.3.7 Program Counter Value to be Saved

When a break has occurred, the address of the instruction to be executed when the program restarts is saved in the SPC then the exception handling state is initiated. A unique instruction causing a break can be identified unless the data value is included in the match conditions.

- When the instruction fetch cycle (before instruction execution) is specified as the match condition:

  The address of the instruction which has satisfied the match conditions is saved in the SPC. The instruction which has satisfied the match conditions is not executed, but a break occurs instead. However, if the match conditions are satisfied for the delayed slot instruction, the address of the delayed branch instruction is saved in the SPC.
- When the instruction fetch cycle (after instruction execution) is specified as the match condition:

  The address of the instruction immediately after the instruction which has satisfied the match conditions is saved in the SPC. The instruction which has satisfied the match conditions is executed, then a break occurs before the next instruction. If the match conditions are satisfied for the delayed branch instruction or its delayed slot, these instructions are executed and the address of the branch destination is saved in the SPC.
- When the operand access (address only) is specified as the match condition:

  The address of the instruction immediately after the instruction which has satisfied the break conditions is saved in the SPC. The instruction which has satisfied the match conditions are executed, then a break occurs before the next instruction. However, if the conditions are satisfied for the delayed slot, the address of the branch destination is saved in the SPC.
- When the operand access (address and data) is specified as the match condition:

  If the data value is added to the match conditions, the instruction which has satisfied the match conditions is executed. A user break occurs before executing an instruction that is one through six instructions after the instruction which has satisfied the match conditions. The address of the instruction is saved in the SPC; thus, it is impossible to identify exactly where a break will occur. If the conditions are satisfied for the delayed slot instruction, the address of the branch destination is saved in the SPC. If a branch instruction follows the instruction which has satisfied the match conditions, a break may occur after the delayed instruction and delayed slot are executed. In this case, the address of the branch destination is also saved in the SPC.

59.4 User Break Debugging Support Function

By using the user break debugging support function, the branch destination address can be modified when the CPU accepts the user break request. Specifically, setting the UBDE bit of break control register CBCR to 1 allows branching to the address indicated by DBR instead of branching to the address indicated by the [VBR + offset]. Figure 59.2 shows the flowchart of the user break debugging support function.

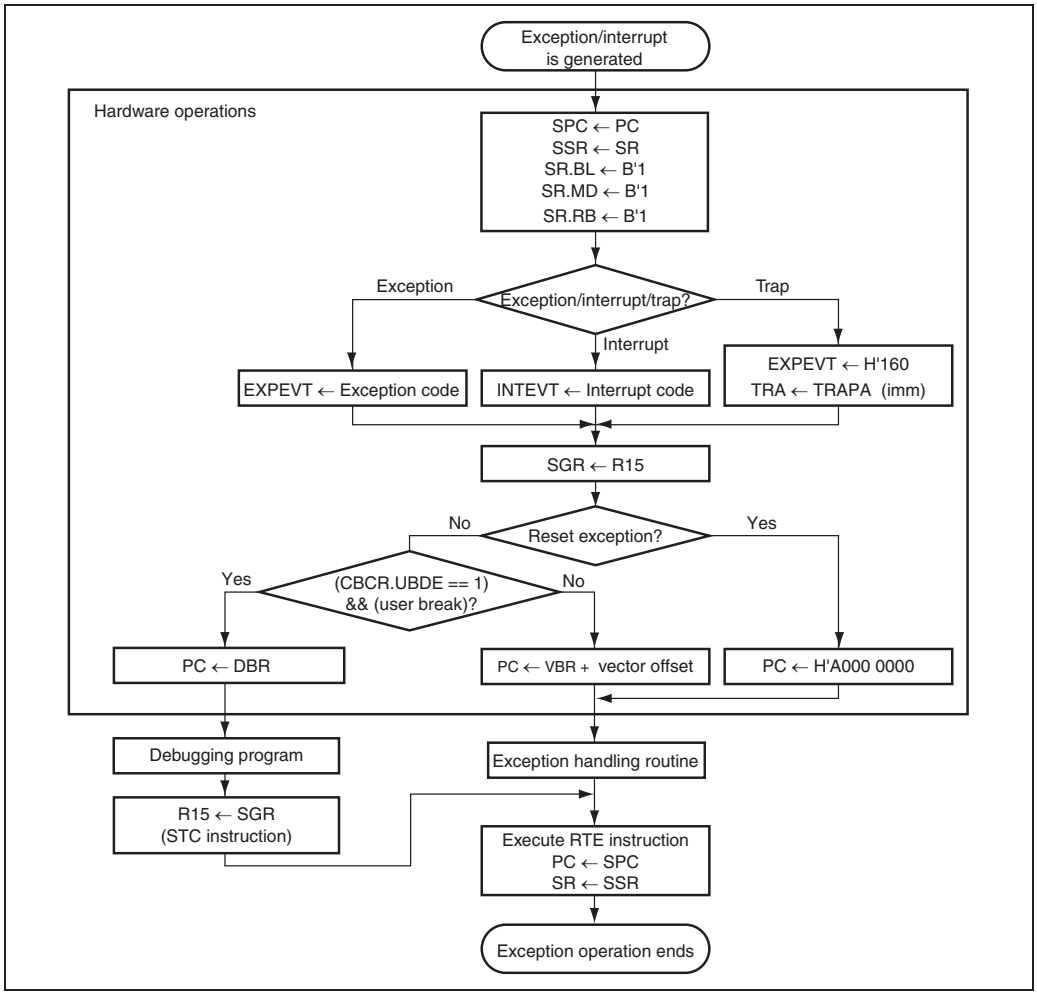


Figure 59.2 Flowchart of User Break Debugging Support Function

59.5 User Break Examples

(1) Match Conditions are Specified for an Instruction Fetch Cycle

- Example 1-1

  Register settings: CBR0 = H'00000013 / CRR0 = H'00002003 / CAR0 = H'00000404 / CAMR0 = H'00000000 / CBR1 = H'00000013 / CRR1 = H'00020001 / CAR1 = H'00008010 / CAMR1 = H'00000006 / CDR1 = H'00000000 / CDMR1 = H'00000000 / CETR1 = H'00000000 / CBCR = H'00000000

  Specified conditions: Independent for channels 0 and 1

  — Channel 0

  Address: H'00000404 / Address mask: H'00000000

  Bus cycle: Instruction fetch (after executing the instruction)

  ASID is not included in the conditions.

  — Channel 1:

  Address: H'00008010 / Address mask: H'00000006

  Data: H'00000000 / Data mask: H'00000000 / Execution count: H'00000000

  Bus cycle: Instruction fetch (before executing instruction)

  ASID, data values, and execution count are not included in the conditions.

  With the above settings, the user break occurs after executing the instruction at address H'00000404 or before executing the instruction at address H'00008010 to H'00008016.

- Example 1-2

  Register settings: CBR0 = H'40800013 / CRR0 = H'00002000 / CAR0 = H'00037226 / CAMR0 = H'00000000 / CBR1 = H'C0700013 / CRR1 = H'00002001 / CAR1 = H'0003722E / CAMR1 = H'00000000 / CDR1 = H'00000000 / CDMR1 = H'00000000 / CETR1 = H'00000000 / CBCR = H'00000000

  Specified conditions: Channel 0 → Channel1 sequential mode

  — Channel 0

  Address: H'00037226 / Address mask: H'00000000 / ASID: H'80

  Bus cycle: Instruction fetch (before executing the instruction)

— Channel 1

Address: H'0003722E / Address mask: H'00000000 / ASID: H'70

Data: H'00000000 / Data mask: H'00000000 / Execution count: H'00000000

Bus cycle: Instruction fetch (before executing the instruction)

Data values and execution count are not included in the conditions.

With the above settings, the user break occurs after executing the instruction at address H'00037226 where ASID is H'80 before executing the instruction at address H'0003722E where ASID is H'70.

- Example 1-3

  Register settings: CBR0 = H'00000013 / CRR0 = H'00002001 / CAR0 = H'00027128 / CAMR0 = H'00000000 / CBR1 = H'00000013 / CRR1 = H'00002001 / CAR1 = H'00031415 / CAMR1 = H'00000000 / CDR1 = H'00000000 / CDMR1 = H'00000000 / CETR1 = H'00000000 / CBCR = H'00000000

  Specified conditions: Independent for channels 0 and 1

  — Channel 0

  Address: H'00027128 / Address mask: H'00000000

  Bus cycle: Instruction fetch (before executing the instruction)

  ASID is not included in the conditions.

  — Channel 1

  Address: H'00031415 / Address mask: H'00000000

  Data: H'00000000 / Data mask: H'00000000 / Execution count: H'00000000

  Bus cycle: Instruction fetch (before executing the instruction)

  ASID, data values, and execution count are not included in the conditions.

  With the above settings, the user break occurs for channel 0 before executing the instruction at address H'00027128. No user break occurs for channel 1 since the instruction fetch is executed only at even addresses.

- Example 1-4

  Register settings: CBR0 = H'40800013 / CRR0 = H'00002000 / CAR0 = H'00037226 / CAMR0 = H'00000000 / CBR1 = H'C0700013 / CRR1 = H'00002001 / CAR1 = H'0003722E / CAMR1 = H'00000000 / CDR1 = H'00000000 / CDMR1 = H'00000000 / CETR1 = H'00000000 / CBCR = H'00000000

  Specified conditions: Channel 0 → Channel 1 sequential mode

  — Channel 0

    Address: H'00037226 / Address mask: H'00000000 / ASID: H'80

    Bus cycle: Instruction fetch (before executing the instruction)

  — Channel 1

    Address: H'0003722E / Address mask: H'00000000 / ASID: H'70

    Data: H'00000000 / Data mask: H'00000000 / Execution count: H'00000000

    Bus cycle: Instruction fetch (before executing the instruction)

    Data values and execution count are not included in the conditions.

  With the above settings, the user break occurs after executing the instruction at address H'00037226 where ASID is H'80 and before executing the instruction at address H'0003722E where ASID is H'70.

- Example 1-5

  Register settings: CBR0 = H'00000013 / CRR0 = H'00002001 / CAR0 = H'00000500 / CAMR0 = H'00000000 / CBR1 = H'00000813 / CRR1 = H'00002001 / CAR1 = H'00001000 / CAMR1 = H'00000000 / CDR1 = H'00000000 / CDMR1 = H'00000000 / CETR1 = H'00000005 / CBCR = H'00000000

  Specified conditions: Independent for channels 0 and 1

  — Channel 0

    Address: H'00000500 / Address mask: H'00000000

    Bus cycle: Instruction fetch (before executing the instruction)

    ASID is not included in the conditions.

  — Channel 1

    Address: H'00001000 / Address mask: H'00000000

    Data: H'00000000 / Data mask: H'00000000 / Execution count: H'00000005

    Bus cycle: Instruction fetch (before executing the instruction)

    Execution count: 5

    ASID and data values are not included in the conditions.

With the above settings, the user break occurs for channel 0 before executing the instruction at address H'00000500. The user break occurs for channel 1 after executing the instruction at address H'00001000 four times; before executing the instruction five times.

- Example 1-6

  Register settings: CBR0 = H'40800013 / CRR0 = H'00002003 / CAR0 = H'00008404 / CAMR0 = H'00000FFF / CBR1 = H'40700013 / CRR1 = H'00002001 / CAR1 = H'00008010 / CAMR1 = H'00000006 / CDR1 = H'00000000 / CDMR1 = H'00000000 / CETR1 = H'00000000 / CBCR = H'00000000

  Specified conditions: Independent for channels 0 and 1

  — Channel 0

  Address: H'00008404 / Address mask: H'00000FFF / ASID: H'80

  Bus cycle: Instruction fetch (after executing the instruction)

  — Channel 1

  Address: H'00008010 / Address mask: H'00000006 / ASID: H'70

  Data: H'00000000 / Data mask: H'00000000 / Execution count: H'00000000

  Bus cycle: Instruction fetch (before executing the instruction)

  Data values and execution count are not included in the conditions.

  With the above settings, the user break occurs after executing the instruction at address H'00008000 to H'00008FFE where ASID is H'80 or before executing the instruction at address H'00008010 to H'00008016 where ASID is H'70.

(2) Match Conditions are Specified for an Operand Access Cycle

- Example 2-1

  Register settings: CBR0 = H'40800023 / CRR0 = H'00002001 / CAR0 = H'00123456 / CAMR0 = H'00000000 / CBR1 = H'4070A025 / CRR1 = H'00002001 / CAR1 = H'000ABCDE / CAMR1 = H'000000FF / CDR1 = H'0000A512 / CDMR1 = H'00000000 / CETR1 = H'00000000 / CBCR = H'00000000

  Specified conditions: Independent for channels 0 and 1

  — Channel 0

  Address: H'00123456 / Address mask: H'00000000 / ASID: H'80

  Bus cycle: Operand bus, operand access, and read (operand size is not included in the conditions.)

  — Channel 1

  Address: H'000ABCDE / Address mask: H'000000FF / ASID: H'70

  Data: H'0000A512 / Data mask: H'00000000 / Execution count: H'00000000

  Bus cycle: Operand bus, operand access, write, and word size

Execution count is not included in the conditions.

With these settings, the user break occurs for channel 0 for the following accesses: longword read access to address H'000123454, word read access to address H'000123456, byte read access to address H'000123456 where ASID is H'80. The user break occurs for channel 1 when word H'A512 is written to address H'000ABC00 to H'000ABCFE where ASID is H'70.

- Example 2-2

  Register settings: CBR0 = H'00002023 / CRR0 = H'00002001 / CAR0 = H'01000000 / CAMR0 = H'00000000 / CBR1 = H'0000A0A5 / CRR1 = H'00002001 / CAR1 = H'0000F000 / CAMR1 = H'FFFF0000 / CDR1 = H'00004567 / CDMR1 = H'00000000 / CETR1 = H'00000000 / CBCR = H'00000000

  Specified conditions: Independent for channels 0 and 1

  — Channel 0

  Address: H'01000000 / Address mask: H'00000000

  Bus cycle: Operand bus, operand access, read, and word size

  ASID is not included in the conditions.

  — Channel 1

  Address: H'F0000 / Address mask: H'0000

  Data: H'00004567 /Data mask: H'00000000

  Bus cycle: Y bus, operand access, write, and word size

  ASID and execution count is not included in the conditions.

  With these settings, the user break occurs for channel 0 by word read access to address H'01000000. The user break occurs for channel 1 when word H'4567 is written to the Y memory address H'F000. The X or Y memory space can be specified by the CD bit of the match condition setting register (CBR0 or CBR1).

59.6 Usage Notes

- A desired break may not occur between the time when the instruction for rewriting the UBC register is executed and the time when the written value is actually reflected on the register.

  After the UBC register is updated, execute one of the following three methods.

  A. Read the updated UBC register, and execute a branch using the RTE instruction.

     (It is not necessary that a branch using the RTE instruction is next to a reading UBC register.)

  B. Execute the ICBI instruction for any address (including non-cacheable area).

     (It is not necessary that the ICBI instruction is next to a reading UBC register.)

  C. Set 0(initial value) to IRMCR.R1 before updating the UBC register and update with following sequence.

     a. Write the UBC register.

     b. Read the UBC register which is updated at 1.

     c. Write the value which is read at 2 to the UBC register.

Note: When two or more UBC registers are updated, executing these methods at each updating the UBC registers is not necessary. At only last updating the UBC register, execute one of these methods.

- The PCB bit of the CRR0 and CRR1 registers is valid only when the instruction fetch is specified as the match condition.
- If the sequential break conditions are set, the sequential break conditions are satisfied when the conditions for the first and second channels in the sequence are satisfied in this order. Therefore, if the conditions are set so that the conditions for channels 0 and 1 should be satisfied simultaneously for the same bus cycle, the sequential break conditions will not be satisfied, causing no break.
- For the SLEEP instruction, do not allow the post-instruction-execution break where the instruction fetch cycle is the match condition. For the instructions preceding the SLEEP instruction by one to five instructions, do not allow the break where the operand access is the match condition.
- If the user break and other exceptions occur for the same instruction, they are determined according to the specified priority. For the priority, refer to the SH4AL-DSP Software Manual. If the exception having the higher priority occurs, the user break does not occur.

  — The pre-instruction-execution break is accepted prior to any other exception.

— If the post-instruction-execution break and data access break have occurred simultaneously with the re-execution type exception (including the pre-instruction-execution break) having a higher priority, only the re-execution type exception is accepted, and no condition match flags are set. When the exception handling has finished thus clearing the exception source, and when the same instruction has been executed again, the break occurs setting the corresponding flag.

— If the post-instruction-execution break or operand access break has occurred simultaneously with the completion-type exception (TRAPA) having a higher priority, then no user break occurs; however, the condition match flag is set.

- When conditions have been satisfied simultaneously and independently for channels 0 and 1, resulting in identical SPC values for both of the breaks, the user break occurs only once. However, the condition match flags are set for both channels. For example,

  Instruction at address 110 (post-instruction-execution break for instruction fetch for channel 0) → SPC = 112, CCMFR.MF0 = 1

  Instruction at address 112 (pre-instruction-execution break for instruction fetch for channel 1) → SPC = 112, CCMFR.MF1 = 1
- It is not allowed to set the pre-instruction-execution break or the operand break in the delayed slot instruction of the RTE instruction. And if the data value is included in the match conditions of the operand break, do not set the break for the preceding the RTE instruction by one to six instructions.
- If the re-execution type exception and the post-instruction-execution break are in conflict for the instruction requiring two or more execution states, then the re-execution type exception occurs. Here, the CCMFR.MF0 (or CCMFR.MF1) bit may or may not be set to 1 when the break conditions have been satisfied.
- When the DSP extended function, repeated loop, is used, even if the break instruction is matched while all or part of instructions in the repeated loop are executed, break occurrence may be retained. For details, refer to the SH4AL-DSP Software Manual.

Section 60. Debugging Specifications (DBG)

60.1 External Pins Related to Debugging

This LSI incorporates two JTAG ports. Of these, one JTAG port is assigned to dedicated JTAG pins and the other is assigned and multiplexed with the SD card pins. There are a total of 29 additional external pins for debug function: 13 (Refer Table 60.3) for control and 16 for data tracing and monitoring. These 16 external pins are also used as the VIO pins.

First, the JTAG pins are explained in Table 60.1.

Table 60.1 JTAG Pins

Pin Name	Polarity	I/O	Description
TRST_N	N	IN	Ports dedicated to JTAG
TCK SWCLKTCK（SWD）	P	IN	
TMS	P	IN	
SWDIOTMS（SWD）	P	IN/OUT （SWD）	
TDI	P	IN	
TDO SWO0(SWD)	P	OUT	
EDBGREQ（ARM） ASEBRK/BRKACK（SH）	P	IN（ARM）	During connection with the ARM-ICE, this pin functions as the external break request to the ARM. During connection with the SH-ICE, meanwhile, this pin functions as the pin break request to the SH or as the internal break state notification
	N	IN/OUT（SH）	
RTCK SWO1 (SWD)	P	OUT	Return TCK for the ARM-ICE This is not use for the ASARM function.

Assignment of the SDHI0 pins to the JTAG system is explained in Table 60.2.

Table 60.2 SDHI0 Pins

Pin Name	Polarity	I/O	Description
SDHID0_1（TCLK、SWCLKTCK：SWD）	P	IN	JTAG ports
SDHICMD0 (TRST_N)	N	IN	
SDHID0_2 (TDI)	P	IN	
SDHICLK0（TDO、SWO0：SWD）	P	OUT	
SDHID0_0（TMS、SWDIOTMS：SWD）	P	IN	
SDHICD0	—	—	Not used as the JTAG.
SDHIWP0 (EDBGREQ: ARM, ASEBRK/BRKACK: SH)	P	IN (ARM)	During connection with the ARM-ICE, this pin functions as the external break request to the ARM. During connection with the SHX2-ICE, meanwhile, this pin functions as the pin break request to the SH or as the internal break state notification.
	N	IN/OUT (SH)	
SDHID0_3（RTCK 、SWO1：SWD）	P	OUT	Return TCK for the ARM-ICE This is not use for the ASARM function.

Note: In debugging modes, debugging functions do not depend on the PORTnCR register settings and are given priority.

A list of the control pins from various external components is shown in Table 60.3.

Table 60.3 Control Pins

Pin Name	Polarity	I/O	Description
DBGMD10	P	IN	DBGMD10 pin input dedicated to debugging control
DBGMD21	P	IN	DBGMD21 pin input dedicated to debugging control
DBGMD20	P	IN	DBGMD20 pin input dedicated to debugging control
DBGMD11	P	IN	DBGMD11 pin input dedicated to debugging control
DBGMDT2	P	IN	Pin dedicated to debugging control DBGMDT2 function
DBGMDT1	P	IN	Pin dedicated to debugging control DBGMDT1 function
DBGMDT0	P	IN	Pin dedicated to debugging control DBGMDT0 function MD12 function (during a reset, but masked during a diagnosis)
TST_N	N	IN	Pin dedicated to debugging control. TST_N function 1: normal mode 0: test mode
MD7	P	IN	MD7 function
MD6	P	IN	MD6 function Pin dedicated to debugging control (for test mode) Endian selection function
MD4	P	IN	MD4 function
MD3	P	IN	MD3 function
MD2	P	IN	MD2 function

Note: Detailed descriptions on TST_N, MD7,MD6,MD4, MD3, and MD2 functions are provided in the chapter of SYSC. Refer to section 13.3.1, Operation Modes, in the chapter.

60.2 Debugging Mode

A debugging mode is a mode in which a debugging operation can be performed through an ICE that is connected to a pin capable of connecting JTAG. This LSI provides the Pin switching mode as the debugging mode:

To use DBG function, Power ON D4 area.

To use Coresight function, select the Coresight debug port by the DBGREG1 register.

Descriptions on these modes are given below.

60.2.1 Pin Switching Mode

Pin switching mode is intended to connect JTAG pins with modules to be debugged by using information about the input of external control pins. Setting the external control pins enables referring to the content of the DBGREG1 register accessible from the CPU and connecting the JTAG pins with modules to be debugged.

The value of the register is specified through pins when the register is initialized. During normal operation, it is necessary for the CPU to access the register and specify its value. Note that in order to establish a connection with JTAG, it is not necessary for software to set the register for the combinations that only require the setting of the five dedicated control pins.

Table 60.4 shows the combinations of debugging resources and their corresponding register settings. Also, Table 60.5 shows the modes that only require pin settings for determining the ICE link destinations.

Table 60.4 Combinations of Register Values and Debugging Resource in Pin Switching Mode

Register Setting（DBGREG1）						JTAG	SDHI0
MD12	MD10	MD21,20	MD11	SDJ[1:0]	DSP[2:0]		
0	0	00	—	—	—	BoundarySCAN	Normal function
		10	0	—	—	Coresight	Normal function
			1	01	—	debugging port (JTAG)	SH-X2
		11	0	—	—	SH-X2	Normal function
			1	00	—		Coresigt debugging port (SWD)
				01	—		Coresight debugging port (JTAG)
	1	10	0	—	—	Not available	Coresight debugging port (JTAG)
		11	0	—	—	Not available	SH-X2
1	0	00	1	—	—	SPU	Normal function
		01	1	—	—	Coresigt	
		10	1	00	—	debugging port (SWD)	SH-X2
	1	00	1	—	—	Not available	Coresight
		01	1	00	—	SH-X2	debugging port (SWD)

Table 60.5 List of Debugging Link Destinations that Only Require Pin Settings

Pin Setting			JTAG	SDHI0
MD12,MD10	MD21,MD20	MD11		
00	10	0	Coresigt debugging port (JTAG)	Normal function
	11	0	SH-X2	Normal function
		1		Coresight debugging port (SWD)
01	10	0	Not available	Coresight debugging port (JTAG)
	11	0	Not available	SH-X2
10	00	1	SPU	Normal function
	01	1	Coresigt debugging port (SWD)	
	10	1		SH-X2
11	00	1	Not available	Coresight debugging port (SWD)
	01	1	SH-X2	

60.2.2 Cooperative Debugging Functions

This LSI supports cooperative debugging functions that generate break trigger to a specified core when either of the SH-X2 core, AP-ARM core, or external-LSI core enters a break state. The cooperative debugging functions support the break triggers in the following four directions:

- SH-X2 → AP-ARM
- AP-ARM → SH-X2
- AP-ARM → external-LSI
- external-LSI → AP-ARM

These cooperative debugging functions are enabled by setting the Cross Triger-IF of the Coresight. At initialization, the cooperative debugging functions are disabled.

To use cooperative debugging functions between external-LSI, set the external-LSI cooperative debugging functions (MDT[2:0]=010) shown in Table 60.9 Trace Functions. VIO_D2 is Input Pin (Signal from external-LSI to AP-ARM), VIO_D1 is Output Pin (Signal from AP-ARM to external LSI). These two signals are connected to Cross Triger-IF of Coresight.

60.2.3 Debugging Mode Setting at Shipment

Since only a secure boot is available in the settings at shipment of mass production version, directions or modes in which breaks can be performed are limited. In addition, the DBGREG1 register does not reflect the settings of pins (the seven external DBGMD10, DBGMD21, DBGMD20, DBGMD11, DBGMD2, DBGMD1, and DBGMDT0 pins). Even if an attempt to read from DBGREG1 is made, 0 is read from the bits intended to reflect the values of the DBGMD10, DBGMD21, DBGMD20, DBGMD11, DBGMD2, DBGMD1, and DBGMDT0 pins. However, setting the DBGREG1 register through the CPU by software allows a debug mode to be entered. After entering the debug mode, the values that have written by software can be read from DBGREG1. The debugging resource and the corresponding register setting at mass-production version of this LSI is listed in Table 60.6.

Table 60.6 Debugging resource and the corresponding register setting at mass-production

Register Setting (DBGREG1)				
MD12	**MD10**	**MD21**	**MD20**	**SDHI0**
0	1	1	0	AP-ARM

60.3 Register Descriptions

A list of implemented registers is summarized in Table 60.7. Of these registers, DBGREG1/2/9 can be accessed from both the CPU and JTAG pins, although they can be accessed only from the CPU if pin-switching mode is selected. The JTAG commands shown in the Table 60.7 serve as commands that will be entered upon access to a register from the emulator. Entering these commands makes it possible to access the corresponding register.

Only after write operations to the KEY register, it is possible to write to DBGREG1, DBGREG2. Note that the KEY register requires two phases of writing.

Table 60.7 Register Configuration

Register Name	Abbreviation	R/W	CPU Address*4	R/W	JTAG Command	Access Size
Debugging function selection register*3	DBGREG1	R/W	H'E610_0020/ H'E610_8020	R/W	B'0011_1000	32
LSI control register	DBGREG2	R/W	H'E610_0024/ H'E610_8024	R/W	B'1011_1000	32
KEY register	DBGREG9	R/W	H'E610_0040/ H'E610_8040	R/W	B'0010_0100	32
Access priority control register*3	DBGREG10	—	—*1	R/W	B'1010_0100	32

Notes: 1. Accessible only from the JTAG.
2. Accessible from the CPU only under software control.
3. Not a target for diagnosis.
4. Address H'E610_0XXX is a non semaphore-address of this register and accessing through this address is not controlled by HPB semaphore.
Address H'E610_8XXX is a semaphore-address of this register and accessing thorough this address is controlled by HPB semaphore.

The initialization condition of these registers is summarized in Table 60.8. Note that the initialization condition of each register depends on the ICE connection conditions and LSI modes such as normal and diagnosis.

Table 60.8 Register Initialization Conditions

ICE Connection Condition	Normal Mode
ICE is connected only to the JTAG pin	Initialization is performed only by a power-on reset (PRESET_N)
ICE is connected only to the SDHI0 pin	Initialization is performed by simultaneously asserting PRESET_N and TRST_N
ICE is connected to the JTAG and SDHI0 pins	Initialization is performed by simultaneously asserting PRESET_N and TRST_N

Note: In normal mode, initialization is performed only by asserting a power-on reset.

60.3.1 Debugging Function Selection Register (DBGREG1)

This register is intended to reflect the values entered into external pins. In pin switching mode, it is possible to perform read/write operations only from the CPU.

The values for external pins are set when initialization is performed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MD11	MD10	MD21	MD20	—	—	—	—	MD12	—	—	—	—	—	SDJ[1:0]	
Initial value:	0	*	*	*	0	0	0	0	*	0	0	0	0	0	0	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31	RSTEN	0	R/W	Prohibits the reset input to each CPU core during debugging. 0: Disables prohibiting control regarding the reset input. 1: Enables prohibiting control regarding the reset input.
30	ARSTEN	0	R/W	Prohibits the area reset issue upon power shutdown during debugging. 0: Disables prohibiting control regarding the area reset issue. 1: Enables prohibiting control regarding the area reset issue.
29	RSTAEN	0	R/W	Prohibits RESETA during debugging. 0: Disables prohibiting control. 1: Enables prohibiting control.
28	RSTBEN	0	R/W	Prohibits RESETB during debugging. 0: Disables prohibiting control. 1: Enables prohibiting control.
27, 26	—	0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
25	ERREN	0	R/W	Prohibits the SHwy error response during debugging. 0: Disables prohibiting control. 1: Enables prohibiting control.
24	CORESTBYEN	0	R/W	Prohibits core standby during debugging. 0: Disables prohibiting control. 1: Enables prohibiting control.
23,22	—	0	R	Reserved
21	APDBGHIST	0	R	Indicates that the ICE of AP-ARM has a history of being ready for connecting. 0: The ICE of AP-ARM has never been ready for connecting before. 1: The ICE of AP-ARM has been ready for connecting before.
20	SHDBGHIST	0	R	Indicates that the ICE of SH has a history of being ready for connecting. 0: The ICE of SH has never been ready for connecting before. 1: The ICE of SH has been ready for connecting before.
19	DBGHIST	0	R	Indicates that any of the ICEs has a history of being ready for connecting. 0: The ICEs have never been ready for connecting before. 1: Any of the ICEs has been ready for connecting before.
18 to 11	—	0	R	Reserved
10	SHRST	0	R	Reports that SH is being reset. 0: Reset being negated 1: Reset being asserted
9	APRST	0	R	Reports that ARM on the system side is being reset. 0: Reset being negated 1: Reset being asserted
8 to 3	—	0	R	Reserved
2	APSH_TRST	0	R/W	Issues a reset to each APSH_JTAG circuit during debugging. 0: Issues no reset. 1: Issues a reset.
1	APARM_TRST	0	R/W	Issues a reset to each APARM_JTAG circuit during debugging. 0: Issues no reset. 1: Issues a reset.
0	—	0	R	Reserved

60.3.3 KEY Register (DBGREG9)

The DBGREG provides registers that control write operation to the DBGREG so that the DBGREG properly functions to establish a link with the ICE during debugging and prevents invalid access due to a program error from breaking the link. This register has a key role in preventing such invalid access. It is possible to perform read/write operations only from the CPU. It is not possible to perform read/write operations from the emulator.

Writing the KEY code into this register in two steps enables access to the DBGREG. Use the following procedure.

1. First, write 8'hA5 to bits 15 to bit 8. This enables writing to bit 0 in the KEY register.
2. Next, write 8'hA5 to bits 15 to bit 8 and 1'b1 to bit 0 at the same time to enable writing to the other DBGREG registers.

To disable access to the DBGREG, write 0 to all the bits in the DBGREG9 register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AID[7:0]								–	–	–	–	–	–	–	KEY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	0	R	Reserved
15 to 8	AID[7:0]	H'00	R/W	KEY Bit Write Aid Use this bit to write a bit pattern (H'A5) to be written to the KEY bit.
7 to 1	—	0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
0	KEY	0	R/W	DBGREG access control Provides access control to the DBGREG. 0: It is not possible to perform read/write operations from/to the DBGREG. 1: It is possible to perform read/write operations from/to the DBGREG. When writing 1 to this bit, be sure to write H'A5 to the AID bits at the same time.

60.3.4 Access Control Register (DBGREG10)

This register specifies settings for determining priority over writing to the DBGREG.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	AI1	AL0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	0	R	Reserved
1	AL1	0	R/W	DBGREG2 access priority control 0: Places priority on CPU access (initial value). 1: Places priority on JTAG access.
0	AL0	0	R/W	DBGREG1 access priority control 0: Places priority on CPU access (initial value). 1: Places priority on JTAG access.

60.4 Trace/Monitoring Functions for Debugging

This section explains how to specify settings for the following debugging functions: trace function from each core and monitoring function. This section also explains the assignment of I/O pins.

60.4.1 Trace Functions

Each of the CPU cores is provided with trace function. Since there are no pins dedicated to outputting trace data, the MDT[2:0] bits in the DBGREG1 register are set to output the data through the VIO pins or the SDHI card pins and to specify trace data.

Table 60.9 shows the MDT[2:0] values and their respective output pins. For more details on the output pins and function assignments, refer to the corresponding tables.

Table 60.9 List of Trace Functions

MDT [2:0]	Function Summary	Output Pin	Refer to	Remark
000	Normal function	—	—	—
001	AP-ARM ETM11 trace data	VIO_D15 to VIO_D0	Table 60.10	—
010	External-LSI cooperative debugging function	VIO_D15 to VIO_D0		—
011	SH-X2 AUD trace data	VIO_D15 to VIO_D0		—
100	Monitoring function for debugging	—	—	*3
101	AP-ARM ETM11 trace data	SDHI0*1, SDHI1*2	Table 60.11	—
111	SH-X2 AUD trace data	SDHI1*2		—

Note: 1. SDHI0 represents the SDHICLK0/SDHICD0/SDHID0_[3:0]/SDHICMD0/SDHIWP0 pins
2. SDHI1 represents the SDHICLK1/SDHID1_[3:0]/SDHICMD1 pins
3. Details on the monitoring function are given in the next section, 60.4.2.

The VIO pins (VIO_D15 to VIO_D0) and changes in their pin functions after enabling the trace function are listed in Table 60.10. The SDHI0/1 pins and changes in their pin functions after enabling the trace function are also listed in Table 60.11.

Table 60.10 VIO Pins and Changes in their Functions

Pin	AP-ETM11 Trace Data	External-LSI cooperative debugging function	SH-AUD Trace Data
VIO_D15	0	—	0
VIO_D14	0	—	0

SDHID1_2	0	AUDATA0
SDHID1_1	0	AUDSYNC
SDHID1_0	TRACECLK1	AUDCLK

60.4.2 Monitoring Functions for Debugging

The monitoring functions are provided as a debugging function in order to monitor the internal state of the LSI through external pins. Since there are no pins dedicated to the monitoring function, the MDA[7:0] bits in the DBGREG1 register are set to output monitoring data through the VIO pins or the SDHI card pins and to specify monitoring settings (note that DBGREG1.MDT[2:0] is assumed to be 100).

Table 60.12 lists the MDA[7:0] values and their respective output pins. For more details on the output pins and function assignments, refer to the corresponding tables listed.

Table 60.12 List of Monitoring Functions for Debugging

MDA[6:0]	Function Summary	I/O Pins	Refer to	Remarks
000_1000	SBSC1 performance monitor 0	SDHI0*[1], SDHI1*[2]	Table 60.13	*[3]
000_1001	SBSC1 performance monitor 1	VIO_D15 to VIO_D0	Table 60.14	*[3]

0111 1111	IIC monitor 2	VIO_D15～VIO_D0	Table 60.30	—

Note: 1. SDHI0 represents the SDHICLK0/SDHICD0/SDHID0_[3:0]/SDHICMD0/SDHIWP0 pins
2. SDHI1 represents the SDHICLK1/SDHID1_[3:0]/SDHICMD1 pins
3. This monitor signal does not pass the TDBG module because the PAD is directly connected to the corresponding module. The TDBG module only outputs selection signal to the PAD.
4. To use this monitoring functions, set MSEL15 to 1.

5. This monitoring functions cannot be used with MSEL15=1.
   To use this monitoring functions, set MSEL15 to 0.

In the following section, the monitoring signals assigned to the VIO pins (VIO_D15 to VIO_D0) and the SDHI0/1 pins are listed. The monitoring signals are available after enabling the monitoring functions.

60.4.2.1 SBSC1 Performance Monitor 0

These functions monitor the performance and internal signals of the SBSC1 (BSC for AP-ARM DDR-SDRAM). Details on the pin assignments are given in Table 60.13

Table 60.13 Details on Pin Assignments for SBSC1

Pin	SBSC1 Performance Monitor 0

60.5 Support Debugging Function Using GPIO Internal Register Settings

The MSEL15 function in the [15] bit in the GPIO can change I/O function pins, described in section, 60.4.2, from the VIO pins to the LCDD pins. Table 60.32 shows the correspondence between these pins.

For details, refer to the chapter of GPIO.

Table 60.31 GPIO Internal Register

Register Name	Abbreviation	R/W	CPU Address	Initial Value	Access Size
Module Selection Function Register 3	MSEL3CR	R/W	H'E605_8020	H'0000_0000	32

Table 60.32 LCDD Pin Assignments for Monitoring Functions

Pin	Assigned Function
LCDD15	Monitoring function corresponding to VIO_D15
LCDD14	Monitoring function corresponding to VIO_D14

LCDD0	Monitoring function corresponding to VIO_D0

60.6 Power Supply Control Function

During debugging with the emulator, all the areas are always powered on by default. In this case, even if the SYSC perform power cutoff a certain area, a power shutdown sequence is performed but the actual power supply status of each area does not change (always powered on). This behavior of power control can be selectable by SYSC registers, and it is possible to cutoff the power supply of the specified area.

For details on register settings, refer to the section 13, System Controller (SYSC).

60.7 Overview of Debugging Functions for ARM Core Blocks

To support the debugging functions, the AP-ARM incorporates the Embedded ICE-RT, and ETM, ETB circuits as component for the Coresight System. The Embedded ICE-RT circuit is incorporated in the Cortex-A8 core (AP-ARM) as standard. Connecting this ICE-RT circuit to the corresponding ICE (such as a RealView-ICE manufactured by ARM Ltd.) allows program execution control and memory dumping.

The ETM component monitor the ARM operating status, then output the monitoring results to the external device as trace information. Using the appropriate ICE trace options allows the debugger on the ICE to trace ARM core execution status without breaking the program running in the ARM core.

The ETB component accumulates trace information in the built-in trace SRAM. The ETB captures trace data from the ETM component and it can accumulate trace data until the capacity (4 KB) of the trace SRAM is reached. The accumulated trace information can be accessed via the debugger of the ARM or via the Debug-APB bus of the Cortex-A8.

Table 60.33 shows detail on the debugging functions incorporated in the AP-ARM.

Table 60.33 ARM Core Configuration

Block		AP-ARM
Installed CPU core		Cortex-A8
Execution control mechanism		Embedded ICE-RT
Trace mechanism		ETM component
	r2p1 (Cortex-A8 version)	r0p2
	V3.3	v3.2
	Protocol version	(No definition)
	Trace output data width	8 bits
	Trace clock system	Half Rate-Clocking
	Upper limit for trace data rate	200MHz
	Variable function for trace data rate	Enabled (controlled by CPG)
	Number of address comparators	
	Number of data comparators	
	Memory map decoder	
	Counter	
	Sequencer	
	Number of FIFO stages	
	Control system used when trace FIFO is full	Suppressing trace output
Trace buffer		ETB component
	Module version	r2p1 (Cortex-A8 version)
	Trace SRAM capacity	4KB
	Connection bus	Debug-APB-Bus of Coresight System

Section 61 USB High-Speed DMAC (USBHS0-DMAC)

61.1 Features

- Two types of clock: ZSϕ and USBHS0 local bus clock (48 MHz), which are asynchronously absorbed in the local bus bridge
- The SHwy bus interface functions are implemented.

The SHwy bus interface handles data transfer with the memory and register settings.

- Data communication is performed using the local DMA protocol.
- Supports two channels that can work concurrently.
- Interrupts

— Setting count end interrupt

— Transfer end interrupt upon receiving a short packet from the USB-IP
This function allows generation of an interrupt even in the case where DMA transfer ends after receiving data less than the transfer size set in the DMAC.

— Timeout interrupt
A timeout interrupt can be generated after the specified cycles after the last USBHS0 transfer request. (This interrupt is used for the timeout when the final packet received is Max packet.)

— Interrupts can also be generated when a NULL packet is received or an address error is detected.

Table 61.1 Main Functions of This Module

Item	Description
Application	Transfer between USB-IP (FIFO) and SHwy bus (4-Gbyte arbitrary space)
Purpose of DMA transfer	High-speed data transfer between USB-IP and SHwy bus
DMA transfer end notification to the software	Interrupt signals (Transfer count end, USB-IP short packet reception, timeout, etc.)
Transfer space/transfer address direction	4-Gbyte arbitrary space (forward direction) to 4-Gbyte arbitrary space (forward direction)
Maximum transfer count	16,777,216
Transfer unit	8, 16, or 32 bytes
Control signals generated	Address/data read/data write conforming to the USB-IP local bus interface and SHwy bus protocols
Number of channels	2 (parallel operation enabled, round-robin control)
Bus specification	SHwy bus (SuperHyWay 64 bits), local bus (USB-IP local bus)
Clock	SHwy clock (130 MHz), USB local bus clock (48 MHz)
Max. Transfer rate	IN transfer: About 350 Mbps (in 32-byte transfer mode) OUT transfer: About 340 Mbps (in 32-byte transfer mode)

Table 61.2 Bus Access Type

	Supported Access Type
SHwy bus access (USBHS0-DMAC master)	8-byte read/write 16-byte read/write 32-byte read/write
USBHS0-DMAC register setting	4-byte read/write 8-byte read/write

The configuration of this module is shown below.

This module is provided with buffers and bus bridges and controls transfers between the SHwy bus and USB High-Speed module (USBHS0).

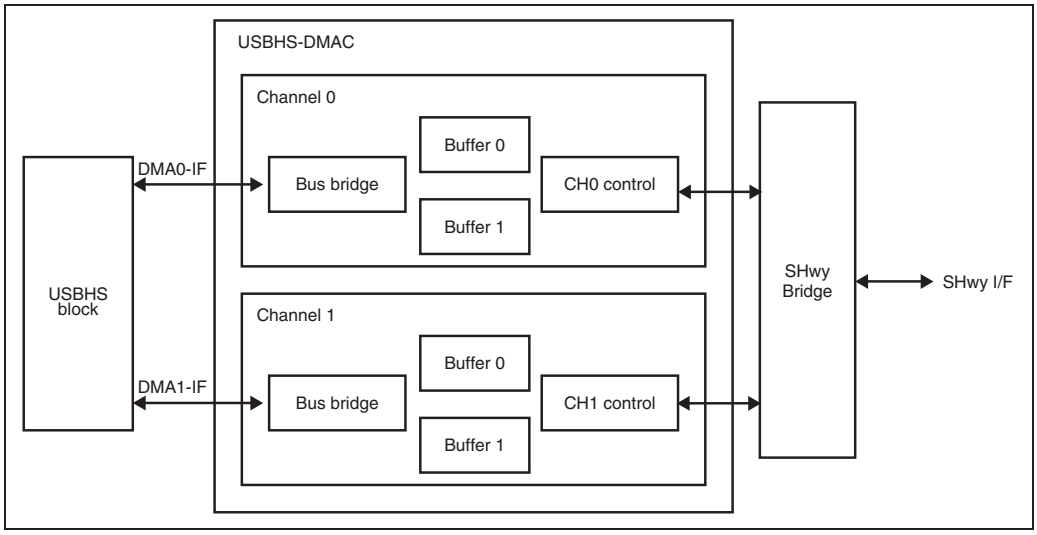

Figure 61.1 USBHS0-DMAC Configuration

61.2 Register Map

Table 61.3 shows the register configuration. Table 61.4 shows the register states in each processing mode.

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SWR	0	R/W	Software Reset 0: Cancels reset. 1: Resets entire system. Note: On software reset, this bit should be held high for long enough until the internal circuit stabilizes. When this bit is set to 1, it is recommended to allow several tens of clocks if operating at 130MHz for a reset period before clearing the reset (setting this bit to 0) as a precaution.

61.2.3 DMA Interrupt Source Register (USBDMA_DMICR)

[Address=USBDMA_BASE+H'10]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SH BSY1	—	—	—	—	—	—	—	SH BSY0	—	—	—	—	—	—	AE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DAR31 to DAR0	All 0	R/W	Destination Address (0x00000000 to 0xFFFFFFFF (4 Gbytes)) Set a value of 8-byte, 16-byte, or 32-byte boundary. Indicate the next transfer destination address during a DMA transfer.

61.2.6 DMA Transfer Count Register_0 to 1 (USBDMA_TCR_0 to 1)

[Address=USBDMA_BASE+H'28,H'48]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TCR[23:16]							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCR[15:0]															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	TCR23 to TCR0	H'FF FFFF*	R/W	Transfer Count • When 0x000001 is set, total transfer volume is as follows: Transfer size = 32 bytes: 32 × 1 bytes Transfer size = 16 bytes: 16 × 1 bytes Transfer size = 8 bytes: 8 × 1 bytes • When 0xFFFFFF is set, 16,777,215 times • When 0x000000 is set, 16,777,216 times (maximum) • Indicate 0 when a DMA transfer completes successfully.

Note: * To read this register, read the internal transfer counter value (the TCR counter value) directly. This register is read as all 1 after a reset is cleared because the initial value of the TCR counter is all 1 (0xFFFFFF). When DMA is enabled (DE in DMACHCR is asserted), the TCR counter is loaded with the value set in this register and decrements during DMA transfers. This means that the remaining transfer count is read back. Note that the read value may be different from the one set in this register due to this reason.

61.2.7 DMA Timeout Count Register_0 to 1 (USBDMA_TOCNTR_0 to 1)

[Address=USBDMA_BASE+H'2C,H'4C]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	TOCNTR[21:16]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOCNTR[15:0]															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 0	TOCNTR21 to TOCNTR0	H'3F FFFF	R	Timeout Counter Value (0x000000 to 0x27AC40) Indicate the remaining timeout count during timeout counting. (Countable up to 0x3FFFFF (approximately 32 ms) by the hardware. See the TOCSTR register.)

61.2.8 DMA Timeout Constant Register_0 to 1 (USBDMA_TOCSTR_0 to 1)

[Address=USBDMA_BASE+H'30,H'50]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	TOCSTR[21:16]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOCSTR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 0	TOCSTR21 to TOCSTR0	H'00 0000	R/W	Timeout Constant Value (0x000000 to 0x27AC40) Sst a timeout value (at 130 MHz cycle). The maximum timeout time is approximately 20 ms. (Setting up to 0x3FFFFF (approximately 32 ms) is allowed by the hardware.)

61.2.9 DMA Channel Control Register_0 to 1 (USBDMA_CHCR_0 to 1)

[Address=USBDMA_BASE+H'34,H'54]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	FTE	—	—	—	SPIM	TRE	BUFE	RWE	NULLE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TR	BUF	RW	NULL	PRI[3:0]				TS[1:0]		IE	TOE	TO	SP	TE	DE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W*	R/W*	R/W*	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	FTE	0	(R)/W	Forced TE Set Register When a NULL packet is received, the TE bit is forced to 1 to terminate the transfer by setting 1 in this register. (The DREQE bit of the UDSB-IP should also be controlled accordingly. For details on the control procedure and restrictions, see section 61.3.2(3).) This bit is always read as 0. 0: No effect (nothing happens). 1: Forces the TE bit to 1.
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	SPIM	0	R/W	Short Packet Receive Interrupt Mask Enables or disables the reflection of the short packet (SP) receive flag in the interrupt signal. If this bit is set to 1, no interrupts are generated when an SP is received. However, the SP receive flag (the SP bit) is set regardless of this register setting. 0: The short packet receive interrupt is enabled (default). 1: The short packet receive interrupt is disabled.

Bit	Bit Name	Initial Value	R/W	Description
19	TRE	0	R/W	Transaction End Detect Interrupt Flag Enable Enables or disables the reflection of TR in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the TR bit is always 0.) 0: The TR flag is disabled. 1: The TR flag is enabled.
18	BUFE	0	R/W	Buffer End Detect Interrupt Flag Enable Enables or disables the reflection of BUF in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the BUF bit is always 0.) 0: The BUF flag is disabled. 1: The BUF flag is enabled.
17	RWE	0	R/W	Final Buffer Access Detect Interrupt Flag Enable Enables or disables the reflection of RW in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the RW bit is always 0.) 0: The RW flag is disabled. 1: The RW flag is enabled.
16	NULLE	0	R/W	NULL Receive Interrupt Flag Enable Enables or disables the reflection of the NULL receive interrupt flag (NULL) in the interrupt signal. 0: The NULL receive interrupt flag is disabled. 1: The NULL receive interrupt flag is enabled.
15	TR	0	R/W*	Transaction End Detect Interrupt Flag When the transaction end is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: An transaction end receive interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
14	BUF	0	R/W*	Buffer End Detect Interrupt Flag When the end of the buffer is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A buffer end detect interrupt is generated.
13	RW	0	R/W*	Final Buffer Access Detect Interrupt Flag When the final access to the buffer is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A final buffer access detect interrupt is generated.
12	NULL	0	R/W*	NULL Receive Interrupt Flag When NULL packet is received, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A NULL packet receive interrupt is generated.
11 to 8	PRI3 to PRI0	All 0	R/W	Priority Set the value of the priority signal to be output to the SHwy bus. 0000: Priority 0 (lowest) 0001: Priority 1 : 1111: Priority 15 (highest)

Bit	Bit Name	Initial Value	R/W	Description
7, 6	TS1 to TS0	00	R/W	MA Transfer Size 00: 8 bytes 01: 16 bytes 10: 32 bytes 11: Setting prohibited Specify the same transfer size and address boundary when setting addresses in DMASAR and DMADAR as a transfer source and transfer destination. If TS = 11 is set, an address error is generated and DMA transfer is disabled.
5	IE	0	R/W	Interrupt Enable Enables or disables an interrupt request to the CPU when DMA transfer ends. When AE, TE, SP, TO, NULL, RW, BUF, or TR bit is set with this bit set to 1, an interrupt request is output to the CPU. However, when the TRE, BUFE, RWE, NULLE, or TOE bit is set to disabled, no interrupt due to TR, BUF, RW, NULL, or TO is generated. 0: An interrupt request is disabled. 1: An interrupt request is enabled.
4	TOE	0	R/W	Timeout Enable Enables or disables the reflection of the timeout flag (TO) in the interrupt. 0: Timeout flag is disabled. 1: Timeout flag is enabled.
3	TO	0	R/W*	Timeout Flag After a transfer request REQ is negated, a timeout interrupt is generated after the specified cycles. (Used for timeout when the final packet is Max packet.) 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: Timeout is generated.

Bit	Bit Name	Initial Value	R/W	Description
2	SP	0	R/W*	Short Packet Receive Flag A transfer end interrupt is generated upon receiving a short packet from the USB-IP. For example, if DMA transfer size is set to 1 MB but actual data transfer is 900 KB, this interrupt is generated when transfer of 900 KB finishes. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A short packet is received.
1	TE	0	R/W*	Transfer End Flag When a DMA transfer ends with DMATCR = 0, the TE bit is set to 1. When a DMA address error occurs before DMATCR is cleared to 0 and the transfer is suspended by clearing the DE bit and the DME bit in DMAOR, the TE bit is not set to 1. To clear the TE bit, write 0 after reading 1.When TE = 1, DMA transfer is disabled even if the DE bit is set to 1. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: DMA transfer end (TCR = 0)
0	DE	0	R/W	DMA Enable Enables or disables DMA transfer. Setting the DME bit in DMAOR and the DE bit for the corresponding channel to 1 starts a DMA transfer, provided that all interrupt flags are 0. Clearing the DE bit to 0 suspends the ongoing transfer after the transfer of one transaction is completed. 0: DMA transfer is disabled. 1: DMA transfer is enabled.

Note: * Only writing 0 to clear the flag is enabled.

61.2.10 DMA Final Transaction Valid Data Transfer Enable Register_0 to 1 (USBDMA_TEND_0 to 1)

[Address=USBDMA_BASE+H'38,H'58]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	EDTEN31 to EDTEN0	H'00000000	R/W	Final Transaction Valid Data Transfer Enable (valid only for IN transfers) Specify valid data size in units of bytes in the final transaction of data transfer. (See section 61.3.2) 0x80000000: 32 bytes × (n-1) + 1 byte 0xC0000000: 32 bytes × (n-1) + 2 bytes : 0xFFFFFFFF: 32 bytes × (n-1) + 32 bytes Notes: 1. n: Transfer count setting (TCR) 2. For the 8-byte transfer, set EDTEN23 to EDTEN0 to 0. For the 16-byte transfer, set EDTEN15 to EDTEN0 to 0.

61.2.11 DMA Operation Register (USBDMA_DMAOR)

[Address=USBDMA_BASE+H'60]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	TID[1:0]		RM	PR[1:0]		AE	DME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W	R/W	R/W	R/W*	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6, 5	TID1 and TID0	00	R/W*	Response Error Channel Identity Information TID1 indicates the channel 1 error information, and TID0 indicates the channel 0 error information. TID1 0: No error 1: Channel 1 response packet error TID0 0: No error 1: Channel 0 response packet error [Setting condition] When a CH0 (1) response error occurs [Clearing condition] Clearing ERR_RCV in VCR (Channel 0/channel 1 concurrent clear)
4	RM	0	R/W	Response Error Mask Mode 0: A response error is output. 1: A response error is masked.

Bit	Bit Name	Initial Value	R/W	Description
3, 2	PR1 to PR0	All 0	R/W	Priority Mode Specify the priority of channels to execute transactions when transfer requests are made simultaneously in both channel 0 and channel 1 as follows: 00: Channel 0 > Channel 1 01: Channel 1 > Channel 0 10: Setting prohibited (If PR = 10 is set, channel 0 > channel 1) 11: Round-robin mode
1	AE	0	R/W*	Address Error Flag Indicates that an address error interrupt occurred when setting SAR or DAR. This flag is set to 1 when the value of SAR or DAR differs from the transfer size (TS) boundary, and when the TS bits are set to 11 (setting prohibited). When the AE bit is set to 1, DMA transfer is not enabled even if the DE bit in DMACHCR and the DME bit in DMAOR are set to 1. 0: No address error interrupt is generated by the DMAC. [Clearing condition] Setting SAR and DAR to values that match the transfer size boundary. 1: An address error interrupt is generated.
0	DME	0	R/W	DMA Master Enable Enables or disables DMA transfers for all channels. When the DME bit and the DE bit in USBDMA_CHCR are set to 1, DMA transfer is enabled, provided that all interrupt flags in USBDMA_CHCR of the transfer channel are 0. Clearing the DME bit suspends the DMA transfer for all channels. 0: DMA transfer for all channels is disabled. 1: DMA transfer for all channels is enabled.

Note: * Only writing 0 to clear the flag is enabled.

61.3 Operation

61.3.1 Interrupt/Error Detection Function

This section describes the interrupt/error detection function that is implemented in this module.

Table 61.5 lists the mask, source, and flag registers for each interrupt type.

Table 61.5 Registers by Interrupts/Errors

	Interrupt Generation	Interrupt Mask Register	Interrupt Mask Register (Individual Mask)	Source Register	Flag Register
Transfer count end	O	CHCR_x.IE	—	DMICR.TEx	CHCR_x.TE
Short packet receive	O	CHCR_x.IE	CHCR_x.SPIM	DMICR.SPx	CHCR_x.SP
NULL packet receive	O	CHCR_x.IE	CHCR_x.NULLE	DMICR.NULLx	CHCR_x.NULL
Timeout	O	CHCR_x.IE	CHCR_x.TOE	DMICR.TOx	CHCR_x.TO
Transaction end detect	O	CHCR_x.IE	CHCR_x.TRE*	DMICR.TRx	CHCR_x.TR
Buffer end detect	O	CHCR_x.IE	CHCR_x.BUFE*	DMICR.BUFx	CHCR_x.BUF
Final buffer access detect	O	CHCR_x.IE	CHCR_x.RWE※	DMICR.RWx	CHCR_x.RW
Address error	O	CHCR_x.IE	—	DMICR.AE	DMAOR.AE
Response packet error	—	—	—	—	VCR.ERR_SNT VCR.ERR_RCV

Note: These registers not only mask interrupt generation but also disable error processing (flag sources and flag clearing).

Table 61.6 shows the processing to be executed when different interrupts occur. DMA transfer control is not affected when the NULL packet receive, timeout, or response packet error interrupt occurs. When the transfer count end interrupt occurs, processing is restarted. Processing can be resumed or restarted after interrupts occur from other sources.

Table 61.6 Processing to be Executed When Interrupts Occur (Suspend/Resume/Restart)

	Suspend/ Resume	Terminate/ Restart	Suspend/Resume/Restart Control Mask Register
Transfer count end	—	o	—
Short packet receive	O	O	—
NULL packet receive	—	O*	—
Timeout	—	O	—
Transaction end detect	O	O	CHCR_x.TRE
Buffer end detect	O	O	CHCR_x.BUFE
Final buffer access detect	O	O	CHCR_x.RWE
Address error	O	O	—
Response packet error	—	—	—

The internal circuit is reloaded register values when restarted, but not when resumed.

* When a NULL packet is received, processing is forced to be terminated and restarted by the FTE register (see section 61.3.2 (3)).

Table 61.7 lists the interrupt generating conditions.

Table 61.7 Interrupt Generating Conditions

Interrupt Name	Interrupt Conditions
Transfer count end interrupt	When the final data transfer of the specified transfer count (in the TCR register) completes IN transfer: When the final access to USB-IP completes OUT transfer: When the data transmission to the SHwy completes
Short packet receive interrupt	When the data transfer at the time the end of a transaction is detected completes
NULL packet receive interrupt	When a NULL packet is detected or the forced TE register is set
Timeout interrupt	When the specified time elapses after the last transfer request
Transaction end detect interrupt	When the end of a transaction is detected
Buffer end detect interrupt	When the end of the buffer is detected
Final buffer access detect interrupt	When the final access to the buffer is detected
Address error interrupt	When invalid access to the DMAC register is attempted (With invalid SAR/DAR values or invalid transfer size (TS) specified)
Response packet error	Error Transmission (err_snt) When accessed by a transaction that is not supported Error Reception (err_rcv) When received a response packet error from the system

Figure 61.2 shows a block diagram of the interrupt circuit.

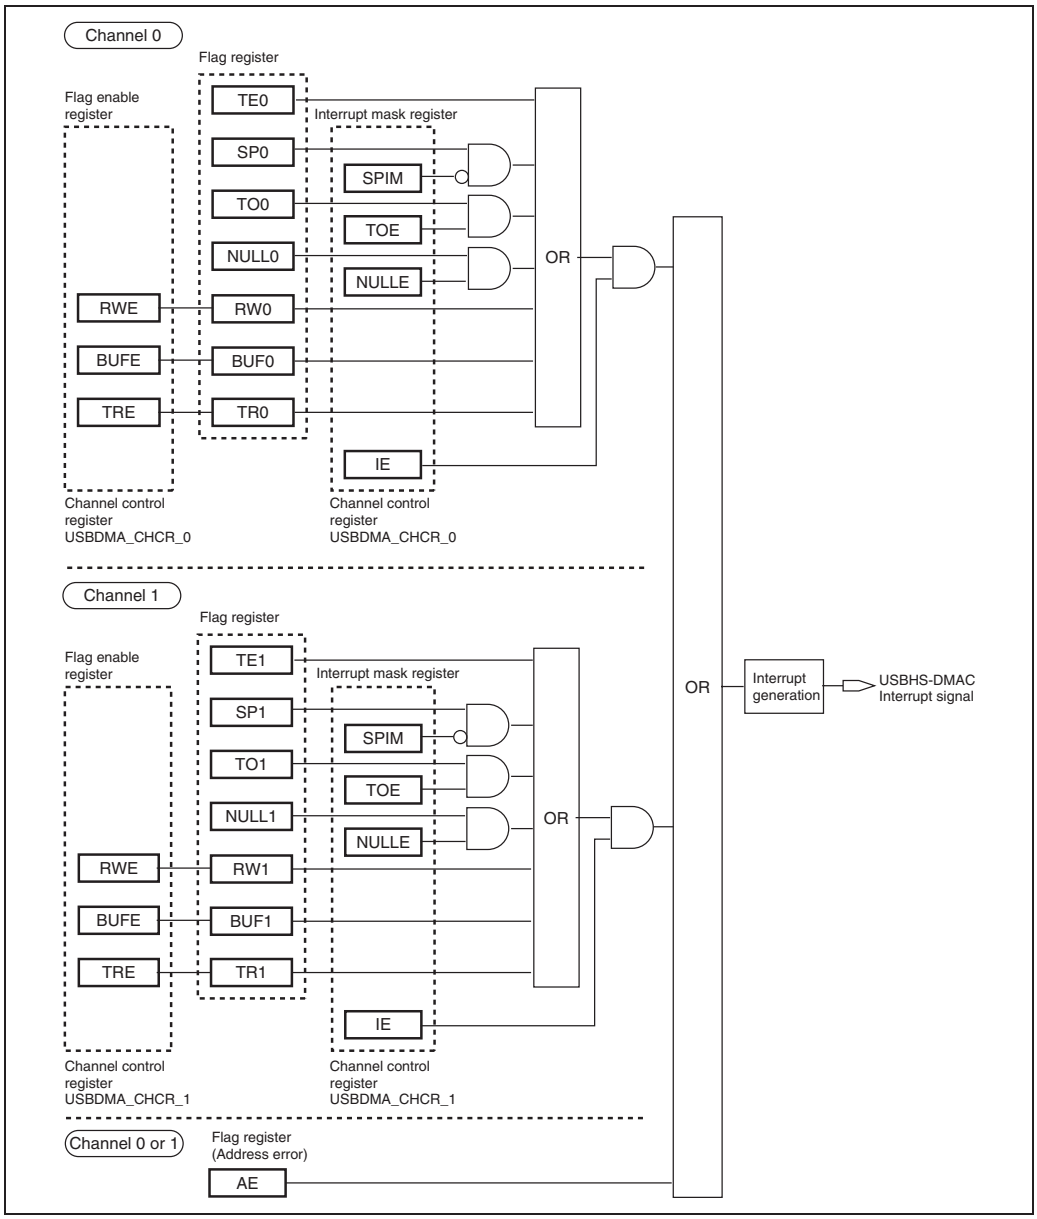

Figure 61.2 Block Diagram of Interrupt Circuit

(1) Transfer Count Ed Interrupt (TE Flag)

Can be generated when the specified number of transfers complete or the FTE bit in the channel control register (USBDMA_CHCR_0 to USBDMA_CHCR_1) is set to 1. When the IE bit in the USBDMA_CHCR_0 to USBDMA_CHCR_1 is set to 0, no interrupts are generated. However, the TE bit in USBDMA_CHCR_0 to USBDMA_CHCR_1 and the TE0 or TE1 bit in the interrupt source register (USBDMA_DMICR) are set to 1 regardless of the IE bit setting.

The internal transfer counter is loaded with the value set in the USBDMA_TCR_x register and decrements based on the SHwy clock every time one transaction (8-/16-/32-byte) completes. When the transfer count value reaches 0 (the end of a transfer count), the counter sets the TE (transfer end) flag from 0 to 1 (when the FTE bit is set, it is reflected on the TE flag immediately). The TE bit is cleared by writing 0 to it after reading it as 1 by software.

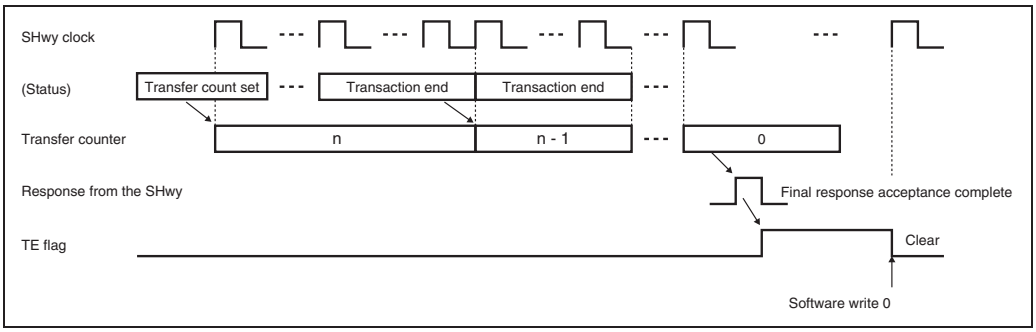

Figure 61.3 Transfer Count End Interrupt (TE) Generation Timing

(2) Short packet receive interrupt (SP flag)

Can be generated when a short packet is detected. When the SPIM bit in the USBDMA_CHCR_x register is set to 1, no interrupts are generated. However, the SP bit (SP flag) in the USBDMA_CHCR_x register and the SP0 or SP1 bit in the USBDMA_DMICR register are set to 1, regardless of the SPIM bit setting. The SP bit is cleared by writing 0 to it after reading it as 1 by software.

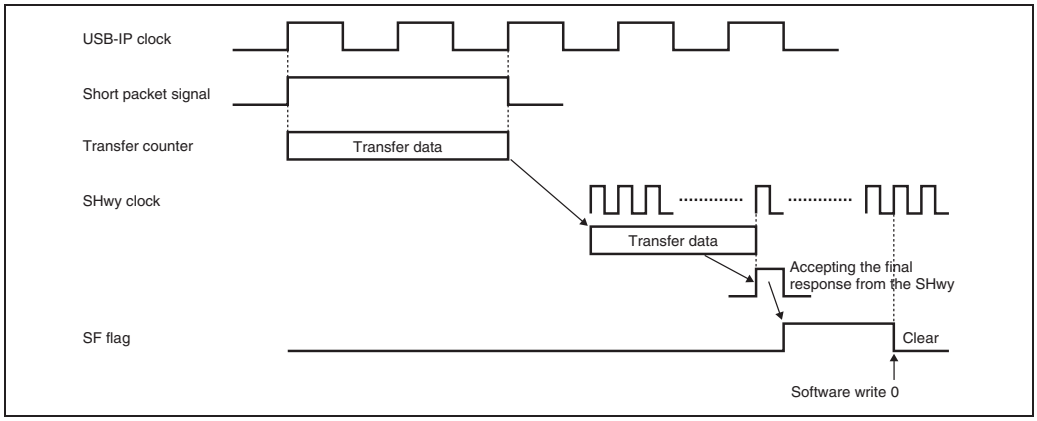

Figure 61.4 Short Packet Receive Interrupt (SP) Generation Timing

(3) NULL packet receive interrupt (NULL flag)

Can be generated when a NULL packet is detected. When the NULLE bit in the USBDMA_CHCR_x register is set to 0, no interrupts are generated. However, the NULL bit (NULL flag) in the USBDMA_CHCR_x register and the NULL0 or NULL1 bit in the USBDMA_DMICR register are set to 1, regardless of the NULLE bit setting. Note also that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a NULL packet is received. The software is responsible for implementing special processing if necessary since in this module this interrupt is designed only to signal the software that a NULL packet is received.

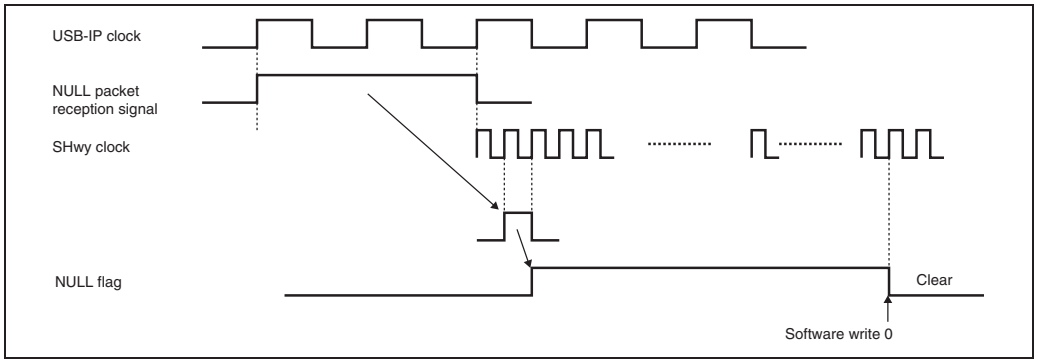

Figure 61.5 NULL Packet Receive Interrupt (NULL) Generation Timing

(4) Timeout interrupt (TO flag)

Can be generated when the time period that is specified in the timeout constant register (USBDMA_TOCSTR_0 or USBDMA_TOCSTR_1) elapses after the final transfer request is received from the USB-IP. On detecting the final transfer request, the internal counter is loaded with the value set in the USBDMA_TOCSTR_x register and starts counting down. When the counter reaches 0, it generates a timeout interrupt. Note that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a timeout interrupt occurs. The TO bit is cleared by writing 0 to it after reading it as 1 by software. Figure 61.6 and 61.7 show the timeout interrupt generation timing.

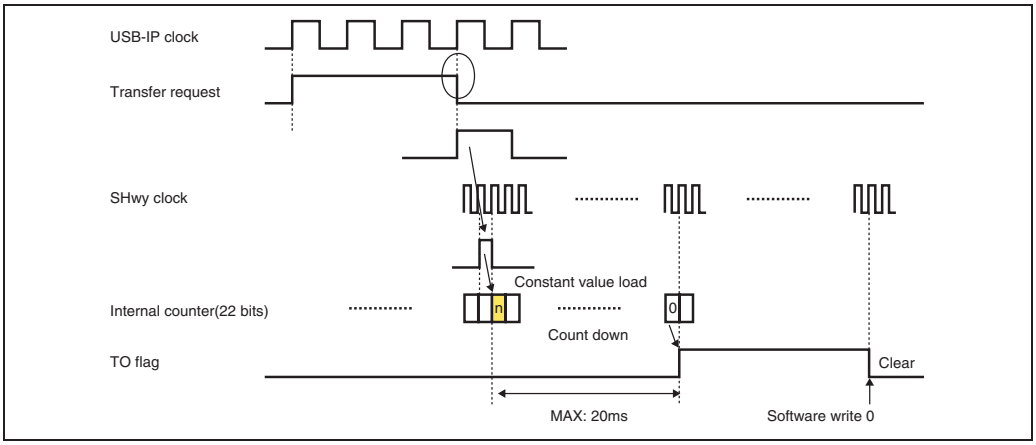

Figure 61.6 Timeout Interrupt (TO) Generation Timing

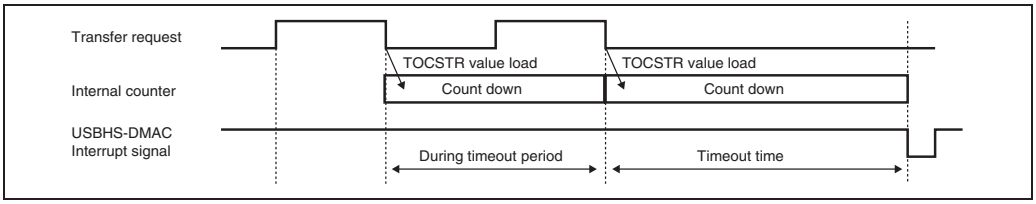

Figure 61.7 Timeout Interrupt Timing

The functions described in 61.3.1(5) to 61.3.1(9) are added to detect and notify the transitions on an individual signal line to the software, but no use is defined. They can be used as required.

(5) Transaction end detect interrupt (TR flag)

Can be generated when the end of a transaction is detected within the USB-IP. Note that the TR bit in the USBDMA_CHCR_x register and the TR0 or TR1 bit in the USBDMA_DMICR register are not reflected in the interrupt signal when the TRE bit in the USBDMA_CHCR_x register is set to 0.

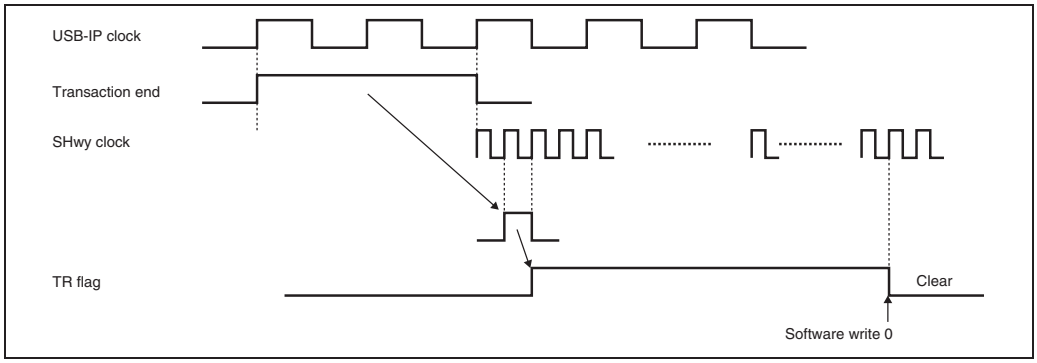

Figure 61.8 Transaction End Detect Interrupt Timing

(6) Buffer end detect interrupt (BUF flag)

Can be generated when the end of the buffer in the USB-IP is detected. Note that the BUF bit in the USBDMA_CHCR_x register and the BUF0 or BUF1 bit in the USBDMA_DMICR register are not reflected in the interrupt signal when the BUFE bit in the USBDMA_CHCR_x register is set to 0.

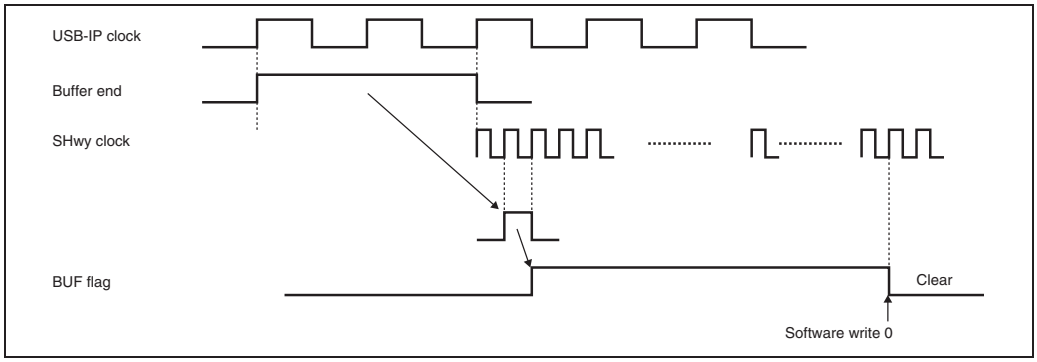

Figure 61.9 Buffer End Detect Interrupt Timing

(7) Final buffer access detect interrupt (RW flag)

Can be generated when the final access to the buffer in the USB-IP is detected. Note that the RW bit in the USBDMA_CHCR_x register and the RW0 or RW1 bit in the USBDMA_DMICR register are not reflected in the interrupt signal when the RWE bit in the USBDMA_CHCR_x register is set to 0.

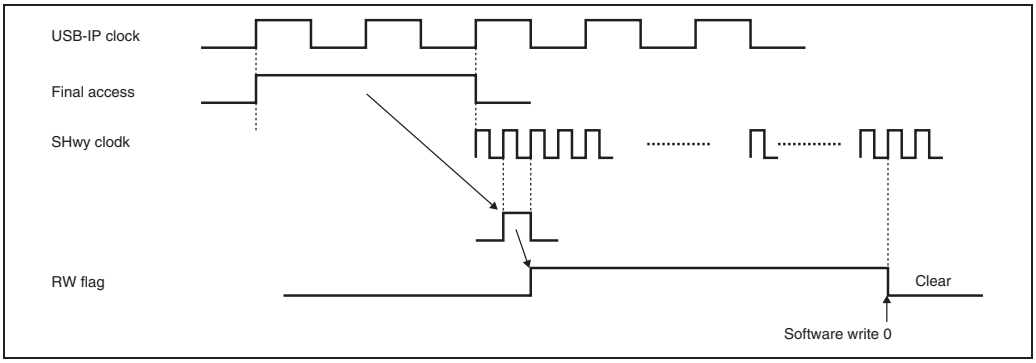

Figure 61.10 Final Buffer Access Detect Interrupt Timing

(8) Address error detection

This is a flag that indicates an address error interrupts has occurred when setting the source address register (USBDMA_SAR0 to USBDMA_SAR1) and the destination address register (USBDMA_DAR0 to USBDMA_DAR1). When the value written to the USBDMA_SAR or USBDMA_DAR register differs from the transfer size (TS) boundary, and when the TS bits are set to 11 (setting prohibited), the AE bit in the USBDMA_DMAOR register is set to 1. There is no distinction between CH0 and CH1 for an address error (the AE bit is set to 1 when an address error occurs on CH0 or CH1).

While the AE is set, no DMA transfer is allowed even if the DE bit in the USBDMA_CHCR_x register and the DME bit in the USBDMA_DMAOR register are set to 1. The address error interrupt is cleared by setting correct addresses in USBDMA_SAR_x and USBDMA_DAR_x.

Table 61.8 Address Error Detection Conditions When Setting Transfer Sizes

Transfer Size	Address Error Detection Conditions
TS=00 (8-byte transfer)	When data that is not aligned to 8-byte boundaries is written to the SAR/DAR registers (Writes to the SAR/DAR registers are valid.)
TS=01 (16-byte transfer)	When data that is not aligned to 16-byte boundaries is written to the SAR/DAR registers (Writes to the SAR/DAR registers are valid.)
TS=10 (32-byte transfer)	When data that is not aligned to 32-byte boundaries is written to the SAR/DAR registers (Writes to the SAR/DAR registers are valid.)
—	When b'11 (setting prohibited) is written to the TS register (Writes to the TS register are valid.)

(9) Response packet error detection

This function reports response packet errors when the interface between the SHwy and this module is accessed in ways that are not listed in table 61.2.

(a) Transmitting response packet errors

When a response packet error occurs during accessing from the SHwy to this module, the err_snt bit in the USBDMA_VCR register is set to 1.* The error signal is also sent to the SHwy bus if the RM bit in the USBDMA_DMAOR register is 0. If the RM bit is set to 1, the error signal is masked (0 is signaled).

Note: When a response packet error occurs, the err_snt bit is set to 1 regardless of the RM bit setting. The err_snt bit is cleared by writing 0 after reading 1.

Table 61.9 Response Packet Error Generation

USBDMA_DMAOR (RM bit) Setting	1 (Mask Mode)	0 (Normal Mode)
Response packet error signal notification to SHwy	Signals the fixed value (0) to the SHwy bus without determining if there is a response packet error.	Reports a response packet error to the SHwy bus when its is accessed with a transfer size other than those supported in this module (4-byte read/write and 8-byte read).

(b) Receiving response packet errors

When a response packet error occurs during accessing from this module to the SHwy, the err_rcv bit in the USBDMA_VCR register is set to 1. The TID bit in the USBDMA_DMAOR register indicates on which channel of this module the error has occurred (TID[1]=1 means it has occurred on CH1 and TID[0]=1 on CH0).

The err_rcv bit is cleared by writing 0 after reading 1.

61.3.2 DMA Transfer Function

(1) Operating mode

The following operating modes (1) to (3) are supported according to the setting of the PR bit in the DMA operation register (USBDMA_DMAOR).

(a) CH0 first control

Forces CH1 to wait to start a DMA transfer until a DMA transfer completes on CH0.

When there is a timing conflict in starting a DMA transfer between CH0 and CH1, CH0 takes precedence over CH1. If a DMA transfer is in progress on CH1 when CH0 tries to start a DMA transfer, CH0 waits to start it until the ongoing DMA transfer completes on CH1.

(b) CH1 first control

Forces CH0 to wait to start a DMA transfer until a DMA transfer completes on CH1.

When there is a timing conflict in starting a DMA transfer between CH1 and CH0, CH1 takes precedence over CH0. If a DMA transfer is in progress on CH0 when CH1 tries to start a DMA transfer, CH1 waits to start it until the ongoing DMA transfer completes on CH0.

(c) Round-robin control

Assigns the lowest priority to the last channel that has completed a transfer. In the initial state, CH0 takes precedence over CH1.

When there is a timing conflict in starting a DMA transfer between CH0 and CH1, the channel with a higher priority is granted to start the transfer and the lower priority channel is forced to wait. If a DMA transfer is in progress on the lower priority channel when the higher priority channel tries to start a DMA transfer, the higher priority channel waits to start it until the ongoing DMA transfer completes on the lower priority channel.

Figure 61.11 shows an overview of the processing of the SHwy bridge in each operating mode.

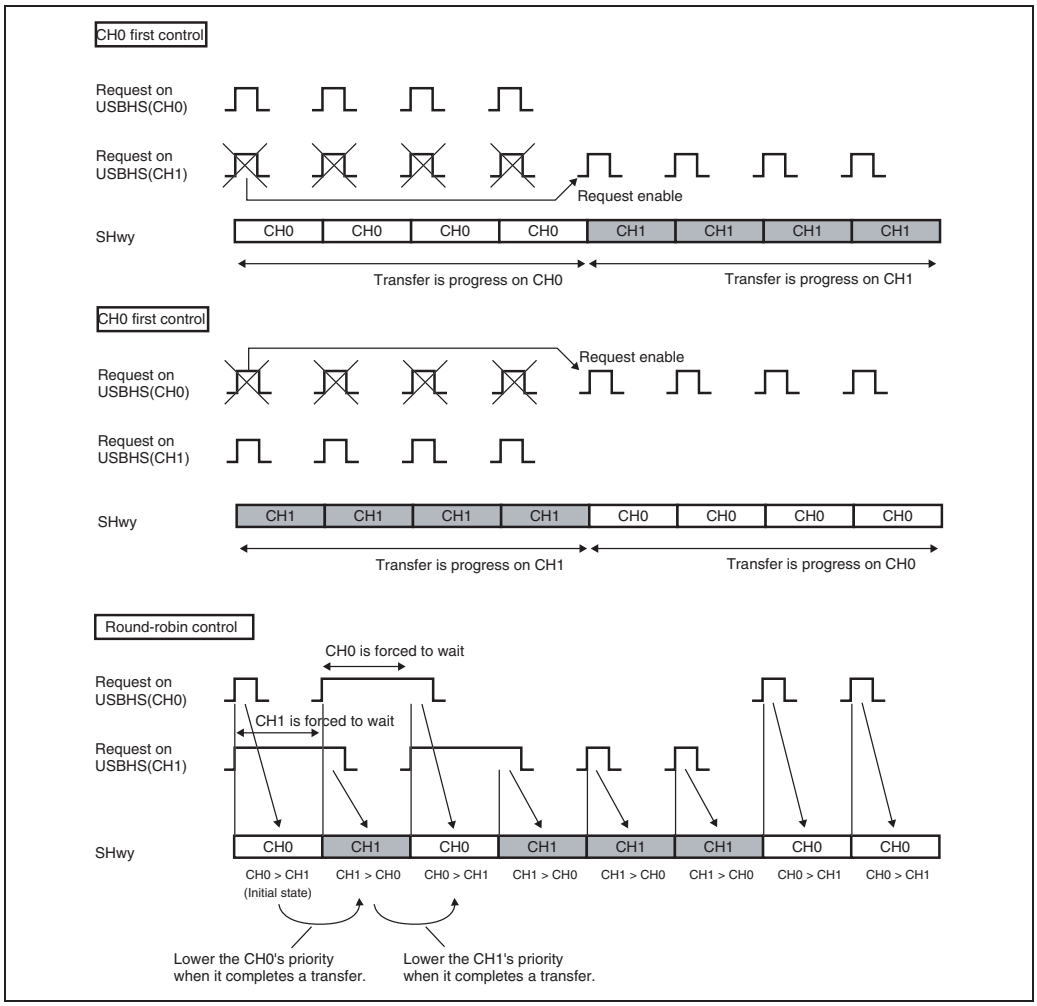

Figure 61.11 Overview of SHwy Bridge Processing in Each Mode

(2) Transfer size

The transfer size on the SHwy can be selected by setting the channel control register (the TS bit).

8-, 16-, and 32-byte can be set for each channel independently.

The following consideration should be observed during IN transfers.

The minimum transfer size that can be set to the TS bit is 8 bytes while the USB-IP can control transfers in 1-byte units. For example, if valid transfer data that is "8 x (n-1) + α" (α is less than 7 bytes) in size is to be transferred to the USB-IP with the transfer size set to 8 bytes and the transfer count set to n, α is transferred as a valid transfer unit by controlling byte enables according to the DMA final transaction valid data transfer enable register (the EDTEN bits) setting. Likewise, data is transferred in "transfer size x transfer count" (the final transaction is controlled by EDTEN) for 16- and 32-byte transfer sizes. The EDTEN setting is valid only for IN transfer and is don't care for OUT transfer.

Figure 61.12 shows an example of EDTEN setting. When only EDTEN31 in EDTEN31 to EDTEN0 is 1 , one byte is enabled. When only EDTEN31 and EDTEN30 in EDTEN31 to EDTEN0 are 1 , two bytes are enabled. Therefore, the total transfer volumes in the example shown above are calculated as "(32 bytesx(n-1)) bytes+10 bytes" for 32-byte transfer, "(16 bytesx(n-1)) bytes+7 bytes" for 16-byte transfer, and "(8 bytesx(n-1)) bytes+2 bytes" for 8-byte transfer. EDTEN15 to EDTEN0 in 16-byte transfer, EDTEN23 to EDTEN0 in 8-byte transfer are invalid (their values are ignored).

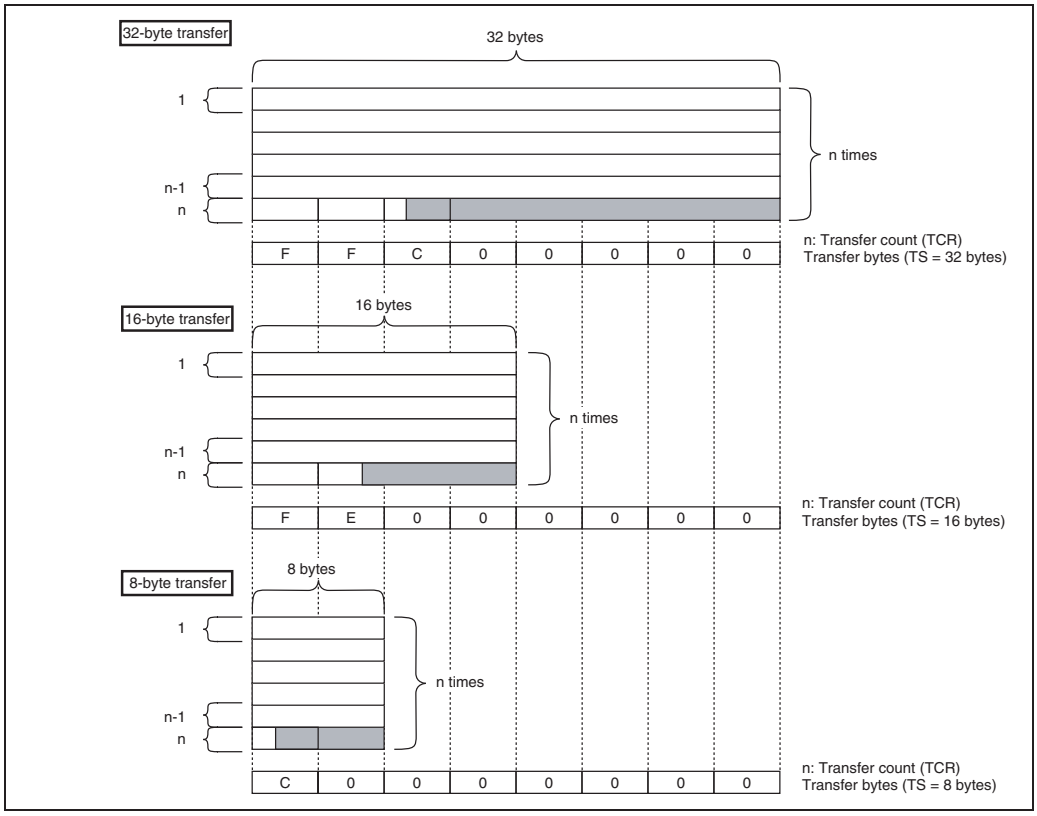

Figure 61.12 Example of Final Transaction Valid Data Transfer Enable (EDTEN) Setting

(3) DMA transfer flow

After the DMA source address register (USBDMA_SAR), DMA destination address register (USBDMA_DAR), DMA transfer count register (USBDMA_TCR), DMA channel control register (USBDMA_CHCR), final valid data transfer enable register (USBDMA_TEND), and DMA operation register (USBDMA_DMAOR) are set appropriately, the DMAC starts data transfer in the following sequence. The DMA timeout constant register (USBDMA_TOCSTR) may also need to be set.

If the transfer enabling conditions are set as DE=1, DME=1, TE=0, AE=0, SP=0, and (TR=0, BUF=0, RW=0), transfers are performed according to the transfer request enables and transfer requests from the USB-IP. The transfer direction (IN/OUT transfer) is determined by the direction signal from the USB-IP. The transfer size is determined by the setting of TS1 to TS0.

Every time one SHwy transaction (in the transfer size specified in the TS bit) completes, the internal counter of this module decrements the USBDMA_TCR value by one. When the specified transfer count ends (the USBDMA_TCR value reaches 0), it means all transfers complete. At this time, an USBHS0-DMAC interrupt is generated if the IE bit in the USBDMA_CHCR register is set to 1.

When a NULL packet is received, transfer can be stopped or restarted by setting FTE=1 after negating the DREQE register of the USBHS0 module. Follow the steps described later in "Control when a NULL packet is received".

Table 61.10 shows the conditions for each DMA transfer.

Table 61.10 DMA Transfer Conditions

Transfer enabling condition	TE=0, SP=0, (*TR=0, BUF=0, RW=0)
Transfer (starting) condition	When a transfer request is enabled by the USB-IP When a transfer request is issued by the USB-IP
Transfer completing (then restarting) condition	When the transfer count ends (the TE flag is set to 1), (can be restarted by setting DE and DME to 1.) When FTE=1 (when DREQE=1 in the USBHS0 module is also set), and the steps described later should be followed. When reset (can enter into standby state by releasing the reset.)
Transfer suspending (then resuming) condition	When DE=0 or DME=0 (can be resumed by setting DE=1 or DME=1.) When SP=1 (can be resumed by clearing the SP flag.) When RW=1, BUF=1, and TR=1 (can be resumed by clearing the RW, BUF, and TR flag.)* When the module stops (can be resumed by resuming the module.)

Note: * Can be ignored when the RWE, BUFE, and TRE registers are disabled (set to 0).

Figure 61.13 illustrates the high-level DMA transfer flow.

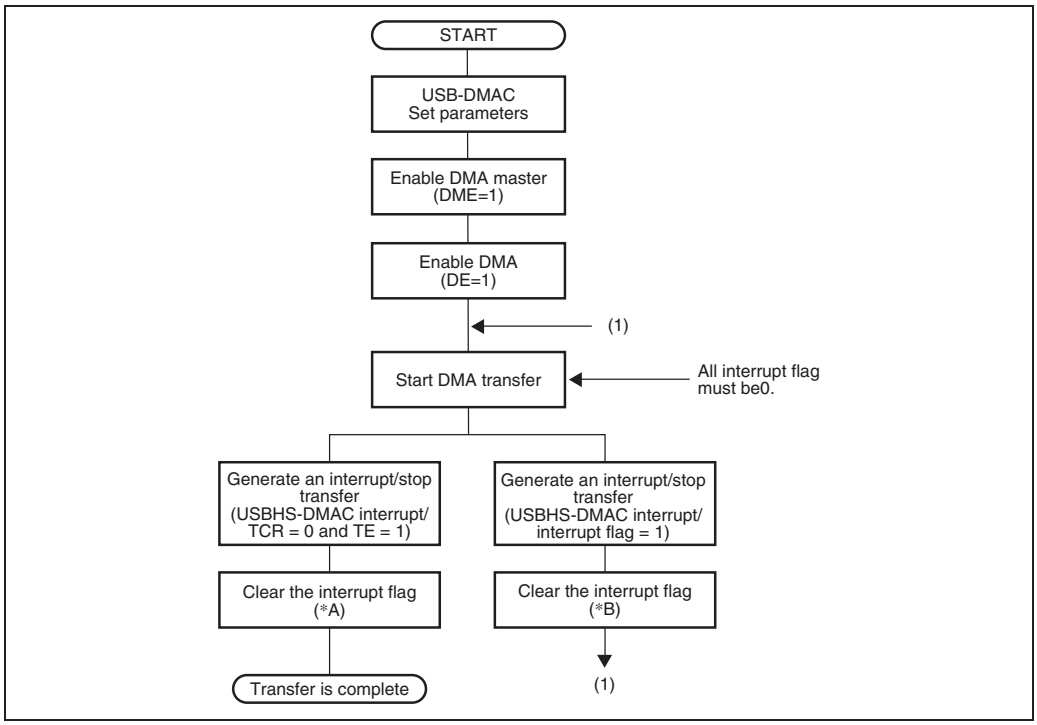

Figure 61.13 DMA Transfer Flow Overview

Where A and B apply to the following flags:

(Note that RW, BUF, and TR are not set when RWE, BUFE, and TRE are disabled, respectively.)

* A: TE flag

* B: SP,(RW,BUF,TR) flags

When to change USB-DMAC parameters

USB-DMAC parameters (such as destination address or transfer count) should be changed while all interrupt flags are cleared and DE=0 and DME=0 are set (a transfer is started with the latest parameters when DME=1 and DE=1 are set). Furthermore, USB-DMAC parameters should not be changed while the DMA is enabled (DME=1 and DE=1).

What to do if freeze

If a transfer should freeze during operation, issue a software reset after setting DE=0 and DME=0 and clearing all interrupt flags. All hardware except configuration registers is initialized. Restart by setting DME and DE to 1 after updating USB-DMAC parameters if necessary.

Control when a timeout occurs

Since this module assumes bus access in the transfer units listed in table 61.2, it cannot be restarted when a timeout occurs in an irregular case where it is being accessed with any size that are not in the table. This irregular case should be handled by software, such as by issuing a software reset (to both CH0 and CH1).

Control when a NULL packet is received

When a NULL packet is received during a DMA transfer, the DMA transfer can be suspended and resumed on each channel independently by controlling the FTE bit of this module and the DREQE bit of the USBHS0 module in the following sequence.

[Control sequence]

During a DMA transfer (A)

(1) A NULL packet is received (an interrupt is generated and the NULL flag is detected).

(2) The DREQE bit of the USBHS0 module is negated (=0).

(3) Wait for the internal bus to be stabilized.

(4) Perform three actions at the same time; setting the FTE bit, clearing the NULL bit and negating the DE bit.

An interrupt is generated due to TE.

(5) Clear the interrupt caused by TE.

(6) Set the parameters (such as TCR or DAR) for the next transfer.

(7) Assert the DE bit (=1). The DMA is restarted.

(8) Assert the DREQE bit (=1).

Start a DMA transfer (B).

[Restrictions]

1) FTE bit set timing

   If this module is accessing the SHwy (SHBSYx bit=1) when setting the FTE bit, you need to wait to set the FTE register until this module's internal buffer is empty and the SHwy bus access is complete (SHBSYx bit=0). Note that if you accidentally set the FTE register while an SHwy bus access is in progress, the transfer fails and transfer data may be lost or the transfer may be unable to be restarted.

2) DREQE register assert (negate clear) timing

   It is necessary to allow at least 20clk@ZSϕ after the DE bit is asserted and before the DREQE is asserted. This is because DREQE needs to be asserted after transfers enabled by the DE bit are ready internally to be started. Asserting DREQE immediately after DE may cause malfunction such as initiating unnecessary bus access.

3) Fractional byte and NULL packet reception

   This module assumes bus access in the transfer units listed in table 61.2 and goes out of control when it receives a NULL packet in an unsupported transfer unit. Therefore, data transfer in any transfer unit that is not in the table is prohibited.

4) IN/OUT switching after NULL packet reception

   After a NULL is received, transfers cannot be restarted with the transfer direction switched from OUT to IN. This is because this module still considers the terminated transfer as an OUT transfer until the transfer count reaches its end. Note that if you switch the transfer direction to IN transfer accidentally after a NULL packet is received, a conflict occurs between an IN and an OUT transfers, which may cause illegal bus access.

   Use CH0 and CH1 with their transfer direction fixed, or if the transfer direction needs to be switched on the same channel, make sure to do it every time a transfer completes successfully due to the end of transfer count or is terminated by software reset.

Figure 61.14 shows the state transitions for DMA transfers.

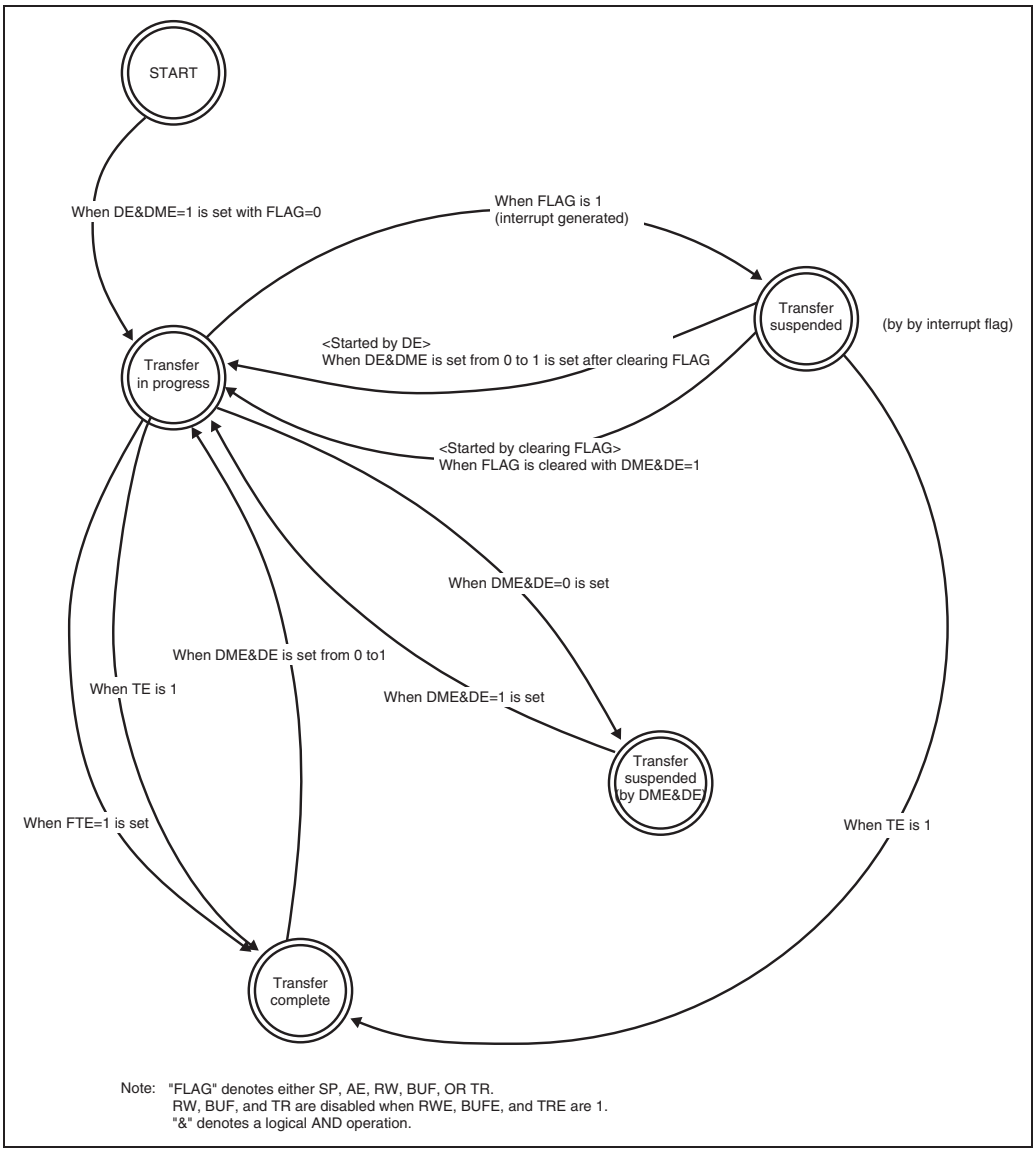

Figure 61.14 State Transitions for DMA Transfer

(4) Control Sequence

Figure 61.15 shows an outline of the control sequence of this module.

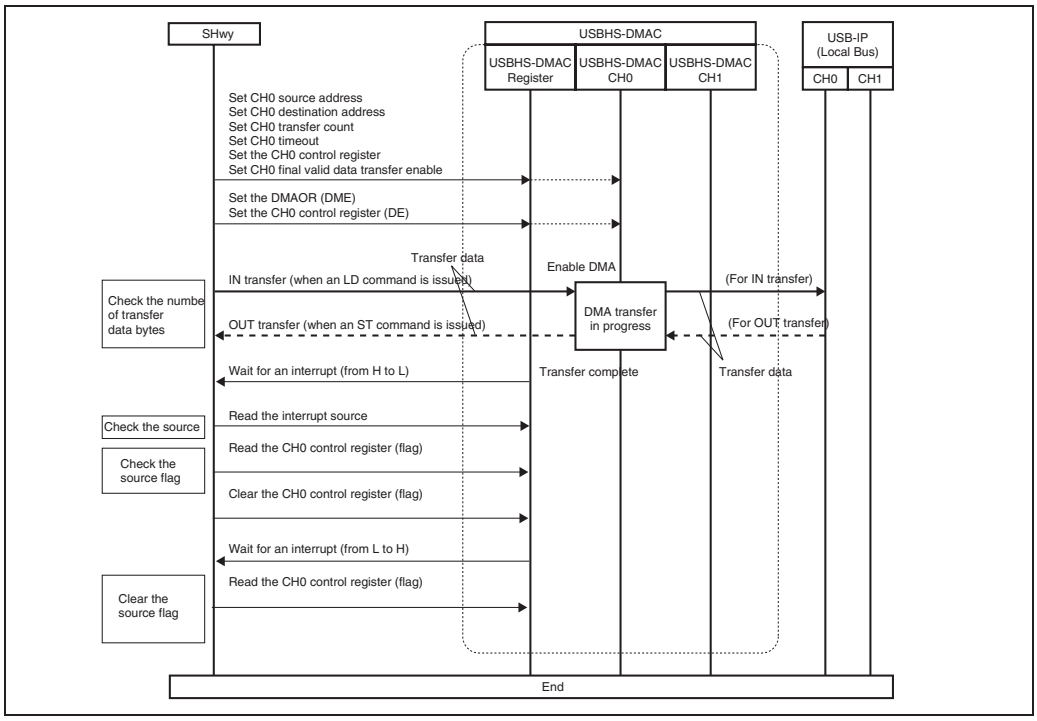

Figure 61.15 Control Sequence Overview

(5) Internal Buffer Configuration

This module has 64 bytes (64 bitsx8 words) of internal buffer for each of two channels. Thus, the total capacity of this module's internal buffers is 128 bytes (1024 bits).

The internal buffers are composed of two planes each of which is organized as 64 bits x 4 words and are readable /writable on per-plane basis from the USB-IP local bus or SHwy bus (plane 1 is writable when plane 0 is readable or vice versa). For 16-byte transfers, only 2 words in plane 0 and 2 words in plane 1 are used. For 8-byte transfers, only 1 word in plane 0 and 1 word in plane 1 are used.

Note that these internal buffers cannot be accessed directly by software.

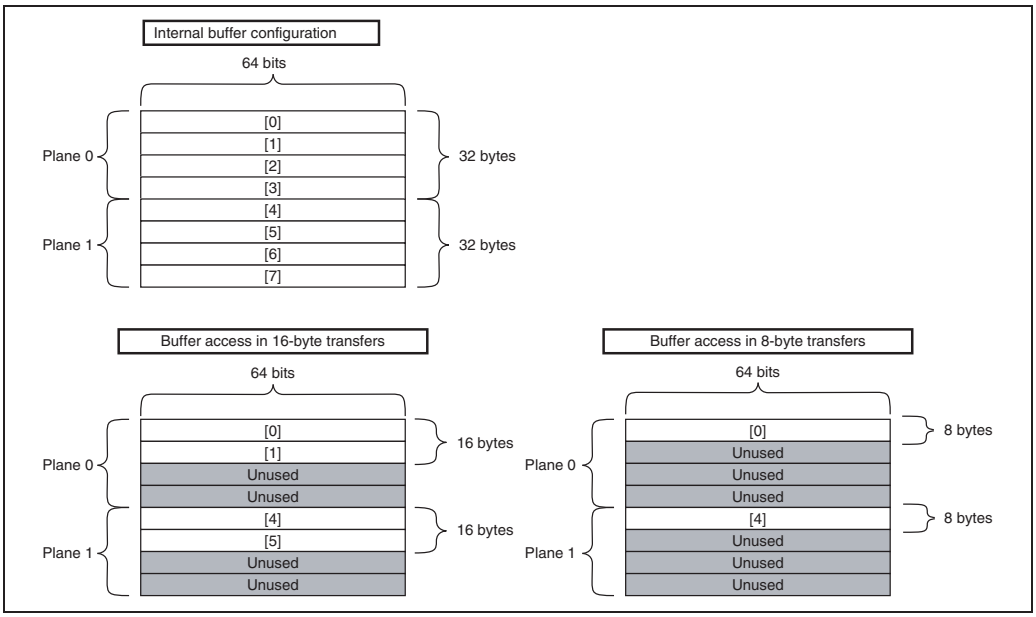

Figure 61.16 Internal Buffer Configuration and Used Area for Each Transfer Size

(6) Internal Buffer Control (Hardware Control, For reference)

(a) IN transfer (from SHwy to USB)

Retrieves transfer data from a source on the SHwy bus and writes it to this module's internal buffer. Reads the written data from the internal buffer and writes it to the USB-IP.

Figure 61.17 shows how the planes of this module's internal buffers are controlled during an IN transfer. In this figure, "read' and 'write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words* and 1 word* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 and a transfer the read data to the USB-IP are complete, the readable plane flag is toggled (every time 2 words* and 1 word* are read for 16-byte and 8-byte transfers, respectively). Access to the SHwy is prohibited during the period when both the writable plane flag and readable plane flag are set on the same plane as a read/write access conflict may occur.

* 1 word=64 bits

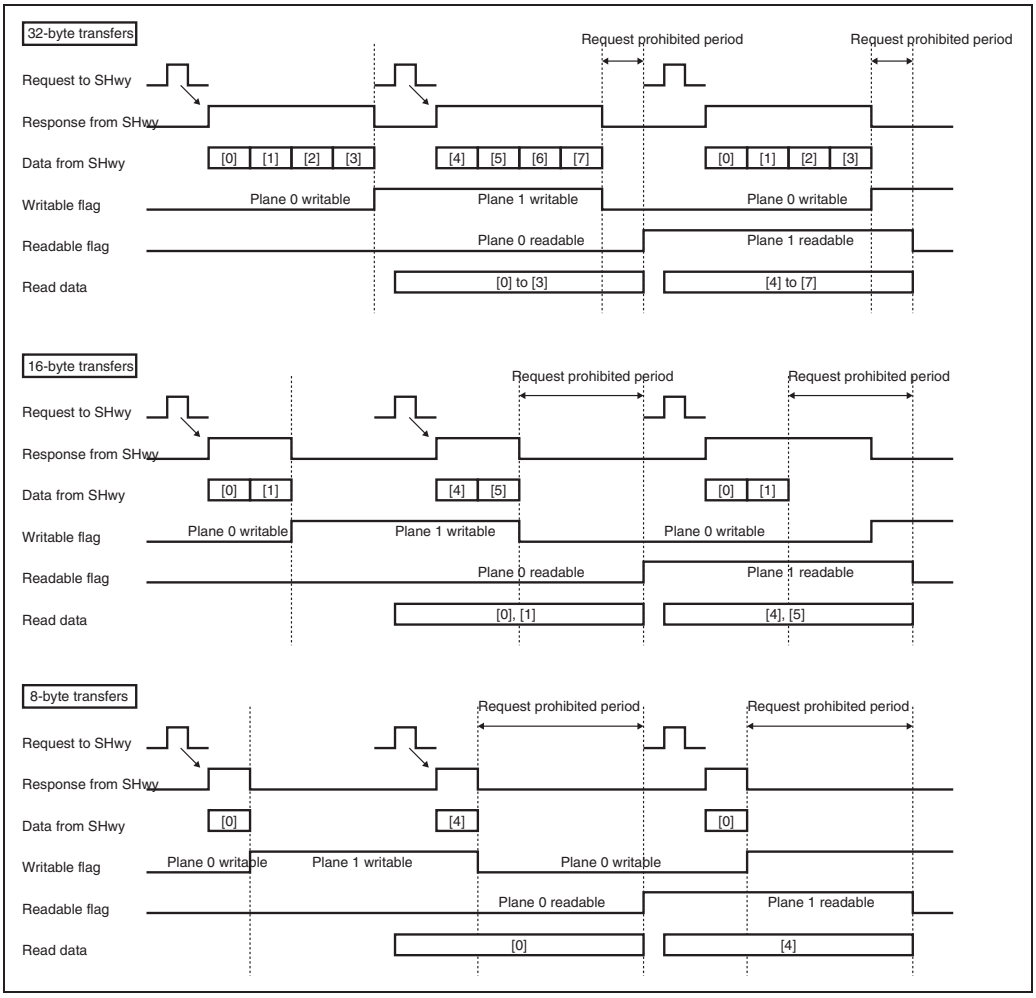

Figure 61.17 Read/Write Control for Internal Buffer: From SHwy to USB (IN Transfer)

(b) OUT transfer (from USB to SHwy)

Writes data read from the USB-IP to the internal buffers. Reads the written data from this module's internal buffers and writes it to the destination on the SHwy bus (OUT transfer).

Figure 61.18 shows how the planes of this module's internal buffers are controlled during an OUT transfer. In this figure, "read' and 'write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words* and 1 word* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 is complete, the readable plane flag is toggled (every time 2 words* and 1 word* are read for 16-byte and 8-byte transfers, respectively). Access to the SHwy is prohibited during the period when both the writable plane flag and readable plane flag are set the same plane as a read/write access conflict may occur.

* 1 word=64 bits

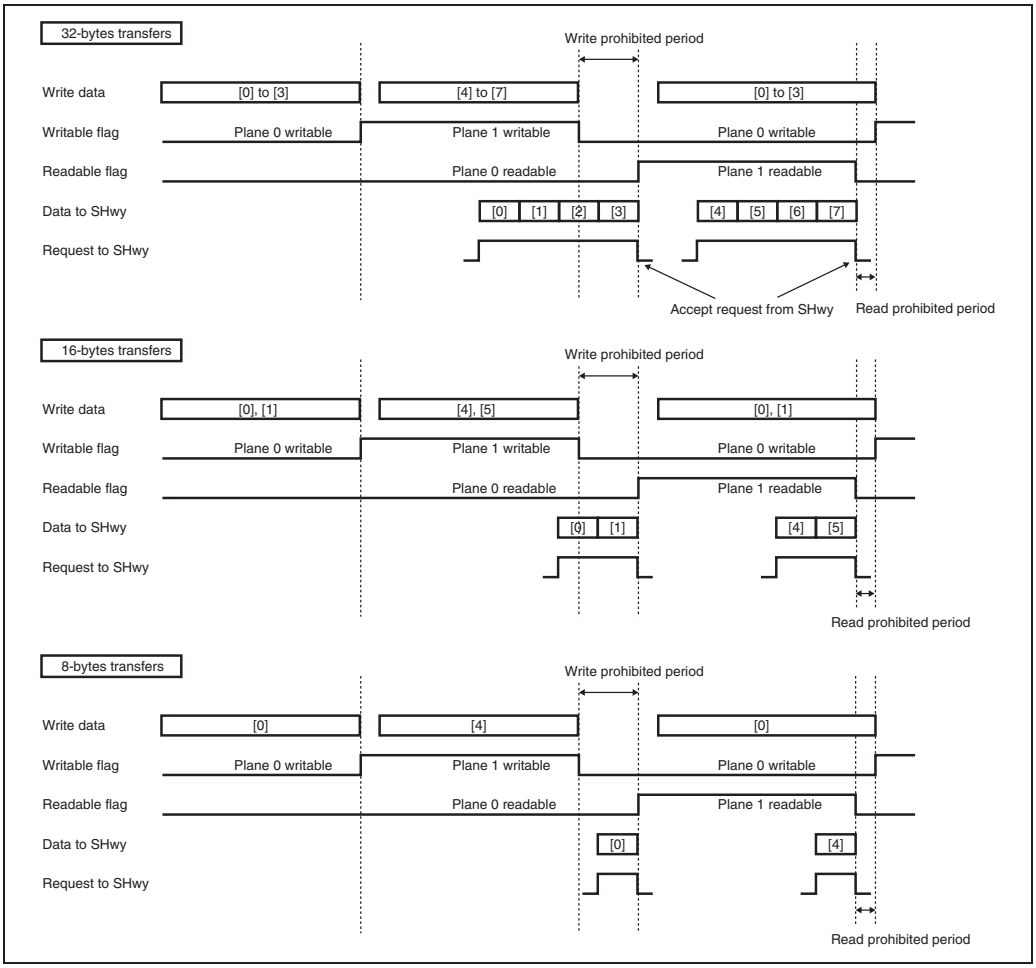

Figure 61.18 Read/Write Control for Internal Buffer: From USB to SHwy (OUT Transfer)

Section 62 USB High-Speed DMAC (USBHS1-DMAC)

62.1 Features

- Two types of clock: ZSϕ and USBHS1 local bus clock (48 MHz), which are asynchronously absorbed in the local bus bridge
- The SHwy bus interface functions are implemented.

The SHwy bus interface handles data transfer with the memory and register settings.

- Data communication is performed using the local DMA protocol.
- Supports two channels that can work concurrently.
- Interrupts

— Setting count end interrupt

— Transfer end interrupt upon receiving a short packet from the USB-IP
This function allows generation of an interrupt even in the case where DMA transfer ends after receiving data less than the transfer size set in the DMAC.

— Timeout interrupt
A timeout interrupt can be generated after the specified cycles after the last USBHS1 transfer request. (This interrupt is used for the timeout when the final packet received is Max packet.)

— Interrupts can also be generated when a NULL packet is received or an address error is detected.

Table 62.1 Main Functions of This Module

Item	Description
Application	Transfer between USB-IP (FIFO) and SHwy bus (4-Gbyte arbitrary space)
Purpose of DMA transfer	High-speed data transfer between USB-IP and SHwy bus
DMA transfer end notification to the software	Interrupt signals (Transfer count end, USB-IP short packet reception, timeout, etc.)
Transfer space/transfer address direction	4-Gbyte arbitrary space (forward direction) to 4-Gbyte arbitrary space (forward direction)
Maximum transfer count	16,777,216
Transfer unit	8, 16, or 32 bytes
Control signals generated	Address/data read/data write conforming to the USB-IP local bus interface and SHwy bus protocols
Number of channels	2 (parallel operation enabled, round-robin control)
Bus specification	SHwy bus (SuperHyWay 64 bits), local bus (USB-IP local bus)
Clock	SHwy clock (130 MHz), USB local bus clock (48 MHz)
Max. Transfer rate	IN transfer: About 350 Mbps (in 32-byte transfer mode) OUT transfer: About 340 Mbps (in 32-byte transfer mode)

Table 62.2 Bus Access Type

	Supported Access Type
SHwy bus access (USBHS1-DMAC master)	8-byte read/write 16-byte read/write 32-byte read/write
USBHS1-DMAC register setting	4-byte read/write 8-byte read/write

The configuration of this module is shown below.

This module is provided with buffers and bus bridges and controls transfers between the SHwy bus and USB High-Speed module (USBHS1).

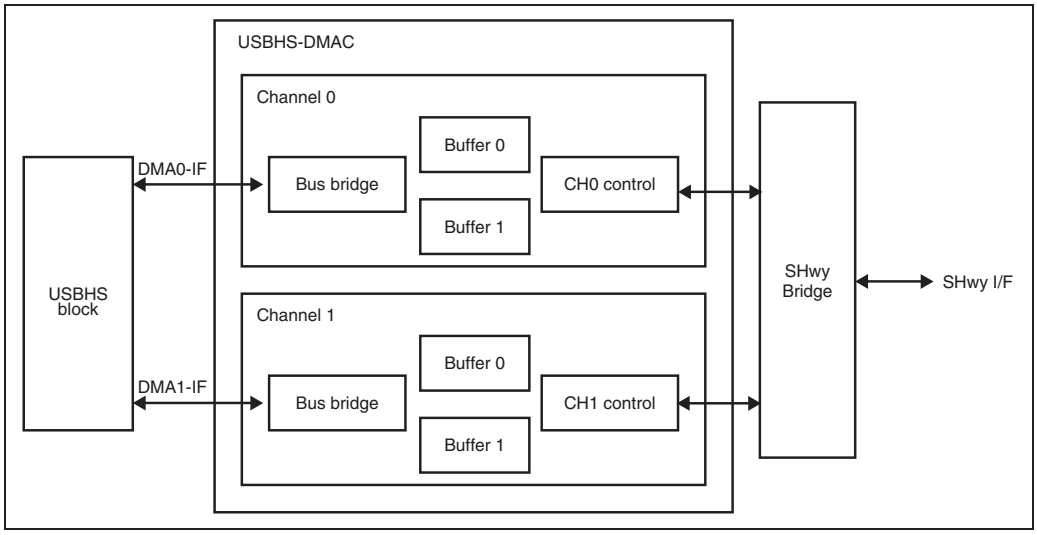

Figure 62.1 USBHS1-DMAC Configuration

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DAR31 to DAR0	All 0	R/W	Destination Address (0x00000000 to 0xFFFFFFFF (4 Gbytes)) Set a value of 8-byte, 16-byte, or 32-byte boundary. Indicate the next transfer destination address during a DMA transfer.

62.2.6 DMA Transfer Count Register_0 to 1 (USBDMA_TCR_0 to 1)

[Address=USBDMA_BASE+H'28,H'48]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TCR[23:16]							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCR[15:0]															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	TCR23 to TCR0	H'FF FFFF*	R/W	Transfer Count • When 0x000001 is set, total transfer volume is as follows: Transfer size = 32 bytes: 32 × 1 bytes Transfer size = 16 bytes: 16 × 1 bytes Transfer size = 8 bytes: 8 × 1 bytes • When 0xFFFFFF is set, 16,777,215 times • When 0x000000 is set, 16,777,216 times (maximum) • Indicate 0 when a DMA transfer completes successfully.

Note: * To read this register, read the internal transfer counter value (the TCR counter value) directly. This register is read as all 1 after a reset is cleared because the initial value of the TCR counter is all 1 (0xFFFFFF). When DMA is enabled (DE in DMACHCR is asserted), the TCR counter is loaded with the value set in this register and decrements during DMA transfers. This means that the remaining transfer count is read back. Note that the read value may be different from the one set in this register due to this reason.

62.2.7 DMA Timeout Count Register_0 to 1 (USBDMA_TOCNTR_0 to 1)

[Address=USBDMA_BASE+H'2C,H'4C]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	TOCNTR[21:16]					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOCNTR[15:0]															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 0	TOCNTR21 to TOCNTR0	H'3F FFFF	R	Timeout Counter Value (0x000000 to 0x27AC40) Indicate the remaining timeout count during timeout counting. (Countable up to 0x3FFFFF (approximately 32 ms) by the hardware. See the TOCSTR register.)

62.2.8 DMA Timeout Constant Register_0 to 1 (USBDMA_TOCSTR_0 to 1)

[Address=USBDMA_BASE+H'30,H'50]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	TOCSTR[21:16]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOCSTR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 0	TOCSTR21 to TOCSTR0	H'00 0000	R/W	Timeout Constant Value (0x000000 to 0x27AC40) Sst a timeout value (at 130 MHz cycle). The maximum timeout time is approximately 20 ms. (Setting up to 0x3FFFFF (approximately 32 ms) is allowed by the hardware.)

62.2.9 DMA Channel Control Register_0 to 1 (USBDMA_CHCR_0 to 1)

[Address=USBDMA_BASE+H'34,H'54]

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	FTE	—	—	—	SPIM	TRE	BUFE	RWE	NULLE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TR	BUF	RW	NULL	PRI[3:0]				TS[1:0]		IE	TOE	TO	SP	TE	DE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*	R/W*	R/W*	R/W*	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W*	R/W*	R/W*	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	FTE	0	(R)/W	Forced TE Set Register When a NULL packet is received, the TE bit is forced to 1 to terminate the transfer by setting 1 in this register. (The DREQE bit of the UDSB-IP should also be controlled accordingly. For details on the control procedure and restrictions, see section 62.3.2(3).) This bit is always read as 0. 0: No effect (nothing happens). 1: Forces the TE bit to 1.
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	SPIM	0	R/W	Short Packet Receive Interrupt Mask Enables or disables the reflection of the short packet (SP) receive flag in the interrupt signal. If this bit is set to 1, no interrupts are generated when an SP is received. However, the SP receive flag (the SP bit) is set regardless of this register setting. 0: The short packet receive interrupt is enabled (default). 1: The short packet receive interrupt is disabled.

Bit	Bit Name	Initial Value	R/W	Description
19	TRE	0	R/W	Transaction End Detect Interrupt Flag Enable Enables or disables the reflection of TR in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the TR bit is always 0.) 0: The TR flag is disabled. 1: The TR flag is enabled.
18	BUFE	0	R/W	Buffer End Detect Interrupt Flag Enable Enables or disables the reflection of BUF in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the BUF bit is always 0.) 0: The BUF flag is disabled. 1: The BUF flag is enabled.
17	RWE	0	R/W	Final Buffer Access Detect Interrupt Flag Enable Enables or disables the reflection of RW in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the RW bit is always 0.) 0: The RW flag is disabled. 1: The RW flag is enabled.
16	NULLE	0	R/W	NULL Receive Interrupt Flag Enable Enables or disables the reflection of the NULL receive interrupt flag (NULL) in the interrupt signal. 0: The NULL receive interrupt flag is disabled. 1: The NULL receive interrupt flag is enabled.
15	TR	0	R/W*	Transaction End Detect Interrupt Flag When the transaction end is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: An transaction end receive interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
14	BUF	0	R/W*	Buffer End Detect Interrupt Flag When the end of the buffer is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A buffer end detect interrupt is generated.
13	RW	0	R/W*	Final Buffer Access Detect Interrupt Flag When the final access to the buffer is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A final buffer access detect interrupt is generated.
12	NULL	0	R/W*	NULL Receive Interrupt Flag When NULL packet is received, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A NULL packet receive interrupt is generated.
11 to 8	PRI3 to PRI0	All 0	R/W	Priority Set the value of the priority signal to be output to the SHwy bus. 0000: Priority 0 (lowest) 0001: Priority 1 : 1111: Priority 15 (highest)

Bit	Bit Name	Initial Value	R/W	Description
7, 6	TS1 to TS0	00	R/W	MA Transfer Size 00: 8 bytes 01: 16 bytes 10: 32 bytes 11: Setting prohibited Specify the same transfer size and address boundary when setting addresses in DMASAR and DMADAR as a transfer source and transfer destination. If TS = 11 is set, an address error is generated and DMA transfer is disabled.
5	IE	0	R/W	Interrupt Enable Enables or disables an interrupt request to the CPU when DMA transfer ends. When AE, TE, SP, TO, NULL, RW, BUF, or TR bit is set with this bit set to 1, an interrupt request is output to the CPU. However, when the TRE, BUFE, RWE, NULLE, or TOE bit is set to disabled, no interrupt due to TR, BUF, RW, NULL, or TO is generated. 0: An interrupt request is disabled. 1: An interrupt request is enabled.
4	TOE	0	R/W	Timeout Enable Enables or disables the reflection of the timeout flag (TO) in the interrupt. 0: Timeout flag is disabled. 1: Timeout flag is enabled.
3	TO	0	R/W*	Timeout Flag After a transfer request REQ is negated, a timeout interrupt is generated after the specified cycles. (Used for timeout when the final packet is Max packet.) 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: Timeout is generated.

Bit	Bit Name	Initial Value	R/W	Description
2	SP	0	R/W*	Short Packet Receive Flag A transfer end interrupt is generated upon receiving a short packet from the USB-IP. For example, if DMA transfer size is set to 1 MB but actual data transfer is 900 KB, this interrupt is generated when transfer of 900 KB finishes. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A short packet is received.
1	TE	0	R/W*	Transfer End Flag When a DMA transfer ends with DMATCR = 0, the TE bit is set to 1. When a DMA address error occurs before DMATCR is cleared to 0 and the transfer is suspended by clearing the DE bit and the DME bit in DMAOR, the TE bit is not set to 1. To clear the TE bit, write 0 after reading 1.When TE = 1, DMA transfer is disabled even if the DE bit is set to 1. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: DMA transfer end (TCR = 0)
0	DE	0	R/W	DMA Enable Enables or disables DMA transfer. Setting the DME bit in DMAOR and the DE bit for the corresponding channel to 1 starts a DMA transfer, provided that all interrupt flags are 0. Clearing the DE bit to 0 suspends the ongoing transfer after the transfer of one transaction is completed. 0: DMA transfer is disabled. 1: DMA transfer is enabled.

Note: * Only writing 0 to clear the flag is enabled.

62.2.10 DMA Final Transaction Valid Data Transfer Enable Register_0 to 1 (USBDMA_TEND_0 to 1)

[Address=USBDMA_BASE+H'38,H'58]

R/W:	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W	R/W	R/W	R/W*	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6, 5	TID1 and TID0	00	R/W*	Response Error Channel Identity Information TID1 indicates the channel 1 error information, and TID0 indicates the channel 0 error information. TID1 0: No error 1: Channel 1 response packet error TID0 0: No error 1: Channel 0 response packet error [Setting condition] When a CH0 (1) response error occurs [Clearing condition] Clearing ERR_RCV in VCR (Channel 0/channel 1 concurrent clear)
4	RM	0	R/W	Response Error Mask Mode 0: A response error is output. 1: A response error is masked.

Bit	Bit Name	Initial Value	R/W	Description
3, 2	PR1 to PR0	All 0	R/W	Priority Mode Specify the priority of channels to execute transactions when transfer requests are made simultaneously in both channel 0 and channel 1 as follows: 00: Channel 0 > Channel 1 01: Channel 1 > Channel 0 10: Setting prohibited (If PR = 10 is set, channel 0 > channel 1) 11: Round-robin mode
1	AE	0	R/W*	Address Error Flag Indicates that an address error interrupt occurred when setting SAR or DAR. This flag is set to 1 when the value of SAR or DAR differs from the transfer size (TS) boundary, and when the TS bits are set to 11 (setting prohibited). When the AE bit is set to 1, DMA transfer is not enabled even if the DE bit in DMACHCR and the DME bit in DMAOR are set to 1. 0: No address error interrupt is generated by the DMAC. [Clearing condition] Setting SAR and DAR to values that match the transfer size boundary. 1: An address error interrupt is generated.
0	DME	0	R/W	DMA Master Enable Enables or disables DMA transfers for all channels. When the DME bit and the DE bit in USBDMA_CHCR are set to 1, DMA transfer is enabled, provided that all interrupt flags in USBDMA_CHCR of the transfer channel are 0. Clearing the DME bit suspends the DMA transfer for all channels. 0: DMA transfer for all channels is disabled. 1: DMA transfer for all channels is enabled.

Note: * Only writing 0 to clear the flag is enabled.

62.3 Operation

62.3.1 Interrupt/Error Detection Function

This section describes the interrupt/error detection function that is implemented in this module.

Table 62.5 lists the mask, source, and flag registers for each interrupt type.

Table 62.5 Registers by Interrupts/Errors

	Interrupt Generation	Interrupt Mask Register	Interrupt Mask Register (Individual Mask)	Source Register	Flag Register
Transfer count end	O	CHCR_x.IE	—	DMICR.TEx	CHCR_x.TE
Short packet receive	O	CHCR_x.IE	CHCR_x.SPIM	DMICR.SPx	CHCR_x.SP
NULL packet receive	O	CHCR_x.IE	CHCR_x.NULLE	DMICR.NULLx	CHCR_x.NULL
Timeout	O	CHCR_x.IE	CHCR_x.TOE	DMICR.TOx	CHCR_x.TO
Transaction end detect	O	CHCR_x.IE	CHCR_x.TRE*	DMICR.TRx	CHCR_x.TR
Buffer end detect	O	CHCR_x.IE	CHCR_x.BUFE*	DMICR.BUFx	CHCR_x.BUF
Final buffer access detect	O	CHCR_x.IE	CHCR_x.RWE※	DMICR.RWx	CHCR_x.RW
Address error	O	CHCR_x.IE	—	DMICR.AE	DMAOR.AE
Response packet error	—	—	—	—	VCR.ERR_SNT VCR.ERR_RCV

Note: These registers not only mask interrupt generation but also disable error processing (flag sources and flag clearing).

Table 62.6 shows the processing to be executed when different interrupts occur. DMA transfer control is not affected when the NULL packet receive, timeout, or response packet error interrupt occurs. When the transfer count end interrupt occurs, processing is restarted. Processing can be resumed or restarted after interrupts occur from other sources.

Table 62.6 Processing to be Executed When Interrupts Occur (Suspend/Resume/Restart)

	Suspend/ Resume	Terminate/ Restart	Suspend/Resume/Restart Control Mask Register
Transfer count end	—	o	—
Short packet receive	O	O	—
NULL packet receive	—	O*	—
Timeout	—	O	—
Transaction end detect	O	O	CHCR_x.TRE
Buffer end detect	O	O	CHCR_x.BUFE
Final buffer access detect	O	O	CHCR_x.RWE
Address error	O	O	—
Response packet error	—	—	—

The internal circuit is reloaded register values when restarted, but not when resumed.

* When a NULL packet is received, processing is forced to be terminated and restarted by the FTE register (see section 62.3.2 (3)).

Table 62.7 lists the interrupt generating conditions.

Table 62.7 Interrupt Generating Conditions

Interrupt Name	Interrupt Conditions
Transfer count end interrupt	When the final data transfer of the specified transfer count (in the TCR register) completes IN transfer: When the final access to USB-IP completes OUT transfer: When the data transmission to the SHwy completes
Short packet receive interrupt	When the data transfer at the time the end of a transaction is detected completes
NULL packet receive interrupt	When a NULL packet is detected or the forced TE register is set
Timeout interrupt	When the specified time elapses after the last transfer request
Transaction end detect interrupt	When the end of a transaction is detected
Buffer end detect interrupt	When the end of the buffer is detected
Final buffer access detect interrupt	When the final access to the buffer is detected
Address error interrupt	When invalid access to the DMAC register is attempted (With invalid SAR/DAR values or invalid transfer size (TS) specified)
Response packet error	Error Transmission (err_snt) When accessed by a transaction that is not supported Error Reception (err_rcv) When received a response packet error from the system

Figure 62.2 shows a block diagram of the interrupt circuit.

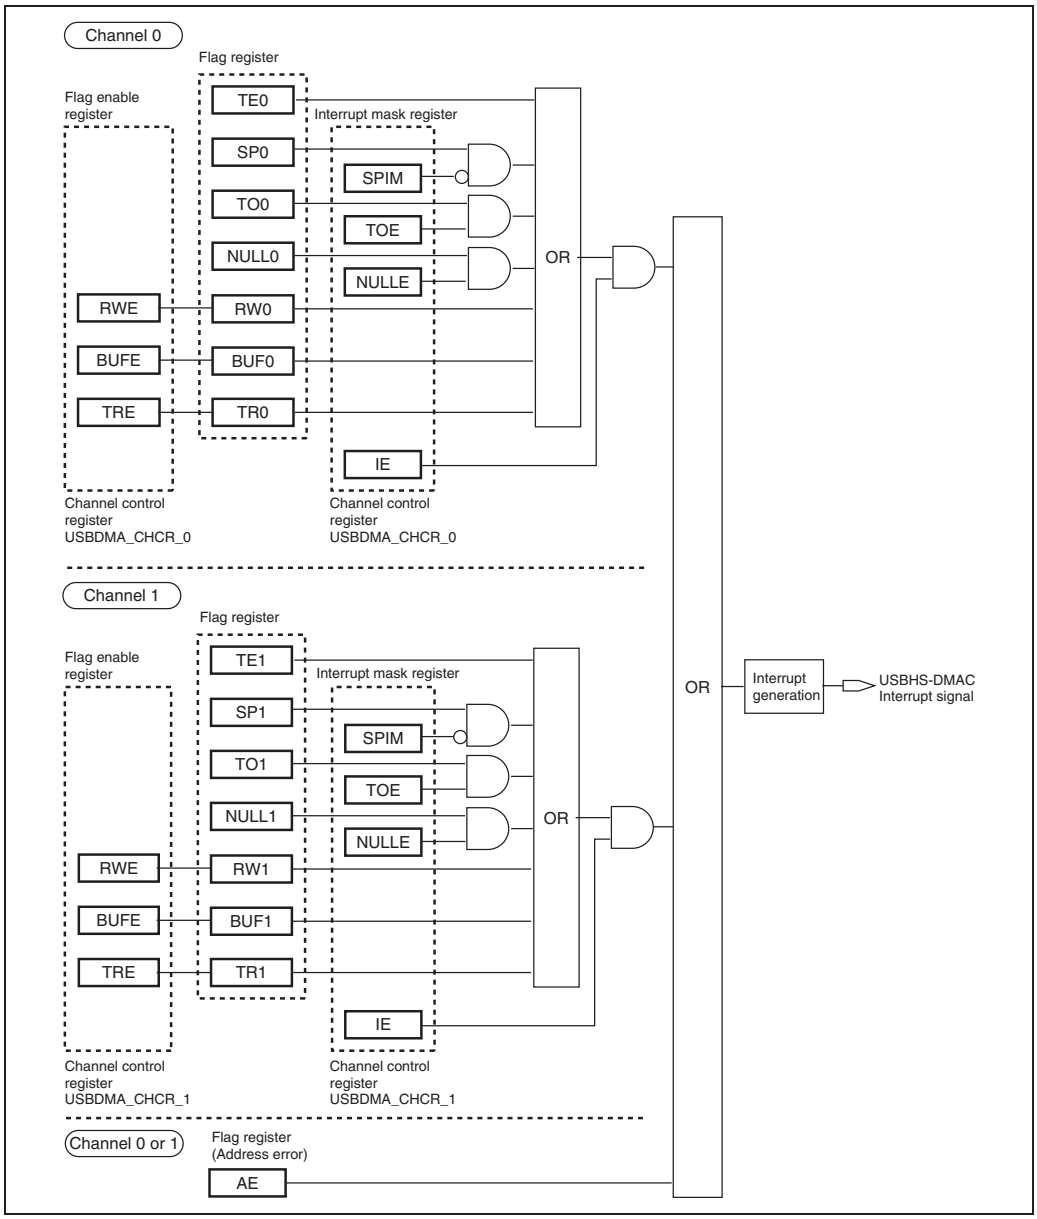

Figure 62.2 Block Diagram of Interrupt Circuit

(1) Transfer Count Ed Interrupt (TE Flag)

Can be generated when the specified number of transfers complete or the FTE bit in the channel control register (USBDMA_CHCR_0 to USBDMA_CHCR_1) is set to 1. When the IE bit in the USBDMA_CHCR_0 to USBDMA_CHCR_1 is set to 0, no interrupts are generated. However, the TE bit in USBDMA_CHCR_0 to USBDMA_CHCR_1 and the TE0 or TE1 bit in the interrupt source register (USBDMA_DMICR) are set to 1 regardless of the IE bit setting.

The internal transfer counter is loaded with the value set in the USBDMA_TCR_x register and decrements based on the SHwy clock every time one transaction (8-/16-/32-byte) completes. When the transfer count value reaches 0 (the end of a transfer count), the counter sets the TE (transfer end) flag from 0 to 1 (when the FTE bit is set, it is reflected on the TE flag immediately). The TE bit is cleared by writing 0 to it after reading it as 1 by software.

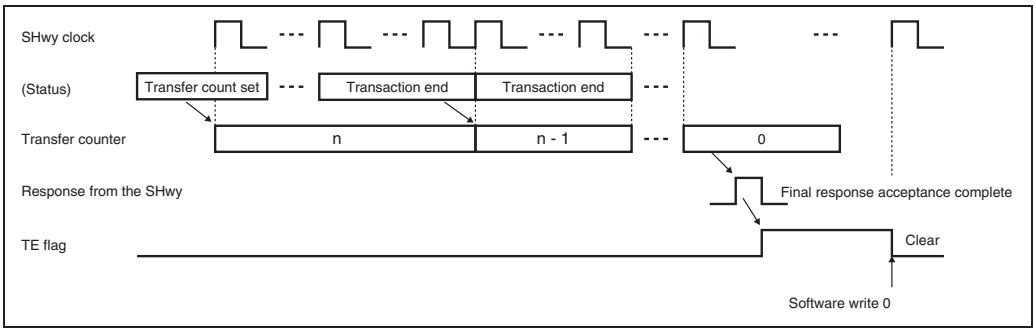

Figure 62.3 Transfer Count End Interrupt (TE) Generation Timing

(2) Short packet receive interrupt (SP flag)

Can be generated when a short packet is detected. When the SPIM bit in the USBDMA_CHCR_x register is set to 1, no interrupts are generated. However, the SP bit (SP flag) in the USBDMA_CHCR_x register and the SP0 or SP1 bit in the USBDMA_DMICR register are set to 1, regardless of the SPIM bit setting. The SP bit is cleared by writing 0 to it after reading it as 1 by software.

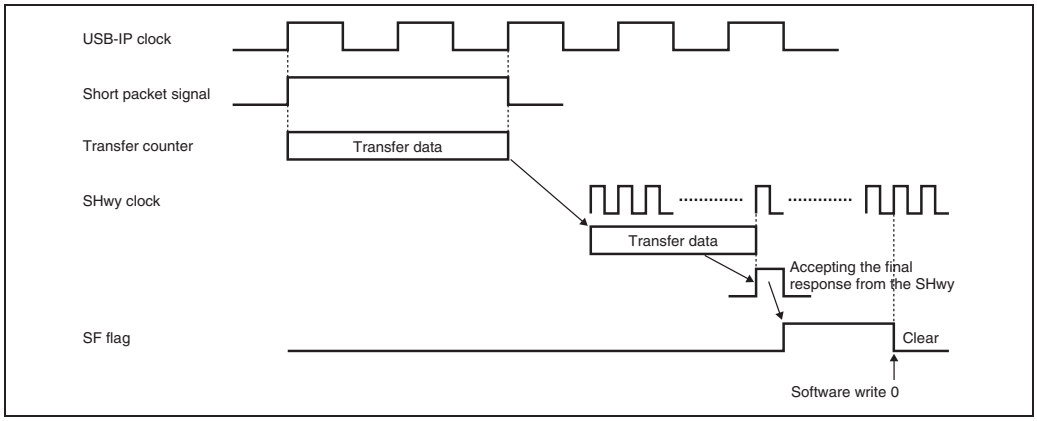

Figure 62.4 Short Packet Receive Interrupt (SP) Generation Timing

(3) NULL packet receive interrupt (NULL flag)

Can be generated when a NULL packet is detected. When the NULLE bit in the USBDMA_CHCR_x register is set to 0, no interrupts are generated. However, the NULL bit (NULL flag) in the USBDMA_CHCR_x register and the NULL0 or NULL1 bit in the USBDMA_DMICR register are set to 1, regardless of the NULLE bit setting. Note also that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a NULL packet is received. The software is responsible for implementing special processing if necessary since in this module this interrupt is designed only to signal the software that a NULL packet is received.

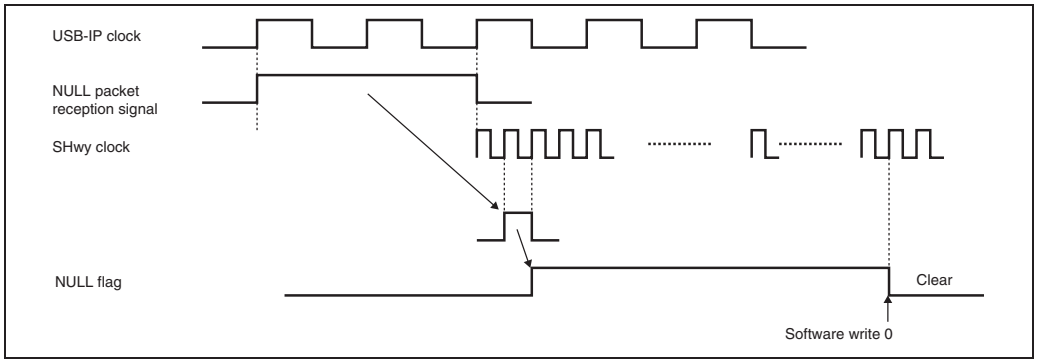

Figure 62.5 NULL Packet Receive Interrupt (NULL) Generation Timing

(4) Timeout interrupt (TO flag)

Can be generated when the time period that is specified in the timeout constant register (USBDMA_TOCSTR_0 or USBDMA_TOCSTR_1) elapses after the final transfer request is received from the USB-IP. On detecting the final transfer request, the internal counter is loaded with the value set in the USBDMA_TOCSTR_x register and starts counting down. When the counter reaches 0, it generates a timeout interrupt. Note that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a timeout interrupt occurs. The TO bit is cleared by writing 0 to it after reading it as 1 by software. Figure 62.6 and 62.7 show the timeout interrupt generation timing.

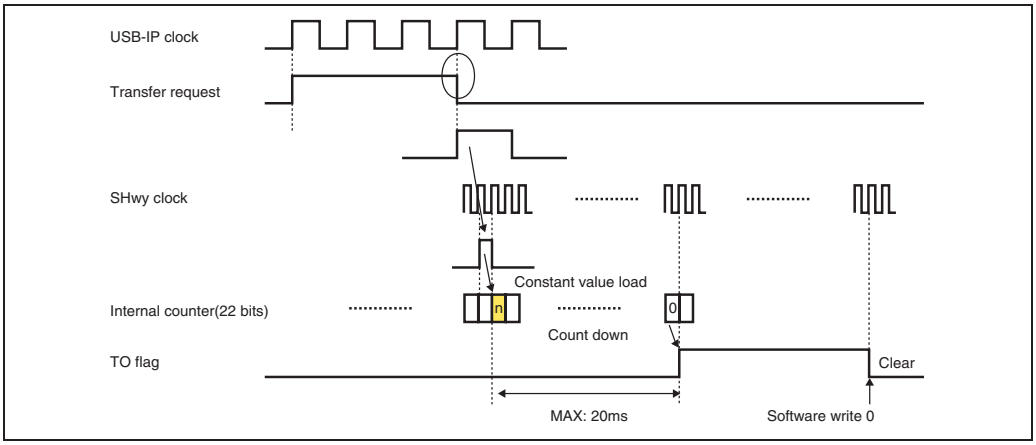

Figure 62.6 Timeout Interrupt (TO) Generation Timing

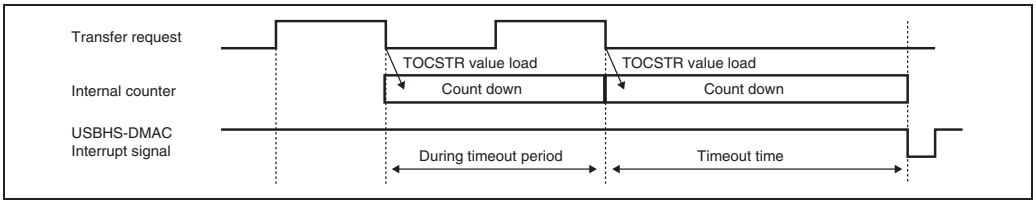

Figure 62.7 Timeout Interrupt Timing

The functions described in 62.3.1(5) to 62.3.1(9) are added to detect and notify the transitions on an individual signal line to the software, but no use is defined. They can be used as required.

(5) Transaction end detect interrupt (TR flag)

Can be generated when the end of a transaction is detected within the USB-IP. Note that the TR bit in the USBDMA_CHCR_x register and the TR0 or TR1 bit in the USBDMA_DMICR register are not reflected in the interrupt signal when the TRE bit in the USBDMA_CHCR_x register is set to 0.

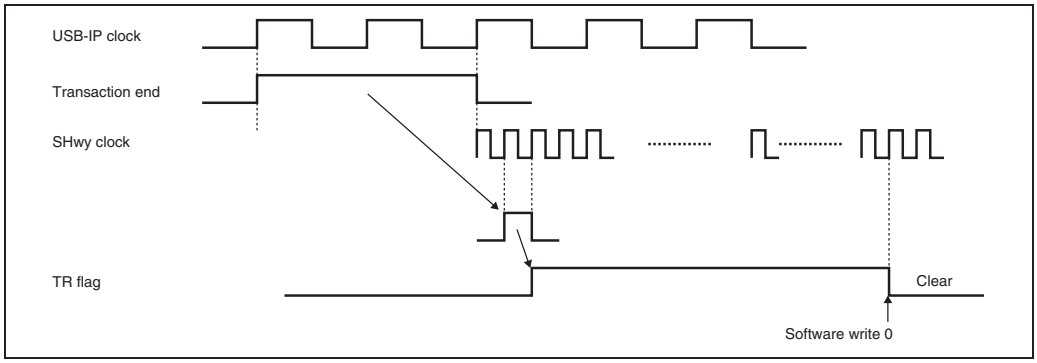

Figure 62.8 Transaction End Detect Interrupt Timing

(6) Buffer end detect interrupt (BUF flag)

Can be generated when the end of the buffer in the USB-IP is detected. Note that the BUF bit in the USBDMA_CHCR_x register and the BUF0 or BUF1 bit in the USBDMA_DMICR register are not reflected in the interrupt signal when the BUFE bit in the USBDMA_CHCR_x register is set to 0.

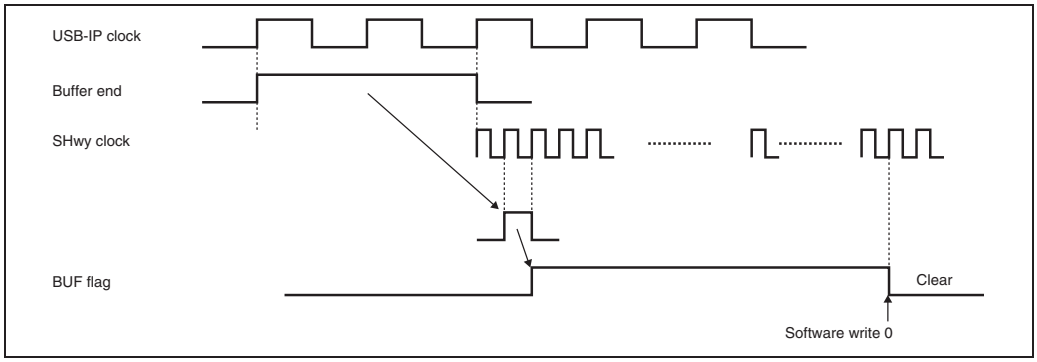

Figure 62.9 Buffer End Detect Interrupt Timing

(7) Final buffer access detect interrupt (RW flag)

Can be generated when the final access to the buffer in the USB-IP is detected. Note that the RW bit in the USBDMA_CHCR_x register and the RW0 or RW1 bit in the USBDMA_DMICR register are not reflected in the interrupt signal when the RWE bit in the USBDMA_CHCR_x register is set to 0.

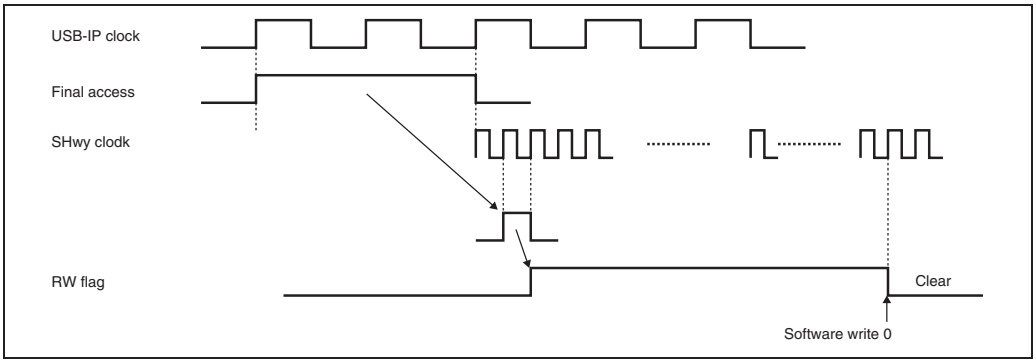

Figure 62.10 Final Buffer Access Detect Interrupt Timing

(8) Address error detection

This is a flag that indicates an address error interrupts has occurred when setting the source address register (USBDMA_SAR0 to USBDMA_SAR1) and the destination address register (USBDMA_DAR0 to USBDMA_DAR1). When the value written to the USBDMA_SAR or USBDMA_DAR register differs from the transfer size (TS) boundary, and when the TS bits are set to 11 (setting prohibited), the AE bit in the USBDMA_DMAOR register is set to 1. There is no distinction between CH0 and CH1 for an address error (the AE bit is set to 1 when an address error occurs on CH0 or CH1).

While the AE is set, no DMA transfer is allowed even if the DE bit in the USBDMA_CHCR_x register and the DME bit in the USBDMA_DMAOR register are set to 1. The address error interrupt is cleared by setting correct addresses in USBDMA_SAR_x and USBDMA_DAR_x.

Table 62.8 Address Error Detection Conditions When Setting Transfer Sizes

Transfer Size	Address Error Detection Conditions
TS=00 (8-byte transfer)	When data that is not aligned to 8-byte boundaries is written to the SAR/DAR registers (Writes to the SAR/DAR registers are valid.)
TS=01 (16-byte transfer)	When data that is not aligned to 16-byte boundaries is written to the SAR/DAR registers (Writes to the SAR/DAR registers are valid.)
TS=10 (32-byte transfer)	When data that is not aligned to 32-byte boundaries is written to the SAR/DAR registers (Writes to the SAR/DAR registers are valid.)
—	When b'11 (setting prohibited) is written to the TS register (Writes to the TS register are valid.)

(9) Response packet error detection

This function reports response packet errors when the interface between the SHwy and this module is accessed in ways that are not listed in table 62.2.

(a) Transmitting response packet errors

When a response packet error occurs during accessing from the SHwy to this module, the err_snt bit in the USBDMA_VCR register is set to 1.* The error signal is also sent to the SHwy bus if the RM bit in the USBDMA_DMAOR register is 0. If the RM bit is set to 1, the error signal is masked (0 is signaled).

Note: When a response packet error occurs, the err_snt bit is set to 1 regardless of the RM bit setting. The err_snt bit is cleared by writing 0 after reading 1.

Table 62.9 Response Packet Error Generation

USBDMA_DMAOR (RM bit) Setting	1 (Mask Mode)	0 (Normal Mode)
Response packet error signal notification to SHwy	Signals the fixed value (0) to the SHwy bus without determining if there is a response packet error.	Reports a response packet error to the SHwy bus when its is accessed with a transfer size other than those supported in this module (4-byte read/write and 8-byte read).

(b) Receiving response packet errors

When a response packet error occurs during accessing from this module to the SHwy, the err_rcv bit in the USBDMA_VCR register is set to 1. The TID bit in the USBDMA_DMAOR register indicates on which channel of this module the error has occurred (TID[1]=1 means it has occurred on CH1 and TID[0]=1 on CH0).

The err_rcv bit is cleared by writing 0 after reading 1.

62.3.2 DMA Transfer Function

(1) Operating mode

The following operating modes (1) to (3) are supported according to the setting of the PR bit in the DMA operation register (USBDMA_DMAOR).

(a) CH0 first control

Forces CH1 to wait to start a DMA transfer until a DMA transfer completes on CH0.

When there is a timing conflict in starting a DMA transfer between CH0 and CH1, CH0 takes precedence over CH1. If a DMA transfer is in progress on CH1 when CH0 tries to start a DMA transfer, CH0 waits to start it until the ongoing DMA transfer completes on CH1.

(b) CH1 first control

Forces CH0 to wait to start a DMA transfer until a DMA transfer completes on CH1.

When there is a timing conflict in starting a DMA transfer between CH1 and CH0, CH1 takes precedence over CH0. If a DMA transfer is in progress on CH0 when CH1 tries to start a DMA transfer, CH1 waits to start it until the ongoing DMA transfer completes on CH0.

(c) Round-robin control

Assigns the lowest priority to the last channel that has completed a transfer. In the initial state, CH0 takes precedence over CH1.

When there is a timing conflict in starting a DMA transfer between CH0 and CH1, the channel with a higher priority is granted to start the transfer and the lower priority channel is forced to wait. If a DMA transfer is in progress on the lower priority channel when the higher priority channel tries to start a DMA transfer, the higher priority channel waits to start it until the ongoing DMA transfer completes on the lower priority channel.

Figure 62.11 shows an overview of the processing of the SHwy bridge in each operating mode.

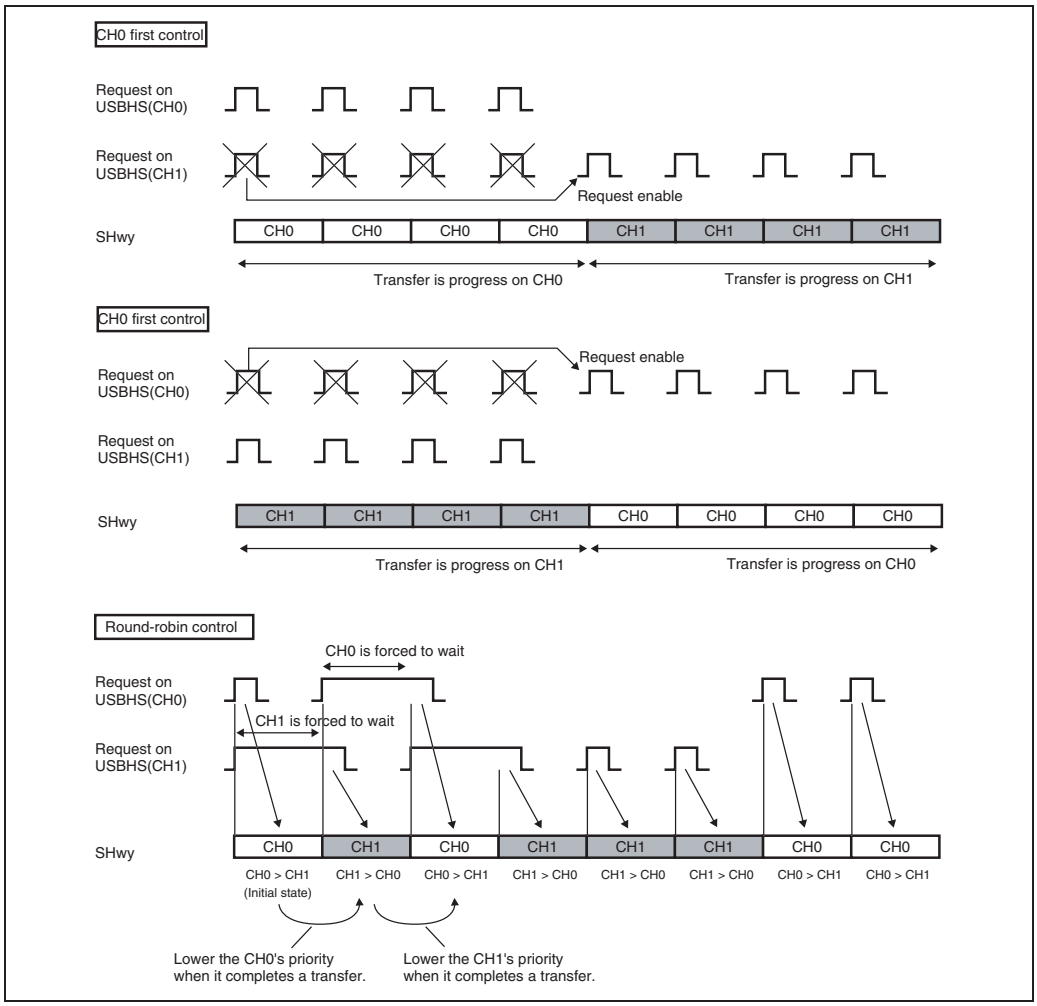

Figure 62.11 Overview of SHwy Bridge Processing in Each Mode

(2) Transfer size

The transfer size on the SHwy can be selected by setting the channel control register (the TS bit).

8-, 16-, and 32-byte can be set for each channel independently.

The following consideration should be observed during IN transfers.

The minimum transfer size that can be set to the TS bit is 8 bytes while the USB-IP can control transfers in 1-byte units. For example, if valid transfer data that is "8 x (n-1) + α" (α is less than 7 bytes) in size is to be transferred to the USB-IP with the transfer size set to 8 bytes and the transfer count set to n, α is transferred as a valid transfer unit by controlling byte enables according to the DMA final transaction valid data transfer enable register (the EDTEN bits) setting. Likewise, data is transferred in "transfer size x transfer count" (the final transaction is controlled by EDTEN) for 16- and 32-byte transfer sizes. The EDTEN setting is valid only for IN transfer and is don't care for OUT transfer.

Figure 62.12 shows an example of EDTEN setting. When only EDTEN31 in EDTEN31 to EDTEN0 is 1 , one byte is enabled. When only EDTEN31 and EDTEN30 in EDTEN31 to EDTEN0 are 1 , two bytes are enabled. Therefore, the total transfer volumes in the example shown above are calculated as "(32 bytesx(n-1)) bytes+10 bytes" for 32-byte transfer, "(16 bytesx(n-1)) bytes+7 bytes" for 16-byte transfer, and "(8 bytesx(n-1)) bytes+2 bytes" for 8-byte transfer. EDTEN15 to EDTEN0 in 16-byte transfer, EDTEN23 to EDTEN0 in 8-byte transfer are invalid (their values are ignored).

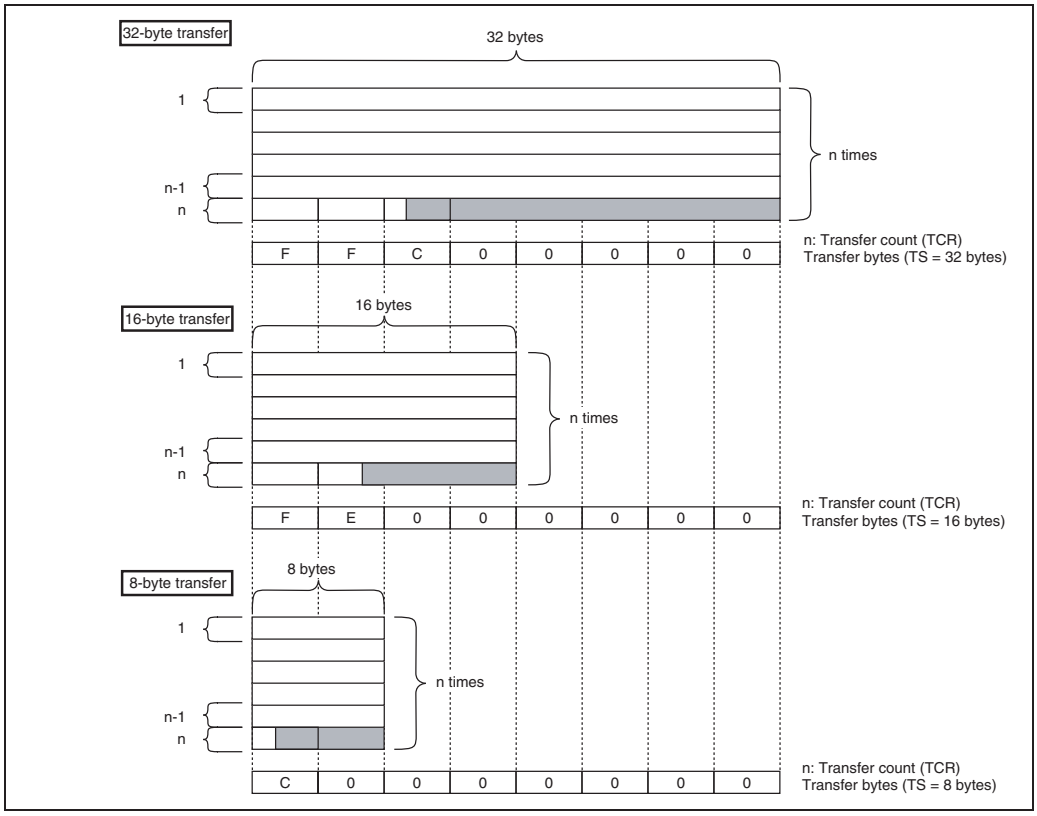

Figure 62.12 Example of Final Transaction Valid Data Transfer Enable (EDTEN) Setting

(3) DMA transfer flow

After the DMA source address register (USBDMA_SAR), DMA destination address register (USBDMA_DAR), DMA transfer count register (USBDMA_TCR), DMA channel control register (USBDMA_CHCR), final valid data transfer enable register (USBDMA_TEND), and DMA operation register (USBDMA_DMAOR) are set appropriately, the DMAC starts data transfer in the following sequence. The DMA timeout constant register (USBDMA_TOCSTR) may also need to be set.

If the transfer enabling conditions are set as DE=1, DME=1, TE=0, AE=0, SP=0, and (TR=0, BUF=0, RW=0), transfers are performed according to the transfer request enables and transfer requests from the USB-IP. The transfer direction (IN/OUT transfer) is determined by the direction signal from the USB-IP. The transfer size is determined by the setting of TS1 to TS0.

Every time one SHwy transaction (in the transfer size specified in the TS bit) completes, the internal counter of this module decrements the USBDMA_TCR value by one. When the specified transfer count ends (the USBDMA_TCR value reaches 0), it means all transfers complete. At this time, an USBHS1-DMAC interrupt is generated if the IE bit in the USBDMA_CHCR register is set to 1.

When a NULL packet is received, transfer can be stopped or restarted by setting FTE=1 after negating the DREQE register of the USBHS1 module. Follow the steps described later in "Control when a NULL packet is received".

Table 62.10 shows the conditions for each DMA transfer.

Table 62.10 DMA Transfer Conditions

Transfer enabling condition	TE=0, SP=0, (*TR=0, BUF=0, RW=0)
Transfer (starting) condition	When a transfer request is enabled by the USB-IP When a transfer request is issued by the USB-IP
Transfer completing (then restarting) condition	When the transfer count ends (the TE flag is set to 1), (can be restarted by setting DE and DME to 1.) When FTE=1 (when DREQE=1 in the USBHS1 module is also set), and the steps described later should be followed. When reset (can enter into standby state by releasing the reset.)
Transfer suspending (then resuming) condition	When DE=0 or DME=0 (can be resumed by setting DE=1 or DME=1.) When SP=1 (can be resumed by clearing the SP flag.) When RW=1, BUF=1, and TR=1 (can be resumed by clearing the RW, BUF, and TR flag.)* When the module stops (can be resumed by resuming the module.)

Note: * Can be ignored when the RWE, BUFE, and TRE registers are disabled (set to 0).

Figure 62.13 illustrates the high-level DMA transfer flow.

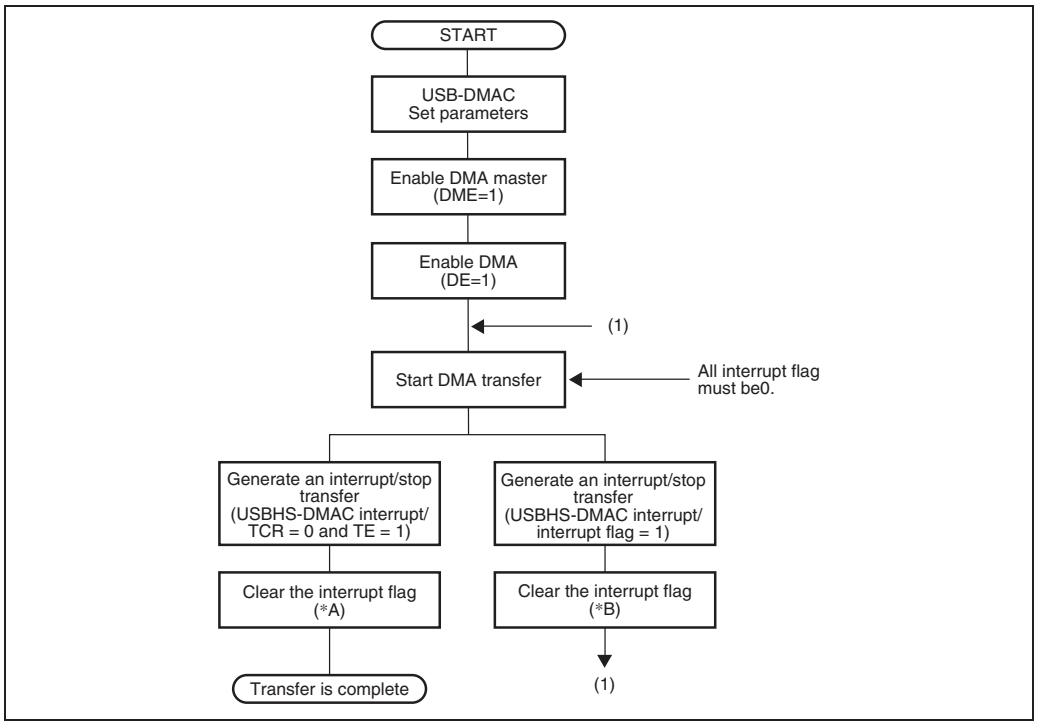

Figure 62.13 DMA Transfer Flow Overview

Where A and B apply to the following flags:

(Note that RW, BUF, and TR are not set when RWE, BUFE, and TRE are disabled, respectively.)

* A: TE flag

* B: SP,(RW,BUF,TR) flags

When to change USB-DMAC parameters

USB-DMAC parameters (such as destination address or transfer count) should be changed while all interrupt flags are cleared and DE=0 and DME=0 are set (a transfer is started with the latest parameters when DME=1 and DE=1 are set). Furthermore, USB-DMAC parameters should not be changed while the DMA is enabled (DME=1 and DE=1).

What to do if freeze

If a transfer should freeze during operation, issue a software reset after setting DE=0 and DME=0 and clearing all interrupt flags. All hardware except configuration registers is initialized. Restart by setting DME and DE to 1 after updating USB-DMAC parameters if necessary.

Control when a timeout occurs

Since this module assumes bus access in the transfer units listed in table 62.2, it cannot be restarted when a timeout occurs in an irregular case where it is being accessed with any size that are not in the table. This irregular case should be handled by software, such as by issuing a software reset (to both CH0 and CH1).

Control when a NULL packet is received

When a NULL packet is received during a DMA transfer, the DMA transfer can be suspended and resumed on each channel independently by controlling the FTE bit of this module and the DREQE bit of the USBHS1 module in the following sequence.

[Control sequence]

During a DMA transfer (A)

(1) A NULL packet is received (an interrupt is generated and the NULL flag is detected).

(2) The DREQE bit of the USBHS1 module is negated (=0).

(3) Wait for the internal bus to be stabilized.

(4) Perform three actions at the same time; setting the FTE bit, clearing the NULL bit and negating the DE bit.

An interrupt is generated due to TE.

(5) Clear the interrupt caused by TE.

(6) Set the parameters (such as TCR or DAR) for the next transfer.

(7) Assert the DE bit (=1). The DMA is restarted.

(8) Assert the DREQE bit (=1).

Start a DMA transfer (B).

[Restrictions]

1) FTE bit set timing

   If this module is accessing the SHwy (SHBSYx bit=1) when setting the FTE bit, you need to wait to set the FTE register until this module's internal buffer is empty and the SHwy bus access is complete (SHBSYx bit=0). Note that if you accidentally set the FTE register while an SHwy bus access is in progress, the transfer fails and transfer data may be lost or the transfer may be unable to be restarted.

2) DREQE register assert (negate clear) timing

   It is necessary to allow at least 20clk@ZSϕ after the DE bit is asserted and before the DREQE is asserted. This is because DREQE needs to be asserted after transfers enabled by the DE bit are ready internally to be started. Asserting DREQE immediately after DE may cause malfunction such as initiating unnecessary bus access.

3) Fractional byte and NULL packet reception

   This module assumes bus access in the transfer units listed in table 62.2 and goes out of control when it receives a NULL packet in an unsupported transfer unit. Therefore, data transfer in any transfer unit that is not in the table is prohibited.

4) IN/OUT switching after NULL packet reception

   After a NULL is received, transfers cannot be restarted with the transfer direction switched from OUT to IN. This is because this module still considers the terminated transfer as an OUT transfer until the transfer count reaches its end. Note that if you switch the transfer direction to IN transfer accidentally after a NULL packet is received, a conflict occurs between an IN and an OUT transfers, which may cause illegal bus access.

   Use CH0 and CH1 with their transfer direction fixed, or if the transfer direction needs to be switched on the same channel, make sure to do it every time a transfer completes successfully due to the end of transfer count or is terminated by software reset.

Figure 62.14 shows the state transitions for DMA transfers.

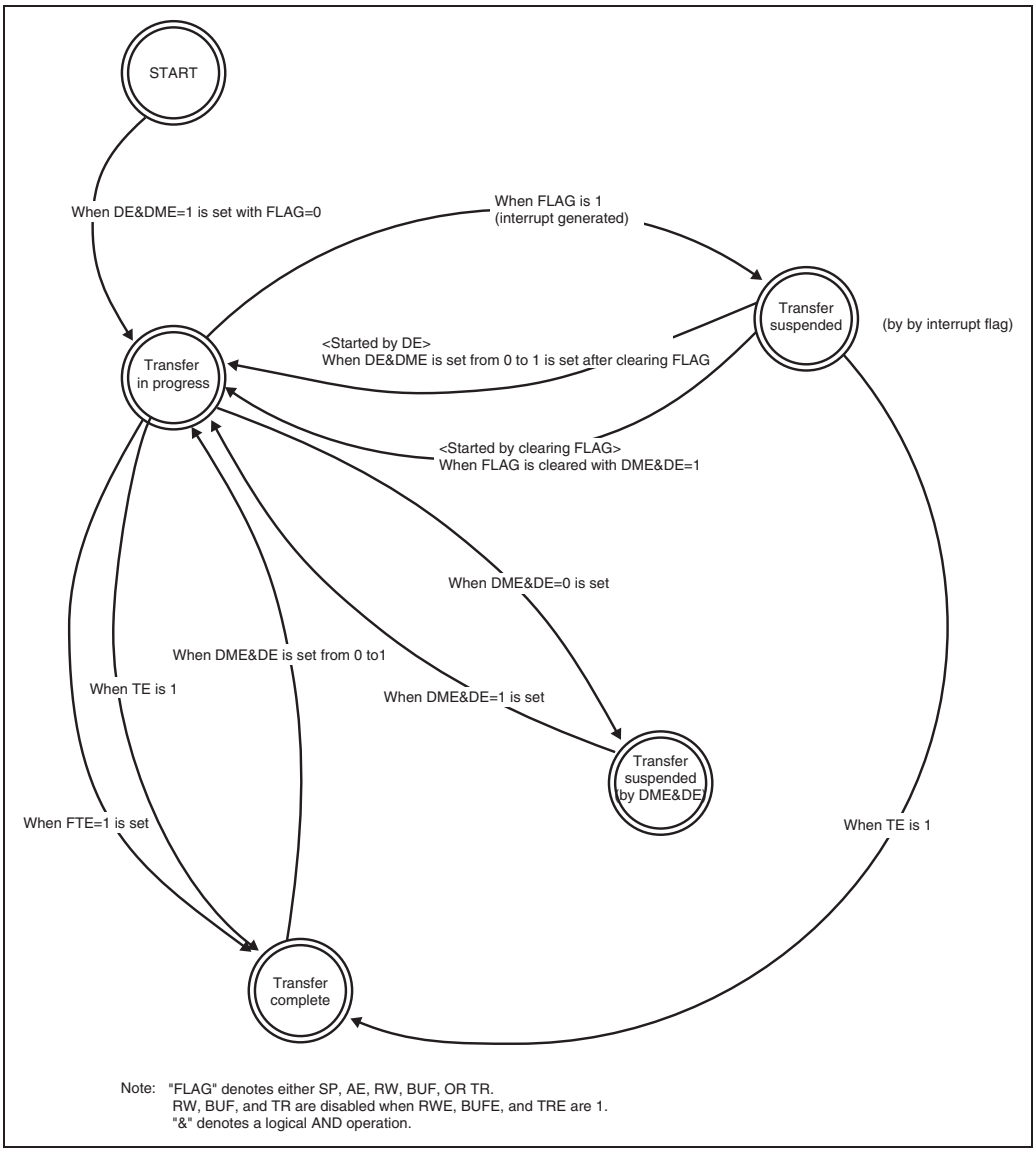

Figure 62.14 State Transitions for DMA Transfer

(4) Control Sequence

Figure 62.15 shows an outline of the control sequence of this module.

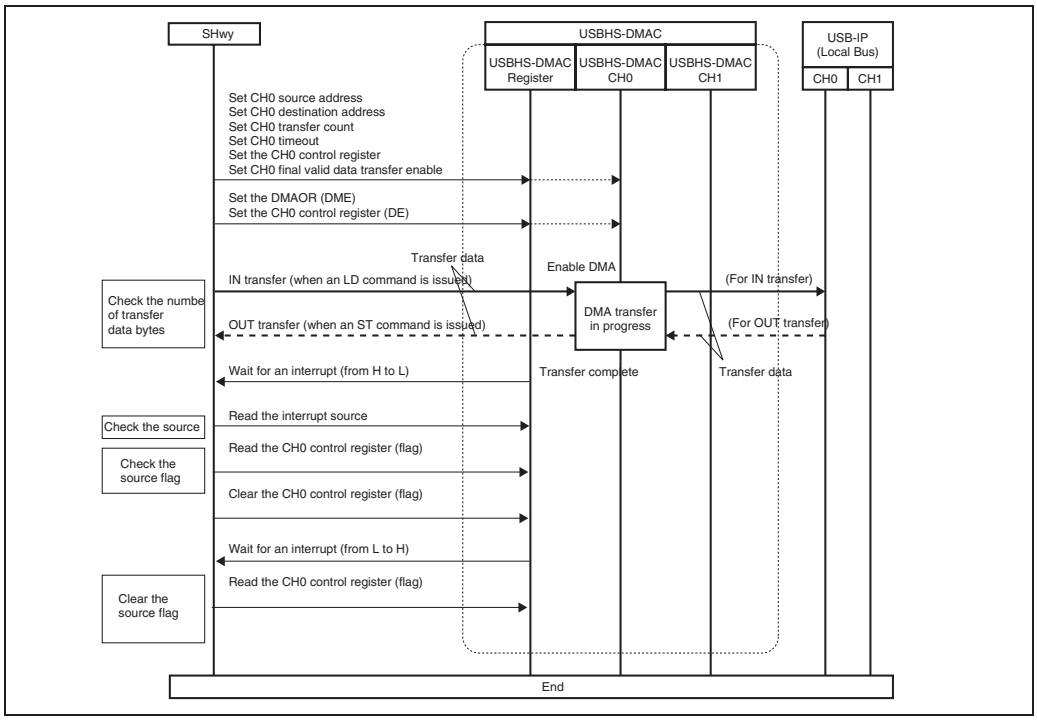

Figure 62.15 Control Sequence Overview

(5) Internal Buffer Configuration

This module has 64 bytes (64 bitsx8 words) of internal buffer for each of two channels. Thus, the total capacity of this module's internal buffers is 128 bytes (1024 bits).

The internal buffers are composed of two planes each of which is organized as 64 bits x 4 words and are readable /writable on per-plane basis from the USB-IP local bus or SHwy bus (plane 1 is writable when plane 0 is readable or vice versa). For 16-byte transfers, only 2 words in plane 0 and 2 words in plane 1 are used. For 8-byte transfers, only 1 word in plane 0 and 1 word in plane 1 are used.

Note that these internal buffers cannot be accessed directly by software.

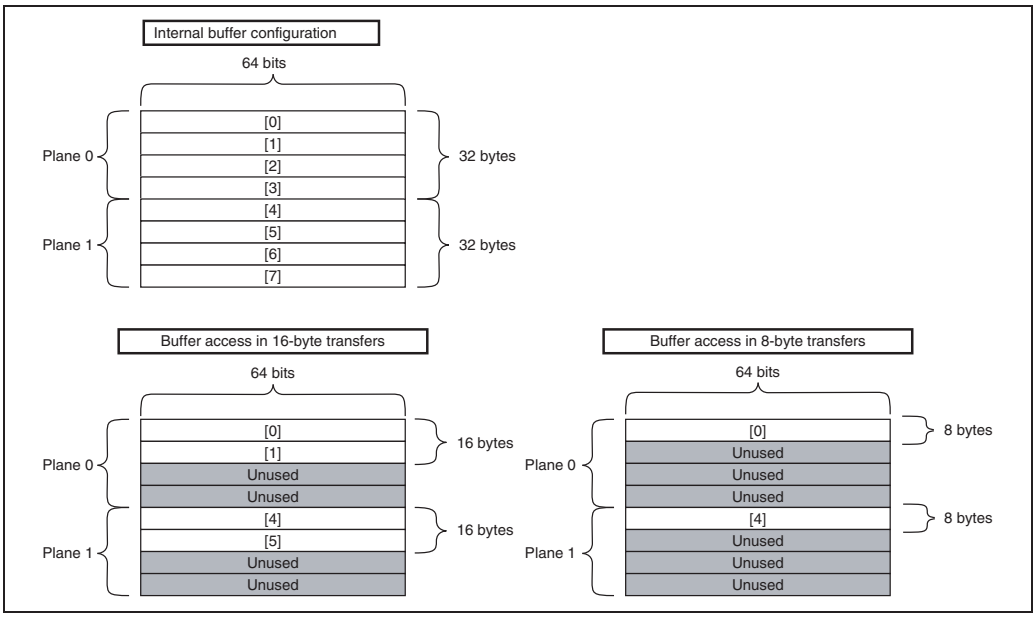

Figure 62.16 Internal Buffer Configuration and Used Area for Each Transfer Size

(6) Internal Buffer Control (Hardware Control, For reference)

(a) IN transfer (from SHwy to USB)

Retrieves transfer data from a source on the SHwy bus and writes it to this module's internal buffer. Reads the written data from the internal buffer and writes it to the USB-IP.

Figure 62.17 shows how the planes of this module's internal buffers are controlled during an IN transfer. In this figure, "read' and 'write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words* and 1 word* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 and a transfer the read data to the USB-IP are complete, the readable plane flag is toggled (every time 2 words* and 1 word* are read for 16-byte and 8-byte transfers, respectively). Access to the SHwy is prohibited during the period when both the writable plane flag and readable plane flag are set on the same plane as a read/write access conflict may occur.

* 1 word=64 bits

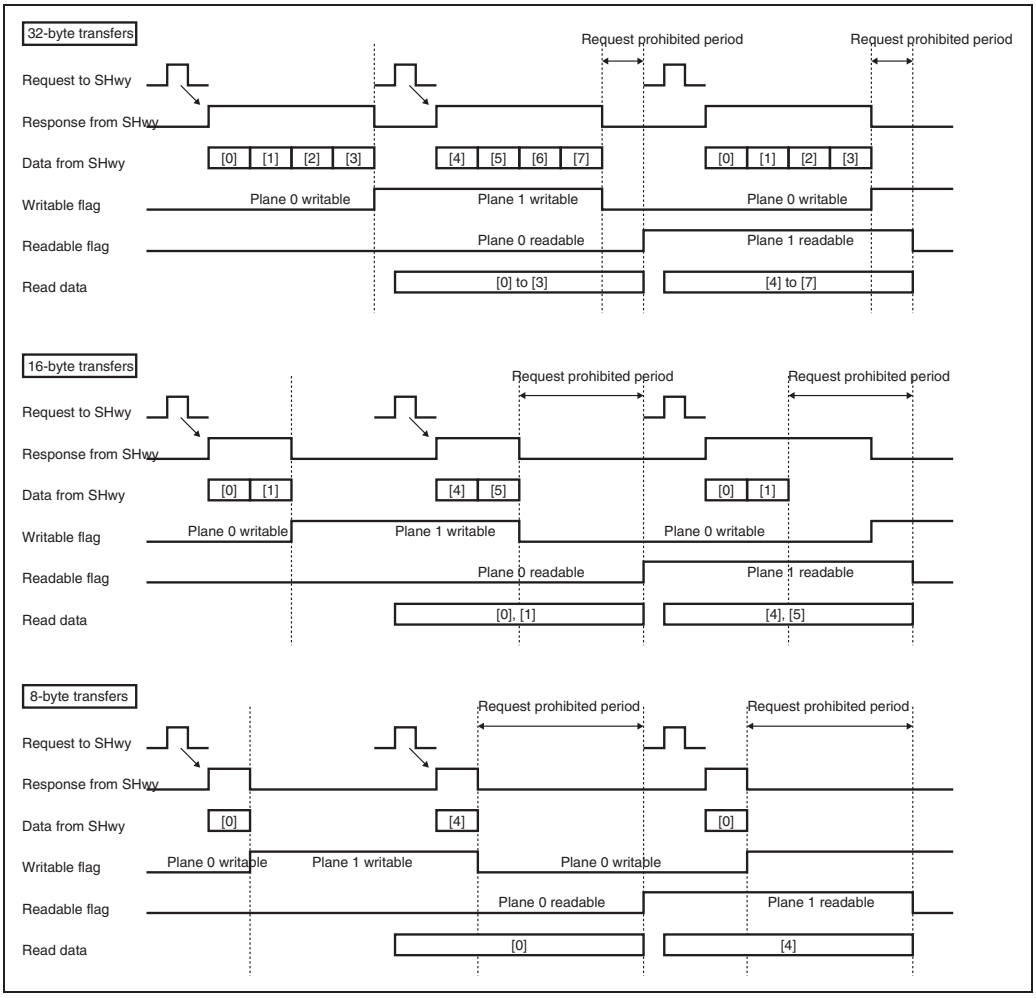

Figure 62.17 Read/Write Control for Internal Buffer: From SHwy to USB (IN Transfer)

(b) OUT transfer (from USB to SHwy)

Writes data read from the USB-IP to the internal buffers. Reads the written data from this module's internal buffers and writes it to the destination on the SHwy bus (OUT transfer).

Figure 62.18 shows how the planes of this module's internal buffers are controlled during an OUT transfer. In this figure, "read' and 'write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words* and 1 word* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 is complete, the readable plane flag is toggled (every time 2 words* and 1 word* are read for 16-byte and 8-byte transfers, respectively). Access to the SHwy is prohibited during the period when both the writable plane flag and readable plane flag are set the same plane as a read/write access conflict may occur.

* 1 word=64 bits

Appendix A Package Dimensions

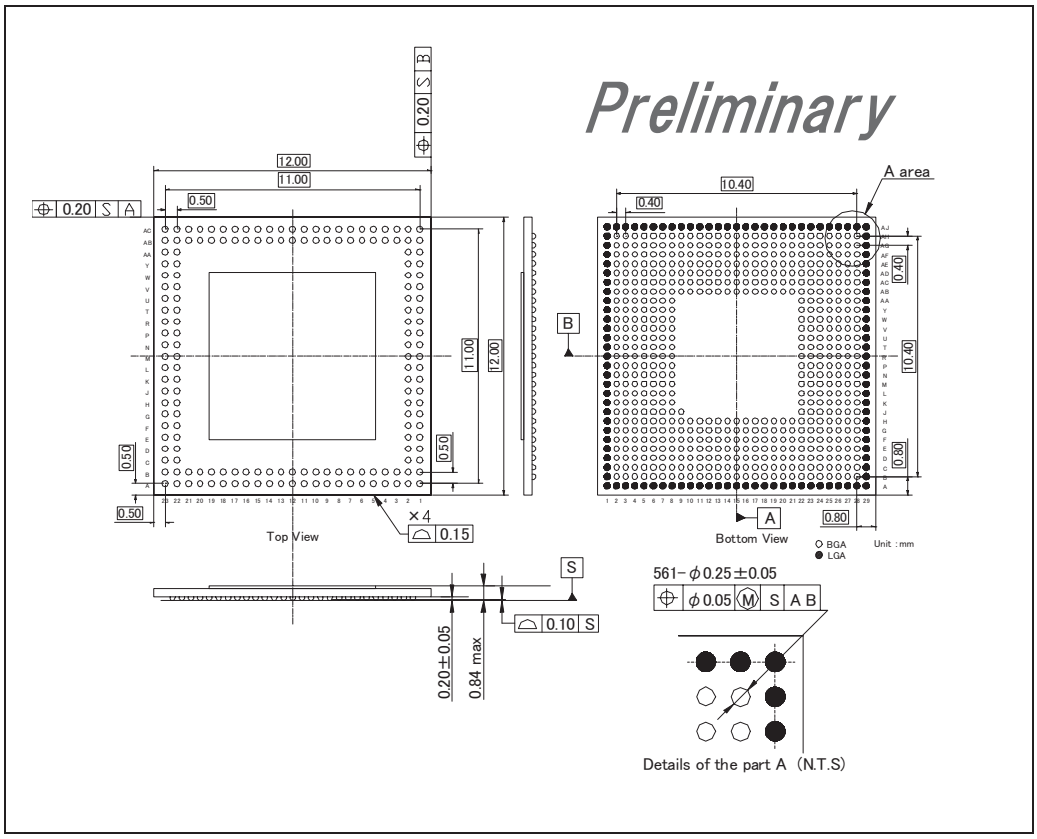

Figure A.1 Package Dimensions (Preliminary)

Appendix B MMFROM Program Functional Specifications

B.1 Overview

This section defines the functional specifications for an MMFROM program (hereafter referred to as mask ROM) loaded to the SH-Mobile AP4 (hereafter referred to as AP4).

The program will be executed when the AP4 is activated. After the initial settings have been made in the LSI, a program in the external device is executed or a program is downloaded from the USB or ACMFI.

B.1.1 Operating Modes

The AP4 has the following boot modes which can be selected by the MD pins as shown in table B.1.

- BSC boot mode (expansion boot options are included)
- BSC development boot mode (expansion boot options are included)
- NAND(4) boot mode
- NAND(4) development boot mode
- NAND(5) boot mode
- NAND(5) development boot mode
- eSD boot mode
- eSD development boot mode
- eMMC boot mode 1A (MFI pins, user area)
- eMMC boot mode 1B (BSC pins, user area)
- eMMC boot mode 2A (MFI pins, boot partition)
- eMMC boot mode 2B (BSC pins, boot partition)
- eMMC development boot mode 1A (MFI pins, user area)
- eMMC development boot mode 1B (BSC pins, user area)
- eMMC development boot mode 2A (MFI pins, boot partition)
- eMMC development boot mode 2B (BSC pins, boot partition)
- Forcible USB boot mode
- MFI1 boot mode (ADDEMUX)
- MFI1 development boot mode (ADDEMUX)

- MFI2 boot mode (ADMUX)
- MFI2 development boot mode (ADMUX)

The above modes which are initiated from mask ROM are described in this section.

The mode can be determined by referencing the MD7, MD6, MD4, MD3, and MD2 bits in RESCNT (SYSC register).

Table B.1 MD Pin Settings

TST	MD4	MD3	MD2	MD6	MD7	Mode Name	Secure Function	Remarks
1	0	0	0	1	0	MFI2 development boot (ADMUX)	No	
1	0	0	0	1	1	MFI1 development boot (ADDEMUX)	No	
1	0	0	1	0	0	MFI2 boot (ADMUX)	Yes	
1	0	0	1	0	1	MFI1 boot (ADDEMUX)	Yes

1	1	1	0	0	1	eSD development boot	No	
1	1	1	0	1	0	Reserved	No	
1	1	1	0	1	1	Reserved	No	
1	1	1	1	0	0	BSC boot	Yes	
1	1	1	1	0	1	eSD boot	Yes	
1	1	1	1	1	0	Forcible USB boot	Yes	
1	1	1	1	1	1	Reserved	Yes	

Note: eMMC boot modes

1A: Uses the MFI pins and boots from the user area.

1B: Uses the BSC pins and boots from the user area.

2A: Uses the MFI pins and boots from the boot partition.

2B: Uses the BSC pins and boots from the boot partition.

B.2 Notes on Hardware Configuration

B.2.1 RAM

The mask ROM uses MERAM as a work area and stack.

The SDRAM related registers (SBSC) are not set.

B.2.2 Connected Device

- For BSC boot mode and BSC development boot mode

  A device that can be accessed with a 16-bit bus and the AP4 initial settings needs to be connected to CS0 (asynchronous bus).

  When performing clock up, the BSC must operate with the AP4 initial settings and the BSC module clock must be 100 MHz.

  When the copy boot option is specified, a program is read out from the lower address in the address order as 16-bit data, and then copied to MERAM.
- For NAND(4) boot mode, NAND(5) boot mode, NAND(4) development boot mode, and NAND(5) development boot mode

  A device with the NAND interface must be connected to the FLCTL and the following conditions (a) to (f) must be met. (For the FLCTL settings, refer to appendix B.7, Settings.)

  (a) The size of one page must be 1 Kbyte + 32 words (16 bits).

  (b) The following command codes must be used.
  - Read command: Cycle 1: 00h, cycle 2: 30h

    The address data issued at the address stage must be 4 bytes or 5 bytes.

    For NAND(4) boot mode and NAND(4) development boot mode: 4 bytes

    For NAND(5) boot mode and NAND(5) development boot mode: 5 bytes
  - Reset command: FFh
  - Status command: 70h

    (In the status data, bit 6 indicates the status as 1: Ready, 0: Busy)

  (c) Connection must conform to the FLCTL pin configuration.
  - The Ready/Busy pin is connected to the FRB pin.
  - The Chipenable pin is connected to the FCE1 pin (multiplexed CS5B/FCE1 pin).

  (d) The device must be able to use 4-symbol ECC for the requested ECC correction. (ECC of four symbols is used.)

(e) Operation must be at 13 MHz with 8-cycle pitch. In addition, operation must be performed with the following clocks when clock up is set.
- 400 MHz is specified: 100 MHz, 16-cycle pitch
- 800 MHz is specified: 100 MHz, 8-cycle pitch

(f) The device can be booted when the first command sent to NAND is a reset command and the next command is a read command with address 0 specified.

- For eSD boot mode and eSD development boot mode

  Only one eSD device that can be connected to the SDHI1 should be connected. Also, the eSD device needs to meet the following conditions (a) to (d).

  (a) The device must satisfy the eSD (Embedded SD) Specification Version 2.10.

  (b) VDDH and VDDF of the device must be between 2.7 V and 3.6 V.

  (c) Physical partition ID #1 must be already created or can be created in the device.

  (d) The device must support the FAST BOOT mode.

- For eMMC boot mode 1A, eMMC boot mode 1B, eMMC development boot mode 1A, and eMMC development boot mode 1B

  Only one eMMC device that can be connected to the MMCIF should be connected. Since the port pins are multiplexed, either the MFI pins or BSC pins are selected depending on the mode.

  Also, the eMMC device needs to meet the following conditions (a) to (d).

  (a) The eMMC device must satisfy the MMCA 4.2 (JESD84-A42) standard.

  (b) The physical format specifications must be satisfied (see appendix B.6.4).

  (c) The power-on time must be within 25 ms.

  (d) Access to the eMMC device in 8 bits or 4 bits must be possible.

- For eMMC boot mode 2A, eMMC boot mode 2B, eMMC development boot mode 2A, and eMMC development boot mode 2B

  Only one eMMC device that can be connected to the MMCIF should be connected. Since the port pins are multiplexed, either the MFI pins or BSC pins are selected depending on the mode. Boot operation mode is used in these modes.

  Also, the eMMC device needs to meet the following conditions (a) to (g).

  (a) The eMMC device must satisfy the MMCA 4.3 (JESD84-A43) or MMCA 4.4 (JESD84-A44) standard.

  (b) The power-on time must be within 25 ms.

  (c) BOOT_PARTITION_ENABLE in PARTITION_CONFIG of EXT_CSD must be set to H'1 or H'2.

  (d) BOOT_ACK in PARTITION_CONFIG of EXT_CSD must be set to H'1.

  (e) BOOT_BUS_WIDTH of EXT_CSD must be set to H'2 (8-bit bus).

(f) A program that satisfies the physical format specifications (see appendix B.6.5) must be written in the boot partition.

(g) The eMMC device must be in the pre-boot state when eMMC boot mode operation starts. (Connecting NBRSTOUT to RST_n is recommended in an MMCA 4.4 device. For an MMCA 4.3 device, circuitry that allows the card power source to be turned on and off in synchronization with the reset signal is recommended.)

B.2.3 WDT Kick Processing

Mask ROM can be operated with the hardware initial values without setting channel 0 in the RWDT.

The counter of channel 0 in the RWDT needs to be cleared at regular intervals within the module that takes over processing from mask ROM.

In this section, the above process of regularly clearing the channel 0 counter in the RWDT is referred to as the WDT kick processing.

Mask ROM performs the WDT kick processing.

For details on how to set and clear the WDT, refer to section 12, RCLK Watchdog Timer (RWDT).

B.3 Functional Description

Mask ROM has the following functions.

- Function to perform mode transition by setting standby control registers and reference the mode transition result (boot control interface function)
- Function to reference the VRL4 (Verification Record List version 4) and execute a program in the device connected to CS0 of the BSC (BSC boot function)
- Function to reference the VRL4 and execute a program in the device connected to the FLCTL (NAND boot function)
- Function to download a program from the USB (USB download function)
- Function to transfer a program from the MFI and execute it (MFI boot function)
- Function to execute the secure check (secure boot function)
- Function to reference the VRL4 and execute a program in the device connected to the SDHI1 (eSD boot function)
- Function to reference the VRL4 and execute a program in the device connected to the MMCIF (eMMC boot function)

Table B.2 Boot Modes and Functions

Boot Mode	Boot Function	Boot Control Interface Function	USB Download Function	Secure Boot Function	Remarks
BSC boot mode	BSC boot function	O	O	O	
BSC development boot mode		O	O		
NAND boot mode	NAND boot function	O	O	O	
NAND development boot mode		O	O		
eSD boot mode	eSD boot function	O	O	O	
eSD development boot mode		O	O		
eMMC boot mode	eMMC boot function	O	O	O	
eMMC development boot mode		O	O		
MFI boot mode	MFI boot function			O	
MFI development boot mode					
Forcible USB boot mode	USB download only		O	O	

B.3.1 Boot Control Interface Function

The boot control interface function enables switching between the USB download function and boot functions of each boot mode by setting standby flag registers B2 and B3 (STBCHRB2 and STBCHRB3).

STBCHRB2 and STBCHRB3 are initialized only by a power-on reset using the $\overline{\text{RESETP}}$ pin. Making use of this characteristic, a mode transition in mask ROM is achieved by setting these registers to generate a power-on reset through software. Several bits which are provided for controlling mask ROM operation can be used to make a transition to the USB download function from a program other than mask ROM.

Table B.3 STBCHRB2 Settings

Bit	Name	Description	Remarks
7 to 5	Reserved		Rewriting is prohibited.
4	Reboot count over flag	Executes USB download depending on the reboot count. 0: Transition to USB download due to reboot count does not occur 1: Reboot count is equal to or higher than the predefined value	Rewriting is prohibited.
3	Secure error flag	Executes USB download when a secure check error occurs. 0: Secure check not performed 1: Secure check error	Rewriting is prohibited.
2	Mode pin specification flag	Mode pins are used to specify forcible USB boot. 0: Mode pins not checked 1: Forcible download by mode pin specification	Rewriting is prohibited.
1	Invalid VRL4 format flag	Executes USB download when the VRL4 format of the boot device is invalid. 0: Signature not checked 1: USB download due to invalid signature	Rewriting is prohibited.
0	Processing status flag	Executes USB download when there was an unpredictable error during mask ROM processing. 0: Processing has finished 1: During processing	Rewriting is prohibited.

Table B.4 STBCHRB3 Settings

Bit	Name	Description	Remarks
7 to 4	Reboot counter	Predefined reboot count The number of times reboot is performed is counted. A transition to USB download is made when the reboot count has reached the boot option setting at reboot.	Clearing by the user is possible. The counter must be cleared when the reboot check option has been specified. Only BSC boot is valid.
3 to 1	Reserved		
0	User specification	0: No specification 1: Specifies to transit to USB download	Rewriting by the user is possible. The secure check after transiting to USB download will be performed depending on the boot mode.

B.3.2 BSC Boot Function

The BSC boot function is used to initiate a program written to an external device in BSC boot mode or BSC development boot mode.

The external device write format needs to be in accordance with the description in appendix B.6.1, Flash ROM Format (VRL4 Format) (hereafter referred to as VRL4 format).

Description on operations:

1. When the signature value in the external device is the predefined value (value indicating that writing has been performed (VRL4 format)), the start address of the area to be booted is set as the boot address.

   When the copy size in the VRL4 is a value other than 0, the following operation can be selected as a copy boot option: copy a program for the specified size (up to 64 Kbytes while including the VRL4) to the fixed MERAM address and set the fixed MERAM address as the boot address. In this case, read operations, including the VRL4 format confirmation, start reading data from the lower address in 2-byte units in the address order.
2. A format check is performed for the VRL4 at the beginning of the boot address, and if the secure function is used, a secure check is performed for the specified area.
3. If the result of step 2 is correct, execution jumps to the start address of the VRL4.

   (If the result of step 2 is erroneous, a transition is made to the USB download function.)

B.3.3 NAND Boot Function

The NAND boot function is used to initiate a program written to a NAND device in NAND(4) boot mode, NAND(5) boot mode, NAND(4) development boot mode, or NAND(5) development boot mode.

The NAND device write format needs to be in accordance with the description in appendix B.6.2, NAND Physical Format, and data in the VRL4 format is stored. This function expands a program in MERAM according to the NAND physical format, performs the VRL4 format check and secure check as like the BSC boot function, and then performs boot processing.

Description on operations:

Carry out the NAND physical block format expansion with steps 1 to 4 and then perform step 5.

1. Read data from the beginning of the control block of the page (reading from pages 0 to 127), and search for the beginning of the boot block (H'5A5A).
2. On finding the beginning of the boot block, copy the data areas of that page to MERAM.
   Calculate the copy size of the boot block and the number of pages to be read from the VRL4 data structure in MERAM.
   (When an ECC error occurs, search for the next boot block (return to step 1).)
   (When the VRL4 data structure is erroneous, search for the next boot block (return to step 1).)
3. Read boot options from the beginning of the boot block with a valid VRL4 header, which was found first and perform clock up processing.
4. Continue to read sequentially from the next page of the found boot block. On finding a page with a page identifier of H'A5A5, determine it as a boot block and copy it to MERAM. Perform this until the specified number of pages has been found.
   (When an ECC error occurs, the block is determined as an invalid block. Start reading the next page.)
   (When an identifier of H'5A5A is found, carry out step 2.)
   (When the specified number of pages has been found, whether there is a subsequent page with a page identifier of H'A5A5 is not investigated.)
   (When the specified number of pages is not yet met after reading up to page 127, a transition is made to the USB download function.)
5. When boot block reading has completed, boot is performed from MERAM. (When a secure boot error occurs, a transition is made to the USB download function.)

- Definition of boot block

  The boot program code is stored in data areas and is configured with two or more pages. The identification data of the first page is H'5A5A, and the identification data of subsequent pages is H'A5A5.

  The data format has a structure in which the VRL4 is stored at the beginning and the boot program code is stored after that.

  More than one boot block can be located in pages 0 to 127.

  (Locating more than one boot block increases the error tolerance.)

B.3.4 eSD Boot Function

The eSD boot function is used to initiate a program written to an eSD device in eSD boot mode or eSD development boot mode.

The program to be written to the eSD device should be in a format conforming to the VRL4 format and should be stored in physical partition #1 of the eSD device.

Description on operations:

1. Read data from the sector 0 area in physical partition #1 of the eSD device and perform the VRL4 format check. (The FAST_BOOT function is used for reading data from the eSD device.)
2. If no errors were found by the format check, the program for the copy size in the VRL4 format and the secure data (288 bytes) are read from the eSD device and copied to the fixed MERAM address. (The maximum size of the program to be copied is 64 Kbytes + 288 bytes (VRL4 format is also included).)
3. When the secure function is used, a secure library is called and a secure check is applied to the specified area.
4. If no error has occurred performing steps 1 to 3, execution jumps to the start address of the program copied to MERAM.

   (If an error has occurred performing steps 1 to 3, the eSD boot function is aborted and a transition is made to the USB download function.)

B.3.5 eMMC Boot Function (MFI Pins/BSC Pins, User Area)

The eMMC boot function (1A/1B) is used to initiate a program written to an eMMC device in eMMC boot mode or eMMC development boot mode. The MMC port pins are multiplexed and the MD pins are used to select from among the MFI pins and BSC pins.

The program to be written to the eMMC device should be in a format conforming to the VRL4 format and should be stored in sector 1 of the eMMC device.

H'0000 must be set for the "boot option" in the VRL4 format. A value other than 0 must be set for the copy size.

Description on operations:

1. Read data from sector 1 (512 bytes) of the eMMC device and perform the VRL4 format check.
2. If no errors were found by the format check, the program for the copy size in the VRL4 format and the secure data (288 bytes) are read from the eMMC device and copied to the fixed MERAM address. (The maximum size of the program to be copied is 64 Kbytes (VRL4 format is also included).)
3. When the secure function is used, a secure library is called and a secure check is applied to the specified area.
4. If no error has occurred performing steps 1 to 3, execution jumps to the start address of the program copied to MERAM.

   (If an error has occurred performing steps 1 to 3, the eMMC boot function is aborted and a transition is made to the USB download function.)

B.3.6 eMMC Boot Function (MFI Pins/BSC Pins, Boot Partition)

The eMMC boot function (2A/2B) is used to initiate a program written to an eMMC device in eMMC boot mode or eMMC development boot mode. The MMC port pins are multiplexed and the MD pins are used to select from among the MFI pins and BSC pins. Boot operation mode is used as the boot mode.

The program to be written to the eMMC device should be in a format conforming to the VRL4 format and it should be stored in sector 0 of boot partition 1 or 2, which has been enabled in advance in the eMMC device.

H'0000 must be set for the "boot option" in the VRL4 format. A value other than 0 must be set for the copy size.

Description on operations:

1. In boot operation mode, 128 Kbytes of data is read from the boot partition that has been enabled in the eMMC device, and copied to MERAM. The copy size is 128 Kbytes regardless of the copy size in the VRL4 format.
2. Perform the VRL4 format check for the data read out from sector 0.
3. When the secure function is used, a secure library is called and a secure check is applied to the specified area.
4. If no error has occurred performing steps 1 to 3, execution jumps to the start address of the program copied to MERAM.
   (If an error has occurred performing steps 1 to 3, the eMMC boot function is aborted and a transition is made to the USB download function.)

B.3.7 USB Download Function

The USB download function is used to transfer a program from the PC to RAM via the USB and execute it in case the VRL4 in an external device does not satisfy the conditions of the predefined value (value indicating that writing has been performed (VRL4 format)) in BSC boot mode, BSC development boot mode, NAND(4) boot mode, NAND(5) boot mode, NAND(4) development boot mode, NAND(5) development boot mode, eSD boot mode, eSD development boot mode, eMMC boot mode (1A, 1B, 2A, 2B), and eMMC development boot mode (1A, 1B, 2A, 2B), or does not satisfy the conditions of the NAND physical format in NAND(4) boot mode, NAND(5) boot mode, NAND(4) development boot mode, and NAND(5) development boot mode.

Mask ROM downloads a program from the PC to a specified RAM area and calls the beginning of the subroutine program defined in the VRL4. Note that the download destination address before the first subroutine call operation takes place is limited to the MERAM area.

Note: When the secure function is selected, a subroutine call is made after the secure check was performed according to the VRL4.
When the secure function is not selected, a subroutine call is made according to the VRL4.
Even in forcible USB boot mode, a transition is made to this function.
A transition to this function can also be made by using the boot control interface function.

Description on operations:

1. Mask ROM reads the signature of the start address of the external device.
   If the signature value does not match the predefined value (value indicating that writing has been performed (VRL4 format)), a transition is made to the USB download function, the USB is enabled, and USB connection is waited for.
   In NAND(4) boot mode, NAND(5) boot mode, NAND(4) development boot mode, and NAND(5) development boot mode, if the specifications of the NAND physical format (appendix B.6.2, NAND Physical Format) are not satisfied, a transition is made to this function, the USB is enabled, and USB connection is waited for.
2. After the PC and USB are connected, a program can be transferred from the PC. After transfer has finished, the transfer destination start address is called. A subroutine call is made when executing the transfer program. The USB is not disconnected here.

B.3.8 Secure Boot Function

The secure boot function is used to perform the secure check of the boot program before it is initiated in BSC boot mode, NAND(4) boot mode, NAND(5) boot mode, forcible USB boot mode, eSD boot mode, eMMC boot mode (1A, 1B, 2A, 2B), MFI1 boot mode, and MFI2 boot mode.

B.3.9 MFI Boot Function

The MFI boot function is used to expand a program and boot it in MFI1 boot mode, MFI1 development boot mode, MFI2 boot mode, or MFI2 development boot mode via the ACMFI1 (ADDEMUX) or ACMFI2 (ADMUX).

B.4 Address Map

Figure B.1 shows the address map.

After a reset is canceled, program execution starts from address H'0000 0000.

Mask ROM addresses: H'0000 0000 to H'0000 FFFF
(located at physical addresses H'E6B0 0000 to H'E6B0 FFFF)

External device addresses: From H'2000 0000 (CS0)

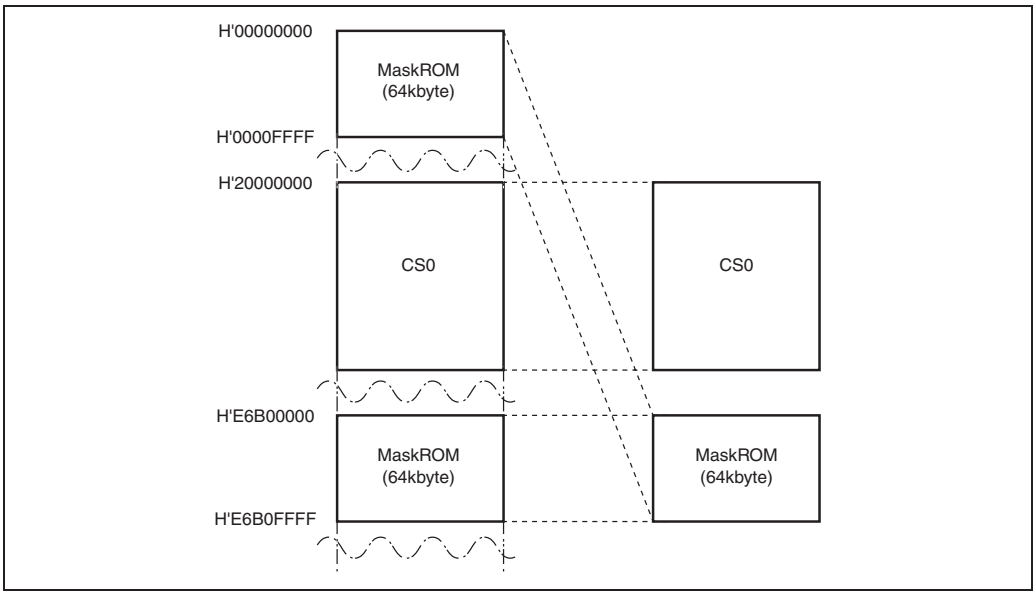

Figure B.1 Address Map at Boot

B.4.1 Addresses for Expansion by USB Download Function

A program transferred by the USB download function is expanded from the following addresses in MERAM.

H'E55B 0000 to H'E55F FFFF

B.4.2 Addresses Used for Work RAM

When mask ROM is executed, the following resources are used.

Table B.5 Addresses Used for Work RAM

Name	Address	Usage	Remarks
MFRAM	H'E6B92000 to H'E6B97FFF	MFI parameter area	
MERAM	H'E558 0000 to H'E55A FFFF	Stack, work RAM	
	H'E55B 0000 to H'E55F FFFF	Area for USB download	
		Area for copy option expansion	

B.5 General Flowcharts

B.5.1 Mask ROM Mode Determination Sequence Flow

The sequence for determining the boot mode at AP4 power-on is shown in figure B.2.

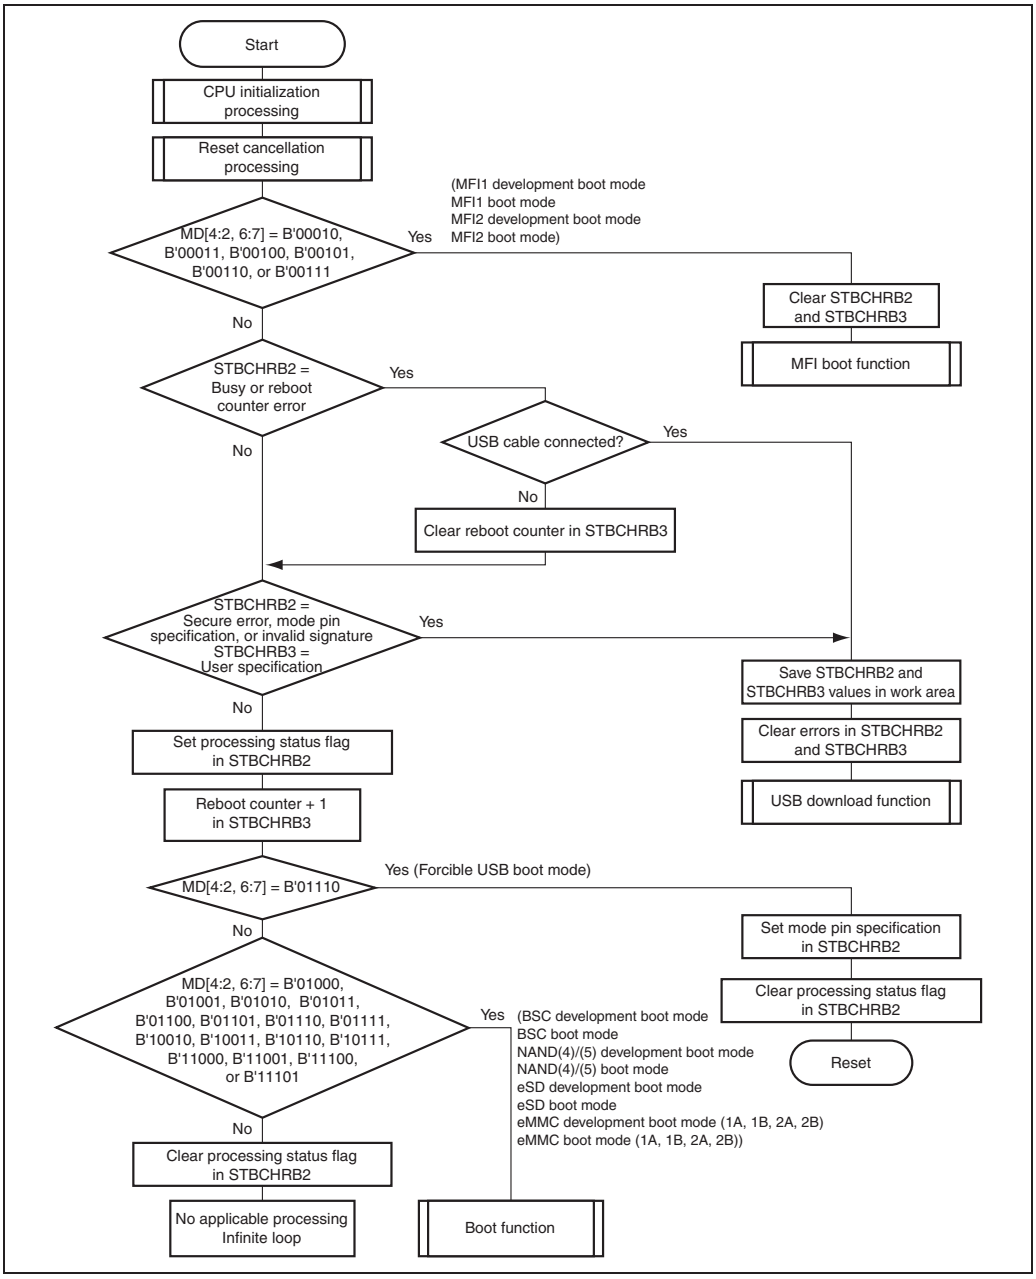

Figure B.2 AP4 Boot Mode Determination Sequence

B.5.2 Boot Processing Flow for Each Boot Function

(a) Boot Function Processing

The processing at boot is shown in figure B.3.

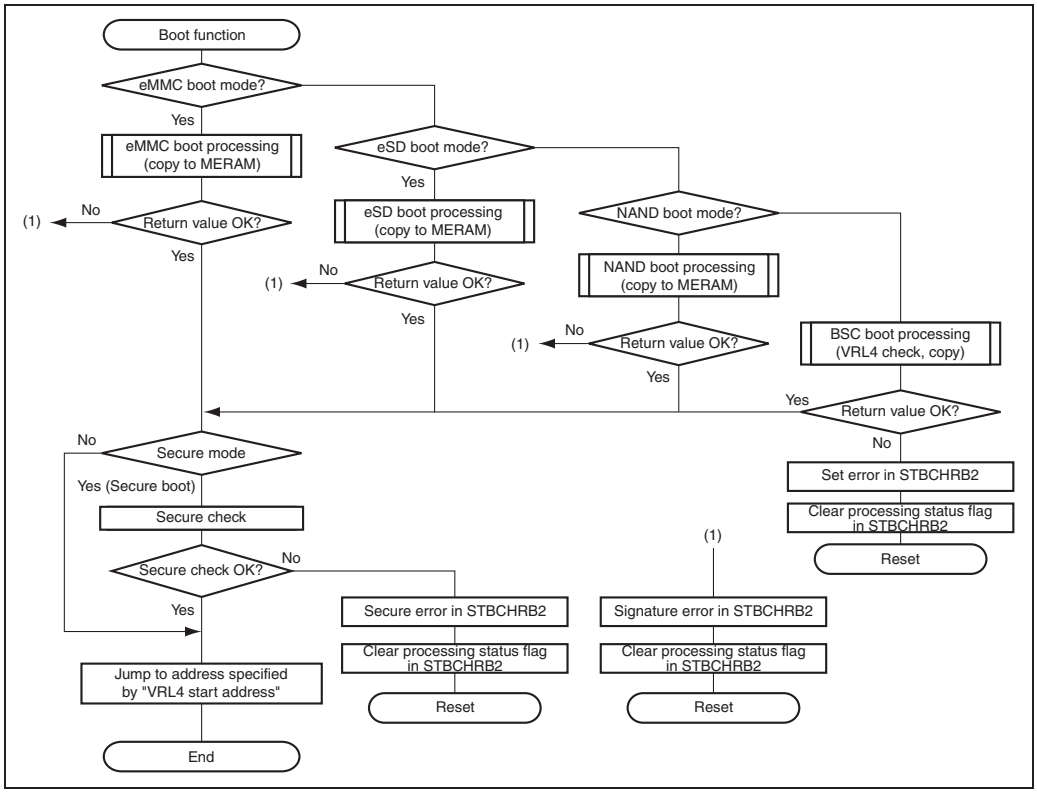

Figure B.3 Normal Mode Flow

(b) BSC Boot Processing

The BSC boot processing is shown in figure B.4.

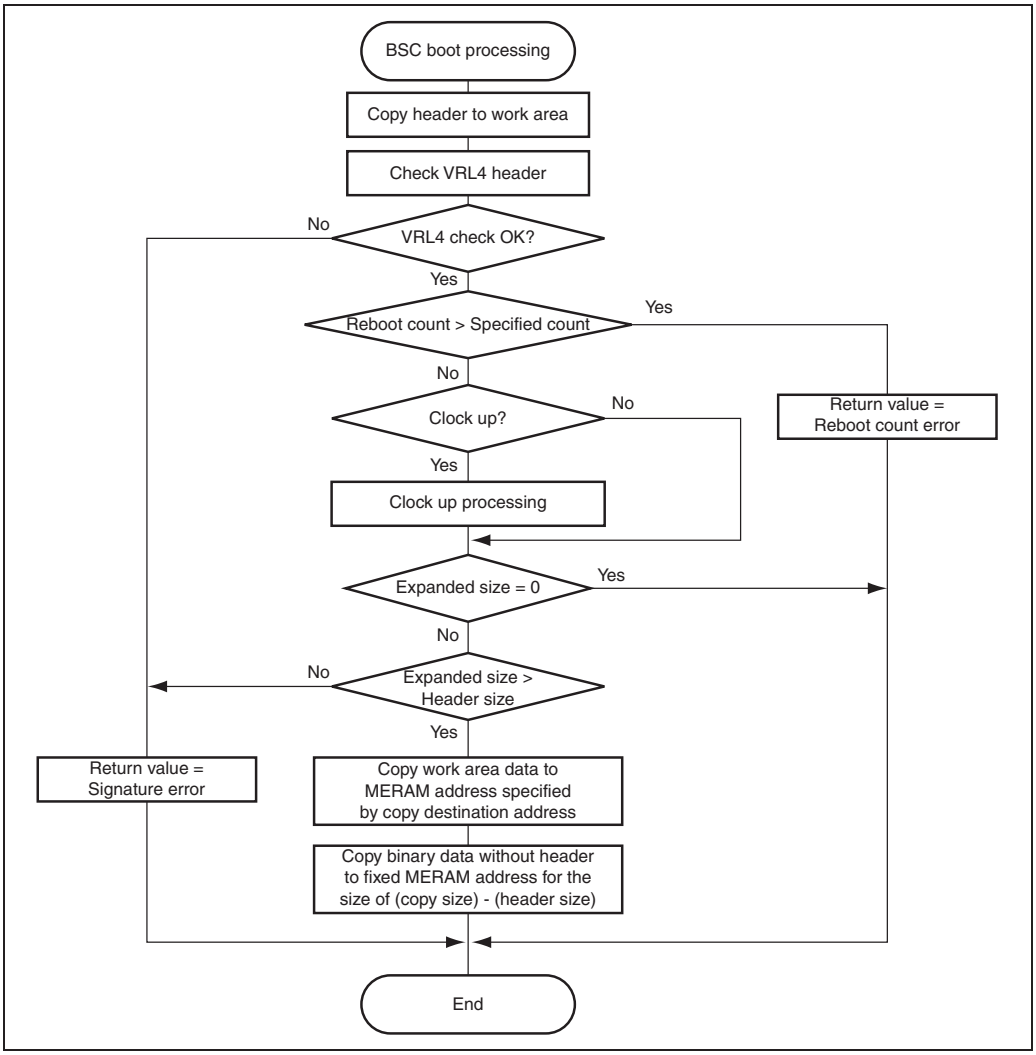

Figure B.4 BSC Boot Processing Flow

B.5.3 USB Download Flow

A flowchart for the USB download function is shown in figure B.12.

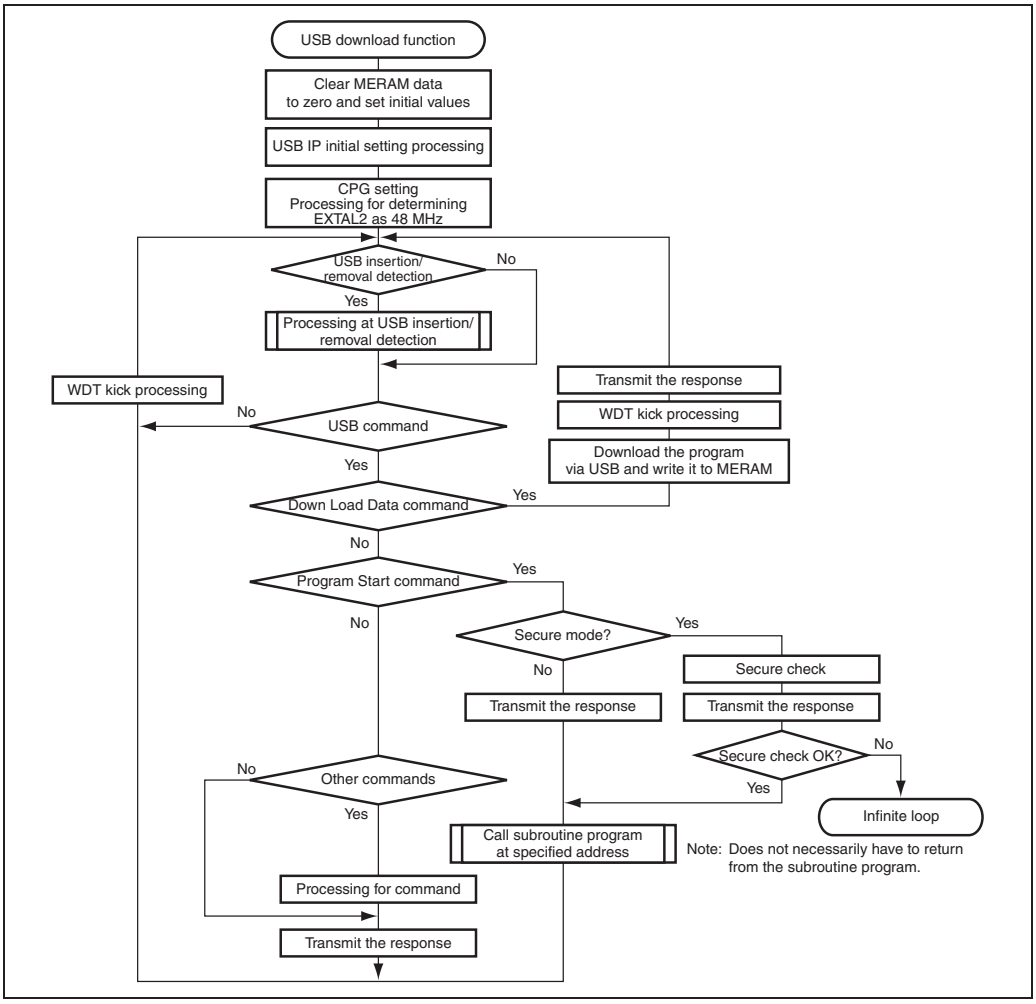

Figure B.12 USB Download Boot Processing Flow

In the USB download function, mask ROM controls the USB device and performs transmit and receive processes. After the Program Start command has been received, the result is sent as the response. If the result is normal, execution jumps to the beginning of the received data.

The USB disconnection processing does not take place here.

B.5.4 USB Insertion/Removal Detection Flow

A flowchart for the USB insertion/removal detection during USB download is shown in figure B.13.

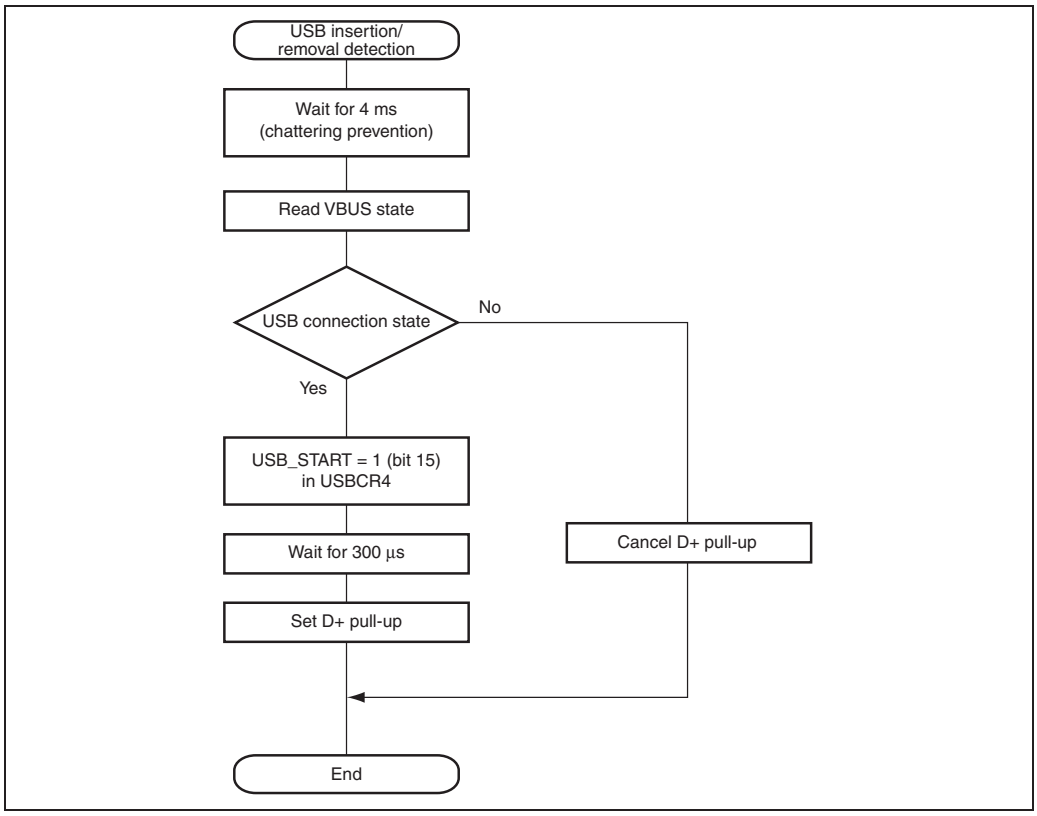

Figure B.13 USB Insertion/Removal Detection Flow

In VBUS detection during USB download, after connection has been detected, the power supply break control register (USBCR4) is controlled. Set the USB_START bit in USBCR4 to 1, wait for 300 μs, and then pull up D+ (default value of USB_COR is used without change).

When disconnection has been detected, pull-up of D+ is canceled.

B.5.5 Secure Check Flow

A flowchart for the secure check is shown in figure B.14.

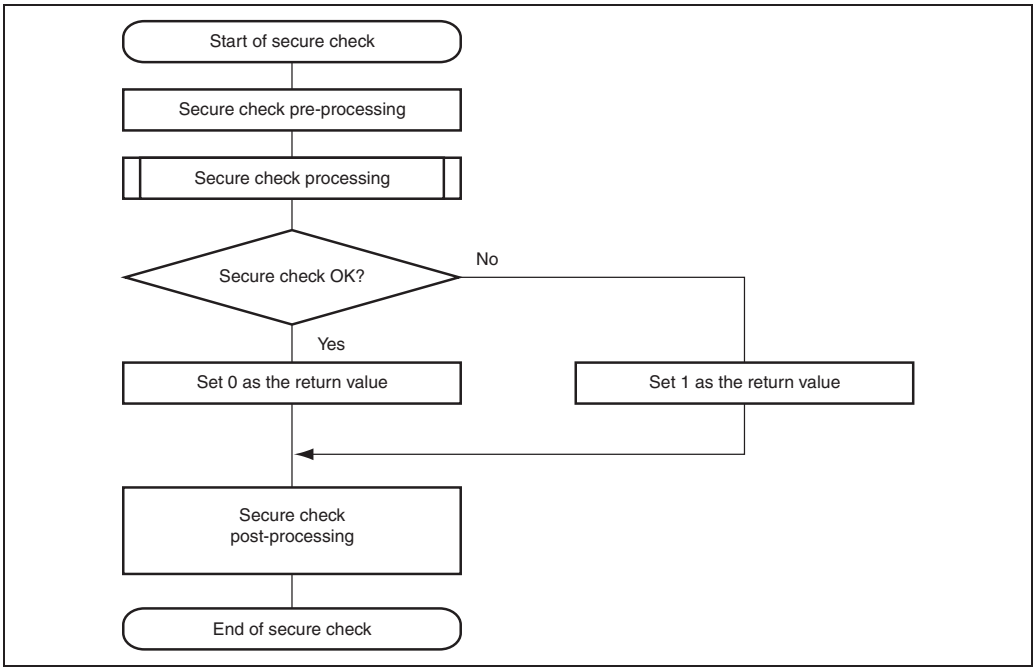

Figure B.14 Secure Check Flow

B.5.6 CPU Initialization Processing

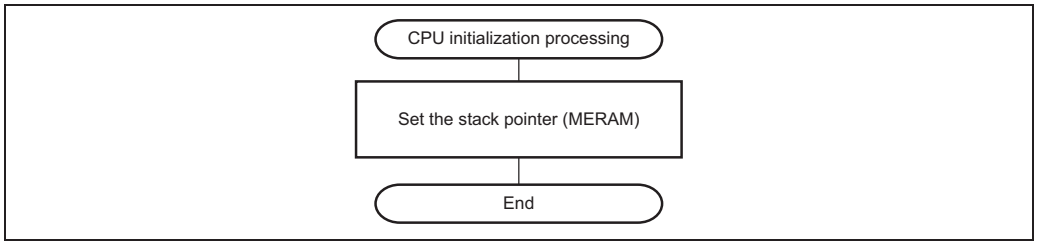

Figure B.15 CPU Initialization Processing Flow

B.6 Formats

B.6.1 Flash ROM Format (VRL4 Format)

This format is a header for a boot block used in all boot modes.

A program is expanded in on-chip ROM according to each boot mode and started according to the flash ROM format (VRL4 format) (a program is started directly without being expanded when the copy boot option for BSC boot mode or BSC development boot has not been specified).

The flash ROM format includes the VRL4 specifications that are used by the secure boot function.

Table B.6 Flash ROM Formats

Offset	Size	Name	Value Evaluation	Remarks
+ H'00	4	Magic number 1	Performed	H'EA000000 must be specified.
+ H'04	4	Reserved	Performed	A value between H'56 and H'2C40 must be specified.
+ H'08	4	Magic number 2	Not performed	H'E59FF008 must be specified.
+ H'0C	4	Reserved	Not performed	
+ H'10	2	Copy size	Performed	The size of the copy option is specified. Copy boot is not performed for H'0000.
+ H'12	2	Boot options	Performed	Clock up specification of 2 bits (bits 14 and 15). Reboot count specification of 3 bits (bits 11, 12, and 13). Other bits are reserved (bits 10 to 0).
+ H'14	4	Reserved	Performed	A value between H'0001 and H'03FF must be specified.
+ H'18	4	Start address	Not performed	Program start address is specified.
+ H'1C	4	Reserved	Not performed	
+ H'20	4	Reserved	Not performed	
+ H'24	308	Reserved	Not performed	

- Magic number: The specified bit pattern is stored.
- Copy size: Size (bytes) of the expanded program.

  Used in BSC boot, BSC development boot, NAND(4) boot, NAND(5) boot, NAND(4) development boot, NAND(5) development boot, eSD boot, eSD development boot, eMMC boot (1A, 1B, 2A, 2B), and eMMC development boot (1A, 1B, 2A, 2B) modes.

  A value between H'0 and H'FFFF must be specified.
- Boot options: The options for boot operation by each function are specified.

  Used in BSC boot, BSC development boot, NAND(4) boot, NAND(5) boot, NAND(4) development boot, and NAND(5) development boot modes.

  — Clock up specification (Used in BSC boot, BSC development boot, NAND(4) boot, NAND(5) boot, NAND(4) development boot, and NAND(5) development boot modes.)

  — Reboot count specification (Used in BSC boot and BSC development boot modes.)
- Start address: Address at which to start execution after copy.

  The specified address is called after the copy processing.

  Since the header will also be copied, specify the address carefully.

  The start address should be aligned to a 4-byte boundary.
- Reserved: Reserved area.

  Only the items for which value evaluation is to be performed are evaluated at boot.

Note: All data is stored in the little endian format.

The VRL4 format in secure mode is specified separately.

The area to transfer the copy size is not specified because it is fixed to MERAM.

Specify 0 for areas not used by the boot options.

B.6.1.1 Clock Up Option

(a) For BSC boot function

Clock up specification (bits 14 and 15):

B'00: Clock setting A (SYS-CPU 800 MHz (see "Clock up SYS-CPU 800 MHz" in appendix B.7, Settings))

B'10: Clock setting B (SYS-CPU 400 MHz (see "Clock up SYS-CPU 400 MHz" in appendix B.7, Settings))

B'01: Reserved (same as clock setting D)

B'11: Clock setting D (Do not make this setting.)

(b) For NAND boot function

For the clock up option when using the NAND boot function, refer to appendix B.6.2, NAND Physical Format.

B.6.1.2 Copy Size

(a) For BSC boot function

When zero bytes are specified as the copy size, expansion is not performed.

When a value other than zero bytes is specified, data for the copy size is copied from offset 0.

If the specified size is not a multiple of 4, copy is performed with the size rounded up to a multiple of 4. Details of the operation are shown in figure B.16.

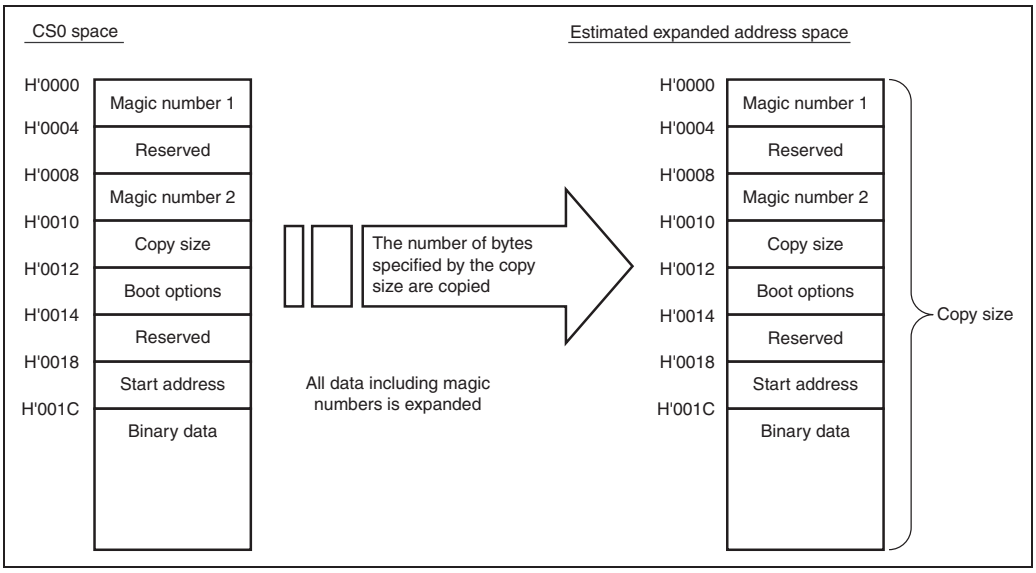

Figure B.16 Expansion Processing for Boot Function

The expansion size of mask ROM includes the VRL4 size.

(b) For NAND boot function

For the copy size when using the NAND boot function, refer to appendix B.6.2, NAND Physical Format.

(c) For eSD boot function

For the copy size when using the eSD boot function, refer to appendix B.6.3, eSD Physical Format.

B.6.1.3 Reboot Count Specification

(a) For BSC boot function

Reboot count specification (reboot count for transition to USB download)

0: This function is disabled

1 to 7: Reboot count to trigger a transition to USB download

B.6.2 NAND Physical Format

In NAND(4) boot mode, NAND(5) boot mode, NAND(4) development boot mode, and NAND(5) development boot mode, the boot program including the VRL4 is stored in the format described in this section.

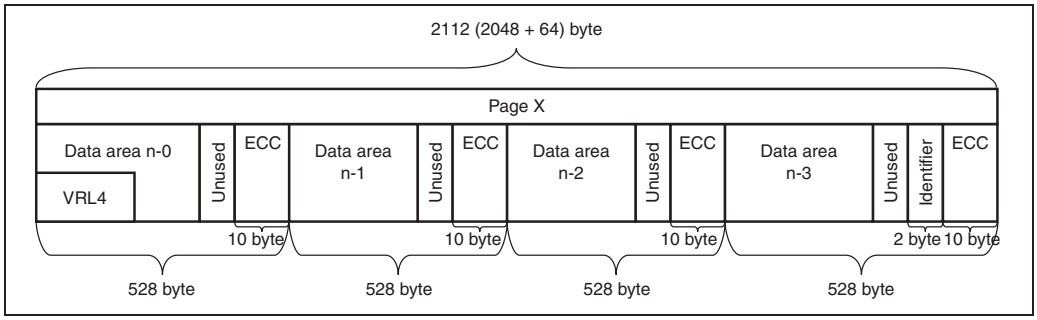

Figure B.17 NAND Page Format

Table B.7 NAND Page Format

Item		Offset	Size	Description
Data area n-0	VRL4	From H'000	—	Locate VRL4 at the start of the area (n = 0 only). (Should conform to VRL4 specifications)
		H'010, H'011	2	VRL4 copy size area Specify the boot program size including VRL4. The size will be rounded up to 2048-byte units.
		H'012, H'013	—	VRL4 boot option Only the clock up specification can be set.
		H'014 to m		VRL4 (continued from above) m is 344 in the VRL4 specifications, but an offset of H'20 or higher will not be inspected.
		H'000 to H'1FF	512	Boot program
Unused area n-0		H'200 to H'205	6	Unused
ECC n-0		H'206 to H'20F	10	ECC of offsets H'0 to H'205
Data area n-1		H'210 to H'40F	512	Boot program
Unused area n-1		H'410 to H'415	6	Unused
ECC n-1		H'416 to H'41F	10	ECC of offsets H'210 to H'415
Data area n-2		H'420 to H'61F	512	Boot program
Unused area n-2		H'620 to H'625	6	Unused
ECC n-2		H'626 to H'62F	10	ECC of offsets H'420 to H'625
Data area n-3		H'630 to H'82F	512	Boot program
Control code area n-3		H'830 to H'833	4	Unused
Identifier for page n		H'834 to H'835	2	Store the boot block identification data Identification data: H'5A5A: First page H'A5A5: Second and subsequent pages Other than above: Invalid page
ECC n-3		H'836 to H'83F	10	ECC of offsets H'630 to H'835

The data areas are expanded in MERAM as shown in figure B.18.

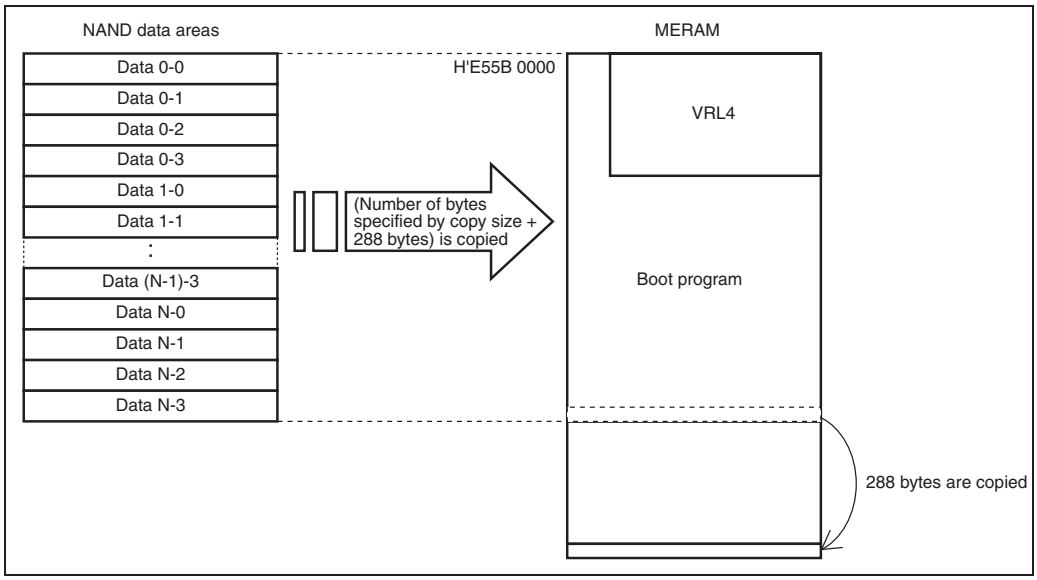

Figure B.18 NAND Data Area Expansion in MERAM

The boot option definitions in the VRL4 format used in these modes are shown below.

- Clock up specification (bits 14 and 15)
  - B'00: Clock setting A (SYS-CPU 800 MHz (see "Clock up SYS-CPU 800 MHz" in appendix B.7, Settings))
  - B'10: Clock setting B (SYS-CPU 400 MHz (see "Clock up SYS-CPU 400 MHz" in appendix B.7, Settings))
  - B'01: Reserved
  - B'11: Clock setting D (Do not make this setting.)
- Copy size specification (specification of the size to be copied)

  Data for the copy size is copied from offset 0.

  If the specified size is not a multiple of 4, copy is performed with the size rounded up to a multiple of 4.

Page X that includes data areas 0 to N is searched as shown in figure B.19.

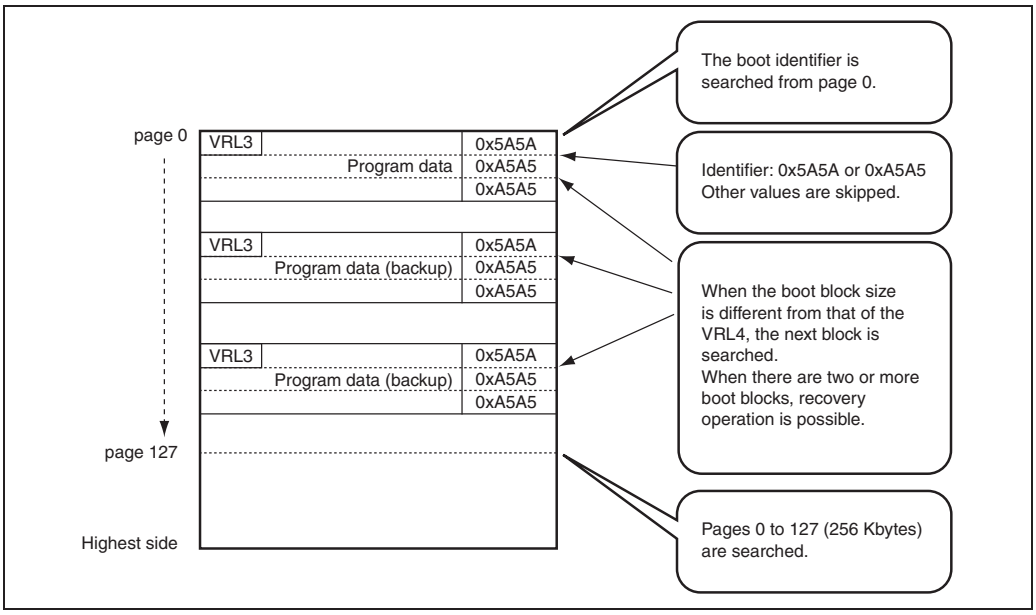

Figure B.19 NAND Block Search

B.6.3 eSD Physical Format

In eSD boot mode and eSD development boot mode, the boot program including the VRL4 format is stored in physical partition #1 of the eSD device in the format shown in figure B.20.

In addition, the boot program of the eSD device is expanded in MERAM, as shown in figure B.20.

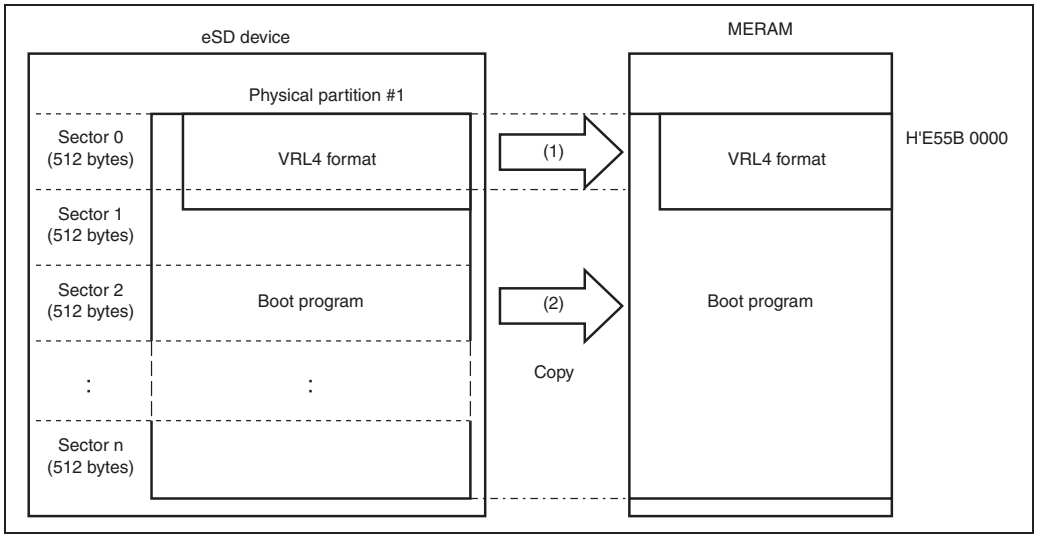

Figure B.20 eSD Physical Format and MERAM Expansion by eSD Boot Function

First, set physical partition #1 in the eSD device.

Next, read data from sector 0 at operation (1), determine the copy size (number of sectors to be copied), and expand the boot program in MERAM for the remaining copy size (number of sectors to be copied) at operation (2).

The boot option definitions in the VRL4 format used by the eSD boot function are shown below.

- Clock up specification (bits 14 and 15)
  Disabled
  Note: In eSD boot modes, the clock setting is the same for all. Operation is performed with SYSCPU as 400 MHz and SDHI as 100 MHz.
  The clock setting for the eSD card is 390 KHz when initializing the eSD card and 25 MHz when reading data from the eSD device.

- Reboot count specification (reboot count for transition to USB download)
  Disabled
- Copy destination specification (expansion address when the copy option is specified)
  Disabled
- Copy size specification (specification of the size to be copied)
  Size of the data to be copied.

  Note: When zero bytes are specified, a transition is made to the USB download function. When a value other than zero bytes is specified, the boot program is copied for the size specified to be copied from sector 0.

  When this size is rounded up to a multiple of 4, the size to be copied is obtained by adding 288 to that value. (In reality, copy is performed in sectors. Therefore, even if the calculated value is not a multiple of 512, data will be copied from the eSD device for a multiple of 512.)

B.6.4 eMMC 1A/1B Physical Format

In eMMC boot mode 1A, eMMC boot mode 1B, eMMC development boot mode 1A, and eMMC development boot mode 1B, the boot program (user program) including the VRL4 format is stored in sector 1 of the eMMC device in the format shown in figure B.21.

In addition, the boot program of the eMMC device is expanded in MERAM, as shown in figure B.21.

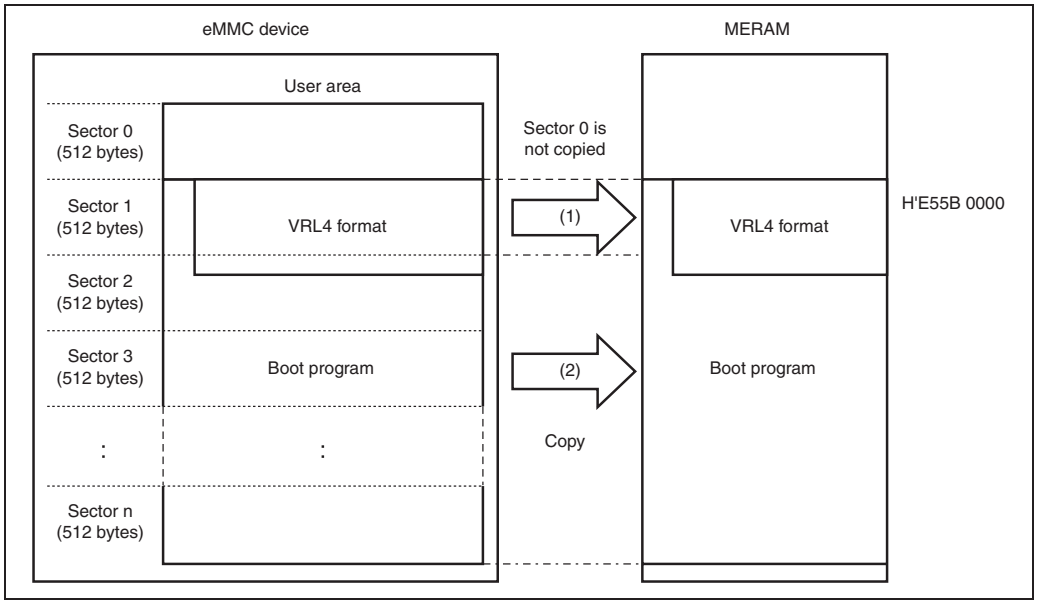

Figure B.21 eMMC 1A/1B Physical Format and MERAM Expansion by eMMC Boot Function

Read data from sector 1 at operation (1), determine the copy size (number of sectors to be copied), and expand the boot program in MERAM for the remaining copy size (number of sectors to be copied) at operation (2).

The boot option definitions in the VRL4 format used by the eMMC boot function are shown below. H'0000 must be set for the boot options (2 bytes).

- Clock up specification (bits 14 and 15)
  Disabled (B'00 must be set)
  Note: In eMMC boot modes, the clock setting is the same for all. Operation is performed with SYSCPU as 400 MHz and MMC as 100 MHz.
  The clock setting for the eMMC card is 390 KHz when initializing the eMMC card and 50 MHz or 25 MHz when reading data from the eMMC device in accordance with the eMMC device.
- Reboot count specification (reboot count for transition to USB download)
  Disabled (B'000 must be set)
- Copy destination specification (expansion address when the copy option is specified)
  Disabled (B'0 must be set)
- Copy size specification (specification of the size to be copied)
  Size of the data to be copied.
  Note: When zero bytes are specified, a transition is made to the USB download function. When a value other than zero bytes is specified, the boot program is copied for the size specified to be copied.
  When this size is rounded up to a multiple of 4, the size to be copied is obtained by adding 288 to that value. (In reality, copy is performed in sectors. Therefore, even if the calculated value is not a multiple of 512, data will be copied from the eMMC device for a multiple of 512.)

B.6.5 eMMC 2A/2B Physical Format

In eMMC boot mode 2A, eMMC boot mode 2B, eMMC development boot mode 2A, and eMMC development boot mode 2B, the boot program (user program) including the VRL4 format is stored at the beginning of the boot area partition of the eMMC device in the format shown in figure B.22.

In addition, the boot program of the eMMC device is expanded in MERAM, as shown in figure B.22.

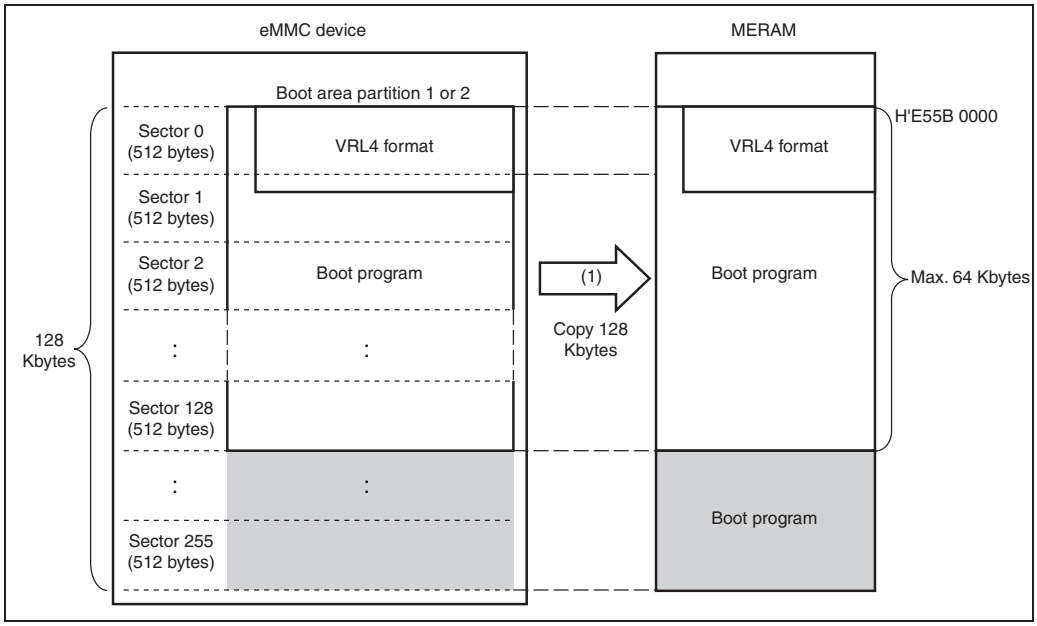

Figure B.22 eMMC 2A/2B Physical Format and MERAM Expansion by eMMC Boot Function

At operation (1), copy 128 Kbytes of data to MERAM by the boot operation. Read data from the boot partition that has been enabled by the eMMC device (boot partition 1 or 2). The copy size is 128 Kbytes regardless of the copy size specified in the VRL4 format. As the maximum boot program size is 64 Kbytes, the latter 64 Kbytes contain invalid data.

The boot option definitions in the VRL4 format used by the eMMC boot function are shown below. H'0000 must be set for the boot options (2 bytes).

- Clock up specification (bits 14 and 15)
  Disabled (B'00 must be set)
  Note: In eMMC boot modes, the clock setting is the same for all. Operation is performed with SYSCPU as 400 MHz and MMC as 100 MHz.
  The clock setting for the eMMC card is 390 KHz when initializing the eMMC card and 12.5 MHz when reading data from the eMMC device.
- Reboot count specification (reboot count for transition to USB download)
  Disabled (B'000 must be set)
- Copy destination specification (expansion address when the copy option is specified)
  Disabled (B'0 must be set)
- Copy size specification (specification of the size to be copied)
  Size of the data to be copied. Though 128 Kbytes are copied regardless of this value in these modes, set the correct value (boot program size).
  Note: When zero bytes are specified, a transition is made to the USB download function after copy has finished.

B.6.6 Message Format between Windows PC and AP4 for USB Download Function

B.6.6.1 Used Class

Communication is performed using the USB communication class.

A USB serial driver of Windows XP standard is used on the PC side. At this time, the applications on the PC side are used as COMx ports.

An inf file needs to be prepared to install the USB serial driver of Windows XP standard.

Note: In the USB download function, operation with several machines connected to the same PC is not guaranteed.
USB transfer is performed by full-speed transfer.

B.6.6.2 Descriptors

(1) Device Descriptors

Field	Value (Hexadecimal)

B.6.6.3 List of Commands and Responses

(1) Commands (Data from PC Side)

Command	Description	Code
Initialize Request	Sets the AP4 clock.	H'A0
Status Request	Confirms the condition of the status.	H'A1
Down Load Start	Notifies the start of download.	H'A2
Down Load Data	Transmits the download data.	H'A3
Down Load End Confirm*	Notifies the end of download.	H'A4
Program Start	Makes a subroutine call.	H'A5
Get Version	Acquires mask ROM version information.	H'AF

Note: * The Down Load End Confirm command can be used after the Down Load Data command has been issued.

(t) Responses (Data from AP4 Side)

Command	Description	Code
Command Response	Returns the response for the command.	H'B0
Down Load Response	Returns the download state.	H'B1
Down Load End Status	Returns the state after download.	H'B2
Version Information	Returns the mask ROM version information.	H'BF

B.6.6.4 Commands (Data from PC Side)

(Refer to appendix B.6.6.6, Details of Commands.)

- Other than Down Load Data

CMD	LEN	DATA1	DATA2	...

CMD: 1 byte, command code

LEN: 1 byte, data length (from DATA1 to end of DATA)

DATA: x bytes, data (number of bytes specified by LEN)

- Down Load Data

CMD	LEN (Upper)	LEN (Lower)	SEQNO (Upper)	SEQNO (Lower)	DATA1	DATA2	...	Checksum (Upper)	Checksum (Lower)

CMD: 1 byte, command code

LEN: 2 bytes, data length (from SEQNO to end of checksum)

SEQNO: 2 bytes, sequence number (from 0 to 65535)

DATA: x bytes, download data

Checksum: 2 bytes, checksum data

B.6.6.5 Responses (Data from AP4 Side)

(Refer to appendix B.6.6.7, Details of Responses.)

RES	LEN	DATA1	DATA2	...

RES: 1 byte, response code

LEN: 1 byte, data length (from DATA1 to end of DATA)

DATA: x bytes, data (number of bytes specified by LEN)

B.6.6.6 Details of Commands

(1) Initialize Request

Sets the clock for the AP4.

After receiving this command, the AP4 sets the clock and returns "Command Response (H'B0)".

CMD	LEN	CLOCK
H'A0	H'01	MODE

CLOCK MODE
- H'00: Clock setting A (SYS-CPU 800 MHz (see "Clock up SYS-CPU 800 MHz" in appendix B.7, Settings))
- H'01: Clock setting B (SYS-CPU 400 MHz (see "Clock up SYS-CPU 400 MHz" in appendix B.7, Settings))
- H'02: Reserved
- H'03: Clock setting D (Do not make this setting.)

(u) Status Request

Confirms the condition of the AP4 status.

After receiving this command, the AP4 immediately returns "Command Response (H'B0)".

CMD	LEN	KIND
H'A1	H'01	

KIND
- H'00: Confirms the command acceptance ready state
- H'01: Acquires the USB operating state (clock setting, and whether MERAM address restriction is applied or not)
- H'02: Acquires the return value from the subroutine call (4-byte return value from subroutine)
- H'03: Acquires the condition for a transition to USB download (standby flag register value)
- H'04: Acquires version information of the device
- H'03: Acquires RESCNT

(v) Down Load Start

Notifies the AP4 that download has started.

After receiving this command, the AP4 immediately returns "Down Load Response (H'B1)".

CMD H'A2	LEN H'08	ADDRESS (Highest)	ADDRESS (Second)	ADDRESS (Third)	ADDRESS (Lowest)	SIZE (Highest)	SIZE (Second)	SIZE (Third)	SIZE (Lowest)

ADDRESS: Download destination address (RAM address)*

DATA: Total size of binary data, including the header, that is to be downloaded by the download command

Note: * The address and size settings must be within the MERAM download area before the Program Start command is executed. If the MERAM area is exceeded, an error is returned.

(w) Down Load Data

Transmits the download data to the AP4.

After receiving this command, the AP4 immediately returns "Down Load Response (H'B1)".

CMD H'A3	LEN (Upper)	LEN (Lower)	SEQNO (Upper)	SEQNO (Lower)	DATA1	DATA2	...	Checksum (Upper)	Checksum (Lower)

LEN: Data length*[1]

SEQNO: Sequence number (The sequence number is incremented sequentially from 0 (max. 65535))

DATA: Download file*[2]

Checksum: Enter 2's complement of the value obtained by adding one byte each to DATA (discard the overflow of 2 bytes).

Notes: 1. Set a value of 6 bytes or more to LEN. If LEN exceeds 30704 bytes, it should be divided. An even value must be set to LEN.
2. Data is packetized sequentially from address 0 in bytes.

(x) Down Load End Confirm

Notifies the AP4 that transmission of download data has finished.

After receiving this command, the AP4 calculates the checksum and returns "Down Load End Status (H'B2)".

CMD H'A4	LEN H'02	Checksum (Upper)	Checksum (Lower)

Checksum: Enter the checksum (2's complement) of the total binary data of the download program (variable length).

(y) Program Start

Notifies the AP4 that download of data has started.

After receiving this command, the AP4 performs the secure check and makes a subroutine call to the last address specified by the Down Load Start command. Before calling the subroutine, the AP4 returns "Command Response (H'B0)". When the secure function is selected, a secure check is carried out and the result is returned. To acquire the return value from the subroutine, use the Status Request command.

CMD H'A5	LEN H'00

Note: For the subroutine format, use the following for reference.
(When a program is executed more than once at the same address, processes such as flushing I-Cache at the start and end of the subroutine are required.)

```
unsigned long func(void){
   Processing
return err;
}
```

(z) Get Version

Acquires the mask ROM version of the AP4.

After receiving this command, the AP4 acquires the version information and returns "Version Information (H'BF)".

The Get Version command must be transmitted before the Down Load Start command.

Note: Transmission of the Get Version command is arbitrary.

CMD H'AF	LEN H'00

B.6.6.7 Details of Responses

(1) Command Response

Returns the return value for the Initialize Request, Status Request, and Program Start commands.

CMD H'B0	LEN H'0x	DATA1	DATA2	...

LEN: Size of DATA

DATA:

- Response for Initialize Request
  DATA1: H'00: OK
  H'01: Error
- Response for Status Request
  When KIND is H'00
  DATA1: Ready state
  In the Busy state, no response is returned because it is waiting for the response.
  When KIND is H'01
  DATA1: CLOCK MODE value set by the Initialize Request command
  DATA2: With/without MERAM address restriction
  H'00: No restriction (subroutine call by the Program Start command already made)
  H'01: Restriction applied

When KIND is H'02

DATA1 to DATA4: Return value from subroutine call (4 bytes) (DATA1 to MSB)

Note: H'0000 0000 when no subroutine call is made

When KIND is H'03

DATA1: Value of standby flag register STBCHRB2

DATA2: Value of standby flag register STBCHRB3

When KIND is H'04

DATA1 to DATA4: Value of AP4 version information (CCCR value) (DATA1 to MSB)

DATA5 to DATA8: Fixed at 0

When KIND is H'05

DATA1 to DATA4: RESCNT value (bits other than MD4, MD3, MD2, MD6, and MD7 are fixed at 0)

- Response for Program Start

  DATA1: State before the program was called

  H'00: Normal activation

  H'01: Download error

  H'02: Secure error

  Note: When the response is H'00, a subroutine call is made after sending the response. For other responses, no subroutine call is made.

(aa) Down Load Response

Notifies that download data has been received.

CMD	LEN	DATA1	DATA2
H'B1	H'02	SEQ	STATUS

SEQ H'00: Success

H'01: Fail–SEQNO error (STATUS: Result of checksum value is returned (H'00 or H'02))

STATUS H'00: Success

H'01: Fail–CMD error (CMD sequence error or the specified address or size exceeds the range)

H'02: Fail–Checksum error in download of data

(bb) Down Load End Status

After download has completed, calculates the checksum and notifies whether download has finished successfully.

CMD	LEN	DATA1	DATA2	DATA3
H'B2	H'03	STATUS	Checksum (Upper)	Checksum (Lower)

STATUS H'00: Success
H'01: Fail (checksum error in download file)
H'02: Fail (secure error)

(cc) Version Information

Notifies the mask ROM version information.

CMD	LEN	DATA1	DATA2	...	DATA16
H'BF	H'10	Version[0]	Version[1]		Version[15]

DATA: Returns the class, date, and creation number of mask ROM (16 bytes).
Data format: "ROM_yymmdd_nn" for the AP4

Note: yy: Year, mm: Month, dd: Day, nn: Version number for each creation
Example: ROM_081020_01 (software version 01 created on October 20, 2008)

B.6.6.8 Timing Chart

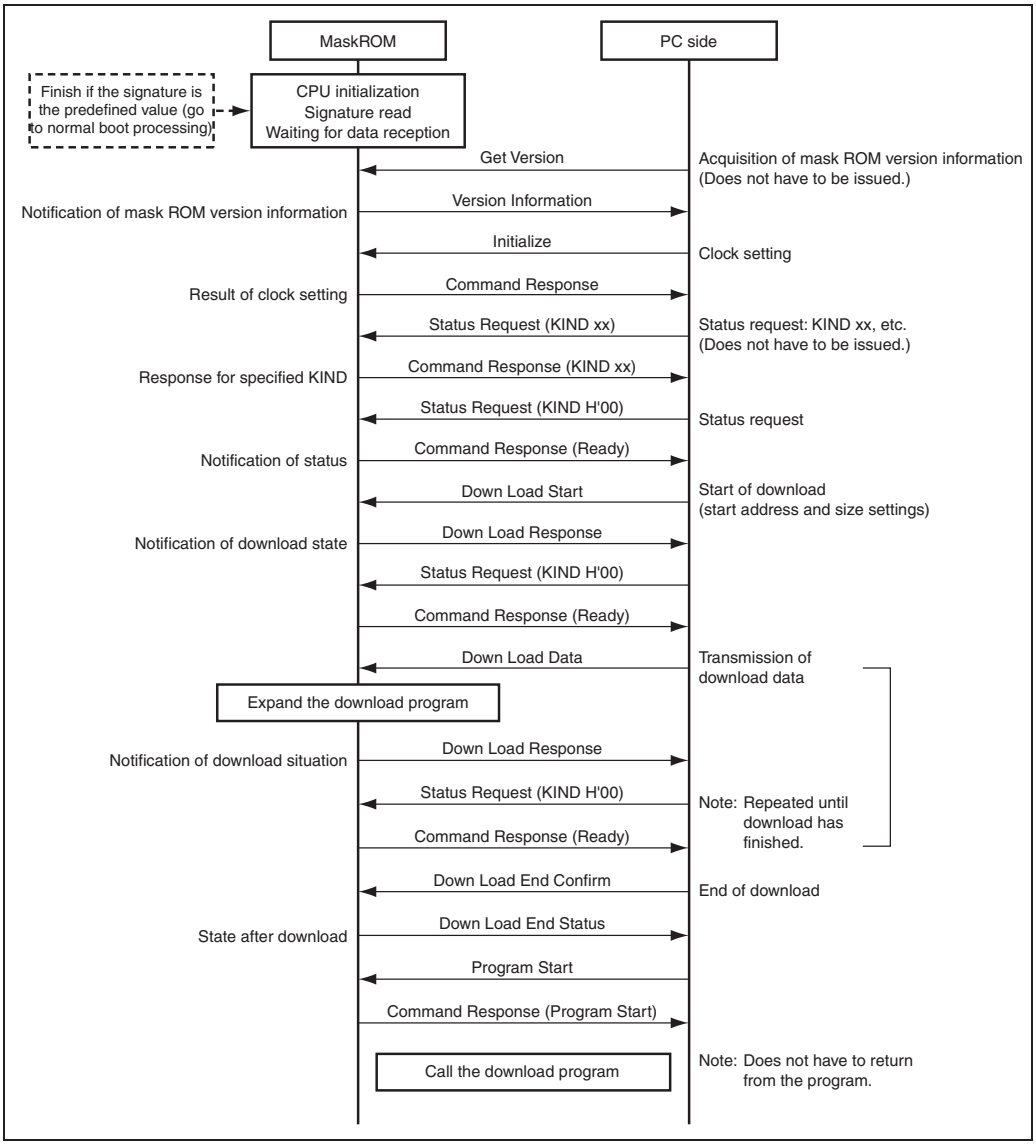

Figure B.23 USB Download Function

B.6.7 Message Format between ACPU and CCPU for MFI Boot Function

B.6.7.1 MFI Message Map

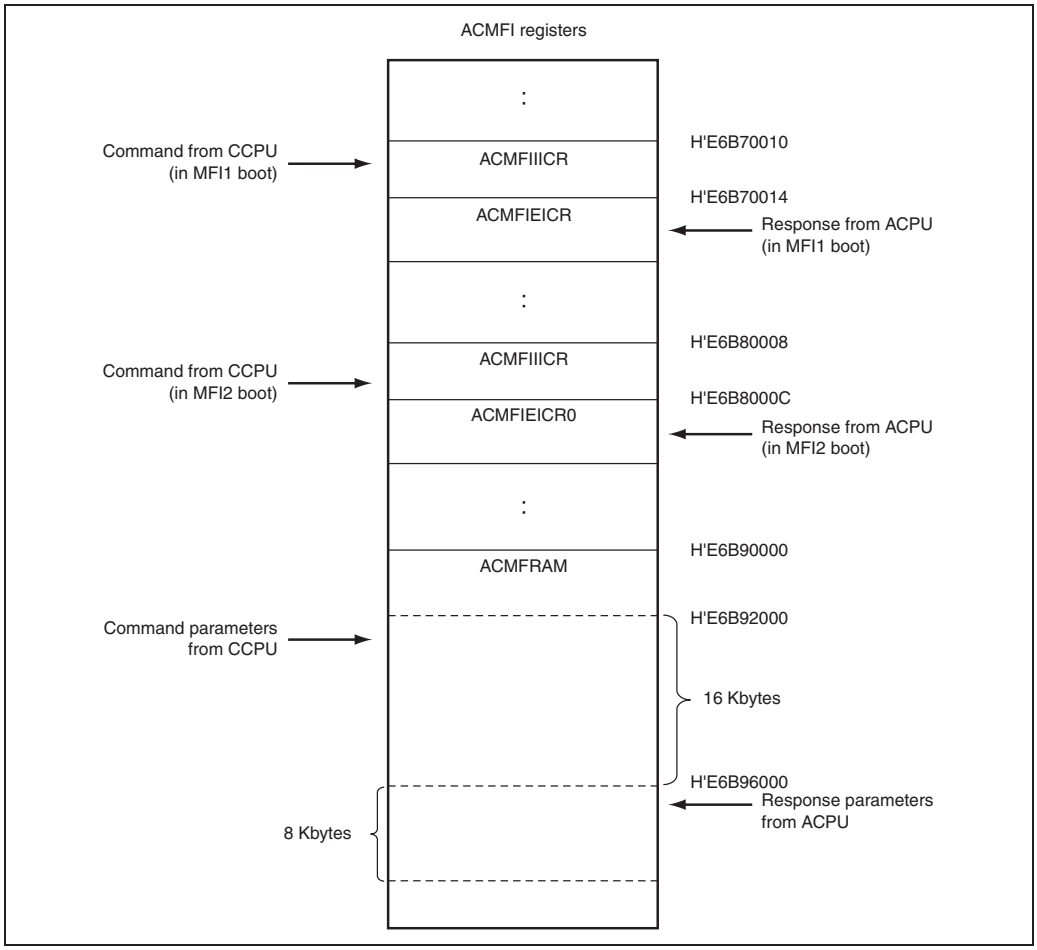

Figure B.24 MFI Message Map

B.6.7.2 List of Commands and Responses

(1) Commands (Data from CCPU Side)

Command	Description	Code (LSB is Command Issuance Bit)
Initialize Request	Sets the AP4 clock.	B'0000 001x
Status Request	Confirms the condition of the status.	B'0000 01H'
Get Version	Acquires mask ROM version information.	B'0000 011x
Program Start	Makes a subroutine call.	B'0000 10H'

(dd) Responses (Data from ACPU Side)

Command	Description	Code (LSB is ACPU Notification Bit)
Initialize complete	Notifies the end of Initialize Request.	B'0000 001x
Status notify	Confirms the condition of the status.	B'0000 01H'
Version notify	Notifies the mask ROM version information.	B'0000 011x
Program complete	Notifies the response for Program Start.	B'0000 10H'
Ready notify	Notifies that the Ready state is entered.	B'1000 00H'
Not Support Command Error	Receives an unsupported command.	B'0111 111x

B.6.7.3 Details of MFI Commands

(1) Initialize Request

Sets the clock for the AP4.

After receiving this command, the AP4 sets the clock and returns "Initialize complete (B'0000 001x)".

This command is arbitrary. (It does not have to be issued when operation continues to be at 400 MHz.)

Clock setting: 4 bytes (Specify it at the beginning of the command parameter area from the CCPU in 32 bits.)
0: 400 MHz
1: 800 MHz

(ee) Status Request

Confirms the condition of the AP4 status.

After receiving this command, the AP4 immediately returns "Status notify (B'0000 01H')".

(This command does not have parameters.)

(ff) Get Version

Acquires the mask ROM version of the AP4.

After receiving this command, the AP4 acquires the version information and returns "Version notify (B'0000 011x)".

Note: Transmission of the Get Version command is arbitrary.

(This command does not have parameters.)

(gg) Program Start

Notifies the AP4 that download of data has started.

(Locate the VRL4 format from the beginning of the command parameter area from the CCPU.)

After receiving this command, the AP4 makes a subroutine call to the start address of the MFRAM command parameter area. Before calling the subroutine, the AP4 returns "Program complete (B'0000 10H')". When the secure function is selected, a secure check is carried out and the result is returned. To acquire the return value from the subroutine, use the Status Request command.

On returning from the subroutine that was called after this command had been issued, cancel protection of the MFRAM area (command parameter and response parameter areas) and SDRAM area.

Note: The protection function is not available in MFI1 boot and MFI1 development boot modes.
For the subroutine format, use the following for reference.

```
unsigned long func(void){
   Processing
return err;
}
```

B.6.7.4 Details of MFI Responses

(1) Initialize complete

Returns the return value in response to the Initialize Request command.

After receiving the Initialize Request command, the CPU clock is set and that result is returned.

Setting result: 4 bytes (Returns it from the beginning of the response parameter area from the ACPU in 32 bits.)
0: OK
1: Error

(hh) Status notify

Notifies the status information in response to the Status Request command.

State: 4 bytes (Returns it from the beginning of the response parameter area from the ACPU in 32 bits.)
0: Ready state (The response is not returned for states other than Ready.)

Clock state: 4 bytes (Returns it from 4 + (beginning of the response parameter area from the ACPU) in 32 bits.)
0: 400 MHz
1: 800 MHz (Initialize Request setting)

Return value: 4 bytes (Returns it from 8 + (beginning of the response parameter area from the ACPU) in 32 bits.)
Return value from the command executed by the Program Start command

Reserved: 4 bytes (Returns it from 12 + (beginning of the response parameter area from the ACPU) in 32 bits.)
Fixed at 0

Device version: 8 bytes (Returns it from 16 + (beginning of the response parameter area from the ACPU) in 64 bits.)
CCCR value (offset0)
Fixed at 0 (offset4)

Boot setting: 4 bytes (Returns it from 24 + (beginning of the response parameter area from the ACPU) in 32 bits.)
Value of MD2 to MD7 bits in RESCNT

(ii) Version Information

Notifies the mask ROM version information in response to the Get Version command.

DATA: 16 bytes (Returns it from the beginning of the response parameter area from the ACPU.)
Returns the class, date, and creation number of mask ROM.
Data format: "ROM_yymmdd_nn" for the AP4

Note: yy: Year, mm: Month, dd: Day, nn: Version number for each creation
Example: ROM_080320_01 (software version 01 created on March 20, 2008)

(jj) Program complete

Notifies the result of the Program Start command.

After receiving the Program Start command, the secure check is performed (if the secure function is selected) and that result is notified just before program execution starts.

Confirm the return value after program execution by using the Status Request command.

Result: 4 bytes (Returns it from the beginning of the response parameter area from the ACPU.)
0: Normal activation (start of program execution)
1: Reserved
2: Secure error

(kk) Ready notify

Notifies that after activation following power supply or reset cancellation, the ACPU is activated in MFI boot mode and notifies that it has become ready to receive commands (MFRAM area (command parameter and response parameter areas) is protected).

After the response from the ACPU is confirmed, the CCPU clears the interrupt with the Ready notify value.

(There are no response parameters from the ACPU.)

Note: The protection function is not available in MFI1 boot and MFI1 development boot modes.

(ll) Not Support Command Error

This response is returned when the command sent from the CCPU is an unrecognizable command (unsupported command).

(There are no response parameters from the ACPU.)

IPMMU translation table base control register	IMTTBCR	R/W	H'xxxx x018	32
IPMMU DMAC channel enable control register *2	IMDCEN	R/W	H'xxxx x020	32
IPMMU PMB address array 0 to IPMMU PMB address array 15	IMPMBA0 to IMPMBA15	R/W	H'xxxx x080 to H'xxxx x0BC	32
IPMMU PMB data array 0 to IPMMU PMB data array 15	IMPMBD0 to IMPMBD15	R/W	H'xxxx x0C0 to H'xxxx x0FC	32

*1 The "xxxx x" parts in the Address column are as follows according to IPMMUs:
IPMMUI: FE951
IPMMUR: FFC30
IPMMUR2:FFC40

*2 IMDCEN exist only on IPMMUR and IPMMUR2

G.4 Register Configuration of INTC

G.4.1 Register Configuration of INTCA

Register Name	Abbreviation	R/W	Address	Access Size

*1. To prevent the erroneous writing, 32-bit write operations only are performed when the upper 16 bits of the write data are H'A55A. Otherwise, write operations are not performed. The upper 16 bits of the data are read as H'0000.

*2. The entity of this register is in SDRAM. Data is written to the register in the SDRAM by accessing the register space for it. For details, refer to section 7.6.2 (3),LPDDR2-S4 internal register access function.

Clock source control register	CKSCR	R/W	H'E615 00C0	32
VREF control register	VREFCR	R/W	H'E615 0108	32

*1 Write access to a register allocated to address H'E615 8*** can be controlled through HPB semaphores. Obtain a semaphore before writing a register and release it after completing the write access.

*2 RMSTPCRn and SMSTPCRn might be collectively written as MSTPCRn.

G.12 Register Configuration of RWDT

Register Name	Abbreviation	R/W	Address*3	Access Size
RCLK watchdog timer counter 0	RWTCNT0	R/W	H'E602 0000 H'E702 0000	8/16*1
RCLK watchdog timer control/status register A0	RWTCSRA0	R/W	H'E602 0004 H'E702 0004	8/16*2
RCLK watchdog timer control/status register B0	RWTCSRB0	R/W	H'E602 0008 H'E702 0008	8/16*2
RCLK watchdog timer counter 1	RWTCNT1	R/W	H'E603 0000 H'E703 0000	8/16*1
RCLK watchdog timer control/status register A1	RWTCSRA1	R/W	H'E603 0004 H'E703 0004	8/16*2

Register Name	Abbreviation	R/W	Address*3	Access Size
RCLK watchdog timer control/status register B1	RWTCSRB1	R/W	H'E603 0008 H'E703 0008	8/16*2

*1 Write is performed in 16 bits and read in 8 bits.

*2 This register is accessible both from HPBC (E6 space) and HPBD (E7 space).

*1 Registers with address H'E618 8*** should be updated through HPB semaphore. Please release the semaphore bit once the write accesses to these registers is completed. (Refer Appendix A for semaphore register details)

*2 The CPU number which can access these registers is registered in one of the semaphore registers. Please don't access these registers from CPU's other than this CPU.

*3 To clear the flag write `0`. Please write 1 to other flag to avoid unintentional clears.

Clock reset register	CLK_RST	R/W	H'FE3C 0610	H'0184	32	24	S
Software reset register	SOFT_RST	R/W	H'FE3C 0614	H'0185	32	24	S
FIFO size register	FIFO_SZ	R	H'FE3C 0618	H'0186	32	24	S

Note: The (FIFO) CLR bit (bit 0) is a static bit; however, all the other bits in the register, that is, interrupt monitoring condition setting bits can be modified dynamically.

There are two types of registers, dynamic and static. Static registers should not be modified when the FSI is in operation (during continuous operation).

The CPU can write/read data to/from the lower bits (23 to 0) in registers. The upper bits are read as 0 and cannot be modified.

For setting the FMSI operation, also see a description of the register for selecting the FSI/FMSI interrupt acknowledge destination in section 52.4.19.

*1 Only I²C2 and I²C3 and I²C4 are effective. Please do not access in I²C0 and I²C1.

The automatic transmission assumes the end of communication by interruption, and error detection, please do not perform principle polling during automatic transmission.

G.51 Register Configuration of KEYSC

Register Name	Abbreviation	R/W	Address*	Access Size

Register Name	Abbreviation	R/W	Address*	Access Size
Manual key scan control register 1	M_KYCR1	R/W	H'E61B 0000 H'E71B 0000	16

*1 For details, see section 5.6, LSI Internal Communication Interrupt/Power Reset (Request to the AP Block) and section 5.7, LSI Internal Communication Interrupt/Power Reset (Request to SYS from RT), section 5.8, LSI Internal Communication Interrupt/Power Reset (Request to RT from SYS).

*2 Accessing Address H'E605XXXX, It is controlled by the GPIO semaphore of HPB.

Accessing Address H'E607XXXX, It is not controlled by the GPIO semaphore of HPB.

*3 When the IE bit of PORTnCR is set to 1, the level of the corresponding pin is read.

G.54 Register Configuration of H-UDI

Register Name	Abbreviation	CPU Side				
		R/W	Logical Address	Physical Address	Size	Initial Value*1
Instruction register	SDIR	R	H'FC11 0000	H'FC11 0000	16	H'0EFF
Data register H	SDDR/SDDRH	R/W	H'FC11 0008	H'FC11 0008	32/16	Undefined
Data register L	SDDRL	R/W	H'FC11 000A	H'FC11 000A	16	Undefined
Interrupt source register	SDINT	R/W	H'FC11 0018	H'FC11 0018	16	H'0000
Bypass register	SDBPR*2	-	-	-	-	Undefined

*1 The low level of the TRST_N pin or the Test-Logic-Reset state of the TAP controller initializes to these values.

*2 SDBPR cannot be accessed from the CPU.

Instruction register	SDIR	R/W	32	H'FFFF FFFD (fixed value*2)
Data register H	SDDR/SDDRH*4	-	-	-
Data register L	SDDRL*4	-	-	-
Interrupt source register	SDINT	W*3	32	H'0000 0000
Bypass register	SDBPR	R/W	1	Undefined

*1 The low level of the TRST_N pin or the Test-Logic-Reset state of the TAP controller initializes to these values.

*2 When reading via the H-UDI, the value is always H'FFFF FFFD.

*3 Only 1 can be written to the LSB by the H-UDI interrupt command.

*4 SDDR(SDDRH, SDDRL) cannot be accessed via the H-UDI.

G.55 Register Configuration of UBC

Register Name	Abbreviation	R/W	P4 Address	Area 7 Address	Access Size
Match condition setting register 0	CBR0	R/W	H'FF20 0000	H'FF20 0000	32

Register Name	Abbreviation	R/W	P4 Address	Area 7 Address	Access Size
Match operation setting register 0	CRR0	R/W	H'FF20 0004	H'FF20 0004	32
Match address setting register 0	CAR0	R/W	H'FF20 0008	H'FF20 0008	32
Match address mask setting register 0	CAMR0	R/W	H'FF20 000C	H'FF20 000C	32
Match condition setting register 1	CBR1	R/W	H'FF20 0020	H'FF20 0020	32
Match operation setting register 1	CRR1	R/W	H'FF20 0024	H'FF20 0024	32
Match address setting register 1	CAR1	R/W	H'FF20 0028	H'FF20 0028	32
Match address mask setting register 1	CAMR1	R/W	H'FF20 002C	H'FF20 002C	32
Match data setting register 1	CDR1	R/W	H'FF20 0030	H'FF20 0030	32
Match data mask setting register 1	CDMR1	R/W	H'FF20 0034	H'FF20 0034	32
Execution count break register 1	CETR1	R/W	H'FF20 0038	H'FF20 0038	32
Channel match flag register	CCMFR	R/W	H'FF20 0600	H'FF20 0600	32
Break control register	CBCR	R/W	H'FF20 0620	H'FF20 0620	32

G.56 Register Configuration of DBG

Register Name	Abbreviation	R/W	CPU Address*4	R/W	JTAG Command	Access Size
Debugging function selection register*3	DBGREG1	R/W	H'E610_0020/ H'E610_8020	R/W	B'0011_1000	32
LSI control register	DBGREG2	R/W	H'E610_0024/ H'E610_8024	R/W	B'1011_1000	32
KEY register	DBGREG9	R/W	H'E610_0040/ H'E610_8040	R/W	B'0010_0100	32
Access priority control register*3	DBGREG10	-	-*1	R/W	B'1010_0100	32

*1 Accessible only from the JTAG.

*2 Accessible from the CPU only under software control.

*3 Not a target for diagnosis.

*4 Address H'E610_0XXX is a non semaphore-address of this register and accessing through this address is not controlled by HPB semaphore.
Address H'E610_8XXX is a semaphore-address of this register and accessing thorough this address is controlled by HPB semaphore.

G.57 Register Configuration of USBHS0-DMAC

Register Name	Abbreviation	R/W	Address	Access Size
VCR register	USBDMA_VCR	R/W	USBDMA_BASE+H'00	32
Software reset register	USBDMA_SWR	R/W	USBDMA_BASE+H'08	32
DMA interrupt source register	USBDMA_DMICR	R	USBDMA_BASE+H'10	32
DMA source address register_0	USBDMA_SAR_0	R/W	USBDMA_BASE+H'20	32
DMA destination address register_0	USBDMA_DAR_0	R/W	USBDMA_BASE+H'24	32
DMA transfer count register_0	USBDMA_TCR_0	R/W	USBDMA_BASE+H'28	32
DMA timeout count register_0	USBDMA_TOCNTR_0	R	USBDMA_BASE+H'2C	32
DMA timeout constant register_0	USBDMA_TOCSTR_0	R/W	USBDMA_BASE+H'30	32
DMA channel control register_0	USBDMA_CHCR_0	R/W	USBDMA_BASE+H'34	32
DMA final transaction valid data transfer enable register_0	USBDMA_TEND_0	R/W	USBDMA_BASE+H'38	32
DMA source address register_1	USBDMA_SAR_1	R/W	USBDMA_BASE+H'40	32
DMA destination address register_1	USBDMA_DAR_1	R/W	USBDMA_BASE+H'44	32
DMA transfer count register_1	USBDMA_TCR_1	R/W	USBDMA_BASE+H'48	32
DMA timeout count register_1	USBDMA_TOCNTR_1	R	USBDMA_BASE+H'4C	32
DMA timeout constant register_1	USBDMA_TOCSTR_1	R/W	USBDMA_BASE+H'50	32
DMA channel control register_1	USBDMA_CHCR_1	R/W	USBDMA_BASE+H'54	32
DMA final transaction valid data transfer enable register_1	USBDMA_TEND_1	R/W	USBDMA_BASE+H'58	32
DMA operation register	USBDMA_DMAOR	R/W	USBDMA_BASE+H'60	32

Note: USBDMA_BASE=H'E68A0000

G.58 Register Configuration of USBHS1-DMAC

Register Name	Abbreviation	R/W	Address	Access Size

Register Name	Abbreviation	R/W	Address	Access Size
VCR register	USBDMA_VCR	R/W	USBDMA_BASE+H'00	32
Software reset register	USBDMA_SWR	R/W	USBDMA_BASE+H'08	32
DMA interrupt source register	USBDMA_DMICR	R	USBDMA_BASE+H'10	32
DMA source address register_0	USBDMA_SAR_0	R/W	USBDMA_BASE+H'20	32
DMA destination address register_0	USBDMA_DAR_0	R/W	USBDMA_BASE+H'24	32
DMA transfer count register_0	USBDMA_TCR_0	R/W	USBDMA_BASE+H'28	32
DMA timeout count register_0	USBDMA_TOCNTR_0	R	USBDMA_BASE+H'2C	32
DMA timeout constant register_0	USBDMA_TOCSTR_0	R/W	USBDMA_BASE+H'30	32
DMA channel control register_0	USBDMA_CHCR_0	R/W	USBDMA_BASE+H'34	32
DMA final transaction valid data transfer enable register_0	USBDMA_TEND_0	R/W	USBDMA_BASE+H'38	32
DMA source address register_1	USBDMA_SAR_1	R/W	USBDMA_BASE+H'40	32
DMA destination address register_1	USBDMA_DAR_1	R/W	USBDMA_BASE+H'44	32
DMA transfer count register_1	USBDMA_TCR_1	R/W	USBDMA_BASE+H'48	32
DMA timeout count register_1	USBDMA_TOCNTR_1	R	USBDMA_BASE+H'4C	32
DMA timeout constant register_1	USBDMA_TOCSTR_1	R/W	USBDMA_BASE+H'50	32
DMA channel control register_1	USBDMA_CHCR_1	R/W	USBDMA_BASE+H'54	32
DMA final transaction valid data transfer enable register_1	USBDMA_TEND_1	R/W	USBDMA_BASE+H'58	32
DMA operation register	USBDMA_DMAOR	R/W	USBDMA_BASE+H'60	32

Note: USBDMA_BASE=H'E68C0000
